We conducted the study at Villamar beach in Tuxpan, Veracruz, that manages the R-5 Turtle Camp. The beach is located in the extreme north of the State of Veracruz (97° 23' 36''N and 20° 83' 47''W). It has an average altitude of 10 m and has an area of 19 km. It borders to the North with the beaches of the municipality of Tuxpan, to the East with the Gulf of Mexico and to the South with the beaches of the municipality of Cazones (INEGI 2012). It has a warm-humid weather, with an average yearly temperature between 22°C and 26°C. The coldest month is lower than 19°. Rain occurs during the summer and winter. Prevailing winds come from the East during summer and this area is influenced by dry winds from the North in winter. The hurricanes season occurs from July to November, therefore maximum precipitation is recorded during these months. Besides hurricanes, the area receives the influence of another important climatic force, North winds, which are cold invasions or anticyclonic wind masses that come from the U.S. interior (CONAGUA 2012).

The coast is variable and has a rugged profile, with intermittent stretches of sandy beaches that alternate with the rocky coastline. Streams, rivers and runoffs are very common. There are areas where accumulation of logs and garbage are found, abundant mainly during rainfall season and are generally found near the rivers' mouths (INEGI 2008).

Coastal vegetation is mainly composed of grasslands and creeping halophyte plants, which can be found up to the high tide line. In some places pastures have replaced natural vegetation, due to cattle ranching in the area (INEGI 2008). Human settlements are limited. Settlements are formed by families that inhabit low profile constructions, and by some temporary visitors interested in participating in the conservation activities during the spawning months of sea turtles. Agriculture, cattle and fishing for local consumption are the main economic activities of this area. There are some industries located at the Northern area of this beach, such as: Gas Maritime Terminal and a power plant (Tuxpan II 495 MW) (Ortiz-Pérez 2012).

#### **Data Recording**

Most species of turtles follow the same behavior pattern during nesting, so that methods for study and management of females at nesting beaches are similar for all species (Choi  $\&$ Eckert 2009). This study was performed during the nesting seasons 2010 and 2011. Morning and night monitoring were carried out according to the nesting habits of each species. To collect data on Kemp's Ridley Turtle females and nests, monitoring was done during the morning. For Green Turtle females and nests, monitoring occurred at night.

During monitoring we conducted walks along the beachfront, data collection started at the moment in which a nest was located, with the help of a GPS GARMIN model GPSmap 60CSx (precision  $\pm 3$  meters) the coordinates of each nest were taken. Afterwards, we recorded the distances between the coastline and the nest, and between the nest and the vegetation with a Truper 50 ft fiberglass tape measure. Later, the nest was excavated and the eggs were counted, measured and deposited back in the nest, which was covered again with sand. To mark nest locations, we used wooden stakes and fluorescent - biodegradable flagging tape. We noted the date, species and nest number on the piece of flagging tape with permanent ink.

In order to determine the number of eggs per season, a Mann-Whitney U test was performed, as data were not normally distributed according to the Kolmogorov-Smirnov test.

#### **Nests Distribution per Area**

To analyze the distribution of the nests along the beach, the 19 km of the beach that was sampled was divided into three zones. Zones division was done accordingly to the methodology mentioned by Azanza et al. (2003), Ferrer et al. (2007), and Zavaleta-Lizárraga & Morales-Mávil (2013). The three zones were:

- Zone A: Inter-tidal section over the entire coastline, ending in the last tide line.
- Zone B: From the point where the zone A ends, covering all the section of the berms up to the beginning of the dunes.
- Zone C: From the point where the zone B ends, up to the interior of the supra-littoral.

Once the nests were located, their location on the corresponding zone of the beach (A, B or C) was determined using a GPS. Maps were elaborated with the obtained UTM coordinates. Maps show the distribution of the nests for both seasons. For this purpose, satellite images from Google Earth Pro and StitchMaps were used. Later on, these maps were analyzed with ArcGIS 9.3 software

#### **Nests Distribution per Site**

Once the distribution of the nests along the 19 km of beach was obtained, it was divided into three similar segments, each of 6.33 km of beach: North area (site 1), Center area (site 2) and South area (site 3).

In order to analyze the distribution of the nests from both species on the beach, a canonical-correlation analysis (CCA) was made with Canoco for Windows 4.51 software. In order to test differences in the distribution of nests from both nesting seasons, a Mann-Whitney analysis was made with SgimaStat 3.1 software.

## **RESULTS**

#### **Nests Number per Month**

A total of 178 nests were registered in 2010, 115 were from Kemp's Ridley Turtles and 63 were from Green Turtles. The month with the highest number of Kemp's Ridley Turtle nests was June with 104 nests, and July was the month with the highest number of Green Turtle nests (51). In these two months the nesting of both species overlapped (Figure 1).

For 2011 season, 133 nests were registered, 56 were Kemp's Ridley and 77 were Green Turtle. Kemp's Ridley Turtle showed a nesting peak during the month of April with 34 nests. July was the month with the highest number of Green Turtle nests with 35 nests. During this nesting season the overlapping month was May, with 22 as the highest number of nests of Kemp's Ridley Turtle, while there were only 4 nests of Green Turtle (Figure 2). It was only possible to quantify the number of eggs from this nesting season. The Green Turtle deposited, on average, more eggs per nest than the Kemp's Ridley Turtle. The average number of eggs per nest was similar during the nesting months, both for the Kemp's Ridley Turtle, 89.73  $\pm$ 29.1 (Mann-Whitney;  $P = 0.921$ ;  $U = 11.000$ ); and for the Green Turtle,  $110.91 \pm 19.5$  eggs  $(Kruskal-Wallis; P = 0.334; H = 2.195).$ 

Figure 1. Number of nests by month of Kemp's ridley turtles and Green turtle in 2010 season.

Figure 2. Number of nests by month of Kemp's ridley turtles and Green turtle in 2011 season.

## **Spatial-Temporal Distribution of Nests**

During the nesting season 2010, the total registered number of nests for Kemp's Ridley turtle and Green turtle was 178. The Kemp's Ridley turtle had the highest number of nests in the North-center area of the beach, while the Green Turtle had a higher nesting preference at site 3 (towards the South). During this season, the species with dominant abundance of nests was Kemp's Ridley turtle with 115 nests.

In the 2011 nesting season we registered 133 nests. Kemp's Ridley Turtles had more nests toward site 1 (North of the beach), while Green Turtles had more nests to the south of the beach (site 3). Distribution of the nests was made irregularly, thus nests were presented sometimes in small groups, leaving greater distance between one group and another.

Figure 3. Distribution of nests in three sites of Villamar beach in 2010 season.

#### **Nest Distribution per Zone (A, B and C)**

Nests distribution was higher in Zone C for both species and for both seasons: in 2010 season 102 nests Kemp's Ridley Turtle (88.7%) and 60 nests Green Turtle (95.24%) were recorded in Zone C, and the rest in Zone B. During 2011 season, 51 Kemp's Ridley nests were recorded (91.1%) and 61 Green Turtle nests (79.22%) in Zone C, the rest rest of the nests were located in Zone B. Zone A did not have any recordings of nesting for any of the species.

#### **Nests Distribution per Site**

For the 2010 nesting season, only Kemp's Ridley nesting was recorded in Site 1, however, it was in Site 2 where the greater nesting for this species occurred, with 58 nests. Green Turtles preferred Site 3 with 57 nests monitored, while Site 2 had the lowest number with only five nests. Site 1 was located toward the North area of the beach. Nests registered during 2010 season belonged only to Kemp's Ridley Turtle (30 nests). The distribution was all over the extension of the beach (Figure 3).

Figure 4. Canonical Correlation Analysis (CCA) of the abundance of nests of *C. mydas* and *L. kempii* in Villamar beach, Tuxpan, Veracruz, in 2010 season  $(F2, 53 = 123.89, P < 0.001, 100\%$  of the total variance).

In Site 2 (central part of the beach), a greater number of Kemp's Ridley was found, registering a total of 58. In this site nesting from Green Turtle also ocurred, but in low numbers (only five nests). Nests distribution for this site also was found all over the extension of the beach (Figure 4).

In Site 3 (Southern part of the beach) some Kemp's Ridley turtle nests were registered mainly in the coastline with Site 2, even though the greatest record was of Green Turtle nests with 57. Most nests were recorded over the extreme South portion. Therefore, nests distribution on this site was performed in groups toward the ends of the beach, leaving a wide empty space at the center portion (Figure 5).

The canonical-correlation analysis of the three sites during 2010 season, showed a greater relation in nesting of Kemp's Ridley Turtle with Sites 1 (North) and 2 (Center). Nesting of Green Turtle was more related with Site 3 (Southern part) (Figure 6).

During 2011 season, Site 3 was the one that registered the greater number of eggs for both species, with 22 Kemp's Ridley Sea Turtle nests and 67 Green Turtle nests. During this season, the number of Green Turtle nests was greater than the Kemp's Ridley's. Few nests (13) were recorded at Site 1, from which the greater part (11) was Kemp's Ridley and they were mainly distributed in the central section of this beach segment. Only two Green turtle nests were registered toward the Southern part of the segment, which is, the coastline with Site 2.

The number of turtle nests (21) was greater in Site 2 than in Site 1. Thirteen Kemp's Ridley nests and eight Green Turtle nests were recorded. All nests were distributed basically in the central part of the segment toward the South, without showing a marked group along this segment of the beach.

Figure 5. Distribution of nests in three sites of Villamar beach in 2011 season.

Figure 6. Canonical Correlation Analysis (CCA) of the abundance of nests of *C. mydas* and *L. kempii* in Villamar beach, Tuxpan, Veracruz, in 2010 season  $(F2, 38 = 16.38, P < 0.03, 100\%$  of the total variance).

Site 3 was the one that showed the greatest number of nests for both species, 22 Kemp's and 67 Green's. It is evident that the greatest part of the nests was grouped to the Southern part of this segment, between the two river mouths located in this Site.

The canonical-correlation analysis for 2011 nesting season showed differences between the sites. Greater relationship in the Green turtle nesting site 3 and Kemp's Ridley with site 2 is seen. Northern area (Site 1) did not have any relevance for nesting of any species during this nesting season.

Considering both seasons (2010 and 2011), nesting of Kemp's Ridley and Green Turtle was similar regarding the number of registered nests (Mann-Whitney: Kemp's,  $U = 8.50$ ,  $p =$ 0.730; Green,  $U = 15.000$ ,  $p = 0.690$ ). However, the number of Kemp's Ridley Turtle nests was significantly higher than Green Turtle nests in 2010 ( $U = 3622.5$ ;  $P < 0.001$ ), while the number of Green Turtles nests was significantly higher than nests of Kemp's Ridley Turtle during 2011 (U = 1771.0;  $P < 0.001$ ).

## **DISCUSSION**

The results show that there are spatial-temporal variations in the nesting of sea turtles in Villamar de Tuxpan, Veracruz. Differences were found in the number of nests registered for Kemp's Ridley and Green Turtles. During the nesting season in 2010, there were more registered nests for Kemp's Ridley Turtle than for the Green Turtle, while in season 2011 the Green Turtle had more registered nests. This annual variation included changes in the nesting peaks. Annual fluctuations are common in sea turtles nesting and have been reported in several species and sites (Meylan & Meylan 2000, Lagueux 2001, and Margaritoulis 2005). For three consecutive years, annual variations in the number of nests have been recorded for the Green Turtle in the central zone of the state of Veracruz, with a spread of 351to 492 nests (Zavaleta-Lizárraga & Morales-Mávil 2013).

The marked variations in the nesting peaks and months are caused by environmental changes in temperature, humidity and wind, which take place differentially each year. These are central factors for the arrival of the Green Turtle, and for the Kemp's Ridley Turtle, which lays its eggs in daylight. Turtles arrive in the beaches and select nesting sites in order to ensure the growth of the embryos (Hawkes et al. 2009). Thus, the nesting month peak variation is connected to the warm season and with specific wind periods, which enhance nesting, oviposition and the embryonic success of the future hatchlings. In other species, such as the Loggerhead Sea Turtle (*Caretta caretta*), Margaritoulis (2005) registered that the months with the highest temperature were July and August and were connected to greater turtle nesting in the island of Zakynthos.

Not every turtle nested every year which may be explained by the annual variations in the climate conditions, and it could reflect in the variations in this study. Variation in nesting over years is a widely documented phenomenon in sea turtles (Meylan & Meylan 2000). Individual sea turtles show annual, biennial, and triennial reproductive periods, or sporadic breeding (Márquez 2003). During the nesting season, the intervals to perform oviposition may vary in different sea turtle species (Lagueux 2001). It is known that the migration cycle of the Green Turtle is biennial, and thus there are high and low nesting seasons, which causes more nesting in one year than in the other (Bowen et al. 1992). Furthermore, inter-annual nesting variation

might be influenced by food availability. Females do not feed before laying their eggs because eggs occupy the major part of their abdominal cavity (Hatase et al. 2004). However, for nesting to succeed, females must load up on nutrients before starting to fast, so that the energy accumulated is sufficient for reproduction. During times of food scarcity, the journey and nesting cannot be accomplished (Hatase et al. 2004).

The number of eggs registered for the two species was different in 2011: Green Turtles laid more eggs (4,247) than Kemp´s Ridley turtles (966). These values are low when compared to the number of eggs registered by García-Romero et al. (2007) during the nesting season in 2001 in 21 turtle centers in Michoacán, Mexico, where 898,134 eggs were registered. This represents over 42,000 eggs per camp, or in other words, ten times than we registered in the present study. Venkatesan et al. (2004) also recorded high nest numbers — 17,964 eggs—for the Green Sea Turtle in the coast of India, during 2000-2002. Although this number was recorded during three years, the annual average is nearly 6,000 eggs, and thus greater than what we recorded. The methods utilized in both studies were similar to ours; however, we could have a more precise appreciation of the extent of differences if we knew the area and distribution of habitat types of the other beaches. Regardless, it is safe to assume that the Villamar has relatively small populations of both species, given that the number of eggs found does not match the quantity found in others.

Regarding the specific nesting zones in the beach, both species preferred nestin in zone C, in the limit or within the dune vegetation area. Surely this behavior allows sea turtles to avoid excessive humidity and nest flooding, and provides better protection from predators. This is the most frequent nesting zone for sea turtles, such as registered for the Hawksbill sea turtle (*Eretmochelys imbricata*) in Barbados (Horrocks & Scott, 1991), and Cuba (Azanza et al. 2003, Ferrer et al. 2007), and the Green turtle in other Mexican beaches (Zavaleta-Lizárraga & Morales-Mávil, 2013).

Despite a clear preference to nest in zone C, nests in zone B were also observed. The nests in this zone are more exposed to predators, and to unfavorable temperature and humidity conditions for the development of embryos, why do females lay their eggs in this zone? There are several explanations. Firstly, nest saturation is possible on the sites with the best conditions, which would force females to use lower quality sites, as has happened in the great arrivals in Tortuguero, Costa Rica (Bjorndal & Bolten 1992). Although due to the low number of nests registered in Villamar, this is not likely. Secondly, the health condition of females is not good enough for them to move and dig for longer time in search for a better site and thus they lay their eggs in zones nearer to the tide line (Moncayo 2014). This is feasible, although blood tests would be needed to verify it. Thirdly, individual differences in corticosterone may compromise the females´ abilities to make good nesting choices, due to stress. Furthermore, female Green Turtles with high levels of corticosterone can make longer movements and greater nesting efforts in search of the best zones to lay their eggs (Ortega-Planell 2013).

Differences with respect to nest distribution of the two species along the coast were registered in this study. The most northern site of the beach (site 1) presented only nests of Kemp's Ridley Turtles during both years. Site 3 presented the highest number of Green Turtle nests during the two nesting seasons. It is likely that the difference in the number of nests along the beach is caused by the presence of reef areas, as well as topographic and humidity differences of the beaches. For example, the greater nesting of Kemp's Ridley in the north side might be connected to the proximity of the reef system Lobos-Tuxpan. This is a

carnivorous species and it most surely finds wide food availability in the reefs, which makes it abundant not only in the region of Tuxpan, but also Rancho Nuevo, Tamaulipas, which is held as its main nesting site (Márquez 2003). The Northern part of the beach can be considered different in terms of humidity conditions, for it is the nearest zone to Tumilco, a wide mangrove area within the RAMSAR site, Tuxpan mangroves and wetlands (Basañez 2005).

The large presence of Kemp's Ridley nests lay towards the central beach, mainly in the zone attached to the north beach. A lower quantity of nests was registered in the rest of the beach, probably because of greater human presence due to Villamar. Villamar has several activities for the residents (fishing, ranching, and tourism), which might deter the turtles from nesting near the settlement. Human settlements also carry artificial lighting, a factor that could affect the females during the oviposition, and later the orientation of the offspring when leaving the nest (Rondón et al. 2009).

On the most southern part of the beach we registered more Green Turtle nests. What are the characteristics of this side of the beach that make it differentiate turtle nesting? To begin with, it is a wider area, farther from the tide line to the dunes, and these present greater vegetation cover. In that sense, dune vegetation has been reported as one of the main nesting sites for the Green Turtle (Ferrer et al. 2007, Azanza et al. 2007, Silveira et al. 2003). While this south beach is not as large as the wetlands of the Ramsar site. It does have good humidity conditions due to the presence of the streams that flow into this zone of the beach (Bouchard & Bjorndal, 2000).

#### **CONCLUSION**

The spatial-temporal distribution of Green Turtle and Kemp's Ridley Turtles shows a connection to the conditions of the beach where they nest. The segregation in the nesting of the two species is evident, where Kemp's Ridley has preference for the north side and Green Turtle for the south part. As well, temporal separation is clear, with greater abundance of Kemp's Ridley in April and May, and Green turtle during June and July. The proximity of the nesting sites to zones with infrastructure makes the beach of Villamar a system vulnerable to human disturbance. Performing long-term monitoring upon the nesting populations in the northern and central beaches of the state of Veracruz appears indispensable, so as to get more information in a regional context. This would lead in to a deeper knowledge that will provide a context to plan better studies and conservation strategy proposals in the north of the state.

#### **ACKNOWLEDGMENTS**

We thank the Turtle Camp Villamar (R5), and especially the Román Reyes Family for permission to conduct the study. In addition, we thank Ascención Capistrán-Barradas, Jimmy Argüelles-Jiménez and Javier Bello-Pineda for their comments and suggestions. We also thank Colleen M. Schaffner for her valuable comments and support in the translation. This study was supported by Fondos Mixtos (CONACyT - Gobierno del Estado de Veracruz), in the project: Evaluación de las poblaciones anidadoras de tortuga marina en el estado de

Veracruz (Clave VER/2008/02/109460). LACV, JCS and LZL were supported by scholarships from CONACYT.

# **MARINE TURTLES: CONSERVATION STRATEGIES AND FUTURE RESEARCH**

# *Ohiana Revuelta\**

Marine Zoology Unit, Cavanilles Institute of Biodiversity and Evolutionary Biology, Science Park, University of Valencia, Valencia, Spain

## **ABSTRACT**

Avoiding species extinction will require rapid, greatly intensified efforts to conserve already threatened species and to alleviate pressures on their populations. Modern marine turtles belong to an ancient group of reptiles inhabiting the Earth for over 110 million years, since the Cretaceous. Nowadays, marine turtles comprise seven extant species grouped into two families: Dermochelyidae, with the leatherback (*Dermochelys coriacea*) as the single extant species, and Cheloniidae, with six species: hawksbill (*Eretmochelys imbricata*), Kemp's ridley (*Lepidochelys kempii*), olive ridley (*Lepidochelys olivacea*), loggerhead (*Caretta caretta*), green (*Chelonia mydas*), and flatback (*Natator depressus*) turtles. With the exception of Kemp's ridley, restricted mainly to the North Atlantic and Gulf of Mexico, and the flatback turtle, endemic to the Australian continental shelf, marine turtles are circumglobally distributed. They inhabit nearly all oceans, occupying unique ecological niches, and exhibiting intra-specific variations in population sizes and trends, as well as reproduction and morphology. Six of these species are classified by the World Conservation Union as either critically endangered (hawksbill and Kemp's ridley), endangered (green turtle) or vulnerable (leatherback, loggerhead and olive ridley). Threats vary across regions, but general categories include fisheries bycatch (i.e., incidental capture by marine fisheries operations targeting other species), exploitation of eggs, meat or other turtle products, coastal development, pollution and pathogens, and climate change. A broad range of conservation programmes have been established around the world to face these threats, but with a general bias toward the protection of nesting females and clutches at their reproductive areas. Current and future efforts for

implementation of effective management and conservation strategies are headed to mitigate the potential impacts of climate change on marine turtle's terrestrial nesting grounds and in-water phases (e.g., loss of nesting beaches, feminization of turtle populations, decreased reproductive success). Although marine turtles are a broadened studied group, there are still many gaps of knowledge on turtle ecology, hatchlings transoceanic migrations and natal philopatry, juvenile developmental and foraging habitats, and potential impacts of climate change. Future researches are targeted to further insight all these questions through the integration of innovative technologies such as telemetry, genetic markers, molecular techniques, stable-isotope analysis and habitat/environmental modelling.

### **1.INTRODUCTION**

Modern marine turtles belong to an ancient group of reptiles inhabiting the Earth for over 110 million years, since the Cretaceous (Hirayama 1998). From the Cretaceous, four families of marine turtles diverged: Protostegidae; Toxochelyidae; Dermochelyidae; and Cheloniidae, but only the latter two have survived until present (Spotila 2004). Nowadays, marine turtles comprise seven extant species grouped into two families: Dermochelidae, with the leatherback (*Dermochelys coriacea*) as the single extant species, and Cheloniidae, with six species: hawksbill (*Eretmochelys imbricata*), Kemp's ridley (*Lepidochelys kempii*), olive ridley (*Lepidochelys olivacea*), loggerhead (*Caretta caretta*), green (*Chelonia mydas*), and flatback (*Natator depressus*) turtles (Pritchard 1996). With the exception of Kemp's ridley, restricted mainly to the North Atlantic and Gulf of Mexico, and the flatback turtle, endemic to the Australian continental shelf, marine turtles are circumglobally distributed (Wallace et al. 2011).

Marine turtles depend on both marine and terrestrial habitats for their growth and development, from high energy beaches to benthic reefs, and the open waters of the seas. The seven species have similar life cycles with variations in the duration of phases (Miller 1997). Nesting females are philopatric to natal regions with sexually mature animals returning to their natal beaches to breed and nest, and both males and females can be philopatric to breeding areas adjacent to a nesting beach (FitzSimmons et al. 1997; Velez-Zuazo et al. 2008). However, a certain degree of variations in philopatry among populations and species has been described. In general, female marine turtles typically nest more than once per reproductive season. They do not nest every year and their nesting behaviour is highly stereotypic (Meylan and Meylan 1999). Only females will come ashore to dig a hole into which they deposit between 50-200 soft-shelled eggs, depending on the species (Miller 1997). From six weeks to two months later (depending on the species), hatchlings make their way to the surface of the sand and head to the water. Hatchlings are transported by ocean currents to oceanic habitats, where they live in flotsam, such as Sargassum mats and have an omnivorous diet. Carr (1987) hypothesized that hatchlings spend their first years in oceanic habitats presumably feeding primarily on sea jellies and salps. This time is often referred to as the "lost years"; but a recent study based on satellite telemetry methods has shed light on this period (Mansfield et al. 2014). After this oceanic phase, they return to coastal waters where they forage and continue to mature. Once adult males and females acquire sufficient resources, they migrate to breeding areas to mate. The time it takes to reach sexual maturity (when they are able to reproduce) varies among species, but ranges between approximately

10-30 years. The distance between feeding and breeding areas can be hundreds to tens of thousands kilometres, with turtles performing seasonal migrations moving across large expanses of the marine environment.

Marine turtles have constituted a main source in different civilizations since the Early Bronze age, providing not only foodstuff but also as sources of fat for oil, bones for medicinal purposes and cultural activities such as religious ceremonies and mortuary objects (Frazier 2003; Encyclopædia Britannica 2016). Evidences of the use of turtles (e.g., remains of shell and bones) by Prehistoric human communities have been registered in the Mediterranean and Caribbean Sea, Arabian Peninsula, and Indian Ocean Basin (Mosseri-Marlio 1998; Cooke 2004; Tripathy and Choudhury 2007). The study of archaeological marine resources exploitation in the Caribbean shows that marine turtle's populations decline was already patent in the prehistoric time periods (O'Day 2001). Despite the status of marine turtles populations was far of pristine before the European conquest of the Americas, it is irrefutable that for hundreds of years, marine turtles provided nourishment for European colonists on Caribbean islands (Lefevre 1992). There are many historical sources about the great presence of marine turtles as well as how appreciated their meat and eggs were (Rodríguez Demorizi 1942; Parsons 1962; Jackson 1997). This heavy harvest of turtles supposed loss of widespread nesting areas and reduction in populations through the world (Meylan 1999; McClenacahn et al. 2006; Campbell 2014; Spotila and Santidrian Tomillo 2015). Consumptive use of marine turtles has continued through centuries until modern day. Turtle meat and eggs have constituted an important resource for coastal communities around the world. The adult females slaughter and eggs harvesting as well as its effects on nesting populations has been extensively documented in nesting beaches of the Caribbean Sea (Lagueux and Campbell 2005; Troëng and Rankin 2005), Atlantic coast of Africa (Formia et al. 2003), Mediterranean Sea (Demetropoulos and Hadjichristophorou 1989), Eastern Pacific (Sarti et al. 2007), Western Pacific (Bhaskar 1987; Hitipeuw et al. 2007). Marine turtles have also been exploited for their skin, fat and blood and especially in the case of green and hawksbill turtles for their shell (Groombridge and Luxmoore 1989; Barr 2001). The decline of the marine turtles populations has continued throughout history, with growing human population, habitat degradation, overfishing and changes in models of subsistence, described as the main causes of this decreasing (Bjorndal and Bolten 2003).

Why and how marine turtles progressed from human exploitation to be considered charismatic species highly needed of protection? The conservation status of marine turtles populations took on importance by the 1950s and is closely related to one name, Dr. Archie Carr, who made extraordinary contribution to sea turtle conservation by way of bringing attention to the world's declining turtle populations due to over-exploitation and loss of safe habitat (Spotila 2004). Dr Carr carried out research in all aspects of the biology of marine turtles, he made the first description of life cycles, nesting process and hatchlings behaviour (emergence, sea finding orientation) and turtles migrations (Carr and Ogren 1960; Carr 1961). Besides the importance of his research, he is considered the origin of the international movement for the conservation of marine turtles; the establishment of Sea Turtle Conservancy in Tortuguero in 1959, to study and protect Caribbean green turtles is a milestone in these species conservation and population recovery. Previous to the STC establishment, the green turtle population is believed that was close to extinction since nearly every female turtle arriving to nest in Tortuguero was taken for the export market for turtle soup. A huge number of conservation efforts and research on physiological and ecological

aspects of marine turtles began in the 1960s and 1970s: studies of ecology and migrations of marine turtles (Carr and Caldwell 1956; Carr and Ogren 1960); nesting beaches conservation programs and nest translocation (Lebuff 1974; Schulz 1975; Márquez 1978), species distribution (Hildebrand 1963; Bleakney 1965), marine turtles phylogeny (Gaffney 1975), marine turtles anatomy and physiology (Frair et al. 1972; Greer et al. 1973). In the 80s, significant progress were made in the study of nesting beaches, evaluating some of the most widespread conservation techniques such as the transfer and ex situ eggs incubation beaches, turtles tagging or head starting programs (Klima and McVey 1995). Over the past three decades, a broad range of conservation programs have been established around the world to face the depletion of marine turtle's populations, but with a general bias toward the protection of nesting females and clutches at their reproductive areas (Reina et al. 2002). Current research attention focusing on a wide variety of topics relating to sea turtle biology and ecology, together with the interrelations of sea turtles with the physical and natural environments (Hamman et al. 2010; Abecassis et al. 2013; Griffin et al. 2013; Hawkes et al. 2014; Metcalfe et al. 2015).

In the present chapter it will be described the main achievement, conservation strategies carried out in the different phases of the marine turtles life cycle until now and future research.

## **2. CONSERVATION STRATEGIES AND FUTURE RESEARCH ON REPRODUCTIVE AREAS**

The actions for marine turtle's conservation have its origins in the activities carried out on nesting beaches to protect both nesting females and eggs (Caldwell et al. 1959; Carr et al. 1978; Hirth 1980). Beaches with presence of marine turtle nesting activity are usually surveyed throughout the entire nesting season to record signs of recent marine turtle nesting activity. Research and management needs on the nesting beach, include studies of the adult females, eggs, and hatchlings (Richardson 1999). Added to these data, female tagging has been widely used in nesting beaches, mostly to obtain information on growth, movement, and population dynamics (Chaloupka and Musick 1997). All these studies have provided considerable knowledge about marine turtle's biology that has been critical for marine turtle's conservation and management.

#### **2.1. Population Genetic Structure Phylogeographic Relationships**

Identifying individual turtles with metal and/or PIT tags allowed use mark-recapture techniques for estimating turtle's population sizes, describing the re-migration interval and internesting behaviour of adult females (Gerrodette and Taylor 1999; Briseño-Dueñas and Abreu-Grobois 1999). Adult turtles returned to the same beach to lay their eggs, the remigration periodicity range between two to four years among species and depend on dietary, behavioural and physiological factors (Márquez et al. 1982; Miller et al. 2003; Beggs et al. 2007; Bailey et al. 2008). This information obtained from tag returns was lately confirmed through molecular techniques. Mitochondrial DNA techniques characterize maternal lineages

within species; these analyses of genetic structuring of nesting beaches in relation to other populations allow determine levels of differentiation (Dutton et al. 1999; Shanker et al. 2004; Leroux et al. 2012). First studies on mitochondrial (mt) DNA variation were carried out to assess loggerhead population genetic structure (Bowen et al. 1993), demonstrating the presence of rookery-specific mtDNA haplotypes that distinguish them from turtles of other nesting areas in these species. Bowen and collaborators analyzed mtDNA variation in samples from four nesting beaches in the northwestern Atlantic Ocean and from one nesting beach in the Mediterranean Sea. Significant differences in haplotype frequency between nesting populations in Florida and in Georgia/South Carolina, and between both of these assemblages and the Mediterranean nesting colony, indicated substantial restrictions on contemporary gene flow between regional populations, and therefore a strong tendency for natal homing by females. This has also been confirmed in green turtles (Bowen et al. 1992), hawksbill turtles (Bass et al. 1996) and leatherback turtles (Dutton 1995). Such studies provide exceptional data about genetic differences among regional populations, but later improvements in sequencing technologies have allowed for the analysis of larger mtDNA fragments that have resulted in a better understanding of complexity of marine turtle's local populations and to resolve structure at finer scales (Chan 2005; Velez Zuazo et al. 2008). On the other hand, these improvements have contributed to solve geopolitical management of these endangered species (Mortimer et al. 2007). To refine the understanding about the genetic composition of green turtle populations in the South West Indian Ocean (Bourjea et al. 2015). The use of larger mtDNA fragments has also allowed to track evolutionary and colonisation events of marine turtles. The evolutionary history of Mediterranean loggerhead turtles population has been elucidated through the analyses of mtDNA from dead hatchlings sampled from a selection of rookeries in the Eastern Mediterranean (Clusa et al. 2013). It seems that current genetic structure of loggerhead rookeries in the Mediterranean would be the result of different colonisation events from the Atlantic, combined with local extinctions during cold periods.

#### **2.2. Natal Homing**

Molecular studies revealed that hatchlings turtles leave their natal beaches and, once reaching sexual maturity, the female turtles make the long trip back to her natal beach to lay her eggs. This process by which some animals return as adults to their natal areas to reproduce after migrate across vast expanses from their birthplace is known as natal homing or natal philopatry (Bowen and Karl 2007). This mechanism is primarily used by aquatic animals, such as marine turtles and salmon (Lohmann et al. 1999). One idea about how animals accomplish natal homing is that they use the magnetic field of the earth to navigate across the globe (Lohman et al. 2012; Putman et al. 2014). The Earth's magnetic field is a useful navigation tool given its properties of being present on the whole ocean, during the day and night and remains unaffected by weather and season. To achieve their migratory routes, animals integrate two distinct types of information from the geomagnetic field: 1) directional or compass information, which enables an animal to maintain a particular direction such as north or south, and 2) positional or `map' information, which some animals use to steer themselves along migratory pathways or to navigate toward specific target areas (Lohman et al. 2007; Lohman et al. 2008).

#### 838 *Ohiana Revuelta*

Recent studies have gone in depth in the specific use of this process by marine turtles with important implications in conservation. One of these findings is that marine turtles are able to imprint on the unique magnetic field that exists in their natal area and to use this information to return years later (Lohman et al. 2012). Brothers and Lohman (2015) have also confirmed the hypothesis that nest site selection depends at least partly on magnetic signatures consisting of inclination angle, field intensity, or a combination of the two and, as a consequence, variations in the convergence of isolines of inclination and intensity along the nesting coast could result in a concentration increase or concentration decrease of the nest density. However, geomagnetic field intensity is continually changing so this phenomenon of imprint could not explain natal homing by itself. A second hypothesis about turtles imprint on distinctive chemical cues associated with their natal beach has been developed. Turtles might hypothetically use both types of information together. For example, they might first use magnetic information to arrive in the general region of the beach, and then use chemical cues to localize a more specific nesting site (Lohmann et al. 2008; Putman and Lohmann 2008). Although marine turtles can detect chemicals dissolved in water and air (Southwood et al. 2008; Endres et al. 2009), there is still no evidence that support this hypothesis and further research is clearly needed. In addition, the geographic precision of natal homing remains to be determined, many turtle populations has showed absence of precise natal homing, while in other cases a great precision has been described (Lee et al. 2007). Recently an astonishingly event of precise site fidelity of flatback turtle has been recorded in the beach of Mon Repos (Western Australia), where a nesting female tagged for the first time in 1976 was observed again in November 2015 constituting the longest studied marine turtle in the wild. Over these 39 years of adult breeding life, she has been reordered coming ashore to lay eggs on 65 occasions and always on the 1.6km of Mon Repos beach. These findings are key in establish of conservation strategies, for example, if future conservation measures are considering replace a depleted population using animals from other regions, it could be possible that the new arrivals will lack the inherited instructions needed to navigate within and from their transplanted homes. Future lines of research will be targeted long-term studies of chemical and geomagnetic imprinting to try elucidating the mechanisms that underlie natal homing and answer questions about the implications of both geomagnetic imprinting and chemical cues (Lohmann et al. 2013).

#### **2.3. Temperature Dependent Sex Determination**

As in a number of reptiles, sexual differentiation in marine turtles depends on the ambient temperature during incubation of the eggs instead of a genetic determination (Pieau 1971; Bull and Vogt 1979). The process is known as temperature-dependent sex determination (TSD) where primary sex ratio is influenced by the temperature experienced by eggs during incubation (Bull 1980). Phenotypic sex in marine turtles is determined by the temperature prevailing in approximately the middle third of the incubation period (Yntema and Mrosovsky 1982). By definition, the pivotal temperature is the temperature at which both sexes are produced in equal proportions (sex ratio= 1:1). The transitional range of temperatures (TRT) is the range of constant temperatures that yields both sexes in variable proportions (Mrosovsky and Pieau 1991). From this TRT, lower temperatures will produce only males and higher temperatures will produce only females.

This knowledge about incubation and effects of temperature has provided considerable progress on eggs management. Since the earliest works carried out in nesting beaches, eggs harvesting has been described as one of the most important threat to many marine turtle populations around the world (Bell et al. 2007; Campbell et al. 2007). Relocation to different sections of the beach or to protected hatcheries has been common management tools in many marine turtle conservation programmes (Pritchard 1995; Abella et al. 2007; Santidrián Tomillo et al. 2009). The incubation of eggs in boxes placed within protective storage was an accepted management practice for many years; however posterior research on incubation temperatures at nesting beaches proved that this measure was ineffective since an abnormally high percentage of male turtles may well have been produced (Whitmore and Dutton 1981; Dutton et al. 1985). The improvement of these ex situ incubation methodologies relies on a number of studies about the effect of temperature on embryonic development that has its origin in the work carried out by Yntema and Mrosovsky (1979) that incubated eggs of loggerhead turtle at different controlled temperatures to determine hatchlings sexual differentiation.

Most of the work on sex ratios of marine turtles has been carried out working with hatchlings; monitoring hatchling sex ratio over time and space and understanding its variation has provided essential information for effective conservation of populations of species with temperature-dependent sex determination. Through laboratory experiments, placing eggs in incubators at different constant temperatures (Godfrey et al. 1999; Mrosovsky et al. 2009), pivotal temperature has been determined for several beaches. The laboratory curves relating incubation temperature to sex ratio are then used to relate field incubation temperature to sex ratios. This information is critical in conservation to avoid produce unnatural skewed sex ratios in those beaches where eggs translocation is still badly needed for nests protection (Abella et al. 2007; Pintus et al. 2009). However, despite the importance of data about pivotal temperature, for most marine turtle populations the pivotal temperature and/or nesting beach temperatures have not been measured; many experts consider collect beach temperature data for nesting sites for all populations a future research priority for marine turtles (Hamann et al. 2010; Fuentes et al. 2011).

For animals that depend on environmental temperatures for sex determination of offspring, there is concern that climate change may put some species at risk altering frequencies of hatchling phenotypes (Hawkes et al. 2007; Hulin et al. 2009). It therefore seems prudent to investigate management techniques with which to mitigate the negative effects of climate change to marine turtles. Baseline information on natural sex ratios in various parts of the world, and on variability in pivotals, is needed before large climate changes occur. Primary sex ratios in nests of all marine turtles species around the world appear to be strongly female biased (Chan and Liew 1995; Wibbels 2003; Glenn and Mrosovsky 2004; Zbinden et al. 2007; Rogers 2013), and there is a widely concern about the effect of increasing temperatures in future climate changes scenarios, in which male production will be severely decreased (Hawkes et al. 2009). Hence, management approaches for future conservation strategies include the protection of beaches that produce male hatchlings, which may be of increased importance (Hawkes et al. 2009). Assuming the fact that artificial shade in hatcheries is a very useful tool to decrease incubation temperature, some experiments have been carried out with the aim of develop ways of experimentally shaded clutches. One example is the use of screening material to manipulate the nesting thermal environment with shade, which seems to be effective in reducing nest temperature,

producing a higher proportion of male hatchlings, without compromising the fitness or hatching success (Patiño et al. 2012). Future changes on precipitation or temperature can have different effects on hatchling output at regional level, thus conservation actions should have into account the heterogeneous effect of climate change (Santidrián Tomillo et al. 2015). Climate change has and will have critical effects on marine turtle populations; however, as the climate changes, biodiversity is beginning to respond, which prompt to think that there are glimmers of hope for their conservation (Morecroft et al. 2012). The threatened Cape Verdean loggerhead population represents this capacity of adaptation to the climate changes in marine turtles; after evaluating some unique features of their habitat use and preferences, researchers conclude that this population should have remarkable resilience to climate change (Abella et al. 2016). Future conservation strategies should consider resilience as a management tool, it is a particularly appealing measure as it is risk averse and seeks to enable current species, communities and systems to persist, rather than to change or move (Lin and Petersen 2013).

It should be consider that the bulk of studies about the effect of climate change on primary sex ratios are mainly focused in direct effects of rising temperatures; however, recent studies show that operational sex ratios (i.e., ratio of total number of males vs females breeding each year) are not as female-biased as previously thought and, and mate choice or competition may play more of a role in marine turtle reproduction (Hays et al. 2010; Wright et al. 2012; Stewart and Dutton 2014). Simultaneously, recent studies highlights the importance of consider other environmental variables such as moisture (sand water content) to predict how sexual differentiation of embryos will be affected under future climate conditions (Santidrián Tomillo et al. 2015; Wyneken and Lolavar 2015). Experiments subjecting loggerhead nests under different hot and wet conditions in the laboratory, and data from nests incubated in years that were wetter than normal, showed that the number of males produced was greater than would be expected based on previous studies of sex ratio and incubation temperature (Wyneken and Lolavar 2015). As a result of all these findings, marine turtle researchers encourage to use more analytical approaches that combine both field and laboratory data and consider both temperature and moisture, for a more accurate set of predictions on hatchling sex ratio biases, but also to anticipate the effects of changing temperature and precipitation on sex ratios. Future research should be also focused on understanding how the primary sex ratio relates to the operational sex ratio and how it varies over an animal's lifetime to better understand population dynamics and assess vulnerability to climate change (Stewart and Dutton 2014).

#### **2.4. Environmental Conditions Affecting Embryonic Development**

Effective management of threatened species requires a deep knowledge on population dynamics and demographic parameters; these demographic parameters are all input parameters for population models used to manage the species and promote conservation measures. In marine turtles hatchling production is a critical demographic parameter; thus improving knowledge of embryology and hatchling production should be included as a priority objectives in future nesting beach management.

Temperature is the main environmental factor that affects embryonic development with sex ratio and growth rates of hatchlings influenced by nest temperatures during incubation.
Temperature is decisive not only in sex determination but also affect embryos development, hatching success and hatchlings locomotor abilities (Matsuzawa et al. 2002; Maulany et al. 2012; Read et al. 2013; Pike 2014). Frequently, the reference used in different studies around the world about the range of temperatures that marine turtle embryos can withstand and at which they can successfully hatch, is based on studies dating 30 years (35°C, Ackerman 1997). However, recent studies have addressed that naturally fluctuating thermal regimes can exceed 35°C, and still produce hatchings (Booth and Evans 2011; Wood et al. 2014). Moreover, these fluctuations varying among species and nesting areas (Booth et al. 2013; Read et al. 2013) making essential in future researches determining the lethal temperature limits to embryonic development as well as identifying which marine turtle populations are most at risk from embryonic mortality (Howard et al. 2014). Current discrepancies about marine turtle's potential to cope with climate change highlight the significant gaps in our knowledge of both the direction and the magnitude of responses by marine turtles to climatic factors (Patiño et al. 2014; Wyneken and Lolovar 2015; Santidrián Tomillo et al. 2015). Forthcoming studies on nesting beaches should include studies pointing to better understand the complex outcomes of climate change for marine turtles, in order to highlight the most vulnerable species and populations, and encouraging prioritization of conservation effort to the most threatened systems.

Besides temperature, other environmental factors, such as shading and sun exposure (Standora and Spotila 1985), gas exchange (Hays et al. 2001), partial pressures of oxygen, pO2, and carbon dioxide, pCO2 (Wallace et al. 2004; Garret et al. 2010), and moisture from rainfall (Godfrey et al. 1996; Houghton et al. 2007) influences embryonic development and phenotype in turtles. Variations of these environmental conditions can alter a large variety of hatchling characteristics, including embryonic growth rates (Kuroyanagi and Kamezaki 1993), hatch success, and sex ratios (Bull 1980; Mrosovsky and Yntema 1980; Carthy et al. 2003). Future global warming will also lead environmental changes such as sea level rise, increase oceans acidity, changes in patterns and amounts of precipitation and coastal erosion (Fuentes et al. 2010; Dutton et al. 2015). All of these changes can increase average moisture levels, flooding and erosion of marine turtle nesting beaches (Katselidis et al. 2014) influencing reproductive success of marine turtles. On the other hand, increased exposure to water can be detrimental to the incubating eggs as a strong negative correlation between sand water content and emergence success exists (Patiño-Martinez et al. 2014). Furthermore, an excess of water above a nest can prevent gas exchanges between the air and the nest and asphyxiate the nest (Yalçin-Özdilek et al. 2007).

It is clear that most of future threats for marine turtles in nesting areas are related to potential changes in their reproduction derived from future global warming (Hamman et al. 2010). However, there are other threats that should be keep in mind such as pollutants and its potential effects, which is a key area for future research. There are a wide range of environmental chemical pollutants like metals, organometallics, petroleum products of several types; oil dispersants; polycyclic aromatic hydrocarbons (PAHs); plastics; plasticizers; surfactants; current-use pesticides. A few of these chemical classes have been assessed in marine turtles; most of knowledge about contaminants in marine turtles has been focused in the effects of Persistent Organic Pollutants (POPs). POPs typically are halogenated organic compounds, including a range of substances such as PCBs, DDT, and dioxins characterized for they persist for long periods of time in the environment and can accumulate and pass from one species to the next through the food chain. POPs exhibit high lipid

solubility and it is likely that are transferred from nesting females to eggs and hatchlings during reproduction; but there are scarce data on the toxicological effects of POPs on marine turtle embryonic development and its consequences for hatchling development. There is also currently limited information on POPs in marine turtle populations or the maternal transfer of these chemicals and the effects this may have on the reproductive success of nesting populations (van de Merwe et al. 2009, 2010). More research is required to investigate geographical trends of contaminant concentrations and potential health effects (i.e., abnormalities) caused by these contaminants on marine turtle development (Alava et al. 2011). Many more studies are needed to understand the toxicological effects of not only POPs but all chemical classes in altered embryonic growth, mortality and reduced reproductive success of marine turtles. In tortoisheshells it has been described that some trace elements are passed to eggs directly through the eggshell from contaminated soil (Tryfonas et al. 2006; Yalçin-Özdilek et al. 2011); to study this possibilities in marine turtles eggs could be focused of future research in nesting areas with high levels of plastics accumulation and in those located in touristic areas. Plastic items have become the principal constituent of marine debris, and its presence in nesting beaches alters factors affecting hatching success (e.g., Temperature, moisture). Moreover, turtles are impacted by plastic pollution through entanglement, ingestion, bioaccumulation, and habitats degradation (Gregory 2009; González Carman et al. 2013; Poli et al. 2015). Hence, future actions are required to better understand this issue and its effects on marine turtles, so that appropriate and effective mitigation policies can be developed (Vetger et al. 2014; Nelms et al. 2015).

## **3. CONSERVATION STRATEGIES AND FUTURE RESEARCH ON OCEANIC PHASES**

### **3.1. Migratory Routes and Movements**

Properly conservation measures for marine turtles require understanding the status and condition of their stocks across all life stages (Heppell et al. 2005); one of the handicaps to establishing conservation strategies for marine turtles is their status of migratory species. As it has been described before, population recruitment begins when hatchlings leave the nesting beach and enter the ocean, where they remain offshore for several years, undergoing long trans-oceanic migrations until they appear as immature turtles in neritic waters (Bjorndal and Bolten 1988). Finally, when turtles reach sexual maturity they migrate among neritic or oceanic foraging, breeding, and nesting grounds (Hopkins-Murphy et al. 2003). Historically, information regarding long range movements has been collected using natural marks and attaching metal or plastic flipper tags or passive integrated transponder (PIT) tags into flipper muscle (Hedrickson 1958; Balazs 1999). The pioneer studies based on tag data provided valuable information on turtle dispersion, nesting frequency and nest site fidelity (Alvarado and Murphy 1999; Schroeder et al. 2003). However they do not provide information on the migratory route followed by the animal, movement patterns and behaviour (e.g., speed, diving). A turning point in the studies of marine turtle's spatial ecology was the use of satellite tracking with an exponential rise in its use in the last decade (Luschi et al. 1996; Godley et al. 2008). Satellite telemetry allows track animals during long periods, provide atsea locations and behavioural data throughout complete migratory cycles and have the advantage that the data can be recovered remotely (Costa et al. 2012).

First studies with this tool focussed on tracking post-nesting females tagged on nesting beaches (Balazs et al. 1994; Godley et al. 2003). Advances in satellite telemetry have been crucial to discover and delve into the behaviour of probably the most inaccessible species in its oceanic phase, the leatherback turtle (Eckert 2006). Studies of leatherback turtle's movements are mostly restricted to adults; in general it has been shown that leatherback nesting populations use diverse migratory routes which allow them exploit several foraging grounds (Benson et al. 2007; Eckert et al. 2009; Bailey et al. 2012). Tracking studies of nesting female leatherbacks allowed find out that many females nesting in the Caribbean carried out migrations northward (Ferraroli et al. 2004; Hays et al. 2004); subsequent studies evidenced that temperate shelf and slope waters of the northwest Atlantic support extensive foraging by adult male and female turtles, as well as subadults (James et al. 2005). It has been possible describe the diving behaviour of this species showing the capacity to achieve depths > 1200 m and dive durations greater than one hour (Doyle et al. 2008; López-Mendilaharsu et al. 2008). Satellite tracking studies have also allowed go in deep in the migratory routes and behaviour of the remaining marine turtle's species with significant contributions to the knowledge of their lifecycle stages and conservation (Schofield et al. 2007; Hawkes et al. 2011). Tracking of olive ridley in Australia revealed that the meandering oceanic movements of turtles in the Pacific resulted in distinct foraging areas and, the locations of important foraging areas overlapped with existing trawl fisheries and oil and gas exploration and mining (Whiting et al. 2007). Studies of movements of adult hawksbill turtles in Pacific coasts of El Salvador, Nicaragua and Ecuador exposed a previously unknown life-history paradigm for adult hawksbill turtles; these turtles where located within confined inshore estuarine bays associated with mangrove saltwater forests and shrimp ponds (Gaos et al. 2012) rather than inhabit open-coast coral reef habitats as other adult hawksbill populations (León and Bjorndal 2002). The authors propose the hypothesis that preferred habitat probably represents a relatively recent adaptation and possibly a unique evolutionary trajectory for this population. This unexpected finding highlights the possibility that marine turtles exhibit different lifehistory strategies to their conspecifics among ocean regions, and the importance of understanding such disparities from an ecological and management perspective. An additional critical knowledge for guiding management decisions is the description of the spatial and temporal habitat use patterns of reproductive adults in the neritic zone (Hawkes et al. 2006). Hence, studies about patterns of movement during the breeding season (internesting periods) have also been carried out (Schofield et al. 2010; Revuelta et al. 2015). For example, the study of movements of the critically endangered kemp's ridley along the Gulf of Mexico, allowed to ascertain the round year residence of males in the adjacent areas to the nesting beach, identify migratory paths and foraging grounds which has been key to develop and implement recovery actions in the area (Shaver et al. 2005). In Central Africa, satellite telemetry was used to assess the efficiency of a National Park in the protection of adult olive ridley nesting females; the results of this study support the proposal of create a transboundary park since only 44.6 percent of high-density areas were found within the current park but the proposed transboundary park would incorporate 97.6 percent of high-density areas (Maxwell et al. 2011).

We are a long way from our goal of developing predictive models of sea turtle distribution patterns in the oceanic zone. Pursuing a better understanding of spatial and temporal ecology of marine turtles, recent studies have integrated satellite telemetry, remotely sensed environmental data, and habitat/environmental modelling to have broadened knowledge on potential influences of environmental variables such as Sea Surface Temperature, Surface chlorophyll concentration on turtle movements (Seminoff et al. 2008; Dodge et al. 2014). These studies will contribute to understanding changes in behaviour, movements and future aggregations for these species. It is recognised that climate change may alter the spatio-temporal abundance of mobile and migratory animals (Robinson et al. 2009; Kaschner et al. 2011), changing the dynamics of trophic food webs and other interspecific interactions (Edwards and Richardson 2004; Both et al. 2010). Predictive models will be elementary in describe the impacts of climate change on these globally distributed species; hence, future experimental and ecological focus should be directed to incorporate climate change into species conservation planning (Araújo et al. 2004; Hannah et al. 2002). Furthermore, models might predict available habitat with greater specificity than temperature alone, which is the predominant variable used in bioclimatic envelope modelling, for example, approaches will need to encompass mapping prey distribution (Witt et al. 2010).

The knowledge achieved during decades of study of marine turtle's migrations has had invaluable conservation implications. Fisheries bycatch constitutes one of the greatest threats for marine turtles during their oceanic phases (Lewison and Crowder 2007). The leatherback turtle illustrates again this contribution since dramatic worldwide decline of these species populations is largely due to high levels of bycatch (Lewison et al. 2004a, b). In the Pacific Ocean, leatherback populations have followed dramatic declines and extinctions over the last 30 years (Liew 2011; Tapilatu et al. 2013). The study of oceanic migratory routes of adult leatherback females in the Atlantic and Pacific Oceans, has allowed to identify 'hot spots' where leatherbacks overlap with fisheries, highlighting the areas where conservation efforts should be focused (Ferraroli et al. 2004; Fossette et al. 2014; Roe et al. 2014). Long-line fisheries effort is also a great anthropogenically-derived threat for loggerhead turtles in the Atlantic around West Africa, including the Cape Verde islands, population which is the only substantial rookery in the eastern Atlantic (Marco et al. 2012; Coelho et al. 2013; Melo and Melo 2013). The habitats frequented by these loggerhead turtle are coincident with greatest longline fisheries catch data within the Exclusive economic zones (EEZs) of Western Sahara, Cape Verde and Mauritania, and with all other gear types within the coastal EEZs of Western Sahara, Mauritania, Senegal, Gambia and Guinea-Bissau (Pikesley et al. 2014). In the Mediterranean Sea, interaction with fisheries is the threat with highest impact on loggerhead turtles, being drifting longline and bottom trawling the fisheries that capture most turtles in the region (Nada and Casale 2011; Domenech et al. 2014). Olive ridley turtles seem to be the most abundant species in the Eastern Pacific ranging from Mexico to Chile (Troncoso and Urbina 2007) and incidental capture in trawl fisheries and pelagic longlines is the main mortality source for the species with an estimated caught of 92,300 adult female olive ridley turtles in a period of 1999 to 2010, only by the Costa Rican longline fishery (Dapp et al. 2013). In the Gulf of Mexico, an estimated 2700 Kemp's ridleys (juveniles and adults) died annually from fisheries interactions even after mitigation efforts (Finkbeiner et al. 2011).

Assessing the impact of bycatch on marine turtles is a difficult work since it is significantly under-recorded and far greater than the total level of directed legal take (Humber et al. 2014). This is specially challenging when we refers to artisanal fisheries, which are recognized as a serious threat in areas where marine turtles congregate in high numbers like in foraging grounds (Kelez Sara 2011). It is a priority broadened current knowledge and fill the gaps about the effects of these small fisheries (Casale 2011). Future studies are highly urged to carry out multinational collaboration for a worldwide assessment of the susceptibility of marine turtles to bycatch; mapping the species spatio-temporal distribution and the extent of interactions with fisheries has been proposed as a key future tool (Fossette et al. 2014). Bycatch of turtles in longline and trawling fisheries results in high rates of post-release mortality that may negatively impact populations. Establishing strategies for mitigate incidental catch is a key conservation measurement to protect specific populations (Gilman et al. 2006). In this connection, a number of operational modifications have been established to modify fishing nets and hooks to reduce turtle's bycatch. Examples of these modifications are increasing gear visibility, incorporating a turtle excluded devices (TEDs), modifying float characteristics (Lucchetti et al. 2008; Gilman et al. 2010). Although there exist data describing the patterns of capture of turtles in various fisheries gear types, knowledge base of post-capture-release survivorship and physiology, both in the short and long term, is very poor. The fate of turtles released alive from fisheries depends on the nature of the interaction and condition at the time of release. A recent study has documented for the first time in marine turtles, the physiological impacts of capture in longline gear on loggerhead turtles in the Mediterranean Sea (Williard et al. 2015). These studies about the effects of bycatch are encouraged to be applicable for other species of marine turtles and regions. On the other hand, there are still places with no data about bycatch levels and mortality rates. Hence, along with the establishment of measures for incidental catch mitigation future research should be focussed on study these unknown areas (Wallace et al. 2013). In other regions the lack of knowledge about what life stages are affected by fisheries have resulted in an inadequate legislation (Stringell et al. 2015), highlighting the importance of streamline the information flow between scientific and policy makers. Incorporating novel techniques already used for the study of bycatch in other marine species such as birds and fishes (Alfonso et al. 2011; Graham and Crawdford 2015), will further improve bycatch mitigation of marine turtles.

### **3.2. Foraging Grounds**

Marine turtles spend the vast majority of their lives in the marine environment; however, yet much less is known about the biology of post-hatchling and early juvenile stages than about the biology of females and hatchlings on the nesting beach (Reina et al. 2002). Hatchlings leave their natal beaches and enter the sea where drift passively with ocean currents which drive their broadscale dispersion into oceanic areas and this likely occurs across the nesting range of marine turtles including the Pacific, Indian, Atlantic and Mediterranean (Lohmann and Lohmann 2003; Boyle et al. 2009; Scott et al. 2014). The juveniles then grow for several years before the ontogenetic behavioural shift from epipelagic to demersal neritic developmental habitats take place (Musick and Limpus 1997; Scott et al. 2012).

The duration of the pelagic state and animal's behaviour during this phase is variable between species with loggerhead turtles spending longer periods as epipelagic within the cheloniid turtles, while for leatherbacks it is hypothesize that hatchlings converge in areas of major upwelling where gelatinous prey are abundant (See Musick and Limpus 1997 for a review). This time lapse of oceanic-stage hatchling has been commonly referred to as the "lost years" due to the lack of knowledge about where these hatchlings go or how they behave

(Miller 1997). The understanding of post-hatchling ecology has primarily been obtained through studies of behaviour and diet and most accepted hypothesis about its behaviour was that they occupy sea surface habitats associate with floating Sargassum communities (Witherington et al. 2012). There is only one recent study that has elucidated the loggerhead oceanic nursery paradigm characterizing neonate oceanic movements and surface habitat use (Mansfield et al. 2014). This study characterize hatchlings loggerhead oceanic movements and surface habitat use, the results show that hatchlings dispersal is not uniformly unidirectional as was previously assumed (Carr 1987); a second important finding is that hatchling actively look for Sargassum habitats that presumably provide favourable foraging and thermal niches. The study opens the opportunity for future studies on hatchlings transoceanic migrations of other species of marine turtles. The study of hatchling dispersal will have important direct implications for conservation of this early life stages but also for turtles throughout adulthood since the adult migration routes can be shaped by their past experiences as drifting hatchlings (Hays et al. 2010a; Scott et al. 2014). More quantitative and novel interdisciplinary approaches are necessary to understand the drivers that underpin the movement patterns and foraging habitat selections of adult turtles. Future studies will be improved merging tracking data with oceanographic models, magnetic navigation behaviour and environmental data that have great utility for assessing spatially and temporally relevant dispersal patterns of drifting organisms (Baltazar-Soares et al. 2014). The ontogenic shift from an oceanic to neritic stage has been mainly studied in the case of loggerhead turtles. Studies on this species reveals that this change of zone is probably a period of transition that implies morphological and behaviour changes (Bolten 2003). The neritic juvenile turtles are active and feed primarily on the bottom (epibenthic/demersal) (Bjorndal et al. 2003). Once these large juveniles have entered a benthic life stage, they inhabit coastal waters and make seasonal latitudinal migrations between neritic feeding grounds (Hopkins-Murphy et al. 2003).

One of the main gaps in the understanding of turtle's life cycle was to know which nesting areas contribute to a particular feeding area (Limpus et al. 1992). This lack of knowledge had critical conservation implications since all efforts carried out in a nesting area could be all in vain if these turtles are then harvested in their foraging areas. In the 1990s there were carried out several studies about demographic links between nesting aggregates and feeding aggregates to shed light on the understanding of marine turtle distribution and population structure. With the development of molecular genetic tools (e.g., mitochondrial DNA sequence analyses), the relative contributions of rookeries to mixed stocks of oceanicstage loggerheads could be evaluated (Bowen et al. 1995). After having been demonstrated the presence of rookery-specific myDNA polymorphism (See above Bowen et al. 1993), the frequency shifts observed between populations were used to indicate the origin of turtles found in distant feeding grounds or in migratory corridors, using a maximum likelihood (ML) algorithm to estimate the relative contribution of breeding stocks to foraging areas (Velez-Zuazo et al. 2008; Jensen et al. 2013). Studies of molecular genetic composition of foraging and developmental grounds for juvenile turtles in different regions and species show that these areas are usually composed of individuals from multiple distant rookeries (Carreras et al. 2011; Anderson et al. 2013). Thus, impacts on such stocks usually affect multiple colonies, which require international efforts for conservation. All these studies have provided evidences regarding migration patterns of marine turtles, offering key information to support the

implementation of mitigation measures (Hart et al. 2012; Dutton et al. 2013; Griffin et al. 2013; Proietti et al. 2014; Prosdocimi et al. 2015).

The advent of molecular techniques has lead important achievements in conservation planning for migratory species such as marine turtles. Genetic analyses have revealed the complex population structure of these species and its importance in defining management units for their conservation at each life stage (Dutton et al. 2014; Phillips et al. 2014). It has been demonstrated that perturbations on pelagic juveniles or subadults would have an impact on nesting colonies, as well as disturbances to adults will have establish impact on corresponding breeding populations (Monzón-Argüello et al. 2010). Knowledge about population structure in different areas have showed the need of preserve the genetic diversity of the marine turtle population; population genetics data have been joined to population abundances and trends, and satellite telemetry data to delimitate Regional Management Units (RMUs) for prioritizing conservation and research across multiple scales (Wallace et al. 2010). RMUs provide a framework for identifying data gaps, assessing high diversity areas for multiple species and genetic stocks, and evaluating conservation status of marine turtles. RMUs allow for identification of geographic barriers to gene flow, and can provide valuable guidance to marine spatial planning initiatives that integrate spatial distributions of protected species and human activities. Despite the advances in the genetic tools (e.g., Bayesian Mixed Stock Analysis (MSA)) there are intrinsic characteristics in the populations structure of marine turtles that should be consider when working with these kind of data. For example, the occurrence of common mtDNA haplotypes that are shared among rookeries may lead to unreliable MSA results with large confidence intervals (Shamblin et al. 2011). Future studies should evaluate the power of specific genetic markers to detect structure in order to correctly identify the appropriate population units to conserve. It is recommended to use fine-scale level through the use of population genetics; large studies comprising vast sampling areas and the use of long segments of mtDNA control region as these highly enhance genetic resolution (LeRoux et al. 2012; Clusa et al. 2014). Additionally, temporal variation in the mtDNA haplotype frequencies of turtles nesting in different years have been observed in some populations (Shamblin et al. 2011) making necessary robust sampling designs to include samples collected across years for the identification of management units. In addition, the employ of longer control region sequences and developments in statistical models for analyzing mixed stock composition will likely result in confidence intervals for the point estimates of rookery contributions to foraging populations (Shamblin et al. 2012, 2014).

Identifying the foraging habitat of marine turtles is vital to understanding the ecology of these species and for their management and conservation. In fact, establishing key foraging areas for marine turtles has been determined as a conservation priority in the 21st century (Hamman et al. 2010). Protection and recovery requires identifying critical at-sea foraging habitats and better understanding the spatial distribution of marine turtles (Blumenthal et al. 2006; Mansfield et al. 2009; Scott et al. 2012). Flipper tagging, satellite telemetry and stable isotope tracking have been key tools for the study and identification of foraging habitats for marine turtle species all around the world. The use of telemetry datasets and modelled movements and behaviour have allowed to discover important habitats for these species (Hays et al. 2002; Hawkes et al. 2011; Hart et al. 2012), to determine distances of foraging grounds from nesting and tagging sites (Troëng et al. 2005; Read et al. 2014), time spent by turtles to cover these distances and fidelity over time to these foraging areas (Esteban et al. 2015) and identify seasonal migrations and home range (Hart et al. 2015; Revuelta et al.

2015). There are numeral examples of application of this knowledge for the development of conservation strategies for marine turtles. The monitoring of adult loggerhead nesting females turtles originating from three separate subpopulations in the Gulf of Mexico revealed the use of a common at-sea foraging area during non-nesting periods, highlighting the importance of protect this area (Hart et al. 2012). In the same region, a different study showed overlapping between areas shared by multiple loggerheads with areas of high fishing effort; this data could contribute to establish efficient conservation management strategies in the area (Hardy et al. 2014).

One of the characteristic of marine turtles foraging grounds is its dynamic condition, which makes difficult distinguish hidden behaviours just analysing satellite tracking data. This hindrance can be enhanced applying modern statistical methods with great potential for modelling population time series (Newman et al. 2006). The State-space models (SSM) refine Argos tracking data by accounting for observation errors and stochasticity in animal movement, incorporate behavioural information estimating the probability that an animal is in a particular discrete behavioural mode, such as transiting or foraging (Jonsen et al. 2003; Patterson et al. 2008; Johnson et al. 2008). The SSM have best recreated habitat use and migration routes of hawksbill turtles nesting on Groote Eylandt, northern Australia (Hoenner et al. 2012); modelling loggerhead turtle movement in the Mediterranean Sea (Eckert et al. 2008) and definition of the different behavioural phases such as migration versus foraging for leatherbacks in the Pacific Ocean (Bailey et al. 2008) and in the northeastern Atlantic (Jonsen et al. 2007).

Molecular and Satellite telemetry studies have also been complemented with stable isotope analyses (Vander Zanden et al. 2015). Stable isotope ratios have been increasingly used as intrinsic markers to trace foraging habits and movements of marine turtle populations (Newsome et al. 2010; Zbinden et al. 2011). The measurement of naturally occurring stable isotopes in animal tissues represents one means of assaying intrinsic markers in animals in order to infer information on their origins. The use of stable isotopes is based on the fact that stable isotope ratios of nitrogen (15N/14N, noted δ15N) and carbon (13C/12C, noted δ13C) concentrations in the consumer tissues reflect those in their resources and those spatial patterns, gradients, or changes in such markers exist in nature (Deniro and Epstein 1978; Hobson 2007). Thus by making isotopic measurements in animal tissues and knowing how stable isotopic patterns in foodwebs change spatially, it is often possible to infer their origins. In the marine environment, stable isotope ratios of nitrogen  $(\delta15N)$  are typically used to assess trophic level and carbon (δ13C) vary little along the food chain and can offer insight into foraging location (Peterson and Fry 1987; Wallace et al. 2009). Using stable isotopes as dietary tracers has been a key tool for describing foraging variations among individuals (Snover et al. 2010) and between life stages (Arthur et al. 2008), for determining the characteristics of feeding grounds, for determining ontogenetic changes in habitat and diet, and for linking breeding and foraging grounds of marine turtles. Accurate data about marine turtles habitat use can facilitate conservation and resource management efforts (Benson et al. 2011; Block et al. 2011). Stable isotopes analysis supplement the information obtained from satellite tracking about the movements and habitat use by turtles. Studies of tracked juvenile loggerhead turtles in North Carolina, USA showed to have significant variation in movement behaviours (oceanic versus neritic) (McClellan and Read 2007); posterior studies of diet composition determined by stable isotope ratios demonstrated that individuals that use openocean habitats have lower stable nitrogen isotope ratios than do those that remain within

neritic areas, indicating a dietary dichotomy (McClellan et al. 2010). Studying isotopic compositions of marine turtle body tissues sampled at nesting beaches showed divergent migratory strategies and within-population segregation of foraging groups of leatherback marine turtles across the Pacific Ocean (Seminoff et al. 2012). In the case of nesting females, foraging ecology can also be characterized using eggshell isotopic signatures (Paddock 2007). Dichotomy in foraging area was also revealed through isotope analysis of egg-yolk and blood for Atlantic leatherback turtles and the results of this work highlighted the urgent need to determine the feeding habitats of the turtle in the Atlantic in order to protect this species from incidental take by commercial fisheries (Caut et al. 2008). These works indicate that egg analysis is a useful and less invasive tool for assessing isotope values in marine turtles. Recent research (Detjen et al. 2015) has demonstrated that it is possible to describe marine turtle migration and habitat use patterns studying isotope signatures in barnacles, an obligate

commensals that have been reported widely from marine turtle populations from across the world (Casale et al. 2004; Frick et al. 2010). In future studies, additional methods such as barnacle proxies could therefore complement other methods in understanding regional movement patterns.

Despite the number of studies and techniques applied, connections that exist among rookeries and foraging grounds, location of oceanic 'hotspots' that include key foraging habitats and mechanisms of foraging site selection remain poorly defined. Future steps proposed to improve knowledge about marine turtles foraging habitats include further integration of disparate tracking data-sets at the oceanic scale along with modelling of movements to identify critical at-sea foraging habitats where individuals may be resident during non-nesting periods (Hart et al. 2013). On the other hand, sex-based dispersal remains poorly understood in marine turtles and still studies have been unable to analyse foraging composition by sex (Jensen et al. 2013). Hence, future researches could take into account to increase studies about tracked males in order to know where are their foraging grounds and test if there are different drift scenarios between females and males hatchlings that could result in differences in adult migration routes and, consequently sex differences in foraging location (Poloczanska et al. 2009; Hays et al. 2010). Long-term monitoring of the composition of foraging grounds may provide an effective way of detecting significant population changes as well as identifying female- and/or male-producing rookeries (Pajuelo et al. 2012). Future effects of climate change on shifts on ocean currents that transport juveniles to those foraging grounds (Fuentes et al. 2009) and this in turn might give rise to new post-breeding adult migrations. Future studies should also pay attention to areas where hybridization is a common process (e.g., loggerhead x hawksbill turtles and loggerhead x olive ridley in Brazilian waters) between breeding groups; understanding the distribution, ecology, and migrations of these hybrids is essential for the development of adequate conservation and management plans (Reis et al. 2010; Proietti et al. 2014). Future studies mixing data from stable isotope and skeletochronology can offer insight into foraging location (nearshore vs. offshore) (Wallace et al. 2009; Snover et al. 2010). Skeletochronology identifies significant increases in marine turtles growth rates (as inferred through skeletal growth increment width) that has been proposed to correspond with an ontogenetic change in foraging habitat and/or prey preference (Snover et al. 2010). There are still many questions to answer about marine turtle's behavioral ecology and habitat use that require the future effort of researchers in this field.

## **CONCLUSION**

Marine turtles are a well-studied group, during decades it has been recorded knowledge about their physiology, behaviour, distribution, habitat use, and different characteristics of their lifecycle stages. However there are still many unfilled gaps in our knowledge of marine turtles that require future studies go in deep on. Stunningly, in the last decade there have been discovered new important areas for marine turtles ignored for so long, showing that scientific community's has much to learn about the questions of how many, where and when marine turtles exist. Increase knowledge about the potential effects of future global warming scenarios would have on this species, are considered as a main objective by scientist. The use of more analytical approaches combining both field and laboratory analyses to improve knowledge about environmental conditions affecting embryonic development, and understanding how the primary sex ratio relates to the operational sex ratio, will be some of the study areas to better understand population dynamics and assess vulnerability to climate change. Since marine turtles are migratory species heavily affected by fisheries, it is necessary continuing working on plans to improve knowledge about fisheries effort, improve tools for diminish marine turtle bycatch rates, and identify the most appropriate mitigation measures. The lack of data of artisanal fisheries is an unresolved matter concerning marine turtle's conservation that should be considered as a main objective to solve by researchers and conservationist. There are also many other key questions like hatchling dispersion, sex-based dispersal, genetic relationships between rookeries, composition of foraging grounds, that are still under resolved. The application of state-of-the-art techniques, such as statistical methods with great potential for modelling population time series, longer control region sequences and developments in statistical models for analyzing mixed stock composition in genetic studies, and tracking animal migration with stable isotopes approaches, will yield a wealth of knowledge that will improve our understanding of these species and their habitats, and that will turn into the establishment of better conservation measures.

# **SPIRORCHIIDIOSIS AND OTHER FORMS OF PARASITOSIS IN SEA TURTLES ON THE COAST OF BRAZIL**

## *Max Rondon Werneck1,\* , Hassan Jerdy Leandro<sup>2</sup> and Eulógio Carlos Queiroz Carvalho<sup>2</sup>*

<sup>1</sup>BW Consultoria Veterinária, São Paulo, Brazil <sup>2</sup>Universidade Estadual do Norte Fluminense Darcy Ribeiro – UENF, Campos dos Goytacazes, Rio de Janeiro, Brazil

## **ABSTRACT**

Spirorchiids (family Spirorchiidae Stunkard 1921) are a group of flukes that inhabit the circulatory system of turtles. The family has approximately 100 species grouped into 19 genera, 10 of which are parasites of sea turtles that have been described for *Chelonia mydas* Linnaeus 1758, *Caretta caretta* Linnaeus 1758, *Eretmochelys imbricata* Linnaeus 1766, *Lepidochelys olivacea* Eschscholtz 1829 and *Chelonia mydas agassizii* Bocourt 1868. Infection by members of the family Spirorchiidae involves egg deposition in the host blood stream, accumulation in tissues, which cause inflammatory reactions and embolisms, leading or contributing to the death of the host. However, little is known regarding this type of parasitosis in sea turtles found on the coast of Brazil. The aim of this chapter was to perform a literature review to provide information on the state of spirorchiidiosis and other forms of parasitosis in sea turtles found along the Brazilian coast. This is pioneering work in the field, as very little information is found on the health status of sea turtles in Brazil, especially with regard to this parasitic disease, which can cause serious injuries in hosts and even death.

**Keywords**: Brazil, parasites, sea turtles, Spirorchiidae

### **INTRODUCTION**

Among the seven species of sea turtles in the world, five are found along the coast of Brazil: the leatherback turtle (*Dermochelys coriacea* Linnaeus, 1758), loggerhead turtle (*Caretta caretta* Linnaeus, 1758), olive ridley turtle (*Lepidochelys olivacea* Escholtz, 1829), hawksbill turtle (*Eretmochelys imbricata* Linnaeus 1766) and green turtle (*Chelonia mydas* Linnaeus, 1758) (Marcovaldi & Marcovaldi 1999). Although knowledge on the health status of a population is considered an important conservation tool, very little is known regarding the health problems of sea turtles on the Brazilian coast. Studies on this issue have mainly addressed fibropapillomatosis, which is a virus characterized by tumor masses with a debilitating and even lethal nature (Rossi et al*.*, 2009; Zwarg et al., 2014; Rodenbusch et al., 2014).

As in other hosts, parasites of sea turtles constitute an important ecological-health factor, as these organisms can cause serious illness and even contribute to the death of chelonians (Gordon et al., 1998; Stacy et al., 2010). Sea turtles have a varied parasitic fauna and many families of parasites have been described (Gibson et al*.*, 2002; Jones et al*.*, 2005). Moreover, like other chelonians, sea turtles are hosts of a distinct family of digenetic flukes that inhabit the circulatory system, denominated Spirorchiidae. Although the debilitating and even fatal potential of this form of parasitosis is known, few chelonians are examined for spirorchiids along the coast of Brazil. The specialized literature has reported this parasitosis and associated injuries in sea turtles (Rand & Wiles, 1985; Gordon et al., 1998; Raidal et al., 1998; Santoro et al., 2007; Stacy et al., 2010; Chen et al., 2012), but few data have been reported for Brazil.

The aim of the present study was to perform a literature review on spirorchiidiosis and other forms of parasitosis in sea turtles found along the Brazilian coast.

## **METHODS**

This study was developed using only scientific papers on the helminths identified as well as the injuries caused by spirorchiids in sea turtles from Brazil published between 1919 and 2016. Dissertations, theses and abstracts from conferences were not considered. While the collection and fixation of parasites were not the main focus of this study, the reader can gain a better understanding of these aspects in studies conducted by Snyder & Clopton (2005) and Greiner (2013). Parasite species richness, prevalence, mean infection intensity and mean abundance were reported when described by the authors cited and followed the definition proposed by Bush et al. (1997). For classification, the taxonomic proposal presented by the World Register of Marine Species (WoRMS, 2015) was used.

## **The Family Spirorchiidae**

The family Spirorchiidae Stunkard 1921 includes approximately 100 species distributed among 19 genera. Members of this family are exclusive parasites of terrestrial and aquatic chelonians and use the circulatory system at their habitat (Smith, 1997; Platt, 2002). Among

the 19 genera currently described for the family, ten are restricted to sea turtles. *Hapalotrema* Looss 1899, *Amphiorchis* Price 1934, *Learedius* Price 1934, *Neospirorchis* Price 1934, *Monticellius* Mehra 1939 and *Carettacola* Manter & Larson 1950 are considered cosmopolitan parasites. *Neocaballerotrema* Simha 1977, *Shobanatrema* Simha & Chattopadhyaya 1980, *Cheloneotrema* Simha & Chattopadhyaya 1980 and *Satyanarayanotrema* Simha & Chattopadhyaya 1980 are only reported for India and none has yet had its biological cycle clarified (Platt, 2002). This parasitosis causes serious harm due mainly to the deposition of eggs in host tissues, which can occasionally lead to death (Gordon et al*.*, 1998). Such findings have been described for *C. mydas* (Greiner et al*.*, 1980; Glazebrook et al*.*, 1981; Glazebrook et al*.*, 1989; Gordon et al*.*, 1998; Santoro et al*.*, 2007; Stacy et al*.*, 2010; Chen et al*.*, 2012), *C. caretta* (Wolke et al*.*, 1982; Stacy et al*.*, 2010), *E. imbricata* (Glazebrook et al*.*, 1989; Dutra et al*.*, 2012) and *L. olivacea* (Santoro and Morales, 2007; Jerdy et al., 2016)

Figure 1. A) Dark nodules in small intestine (arrow), green turtle; B-C) Blood vessel with parasitic embolism composed by spirorchid eggs; D) Eggs of *Learedius learedi* in stereomicroscopy.

The most common macroscopic lesions reported in necropsies are dark nodules measuring approximately 1 to 2 mm in diameter (Figure 1A), which reveal a large amount of fluke eggs when analyzed using stereomicroscopy (Figure 1B,C and D). The histopathology of the nodules reveals chronic inflammation due to the eggs, which, when released into the blood stream, become lodged in different sites of the host organism (Gordon et al*.*, 1998; Santoro et al*.*, 2007; Stacy et al*.*, 2010; Chen et al*.*, 2012). Although a less common finding, adult helminths are also capable of causing inflammatory reactions (Gordon et al., 1998; Santoro et al*.*, 2007). The lesions are granulomatous and contain the parasite eggs, affecting most host organs, such as the central nervous system, cardiopulmonary system, urinary tract, digestive system, salt glands (Glazebrook et al*.*, 1981; Glazebrook et al*.*, 1989; Gordon et al*.*, 1998; Stacy et al., 2010) and gonads. In these lesions of varied intensity and number, lymphocytes and macrophages apparently form the first line of defense against fluke eggs; moreover, macrophages fuse, giving rise to Langhans cells and, at times, foreign-body giant cells (Glazebrook et al*.*, 1981). The presence of eggs in host tissues is irrefutable evidence of parasitosis. Moreover, morphological and morphometric analyses of the eggs contribute to the identification of the genus of the parasite (Wolke et al*.*, 1982).

## **Spirorchiidiosis in Sea Turtles on the Coast of Brazil**

Studies involving the evaluation of cases of spirorchiidiosis remain scarce in Brazil and largely constitute reports conducted with few individuals. The first report of spirorchiidiosis occurred in 2006 (Werneck et al., 2006) and few turtles have been examined for this form of parasitosis whether due to an unawareness of the family or technical problems regarding collection during the necropsy of individual hosts. In recent years, however, a slight increase in the number of reports of lesions caused by spirorchiids along the Brazilian coast has been noted, with descriptions of this form of parasitosis in green turtles (Werneck et al., 2006; Goldberg et al., 2013; Werneck et al., 2015a; Binoti et al., 2016), hawksbill turtles (Werneck et al., 2008a; Dutra et al., 2012) and, more recently, olive ridley turtles (Jerdy et al., 2016).

#### **Spirorchiidiosis in** *Chelonia mydas*

The first case of injuries caused by eggs from the family Spirorchiidae in green sea turtles was described by Werneck et al*.* (2006), who analyzed 11 *C. mydas* juveniles from the coast of the state of São Paulo (southeastern Brazil), six of which (54%) exhibited adult *Learedius learedi* Price, 1934 (Figure 2) in the circulatory system and two exhibited dark nodules measuring 1 to 2 mm containing spirorchiid eggs. Subsequently, Goldberg et al. (2013) reported lesions caused by spirorchiid eggs in the lungs of a specimen of *C. mydas* found in the city of Florianópolis (southern Brazil).

A case of aortic aneurysm and thrombosis caused by *Hapalotrema postorchis* Rao 1976 was reported in a juvenile green sea turtle found on the coast of the state of Espírito Santo (southeastern Brazil). In the same individual, giant cell granulomas due to the parasite eggs were found in the heart, intestines, liver, pancreas, spleen, kidneys and brain (Figure 3). The infection was considered a debilitating factor of the host, but non-fatal. In the same year, Werneck et al*.* (2015a) reported another case of injuries stemming from the deposition of
spirorchiid eggs in a *C. mydas* juvenile also on the coast of the state of Espírito Santo, with granulomatous reaction in the liver. Analyzing the tissues of 16 green sea turtles found in the same state of southeastern Brazil, Binoti et al. (2016) reported the occurrence of fluke eggs mainly in the spleen and lungs, at times surrounded by giant cells. Less intensive lesions were found in striated muscle tissue, the digestive tract, salt glands, kidneys, heart, pancreas, skin and adrenal glands. Moreover, concomitant infection of parasitic forms and eggs were found in the brain.

Figure 2. *Learedius learedi* Price, 1934, heart of Green turtle.

## **Spirorchiidiosis in** *Eretmochelys imbricata*

Granulomas due to egg deposition in a hawksbill turtle have been found in the brain, salt glands, pancreas, mesentery as well as the large and small intestines (Werneck et al., 2008a; Dutra et al., 2012; Werneck et al., 2015b). The duodenum exhibited necrosis and lymphoplasmacytic inflammatory infiltrate related to the eggs, whereas the heart and liver exhibited fewer eggs and giant cells were found in the liver and lungs (Dutra et al., 2012).

## **Spirorchiidiosis in** *Lepidochelys olivacea*

The only record of spirorchiidiosis in *L. olivacea* in Brazil was made by Jerdy et al. (2016), who reported the occurrence of lesions in five individuals. The diagnosis was performed by microscopy of giant cell granulomas caused by spirorchiid eggs found in samples obtained from necropsies. The lesions affected the brain, thyroid glands, heart, lungs, spleen, liver and intestines. None of the five turtles had massive infection; all exhibited lesions with few eggs and small granulomas. Giant cells were found in the lesions of the spleen, lungs and intestines. The eggs in the brain, thyroid glands, heart and liver did not cause an apparent inflammatory response. No adult parasite specimens were found and the eggs in all five cases were types 1 and 3 (see Wolke et al., 1982). Type 1 eggs are characteristic of the genera *Hapalotrema*, *Learedius* and *Monticellius*, whereas type 3 eggs

are characteristic of the genus *Neospirorchis*, demonstrating possible infection of the olive ridley turtel by some of these genera.

Figure 3. A: Multifocal giant cell granuloma surrounding spirorchid eggs in spleen; B: Granulomatous meningitis with aggregations of spirorchid eggs (Asterisk) and caseous necrosis association, cerebral córtex was compressed (arrow); C: Salt gland with giant cell granuloma and caseous necrosis caused by spirorchid eggs; D: Embolism in salt gland by spirorchid eggs; E: Spirorchid eggs associated with giant cell granuloma in myocardium and epicardium; F –Severe granulomatous pneumonia with gigant cell surrounding inumerous spirorchid eggs; G: Aorta aneurysm associated with spirorchids eggs inside thrombus. Note thickness difference between túnica media (Lines B/D) artery wall layers (A/C); H: Granulomatous nephritis with giant cell surrounding spirorchid eggs.

## **Parasites in Sea Turtles on the Coast of Brazil**

According to Ruiz (1946), the first record of parasites in sea turtles in Brazil was possibly that made by Diesing in 1850, who reported the occurrence of *Monostomu trigonocephalum*

(currently *Cricocephalus albus*) (Digenea: Pronocephalidae) in a sea turtle (likely *C. mydas*). The material was sent to Europe for study.

Although the Brazilian coast is inhabited by five species of sea turtles, studies on the helminth fauna in the individuals found remain scarce, demonstrating a huge gap in knowledge regarding the parasitology of these chelonians. *C. mydas* is the best studied host on the coast of Brazil, followed by *E. imbricata*, *C. caretta*, *D. coriacea* and *L. olivacea*. Most reports are case descriptions in few host individuals, although a gradual increase in studies with a larger number of turtles has been observed.

#### **Parasites in** *Chelonia mydas*

Travassos (1918) was the pioneer in studies on these organisms in Brazil. The author reported the occurrence of a nematode from the family [Kathlaniidae](http://marinespecies.org/aphia.php?p=taxdetails&id=22910) denominated *Kathlania leptura* (Rudolphi, 1819). The parasite was found in *Testudo mydas* (*C. mydas*), possibly on the coast of the southeastern region of the country.

After the necropsy of a juvenile individual found on the coast of the state of Rio de Janeiro, Freitas & Lent (1938) collected three specimens of an unknown fluke, which was described as *Metacetabulum invaginatum* Freitas & Lent, 1938. The authors created a new family based on this species denominated Metacetabulidae, but the species was subsequently transferred to the family Pronocephalidae. In the same study, the authors described two other parasites based on samples deposited in the helminth collection of the Oswaldo Cruz Institute that had not previously been reported for Brazil: *Orchidasma amphiorchis* Braun 1899 and *Polyangium linguatula* Looss 1899.

Ruiz (1943) identified *Neoctangium travassosi* Ruiz 1943, as a new species of fluke found in a sea turtle rescued on the southern coast of the state of São Paulo (southeastern Brazil). However, the author did not identify the species of sea turtle from which the parasite was collected (*C. mydas*, see Muniz-Pereira et al. 2009).

After a literature review and analysis of material deposited in helminth collections of the Butantã Institute in the state of São Paulo and the Oswaldo Cruz Institute in the state of Rio de Janeiro, Ruiz (1946) presented a revision of the family Pronocephalidae, describing the species encountered in Brazil as well as those described in other regions. Through this bibliographic analysis, the authors presented a reorganization of the family Pronocephalidae, describing 28 genera grouped in seven subfamilies, but only five genera were described for C. *mydas* on the coast of Brazil: *Pronocephalus* Looss, 1899, with the species *Pr. Trigonocephalus* Looss, 1899 and *Pr. minutus* Ruiz, 1946; *Cricocephalus* Looss, 1899, with the species *C. albus* Kuhl et Hasselt, 1822; *Pyelosomum* Looss, 1899, with the species *P. crassum* Loss, 1901; *Pleurogonius* Looss, 1901, with the species *P. longiusculus* Looss, 1901, *P. trigonocephalus* Rudolphi, 1809, *P. linearis* Looss, 1901 and *P. lobatus* Looss, 1901; and *Metacetabulum* Freitas & Lent, 1938, with the species *M. invaginatum*. In the same year, Freitas & Lent (1946) reported the occurrence of *Porrocaecum sulcatum* (Rudolphi, 1819) in a green sea turtle found on the coast of the state of Rio de Janeiro (southeastern Brazil) as well as the description of the diagnosis of chronic and acute gastritis due to a fibrinous, purulent exudate stemming from the action of parasites and their eggs. As far as it is known, this is the first report of lesions caused by helminths in sea turtles on the coast of Brazil.

Vicente and Santos (1968) described *Tonaudia freitasi* Vicente and Santos, 1968 based on "*numerous specimens of nematodes*" collected from the stomach of a *C. mydas* individual from the state of Ceará (northeastern Brazil). Travassos et al. (1969) conducted a study on flukes occurring in Brazil and recorded 14 species found in sea turtles – one in *C. caretta* (*Rhytidodes gelatinosus* Braun, 1899) and 13 in *C. mydas***:** *N. travassosi*, *P. linguatula*, *M. invaginatum*, *O. amphiorchis*, *Rhytidodes gelatinosus* Braun, 1899, *P. lobatus* (synonym of *Glyphicephalus lobatus* Looss, 1901), *Pronocephalus obliquus* Looss, 1901 (synonym of *Pr. trigonocephalus*), *C. albus*, *P. linearis*, *P. longiusculus*, *Pleurogonius trigonocephalus*, *P. crassum* and *Ruicephalus minutus* Ruiz, 1946 as a new denomination for *Pr. minutus*.

After more than three decades, Werneck et al*.* (2006) analyzed 11 *C. mydas* juveniles from the municipality of Ubatuba on the northern coast of the state of São Paulo (southeastern Brazil). Specimens of *L. learedi* Price were found in six individuals (54.6%). This was the first report of parasites from the family Spirorchiidae in hosts on the coast of Brazil. In the same region, *Monticellius indicum* Mehra, 1939 was found in the heart of two *C. mydas* juveniles (prevalence: 0.83%) among a total of 239 individuals submitted to necropsy in the state of São Paulo between 2005 and 2008 (Werneck et al*.*, 2008b).

The analysis of a *C. mydas* individual from the state of Ceará (northeastern Brazil) revealed the occurrence of *Amphiorchis solus* (Simha & Chattopadhyaya, 1970) Platt, 2002 (Digenea: Spirorchiidae) in the heart of the host (Werneck et al., 2011). This species may be considered one of the rare taxa in the family Spirorchiidae, as only three specimens have been reported to date (Simha & Chattopadhyaya, 1970; Santoro et al., 2006; Werneck et al., 2011).

Werneck & Silva (2013) reported the occurrence of *Amphiorchis indicus* Gupta & Mehrotra, 1981 in six hosts among a total of 348 *C. mydas* individuals found on the southern coast of the state of Rio de Janeiro and northern coast of the state of São Paulo (prevalence: 1.7%). A total of 14 flukes were found in the samples analyzed: liver  $(n = 6)$  and small intestine (n = 8). In the same year, Werneck et al. (2013) found *Carettacola stunkardi* (Martin & Bamberger, 1952) in a *C. mydas* juvenile from the coast of the state of Espírito Santo (southeastern Brazil). Also in the same year, the analysis of another *C. mydas* juvenile from the state of Espírito Santo revealed *Rhytidodoides similis* Price, 1939 (Digenea: Rhytidodidae), which was collected from the gall bladder. Moreover, lesions were found in the liver due to parasite eggs from the family Spirorchiidae (Werneck et al., 2015c).Werneck et al. (2015a) also found an aneurism in the aorta of a *C. mydas* juvenile from the state of Espírito Santo due to the occurrence of *H. postorchis* as well as tissue lesions in different organs due to the deposition of eggs from the same parasite One of the broadest-scoped studies on parasites of *C. mydas* in southeastern Brazil was conducted between 2004 and 2011. A total of 136 juveniles from the coast of the states of São Paulo and Rio de Janeiro were evaluated, 90 (prevalence: 66.2%) of which were infected with helminths. The parasite species richness was 4.74, mean intensity was 327 and mean abundance was 216. The researchers found a total of 26 species of flukes belonging to six families (Brachycoeliidae, Cladorchiidae, Microscaphidiidae, Pronocephalidae, Rhytidodidae and Spirorchiidae) as well as the larvae of unidentified nematodes (Werneck & Silva, 2015) (Figure 4A, C, D, E, F).

Analyzing 50 sea turtles from the coast of the state of Espírito Santo, Binoti et al. (2016) found 19 flukes belonging to seven families (Calycodidae, Cladorchiidae, Gongoderidae, Microscaphidiidae, Pronocephalidae, Spirorchiidae and Telorchiidae) as well as lesions caused by parasite eggs in different tissues of the hosts. More recently, Werneck et al. (2016) reported the occurrence of *Neospirorchis schistosomatoides* Price 1934 in the heart of a juvenile green sea turtle found in the state of Espírito Santo.

Figure 4. Figures A and C through F parasites from green turtle. Figure B, parasite from loggerhead turtle. A: *Cricocephalus megastomum*; B: *Pyelosomum renicapite*; C: *Neoctangium travassosi*; D: *Metacetabulum invaginatum*; E: *Deuterobaris proteus*; F: *Pronocephalus obliquus*.

# **Helminths Reported in Green Sea Turtles on the Coast of Brazil**

## **Family Calycodidae**

*Calycodes anthos* (Braun, 1899) Looss, 1901.

## **Familia Rhytidodidae**

- *Rhytidodes gelatinosus* (Rudolphi, 1819) Looss, 1901
- *Rhytidodoides similis* Price, 1939

## **Family Cladorchiidae**

*Schizamphistomum scleroporum* (Creplin, 1844) Looss, 1912

## **Family Microscaphidiidae**

- *Angiodictyum longum* Blair, 1986
- *Angiodictyum parallelum* (Looss, 1901) Looss, 1902
- *Deuterobaris proteus* (Brandes, 1891) Looss, 1900
- *Microscaphidium reticulare* (Van Beneden 1859) looss, 1900
- *Neoctangium travassosi* Ruiz, 1943
- *Polyangium linguatula* Looss, 1899

## **Family Pronocephalidae**

- *Charaxicephalus robustus* Looss, 1901
- *Cricocephalus albus* Kuhl & Van Hasselt, 1822
- *Cricocephalus megastomum* Looss, 1902
- *Diaschistorchis pandus* (Braun, 1901) Johnstone, 1913
- *Metacetabulum invaginatum* Freitas & Lent 1938
- *Pleurogonius linearis* Looss, 1901
- *Pleurogonius longiusculus* Looss, 1901
- *Pleurogonius trigonocephalus* (Rudolphi, 1809) Looss, 1901.
- *Pleurogoius lobatus* (Looss, 1901).
- *Pronocephalus obliquus* Looss, 1899.
- *Pronocephalus trigonocephalus* Looss, 1899
- *Pyelosomum cochlear* Looss, 1899
- *Pyelosomum crassum* (Looss, 1901) Ruiz, 1946.
- *Rameshwarotrema uterocrescens* Rao, 1975.
- *Ruicephalus minutus* (Ruiz, 1946) Skrjabin, 1955.

## **Family Gongoderidae**

*Plesiochorus cymbiformis* (Rudolphi, 1819) Looss, 1901.

# **Family Brachycoeliidae**

*Cymatocarpus solearis* (Braun, 1899) Braun, 1901

# **Family Telorchiidae**

*Orchidasma amphiorchis* (Braun, 1899) Braun, 1901

# **Family Spirorchiidae**

- *Amphiorchis indicus* Mehrotra, 1973.
- *Amphiorchis solus* (Simha & Chattopadhyaya, 1970) Platt, 2002
- *Carettacola stunkardi* (Martin & Bamberger, 1952)
- *Hapalotrema postorchis* Rao, 1976
- *Learedius learedi* Price, 1934
- *Monticellius indicum* Mehra, 1939
- *Neospirorchis schistosomatoides* Price 1934.

#### **Family Ascarididae Baird, 1853**

*Porrocaecum sulcatum* (Rudolphi, 1819)

#### **Family Kathlaniidae**

- *Kathlania leptura* Rudolphi (1819).
- *Tonaudia freitasi* Vicente e Santos, 1968.

#### **Parasites in** *Eretmochelys imbricata*

Few *E. imbricata* individuals have been studied on the Brazilian coast. The first description of parasites was performed by Werneck et al*.* (2008a). The authors reported the occurrence of *Amphiorchis caborojoensis* Fischthal & Acholonu, 1976 and *C. stunkardi* in a juvenile from the northern coast of the state of São Paulo (southeastern Brazil). Werneck & Silva (2012) reported the occurrence of *Styphlotrema solitaria* Looss, 1899 in two juveniles rescued on the coast of the state of São Paulo. In the same year, Dutra et al. (2012) reported *A. caborojoensis* associated with tissue lesions due to the eggs of this parasite in a juvenile beached on the southern coast of the state of São Paulo.

After two years, the first occurrence of *H. postorchis* in an *E. imbricata* from the coast of the state of Espírito Santo (southeastern Brazil) was reported. This parasite had previously only been described in *C. mydas* individuals found in India, the USA, Australia, Costa Rica and Taiwan (Werneck et al., 2014). In 2015, the first occurrence of *M. indicum* was recorded for an *E. imbricata* from the state of Espírito Santo, which had previously been considered exclusive to *C. mydas* and only reported in India, Brazil and Costa Rica (Werneck et al., 2015d). More recently, Werneck et al. (2015b) analyzed 31 *E. imbricata* juveniles from the northeastern and southeastern regions of Brazil and found the following parasites in 17 individuals (prevalence: 54.8%): *Diaschistorchis pandus* (Braun, 1901) Johnstone, 1913, *C. albus*, *M. invaginatum*, *P.s obliquus* (Pronocephalidae), *Cymatocarpus solearis* (Braun, 1899) Braun, 1901 (Brachycoeliidae), *S. solitaria* (Styphlotrematidae), *C. stunkardi*, *A. caborojoensis* (Spirorchiidae) and *O. amphiorchis* (Telorchiidae) as well as *Anisakis* nematode larvae. The parasite species richness was 1.38, mean intensity was 25.1 and mean abundance was 13.8.

## **Helminths Reported for the Hawksbill Sea Turtle along the Coast of Brazil**

#### **Family Pronocephalidae**

- *Diaschistorchis pandus* (Braun, 1901) Johnstone, 1913
- *Metacetabulum invaginatum* Freitas & Lent 1938
- *Pronocephalus obliquus* Looss, 1899.

### **Family Brachycoeliidae**

*Cymatocarpus solearis* (Braun, 1899) Braun, 1901

#### **Family Styphlotrematidae**

*Styphlotrema solitaria* (Looss, 1899) Odhner, 1911

#### **Family Spirorchiidae**

- *Amphiorchis caborojoensis* Fischthal & Acholonu, 1976
- *Carettacola stunkardi* (Martin & Bamberger, 1952)
- *Hapalotrema postorchis* Rao, 1976
- *Monticellius indicum* Mehra, 1939

#### **FamilyAnisakidae**

Anisakis larvae

## **Parasites of** *Caretta caretta*

Viana (1924) made the first report of parasites in *C. caretta* on the coast of Brazil. The author offered a broad record of parasite species in different hosts and cited *R. gelatinosus* (family Rhytidodidae) in this host in Brazil. Araújo (1941) reported the occurrence of *Lophotasphis vallei* (Stossich, 1899) in the esophagus and stomach of a *C. caretta* individual from the coast of the state of São Paulo (southeastern Brazil). In the same study, the author cited the occurrence of other helminths in the esophagus and stomach, but did not report the identification of these parasites. Werneck et al. (2008c) analyzed 12 *C. caretta* individuals found on the coast of the state of São Paulo and reported the occurrence of *Sulcascaris sulcata* (Rudolphi, 1819), *K. leptura*, *O. amphiorchis, Pyelosomum renicapite* (Leidy, 1856) (Figure 4B) and *C. anthos* in five hosts (prevalence: 41.7%).

## **Helminths Reported in the Loggerhead Sea Turtle along the Coast of Brazil**

## **Family Aspidogastridae**

*Lophotaspis vallei* (Stossich, 1899)

#### **Family Calycodidae**

*Calycodes anthos* (Braun, 1899) Looss, 1901.

#### **Familia Rhytidodidae**

*Rhytidodes gelatinosus* (Rudolphi, 1819) Looss, 1901

#### **Family Pronocephalidae**

*Pyelosomum renicapite* (Leidy, 1856).

### **Family Telorchiidae**

*Orchidasma amphiorchis* (Braun, 1899) Braun, 1901

#### **FamilyAnisakidae**

*Sulcascaris sulcata* (Rudolphi, 1819)

#### **Family Kathlaniidae**

*Kathlania leptura* Rudolphi (1819).

#### **Parasites of** *Dermochelys coriacea*

Analyses of *D. coriacea* are scarce and only 15 individuals have been studied throughout the entire world. Seven of these individuals were studied in Brazil, with the occurrence of *P. renicapite* found in three of these individuals. This is the only parasite described for *D*. *coriacea* in Brazil (Werneck et al., 2012).

#### **Parasites of** *Lepidochelys olivacea*

There has been only one report of parasites in *L. olivacea* on the coast of Brazil, which was the first occurrence of *Pyelosomum cochlear* Looss, 1899 collected from the urinary bladder of an individual from the state of Rio Grande do Sul (southern Brazil). This species had previously only been reported in *C. mydas* (Werneck et al., 2015e).

#### **Challenges for the Future**

As endangered creatures, the study of sea turtles and the parasites found in these chelonians can have legal implications. Moreover, all five species of sea turtles found in Brazil are reported throughout most of the more than 8000 kilometers of coastline. There has been a clear increase in cases of parasitosis in Brazil, especially since the year 2000, when more studies on this topic began to be conducted. There are currently a greater number of rehabilitation centers on the coast of Brazil, which have been monitoring beaches as the result of environmental impact studies regarding maritime activities of oil and gas exploration and production. Such initiatives allow greater access to dead beached sea turtles and those that died at rehabilitation centers, thereby leading to greater knowledge on the helminths that affect these turtles and their impact on this group of hosts.

#### **ACKNOWLEDGMENTS**

The authors wish to express their special thanks to Dra. Paula Baldassin for critical reading and suggestions to improve this chapter and Dr. Reinaldo Jose da Silva for the parasites images.

# *BIOGRAPHICAL SKETCHES*

## *Max Rondon Werneck*

**Affiliation:** BW Consultoria Veterinaria

# **Education:**

**2007 - 2011** PhD in Biology (Universidade Estadual Paulista Júlio de Mesquita Filho, UNESP, São Paulo, Brasil) Title: Helminth fauna of sea turtle from the Brazilian Coast. Year of Degree: 2011

**2005 - 2007** Master's in Biology (Universidade Estadual Paulista Júlio de Mesquita Filho, UNESP, Sao Paulo, Brasil) Title: Helminth fauna of *Chelonia mydas* necropsied on the Project Tamar in Ubatuba city, Estate of São Paulo, Brazil. Year of Degree: 2007

**1997 - 2002** Graduation in Veterinary Medicine. Universidade para o Desenvolvimento do Estado e da Região do Pantanal, UNIDERP, Campo Grande, Brasil

#### **Address:**

BW Consultoria Veterinária Rua Ponciano Eugênio Duarte N. 203 Centro - Ubatuba 11660903, SP - Brasil

#### **E-mail:**

max@bwvet.com.br. maxrwerneck@gmail.com.

## *Hassan Jerdy Leandro*

**Affiliation:** State University of Norte Fluminense Darcy Ribeiro

#### **Education:**

2013 – 2015 Master of Animal Science. State University of Norte Fluminense Darcy Ribeiro, UENF, Brasil. Title: Patologias Digestivas por Resíduos Antrópicos em Tartarugas Marinhas, Completion of the Course: 2015.

2008 – 2013 Graduated in Veterinary Medicine. State University of Norte Fluminense Darcy Ribeiro, UENF, Brasil. Completion of the Course: 2013

#### **Address:**

UENF -Av. Alberto Lamego, 2000 - Parque California, Campos dos Goitacazes - RJ, 28035-200, Brazil

**E-mail**: hjerdy@hotmail.com.

#### **Research and Professional Experience:**

Pathologist at Univale – 2016

#### **Honors:**

2013 - Honorable Mention in II Congresso Brasileiro de Patologia Veterinária (XVI ENAPAVE), Association of Veterinary Pathology (ABPV).

2013 - Award Professor Jefferson Andrade dos Santos – First Place, Association of Veterinary Pathology (ABPV).

## **ABSTRACT**

The use of clays for mitigating the effects of toxic episodes causing continuous shellfish harvesting closures owing to lipophilic toxins remains unexplored. This strategy is promising for clearance of microalgae through flocculation, but few studies evaluate toxins elimination. This study presents preliminary data on the withdrawal of okadaic acid, testing different clays in seawater, in laboratory conditions. Clays were assayed based on the potential effectiveness in terms of specific surface, particle size and colloidal properties, as well as their local abundance: three kinds of bentonites (one containing sodium bentonite particles  $\langle 70 \mu m$ , other,  $83\% \langle 2 \mu m$ , and bentonite mainly composed of muscovite, particles  $>45 \mu m$ ) and kaolinites of different origins and grain size (69%  $\lt 2 \mu$ m and 57%  $\lt 2 \mu$ m). Bentonite (83%  $\lt 2 \mu$ m) had the best toxin removal ability in our study (68%), while kaolinites with longer decantation times (69%  $<$  2  $\mu$ m) were the least effective material. The particles with the highest size (bentonite  $>45 \mu m$ ) showed a lower efficiency, probably related to the fast decantation process. Altogether, clay applications offer an opportunity for toxin removal that should be explored in depth.

# **1.INTRODUCTION**

Harmful algal blooms (HABs) pose a serious concern in many coastal zones all over the world, especially those where aquaculture activities are relevant. In the northwest of Spain, Galicia, where the Rías conform a particular habitat supporting aquaculture and fishing activities, toxic episodes are associated to atmospheric and oceanographic interactions, specifically upwelling and downwelling, and transitions between water column stability and vertical mixture. When phytoplanktonic toxin producer species are transported and aggregated influenced by oceanographic conditions, and their trophic needs are covered by the abundance of prey species, massive proliferations of toxic phytoplankton occur [1]. One of the species of concern in Galicia is *Dinophysis* spp., a dinoflagellate responsible for lipophilic toxins production, formerly known as "diarrhetic" toxins, because they trigger the Diarrhetic Shellfish Poisoning (DSP) when contaminated mollusks are consumed. Okadaic acid and dinophysistoxins are the main analogues involved in toxic episodes in Galicia, causing closures in harvesting areas and producing an economical detriment of the bivalve aquaculture sector. Mussels growing in rafts in floating settlements are the most affected species, when they ingest the toxins by filter feeding. Although they do not suffer adverse effects, several weeks are necessary for depuration. At present, this natural elimination of toxins in the marine environment is the only allowed process in shellfish aquaculture.

Closure periods with prohibition of mollusk extraction, have grown in frequency and duration during the last years [2]. Although the spring and the autumn are the main periods of toxic episodes, closures have been extended during 4 consecutive months, or even more, in the worst cases. Estimation of costs associated to the toxic episodes in Galicia ascended to 40 million  $\epsilon$  in 2010 [3].

Clays have been used in control of harmful algal blooms (HABs) in Asia [4, 5], laboratory and field studies have been performed in several countries over the past 30 years. Some assays reproducing environmental conditions have been performed with the aim of using these kind of materials for mitigation of toxic blooms [6, 7], and clay dispersal was tested in situ in Japan, Korea and Australia [8].

Clearance of microalgae is possible through flocculation processes by use of mineral particles. This mechanism poses a promising strategy for control of the harmful algal blooms and for mitigating the impact on the local resources [9]. Clay dispersal and flocculation has been used in Korea for mitigation of *Cochlodinium polykrikoides* blooms, a dinoflagellate causing fish and shellfish mortality, as a strategy included in the management scheme [8]. Experiments have been done with *Karenia brevis,* a toxic dinoflagellate producing brevetoxins, responsible for mortalities of fish, invertebrates and marine mammals in coastal waters of Florida and Gulf of Mexico [10]; *Prymnesium parvum,* a potent fish killing organism that produces prymnesins, commonly found in low salinity or mesohaline waters [5, 11], and more recently, with paralytic shellfish poisoning causative organisms in the Philippines [12], among others. Nevertheless, few studies have been performed to evaluate the toxins removal when applying these strategies.

Some reports have shown that the cyanobacterial hepatotoxin microcystin-LR can be adsorbed by clay particles, enabling the removal of 81% of this toxin from the water [13], and also the removal of prymnesins [5], and 70% of extra-cellular brevetoxins, from *Karenia brevis,* in seawater [14]. Natural clays and its composites are known to trap pollutants by

taking up cations and anions through ion exchange and/or adsorption, removing different organic and inorganic contaminants from water. Moreover, it has been proved that in many cases clays are better or comparable with commercial filter materials for drinking water, with the advantage of being a low-cost green, nontoxic adsorbent [15]. Some recent studies focus on modified clays or even modified sand [16, 17] and their effects on algal cells and toxins, with the aim of maximizing effectiveness, and to minimize costs and environmental impact. Some examples are assays for removal of microcystins from drinking water using nano-sized montmorillonite K10 [18, 19], nanosilicate platelet derived from natural clay mineral [20], kaolin modified with polyaluminium chloride for removing *Alexandrium tamarense* and paralytic shellfish poisoning toxins [21]. Other recent approach is the development of claymimicking materials, such as aminoclays, with algicidal activity [22].

To our knowledge, no studies have been published regarding the effect of natural clays on the okadaic acid group of lipophilic toxins. During proliferations of *Dinophysis*, an important proportion of their toxins are released into the seawater [23]. Mussels ingest toxic phytoplankton and accumulate lipophilic toxins mainly in the digestive gland [24]. Recently, it was described that dissolved azaspiracids are absorbed and metabolized by blue mussels, showing that toxins uptake from the dissolved phase through the gills is a possible route of accumulation [25], although no results on accumulation by the gills have been reported using only dissolved lipophilic toxins. It was suggested that mussels can accumulate diarrhetic toxins dissolved in the seawater, from an experimental study [26], but these results have not been confirmed from field studies. Dissolved toxins may pose a further risk to shellfish farms if mussels are able to take up the toxins in the dissolved form in the same manner as ingesting toxic algae.

This study proposes testing different clays in seawater naturally contaminated with okadaic acid from a toxic episode in the Galician coast and obtain a preliminary evaluation of the possible removal of this toxin from seawater in laboratory conditions, with the aim of providing evidence that further research would be of interest.

Different clays were selected based on the potential effectiveness in terms of specific surface, particle size and colloidal properties, as well as their local abundance. Bentonites have been shown in former studies to be effective against a broad range of algal species, due to their ability to expand in water [5]. Then, three varieties of bentonite were assayed: "Bentonite P" was sodium bentonite, and contained particles <70 μm, "Bentonite C" (83% < 2 μm) and "Bentonite > 45 μm", the mineral composed mainly by muscovite, with particle size  $> 45$  μm. Other compounds tested in this preliminary study were local clays ("Grove",  $69\% < 2 \mu m$ , and "Lendo",  $57\% < 2 \mu m$ ) mainly composed by kaolinite.

# **2. MATERIALS AND METHODS**

## **2.1. Selection of Clays**

Clays were provided by two Galician companies: "Caolines de Vimianzo, S.A." (CAVISA) a company that commercializes kaolins, micas and sands; and "Peloides Termales", that designs products for balneotherapy and thalassotherapy. Clays were selected for the specific surface and the particle size.

The clay supplied by Peloides Termales, "Bentonite P" was sodium bentonite, and contained particles <70 μm. The studied sample showed a high percentage of phyllosilicates in the total fraction (98%). The clay fraction included the following minerals in decreasing amounts: smectite (56%), sepiolite (29%) and illite (15%) [27, 28]. Sodium bentonite expands when wet, absorbing as much as several times its dry mass in water. It was selected because of its excellent colloidal properties.

The clays supplied by CAVISA were "Bentonite C"  $(83\% \le 2 \text{ µm})$ , "Bentonite > 45  $\mu$ m" (mainly muscovite) and kaolinites locally available from the regions Lendo and Grove, near the Galician coast: "Lendo Clay" (57%  $\leq$  2  $\mu$ m), "Grove Clay" (69%  $\leq$  2  $\mu$ m). Figure 1 shows size distribution (granulometry) of the clays.

Figure 1. Granulometry of the clays selected in the study. The "passing fraction" is the total percentage of clay that passes through the sieve of a given size (indicated by parameter "diameter").

## **2.2. Seawater Sampling**

Seawater from the Galician coast was sampled during a toxic episode in Ría de Aldán, Galician coast, northwest of Spain (Figure 3) at a depth of about 1 meter, and kept frozen in plastic containers. The species involved in this toxic episode was *Dinophysis acuminata*, registered at densities of 2000-6000 cells/liter in the 10-day period around the sampling date. The harvesting area was closed, with okadaic acid levels higher than the legal limit ( $>160 \mu$ g) kg) in the mollusks. Okadaic acid content was measured using the enzyme-linked immunosorbent assay (ELISA) from Abraxis; the obtained value was  $0.37 \pm 0.05$  ng / mL  $(n = 11)$  (mean value  $\pm$  SEM). These results were obtained before and after freezing, and analyses were done at different times, during a period of several months. Figure 2 shows the distribution of the obtained values of okadaic acid in seawater throughout the study.

Figure 2. Distribution of values of okadaic acid in seawater during the study.

## **2.3. Clay Suspensions Preparation**

The clays concentrations tested in the present study were in the range from 2.5 to 15.0 g/L. Seawater and clays suspensions were prepared as follows: 50 mL of water were dispensed in test tubes and the corresponding clay was added to achieve 5 different concentrations (0.25, 0.50, 0.75, 1.00 and 1.50 % clay) in the seawater. The mixtures were allowed to settle and separate by gravity. Decantation took place in the tubes, containing each clay/concentration. Seawater subsamples were taken at different sampling times (12, 24, 48 and 72 hours) using a syringe and taking care for not disturbing the sediment. Water samples obtained were analyzed for okadaic acid.

#### **2.4. Okadaic Acid Analysis**

Enzyme-Linked Immunosorbent Assay (ELISA) from Abraxis (Warminster, Pennsylvania, USA) was used for the determination of okadaic acid. The test was performed following specifications of the manufacturer. The final color was evaluated using a spectrometer Spectramax M5 microplate reader (Molecular Devices Inc., Sunnyvale, CA, USA) at 450 nm, and the concentrations of the samples were determined by interpolation using the standard curve constructed with each run, covering the range of concentrations from 0.1 to 5.0 ng / mL.

# **3. RESULTS**

First, we tested the effect of the different clays, by preparing suspensions in seawater collected during a toxic episode in Ría de Aldán, Galician coast (Figure 3).

Several clay concentrations were prepared, in test tubes (0.25, 0.50, 0.75, 1.00 and 1.50%) and allowed to stand, until decantation (allowing the mixture to settle and separate by gravity). Seawater was extracted at different sampling times: 12, 24, 48 and 72 hours.

Results obtained after experiments with clays are shown in Figures 4 - 8. Mean value of duplicates obtained in the ELISA test are represented; the coefficients of variation for replicates are <5% in most cases, and <15% in all of them, within the method specifications.

A decrease in the okadaic acid content of the seawater after decantation of clay was registered (Figures 4-8). Figure 4 shows variations in okadaic acid content from seawater after addition of clay "Bentonite P" (<70 μm), results of replicate analyses are shown (mean values  $\pm$  Standard Error of the Mean (SEM)).

Figure 3. Sampling site for seawater during a toxic episode in Ría de Aldán (Galician Coast, Spain).

Figure 4. Variations in the okadaic acid content from seawater after addition of clay "Bentonite P" ( $\lt$ 70 µm) at different concentrations (0.25 – 1.50%) and sampling times (12 – 72 hours).

The decrease of okadaic acid in the seawater after addition of clay was evident after the first 12 hours with Bentonite P ( $\leq$ 70 µm) (Figure 4) and Bentonite C ( $83\%$   $\leq$  2 µm) at all the concentrations tested, obtaining a mean decrease of 68% (8% CV) (Figure 5).

Figure 5. Variations in the okadaic acid content from seawater after addition of clay "Bentonite C"  $(83\% < 2 \,\mu\text{m})$  at different concentrations  $(0.25 - 1.50\%)$  and sampling times  $(12 - 72 \text{ hours})$ .

With kaolinitic clays from Lendo and Grove, results were also promising, although more variations were observed. At 24 hours, the reduction of okadaic acid was maximum when Lendo clay  $(57\% \le 2 \mu m)$  (Figure 6) and Grove clay  $(69\% \le 2 \mu m)$  (Figure 7) were used at all the concentrations tested, 66 and 67% in average, respectively (8 and 13% CV). The increase of okadaic acid observed at 48 h (from 0.1 or  $< 0.1$  ng / mL at 24 h to values of 0.26 - 0.28 ng / mL at 48 h) at the lower concentrations  $\langle$  <0.75%) of Grove clay may be related to the lower particle size of Grove clay  $(69\% \le 2 \mu m)$ , compared to Lendo clay  $(57\% \le 2 \mu m)$ , involving a possible resuspension or not enough "attachment" of the toxin to the deposited clay.

This effect was not observed at higher concentrations of this clay, possibly owing to a more stable settlement of this higher amount of particles and "attached" molecules on the bottom. Higher values than the initial okadaic acid concentration obtained at 12 hours in both clays seemed to be experimental artifacts, probably related with longer decantation times, and hence longer time in suspension in the seawater, possibly causing interference in the ELISA measurement.

Figure 6. Variations in the okadaic acid content from seawater after addition of kaolinitic "Lendo clay"( $57\% < 2 \mu$ m) at different concentrations (0.25 – 1.50%) and sampling times ( $12 - 72$  hours).

Figure 7. Variations in the okadaic acid content from seawater after addition of kaolinitic "Grove clay"(69%  $<$  2  $\mu$ m) at different concentrations (0.25 – 1.50%) and sampling times (12 – 72 hours).

Both bentonites ( $83\% < 2 \mu$ m and  $\leq 70 \mu$ m, respectively) and kaolinitic Lendo clay (57%)  $\leq$  2  $\mu$ m) showed a high degree of decantation 2 hours after the suspensions preparation, in the laboratory conditions. By contrast, kaolinitic Grove clay (69% < 2 μm) needed about 22 h for decantation and clarification of the solutions, staying in suspension a longer time than the remaining clays assayed in this study.

The highest particle size material, bentonite  $>45 \mu m$ , also caused a reduction in seawater OA content (Figure 8), but at longer exposure times of the experiment, 48-72 hours, and to a lesser extent, about 43-46%, respectively. Longer time was needed for toxin removal from the seawater, at concentrations over 0.25%. This material was totally decanted after the first 10 minutes of suspension preparation.

Figure 8. Variations in the okadaic acid content from seawater after addition of clay "Bentonite >45  $\mu$ m" at different concentrations (0.25 – 1.50%) and sampling times (12 – 72 hours).

In summary, the most promising results of toxin removal from seawater obtained with clays, were obtained at 12 hours after the addition of bentonites C (83%  $\leq$  2 µm) and P ( $\leq$ 70 μm), 24 hours for kaolinitic clays 57% and 69% < 2 μm (Lendo and Grove clays), and 72 hours with bentonite  $>45$  µm. Bentonite C (83%  $<$  2 µm) seems to offer the highest decrease of okadaic acid in seawater.

## **4. DISCUSSION**

Recovery of hydrophobic toxins from seawater by adsorption of toxins onto hydrophobic substances is usually carried out for analyses. It was shown that the finest particles of marine sediment consisting mainly of montmorillonite adsorbed oleic acid (references cited by [13]). Clay properties of fine-grained particles, high surface area and charge suggest that this material could be effective for adsorbing hydrophobic molecules from water, as proposed by others for microcystins and extra cellular brevetoxin molecules [13, 14]. Okadaic acid and dinophysistoxins are fat soluble, have high molecular weights, and belong to a class of compounds called polycyclic ethers. These compounds are similar in chemical structure to other marine toxins such as yessotoxins, brevetoxins, ciguatoxins and palytoxins [29]. Okadaic acid consists structurally in a relatively rigid hydrophobic tail structure connected via a flexible arm to a very rigid spiroketal structure with an acidic group, capable of coordination to the metals and/or the aquo ligands at the active site of the enzyme protein phosphatase-1 [30]. Toxins are associated in most cases with the presence of their producers, inside algal cells, but in some cases, toxins may be present in the water column associated with suspended matter and bottom sediments or water bodies [31]. It is known that microcystins, and especially anatoxin-a, adsorb to fine clay material, and can accumulate in the sediment; a recent study found that okadaic acid was detected at remarkable levels in suspended solids during *Dinophysis* bloom in Alfacs Bay, one of Ebro´s associated marine bays [31]. The present study intends to explore the use of clays for mitigating the effects of the toxic episodes in Galicia, especially those originating from *Dinophysis* sp., dinoflagellates responsible for the production of the formerly known as "Diarrhetic Shellfish Poisoning" toxins, or DSP toxins. The incidence of these lipophilic toxins in the mussel and other bivalve mollusks aquaculture sector is increasing in the last years, globally, possibly influenced by eutrophication, maritime transport and climatic change [2]. Bentonites have been effective in previous studies for a broad range of algal species, due to their ability to expand in water, and to develop strong surface change [5]. As observed by others, bentonite  $(83\% \leq 2 \text{ }\mu\text{m})$  had the best removal ability in our study (68%). Theoretically, larger particle size would increase the rate of particle collision, while a stronger surface charge would lead to a higher proportion of particle adhesion on contact, and both processes would lead to higher flocculation rates [5]. On the other hand, kaolinite  $(43\% \leq 2 \text{ µm})$  was the least effective material, only showing a remarkable decrease of okadaic acid at 24 h (58%), but increasing again afterwards. It was described that kaolinites did not swell when wetted, and had a much lower charge density than bentonites [5], so, agreeing with previous studies, they were less effective in toxin removal. Particle concentration is another important factor, as described by others, in flocculation rates, along with particle size and charge [32]. This effect might explain the behavior of the kaolinitic clays locally available from Lendo and Grove, with a high proportion of particles <2 μm, and with better results in okadaic acid removal from seawater at higher concentrations of both clays, especially in Grove clay, with a higher proportion of small particles (69%  $\lt 2 \mu m$ ) than Lendo clay (57%  $\lt 2 \mu m$ )). It has been suggested that when aggregates are  $>1$  µm, differential sedimentation, i.e., collisions resulting from the interception of smaller particles by larger, more-rapidly sinking particles, is the dominant transport mechanism (reported by [33]). The effectiveness of differential sedimentation may also diminish in time as the aggregates attain a certain size and displace increasing amounts of water during their descent, which can push away smaller particles instead of colliding and attaching with them, phenomenon known as hydrodynamic retardation [33]. This effect would explain the behavior of the clay mainly composed of muscovite, bentonite >45 μm, at concentrations higher than 0.25%, with lower efficiency of toxin removal from the seawater. As expected, practically complete decantation of these particles occurred within the first 10 minutes, after the suspension preparation. Use of clays in the field pose environmental concerns, since the toxic cells and/or toxins sedimentation could lead to toxin accumulation by benthic organisms [34], and also impacts of clay on sessile organisms and other cooccurring species should be evaluated. Nevertheless, the number of studies, although limited, shows only low or no impact on co-occurring species, and a negative effect on bivalve growth [35]. On the other hand, clay treatment would not be recommended if flocculation required several hours to take effect, as no water column would be static for such a length of time in

nature [5]. Then, the materials composed by kaolinite, would not be the most adequate for achieving okadaic acid toxins removal from the water column. Further studies assaying shorter periods of time, lower clay concentration and tests with the causative organisms, *Dinophysis* sp. and *Prorocentrum* sp. would be desirable.

In summary, use of clays as a mitigation strategy for microalgal toxins contamination offered promising results. However, further research on the toxin and/or causative agent removal efficiency and the environmental implications of this strategy should be evaluated.

## **CONCLUSION**

Bentonite  $(83\% \leq 2 \mu m)$  had the best okadaic acid removal ability from seawater in our study (68%). By contrast, kaolinite (43%  $\leq$  2 µm) was the least effective material, only showing a remarkable decrease of okadaic acid at 24 h (58%), but increasing again afterwards. The other kaolinite clays, from Lendo (57%  $\leq$  2 µm) and from Grove (69%  $\leq$  2 μm), also showed promising results, although longer decantation times in Grove clay and kaolinite limit their possible usefulness.

The particles with the highest size (bentonite  $>45 \mu m$ ) showed a lower efficiency, probably related to the fast decantation process. Altogether, clay applications offer an opportunity for toxin removal that should be explored in depth.

#### **ACKNOWLEDGMENTS**

The Authors are grateful to Jesús Pais, from Caolines de Vimianzo S.A.U. (CAVISA), Vimianzo, A Coruña, Spain, for providing the clay materials for the study, and to María Perfecta Salgado González, for collaborating in the experimental setup. The research leading to these results has received funding from the following FEDER cofounded-grants: Centre for Industrial Technological Development (CDTI) and Technological Funds, supported by Ministerio de Economía y Competitividad, AGL2012-40185-CO2-01 and through the Galician Agency of Innovation (GAIN), Spain ITC-20133020 SinTox, supported by the program FEDER-INNTERCONECTA by GAIN and CDTI, and cofunded by the Technology Fund.

# **ABSTRACT**

Parasitism is an extraordinary life-strategy that largely influences that of most freeliving organisms, including cetaceans. Parasites of cetaceans have a positive intrinsic and instrumental value, but also a potential pathogenic impact on host populations and, therefore, they should be considered in any biodiversity or conservation program. Yet, a starting point for understanding the relationships between cetaceans and their parasites is to have a detailed account on parasite diversity. The knowledge of the parasite fauna of cetaceans goes back to the time when commercial whaling was allowed and material for scientific purposes was available. Over the last decades, however, parasites have been obtained mainly from stranded or by-caught animals, and regular updates of host-parasite lists have been published until the 1990's. In this chapter we provide an updated review of the helminth fauna of cetaceans. The data here presented constitutes a baseline for future diversity surveys and a way to encourage researchers towards a greater awareness about the biological importance of the helminth fauna of cetaceans. Out of the 90 species currently recognized in the order Cetacea, 72 have hitherto been examined for helminths. The family Balaenopteridae among baleen whales and the family Delphinidae among toothed whales harbor the most diverse helminth fauna, which is partly accounted for by a higher sampling effort. In contrast, the helminth fauna of the beaked whales (family Ziphiidae) is the least known since only 9 out of the 22 species in the family have been examined for parasites. Currently, there are 174 helminth species reported in cetaceans, from which nematodes is the most speciose group (62 spp.), followed by digeneans (54 spp.), cestodes (38 spp.) and acanthocephalans (20 spp.). However, 20 (11.5%) of these

 $\overline{a}$ 

Corresponding Author's Email: natalia.fraija@uv.es.

species represent accidental infections that occur because cetaceans and other marine vertebrates (i.e., pinnipeds and marine birds) share common prey. The families Anisakidae, Pseudaliidae and Tetrameridae (Nematoda), Brachycladiidae, Notocotylidae, Heterophyidae and Brauninidae (Digenea), Diphyllobothriidae, Phyllobothriidae and Tetrabothriidae (Cestoda), and Polymorphidae (Acanthocephala) have a major speciesrepresentation in the helminth fauna of cetaceans.

## **PARASITISM IN CETACEANS**

Parasitism is an extraordinary and widespread life-strategy because parasites are able to infect almost every living organism, including cetaceans. Previous studies have highlighted the importance of including parasites in biodiversity and conservation programs for their cetacean hosts (Aznar et al. 2010). Like any other organism, parasites have an intrinsic value and should be considered as an integral part of the Biosphere. Parasites also have an instrumental value, and have commonly been used as natural tags for their host populations. Studies concerning cetacean social behaviour (Balbuena and Raga 1994), diet (Blazekovic et al. 2015), distribution (Aznar et al. 1995), stock identity (Marigo et al. 2015) and health status (Aznar et al. 2005) have benefited from the use of parasites as biomarkers. For instance, Blazekovic et al. (2015) found a relationship between the prevalence of three nematode species, i.e., *Anisakis simplex* sensu stricto*, A. physeteris* and *A. pegreffii* and the population structure of four toothed whales in the eastern Adriatic. On the other hand, heavy parasite loads are often detected in apparently healthy cetaceans (Rogan et al. 1997), but some species may have a clear pathogenic impact on cetacean populations. For instance, digeneans of the genus *Nasitrema,* which usually occur in the pterygoid sinuses of some dolphin species, may cause brain injuries (Arbelo et al. 2013). Details about the negative impact of parasites on cetacean populations have been explored in previous studies (see e.g., Aznar et al. 2001a, Raga et al. 2009).

In any event, our understanding of the historical and present-day interactions between cetaceans and their parasites require a detailed and updated account of its biodiversity. Helminths, i.e., acanthocephalans, cestodes, nematodes and digeneans, constitute the most significant portion of the metazoan parasitic fauna of cetaceans (Figure 1). Records of helminths in cetaceans go back to the early 1900's, and efforts for updating data have regularly been made until the 1990's (e.g., Baylis 1932, Price 1932, Delyamure 1955, Tomilin 1967, Yamaguti 1971, Dailey and Brownell 1972, Gibson and Harris 1979, Raga 1994). In this chapter we provide the reader with an updated review of the helminth fauna occurring in cetaceans. This goal is justified for several reasons, including, 1) an increase, over the last two decades, of the sampling effort on poorly known cetaceans and unexplored areas; 2) significant taxonomic changes and re-arrangements of helminth taxa; and 3) an increased use of molecular markers, which have helped to unveil a significant portion of hidden biodiversity (i.e., cryptic species). In the next section, we outline major diversity patterns of the helminth fauna of cetaceans. A host-parasite list is then presented in Tables 1 and 2.

### **HELMINTHS OF CETACEANS**

Currently, there are 174 helminth species reported from cetaceans, which can be grouped into 4 major taxa as follows: Acanthocephala (20 spp.), Cestoda (38 spp.), Nematoda (62 spp.) and Digenea (54 spp.) (Table 1). However, a total of 20 species from these taxa represent accidental infections, which occur because cetaceans and other marine vertebrates (e.g., marine birds or pinnipeds) share prey and parasite larvae are exchanged among hosts through the trophic webs. Accidental infections include 7 species of acanthocephalans, 4 of cestodes, 6 of nematodes and 3 of digeneans (Table 1). Most of these taxa are typical from pinnipeds and marine birds. Interestingly, several helminth species that reproduce in cetaceans also have congeneric taxa infecting pinnipeds and/or marine birds, i.e., *Corynosoma* spp. (Acanthocephala), *Tetrabothrius* spp., *Diplogonoporus* spp. and *Diphyllobothrium* spp. (Cestoda), and *Orthosplanchnus* spp. and *Ogmogaster* spp. (Digenea). Also, *Anisakis simplex* sensu lato, which is typical from cetaceans, has also been reported as adult in some pinnipeds (Brattey and Stenson 1993). These observations illustrate the high potential for host-switching events between marine mammals and birds (see Fraija-Fernández et al. 2015 and references therein).

A total of 72 out of 90 species currently recognized within the order Cetacea have ever been examined for helminths. The family Balaenopteridae among baleen whales, and the family Delphinidae among toothed whales, have the most diverse helminth fauna, which is not particularly surprisingly because they concentrate the highest sampling effort (Table 2). The helminth fauna of beaked whales (family Ziphiidae), on the other hand, is very poorly known, and not a single parasitological datum exists for 9 out of the 22 species included in this family.

As noted above, the helminth fauna of cetaceans is, as a whole, highly specific. At a lower taxonomic scale, highly specific taxa have a major representation among digeneans (14 spp. reported in single cetacean species), followed by nematodes (13 spp.), cestodes (8 spp.) and acanthocephalans (3 spp.) (Table 1). Only 19 species (10.9% of the total) has been reported just once. Among the species of Acanthocephala, only species from two genera of the family Polymorphidae, namely *Bolbosoma* and *Corynosoma*, occur in the intestine, and occasionally in the stomach, of cetaceans (Table 2). Three families of cestodes have species infecting cetaceans, namely Tetrabothriidae, Diphyllobothriidae, and Phyllobothriidae, whereas nematodes are represented by taxa of three families, i.e., Pseudaliidae, Anisakidae and Tetrameridae. Finally, the bulk of digeneans reported in cetaceans belong to four families: Brachycladiidae, Notocotylidae, Heterophyidae and Brauninidae (Table 2).

In the Tables 1 and 2 below, information for helminth species, locality and references for each record is organized according to each cetacean species. Cetacean taxonomy follows the lists of species and subspecies of marine mammals made by the Committee on Taxonomy (2014). Only taxonomically accepted parasite name species are included as they were verified with the WoRMS Editorial Board (2015) and the Global Biodiversity Information Facility database (www.gbif.org). Parasite taxa not identified to the species level are not included, except in the cases in which the genus of the named species has not been previously recorded in the cetacean species. References are organized in chronologically order and are identified by numbers in the reference list. The information here presented may constitute a baseline for diversity studies. We encourage researchers to carry out parasite surveys of poorly studied cetacean species and areas, paying special attention to cryptic diversity.

# **INFLUENZA VIRUSES: ATHREAT TO MARINE MAMMALS POPULATIONS**

## *Sasan Fereidouni\**

Research Institute of Wildlife Ecology, University of Veterinary Medicine Vienna, Austria

### **ABSTRACT**

Marine mammals may have an important influence on the marine communities and their conservation has a great impact on balance in the ocean's ecosystems. Marine mammals mortality due to infectious disease and algal biotoxins are increasing worldwide. Morbilliviruses and influenza viruses are two major viral infections that caused several outbreaks with high morbidity and mortality among marine mammals. Influenza viruses are among few zoonotic pathogens known to have caused infections in marine mammals. Direct transmission of influenza A and B viruses from humans to seals and vice versa, and mass die-off of seals due to influenza virus infections in several occasions accentuates their importance for the conservation of marine mammals population.

**Keywords:** marine mammals, influenza viruses, zoonotic diseases

## **INTRODUCTION**

Marine mammals are an important part of the marine communities and their conservation has a great impact on balance in the ocean's ecosystems. Marine mammals face a wide range of threats from human activities, hunting, climate change, pollution, diseases, and habitat degradation. Marine mammals mortality due to infectious disease and algal biotoxins are increasing worldwide.

#### 966 *Sasan Fereidouni*

Various disease outbreaks and mass mortality events, some involving hundreds to thousands of animals, affected the marine mammal populations. Mass mortality events due to outbreaks of phocine distemper virus (PDV) infections occurred in European harbour seals (Phoca vitulina) in 1988 with more than 23000 and again in 2002 with more than 30000 dead cases (Härkönen et al., 2006; Kreutzer et al., 2008). Outbreaks of dolphin morbillivirus infections in bottlenose dolphins along the Atlantic coast accounted for 750 dead dolphins in 1987-1988 (Lipscomp et al., 1994; Taubenberger, et al., 1996) and again in 2013-2015 with approximately 2000 dead cases. In the Mediterranean Sea also dolphin morbilliviruses caused striped dolphins die-off in 1990-1992 with more than 1000 found carcasses (Aguilar & Raga, 1993), and again in 2006-2007 with approximately 100 striped dolphins and additional 60 long-finned pilot whales in the Spanish Mediterranean coast (Fernández et al., 2008). Morbilliviruses also killed Baikal seals in Lake Baikal in 1988 (Mamaev et al., 1996) and thousands of Caspian seals in the Caspian Sea in 2000 (Kennedy et al., 2000).

The importance of marine mammals as hosts or carriers of potential zoonotic pathogens such as influenza viruses is not well understood. The fact that influenza viruses are some of the few zoonotic pathogens known to have caused infections in marine mammals and evidence for direct transmission of influenza viruses from seals to humans and vice versa, underlines the importance of investigation and monitoring of influenza viruses in marine mammal populations (Fereidouni et al., 2014).

### **INFLUENZA OUTBREAKS IN SEAL AND WHALE POPULATIONS**

Our knowledge of disease outbreaks in seal populations is restricted to how efficient are reporting systems in the countries that are close to marine mammals communities. Therefore the real rate of infection most probably be higher than we expect. Influenza viruses were partly isolated from marine mammals during outbreaks with clinical symptoms and mortality, and partly just during conventional monitoring studies from apparently healthy animals (Fereidouni et al., 2014). The first reported case of influenza virus isolation from marine mammals dates back to 1975/76. In this study, tissue samples were collected from 72 whales hunted in the South Pacific and influenza viruses were isolated from 13 lung and one liver specimens. Only detailed data on one H1N3 subtype that isolated probably from a striped whale (family Balaenopteridae) was reported (Lvov et al. 1978).

The first reported case of influenza virus induced mortality in marine mammals dates back to December 1979 (Figure 1). Approximately 500 mainly juvenile harbour seals (Phoca vitulina) carcasses were found along the north-eastern coast of the United States. The causal virus was identified as an influenza A virus of the H7N7 subtype (Webster et al. 1981a; Lang et al. 1981). This epizootic infection affected at least 20% of the local seal population and some animals developed severe acute haemorrhagic viral pneumonia (Geraci et al. 1982). The causative virus was antigenically similar to an avian H7N7 virus. However, as its biological properties was more like a mammalian strain, the virus was probably adapted to mammalian hosts during replication in seals (Webster et al. 1981a; Kida et al. 1982; Naeve & Webster, 1983; Callan et al. 1995).

The next reported influenza outbreak occurred in the same location in Massachusetts, from June 1982 to August 1983 (Figure 1). Approximately 60 harbour seals died due to the infection with an H4N5 influenza A virus. The main pathological findings was pneumonia and the causative virus was isolated from the lungs and brains of dead seals (Hinshaw et al. 1984). This outbreak focused the scientific attention on the role of marine mammals in the ecology and epidemiology of influenza viruses in nature (Webster et al. 1992).

In 1984, two influenza A viruses (H13N2 and H13N9) were isolated simultaneously from the hilar lymph nodes and lungs of a sick long-finned pilot whale (Globicephala melas) near Portland, Maine, USA. In post-mortem examination, pathological findings included a large hilar lymph node and haemorrhagic lungs (Hinshaw et al. 1986). It was speculated that these H13 influenza viruses had probably been related with two mass stranding of long-finned pilot whales (97 whales in October, 23 whales in November 1984) along the New England coast (Hinshaw et al. 1986; Van Bressem et al. 1999; Waltzek et al. 2012).

In 1991, two influenza viruses of the H4N6 subtype were isolated from the lung tissue of two dead harbour seals. Pathological lesions consistent with influenza virus infection, such as acute interstitial and/or haemorrhagic pneumonia and subcutaneous emphysema were observed. There was no indication for an extensive outbreak in that period along the New England coast, and the viruses were found within the framework of an surveillance study (Callan et al. 1995).

Again in September 1991 to April 1992, an increase in the number of stranded seals along Cape Cod was reported. A severe epizootic of viral pneumonia in the seal population was not observed, but pathologic lesions in respiratory system, including acute interstitial pneumonia and subcutaneous emphysema were found in dead seals. For the first time influenza viruses of the H3N3 subtype were isolated from the harbour seals (Callan et al. 1995).

An influenza B virus was isolated in 1999 from a throat swab of a juvenile seal in a rehabilitation centre in the Netherlands. Phylogenetic analysis of the HA gene showed a close relation to viruses which had been circulating in humans in 1995 (Osterhaus et al. 2000). No influenza virus infection-specific clinical symptom was reported in that juvenile seal. A retrospective study of seal serum samples, collected before and after 1995 indicated the introduction of influenza B virus into the seal population in 1995. Less than 2% of sera collected after 1995 tested positive for antibodies to the influenza B virus, which indicated low incidence of infection (Fouchier et al. 2001).

Figure 1. Influenza virus outbreaks/infections reported during 1975-2015. Arrows indicate known transmission routes between each species based on reported cases, phylogenetic analysis and experimental studies.

#### 968 *Sasan Fereidouni*

Following the human pandemic caused by a new H1N1 influenza virus (H1N1pdm09), nasals swabs were collected from 42 female free-ranging Northern elephant seals (Mirounga angustirostris) in a surveillance study along California's central coast in April 2010 (Goldstein et al. 2013). Two swab samples tested positive and the isolated H1N1 viruses showed an homology greater than 99% to influenza viruses isolated from humans in 2009. Serological analyses of serum samples collected between January 2010 and April 2011 indicated a recent introduction of the virus into the local seal population in April 2011. No mortality was seen in that seal population during the period of study (Goldstein et al. 2013).

In September - December 2011 higher mortality of harbour seals compared to previous years was reported from the New England coast. An avian influenza virus of the H3N8 subtype was isolated from several tissues of five out of 162 dead harbour seals. The main pathological findings were pneumonia and ulcerations of the skin and oral mucosa.

The first reported mass mortality of harbour seals in Europe due to influenza virus infections occurred in the Baltic Sea in 2014. From March to October, 425 carcasses were detected at the west coast of Sweden (Zohari et al., 2014), 152 carcasses on the small island of Anholt in Denmark (Krog et al., 2015), and approximately 1,400 carcasses in the north coastal waters of Germany (Bodewes et al., 2015). Avian influenza A virus (H10N7) was detected in the lungs of affected animals in all three occasions with close genetic relatedness. This subtype had not been reported in seals until 2014 and was associated with the highest mortality ever has been reported in seals due to influenza viruses. In addition, preliminary analysis of the haemagglutinin gene (HA) sequence of the causative influenza virus suggested the presence of molecular determinants that indicated mammalian adaptation (Bodewes et al., 2015).

Several serological studies have been carried out since 1978 to estimate the prevalence of influenza virus infections among marine mammals. Different methods such as haemagglutination inhibition (HI), indirect enzyme linked immunosorbent assay (ELISA) and competitive ELISA were used. Each method had its intrinsic sensitivity and specificity, positive predictive values (PPV) and negative predictive value (NPV); however, in most cases these methods were never validated for marine mammal serum samples (Fereidouni et al., 2014). Nevertheless, positive serum samples were found for harbour seals and sea lions (de Boer et al., 1990), harp and hooded seals (Stuen et al., 1994), ringed seal and beluga whales (Austin & Webster, 1993; Nielsen et al., 2001), Caspian seals, common minke whales and Dall's porpoise (Ohshi et al., 2002, 2006), Pacific walrus and bearded seals (Calle et al., 2002, 2008), Kuril harbour seals (Fujii et al., 2007), and fur seals (Blanc et al., 2009). In addition, influenza B antibodies were found in harbour and gray seals (Fouchier et al., 2001; Bodewes et al., 2013).

## **GENETIC BACKGROUND OF MARINE MAMMALS INFLUENZA VIRUSES**

Several influenza viruses have been isolated from marine mammals since the 1970s and sequence data of one to eight genome segments of them were obtained using different sequencing methods. Phylogenetic, genetic and/or antigenic analyses using different methods has been indicated that the majority of marine mammal influenza viruses showed high genetic relatedness with those viruses reported from wild birds.

Figure 2. Inter-species transmission of influenza viruses between marine mammals and other species based on genetic relatedness of the isolated influenza viruses. Arrows indicate known transmission routes between each species based on reported cases, phylogenetic analysis and experimental studies (adapted from Fereidouni et al., 2014).

Probably the first phylogenetic analysis for marine mammals influenza viruses was performed in 1982 using the full sequenced haemagglutinin gene of H7N7 virus and its association with avian H7 viruses was proved (Kida et al. 1982; Naeve & Webster, 1983).

Another phylogenetic analysis was performed in 1990, to make a comparison between the nucleoprotein (NP) gene sequence of three influenza viruses, H1N3, H13N2 and H7N7 isolated from stripped whales, long-finned pilot whales and harbour seals, respectively. The results indicated again high genetic relatedness between marine mammal viruses and those reported from wild birds (Mandler et al. 1990).

No sequence of seal H4N5 virus is available in GenBank and only based on the HI assay of the virus and due to the high replication of the virus in avian hosts, it was concluded that the HA was antigenically and biologically similar to avian viruses (Hinshaw et al. 1984). In 1991, when two H4N6 influenza viruses were isolated from harbour seals, based on presence of H4 HA, it was concluded that they should originated from wild bird isolates (Callan et al. 1995).

In 1984, two whale influenza viruses, H13N2 and H13N9, were shown to be closely related to the H13 influenza viruses circulating among seagulls in the USA (Hinshaw et al. 1986). The seal H3N3 influenza isolate was first suspected to be related to seasonal human H3 influenza viruses, but later phylogenetic analysis demonstrated a close relationship to North American avian influenza viruses (Callan et al. 1995). The phylogenetic analyses of all eight segments of H3N8 seal influenza virus demonstrated also the closest relationship to waterfowl influenza viruses (Anthony et al. 2012).

At last, influenza viruses of H10N7 subtype, commonly found in migratory waterfowl, caused highest reported influenza-related mortality among harbour seals in 2014. Phylogenetic analyses showed that the HA of this virus is genetically closely related to Eurasian H10 viruses recently found in migratory ducks in Sweden, Denmark and Georgia (Zohari et al., 2014; Krog et al., 2015; Bodewes et al., 2015).

The 2010 influenza viruses isolated from free-ranging Northern elephant seals were the only influenza A viruses showed an homology to human and not avian viruses. Those viruses showed an homology greater than 99% to the pandemic influenza viruses (H1N1pdm09) isolated from humans in 2009 (Goldstein et al. 2013).

The evidence indicated that introduction of influenza viruses from wild birds and humans into marine mammal populations might have occurred on several occasions independently. High mortality of marine mammals, in several occasions, after transmission of avian influenza viruses to their population pose a great concern regarding the conservation of the population. Avian influenza viruses are known to be circulating at high prevalence in aquatic birds, and there is a continuous potential for transmission of viruses through direct or indirect contact of marine mammals with wild birds or their droppings at hauling-out sites or during feeding on the same food resources, although establishment of infection requires numerous factors (Fereidouni et al., 2014).

## **MARINE MAMMALS AND PUBLIC HEALTH**

Circulation of avian influenza viruses in marine mammals may potentially have implications for public health, although the only reported evidence for transmission of influenza viruses from marine mammals to humans dates back to the 1979 outbreak of influenza in harbour seals with H7N7 subtype, which caused purulent keratoconjunctivitis in humans who handled the dead seals (Webster et al. 1981b). The virus raised concern as a zoonotic threat but it did not spread further. Affected people recovered without complications, and antibodies to the virus were not detectable in the serum samples of infected persons.

On the other hand, isolation of H1N1pdm09 influenza viruses from healthy seals in 2010 provided evidence for crossover transmission of influenza viruses from humans to marine mammals. The isolated viruses replicated in human epithelial respiratory cells not as efficient as human reference strains (Goldstein et al. 2013). This finding may indicating that these isolates adopted to elephant seal and lost potential to infect humans efficiently.

Genetic analyses of the isolated H3N8 viruses from harbour seals in 2011 indicated presence of mutations in the viral PB2 protein that increase transmissibility and virulence of influenza viruses in mammalian (Anthony et al. 2012). However, there is no evidence for transmission of those H3N8 viruses to other mammalian species, including humans.

Serological and virological data have shown that influenza B viruses could have persisted in the seal population for a long time without significant changes, a fact which may be considered as a risk for the re-introduction of the viruses to the human populations. However, at present no evidence is convincing enough to conclude that seals play a role as reservoir species for human influenza A or B viruses (Fereidouni et al., 2014).

#### **CONCLUSION**

In summary, interspecies transmission of influenza viruses is an important event in the evolution and ecology of these viruses. Influenza viruses are among the few zoonotic pathogens known to have caused infections in seals and whales. Infection of seals and other marine mammals with influenza A and B viruses have been reported on several occasions. Many constraints made it difficult to determine the real incidence of influenza virus infections in marine mammals. Nevertheless, data from several outbreaks and also serological results show that this is not a rare event, and probably the real prevalence has been underestimated (Fereidouni et al., 2014). Close genetic relatedness of influenza viruses isolated from marine mammals and wild birds suggests that wild birds are the main source of influenza virus infections of marine mammals (Figure 2). However, our knowledge is yet insufficient to make any general conclusion about transmission routes of the influenza viruses between wild birds and marine mammals or the role of them in ecological persistence of influenza viruses in the nature; therefore more detailed and validated monitoring as well as experimental studies are necessary to clarify the ecological and zoonotic importance of influenza viruses circulating in marine mammals.

# **ECOLOGICAL INTERDEPENDENCE IN MARINE HABITATS: BIO-ECONOMIC MANAGEMENT OF A SPANISH MIXED FISHERY**

*M. Dolores Garza-Gil\* , Marcos I. Pérez-Pérez, Manuel M. Varela-Lafuente and Juan C. Surís-Regueiro* Department of Applied Economics, University of Vigo, Vigo, Spain

## **ABSTRACT**

Ecological interactions amongst fish stocks can play a dominant role in how marine ecosystems are structured, and they can have a significant impact on the populations' growth dynamics. The analytical framework for proposing management guidelines has been developed based on bio-economic models that only account for a single species, both in terms of biological and well as economic aspects, and this diminishes the importance of interactions among the various marine community components. Bearing in mind the implications of the ecological dependencies that are created in multi-species fisheries, that bio-economic model can be extended. A better understanding of trophic relationships among fish stocks enables the development of management models for multi-species fisheries—that is, for most European fisheries. This chapter examines a fishery encompassing two of the Spanish fleet's target species that exhibit a significant ecological predatory interdependence: the blue whiting and the southern stock of European hake. Such interactions should be considered when establishing the Total Allowable Catch (TAC) because the catch level for one species will alter populations of the other, thereby affecting long-run sustainability of commercial fishing and of the marine environment. Within this fishery, both the catch and the spawning biomass for each species are trending downward. The trophic interaction between predator (hake) and prey (blue whiting) is included into the management problem of jointly determining fishing quotas for each species. The estimations indicate that increases in blue whiting biomass (prey) have generated a positive effect on hake biomass along that period 1988- 2014, it is represented by a plus sign in the parameter for interdependence in the hake growth function. However, increases in hake biomass (predator) lead to a reduction in

 $\overline{a}$

blue whiting biomass and this is represented by a minus sign in the parameter for interdependence in the blue whiting growth function. These results are consistent with a relationship of interdependence predator-prey. Incorporating this interaction into stock dynamics for both species and applying optimum control theory, we obtain the optimal spawning stock biomass values for both species and the corresponding catch values. The results show catch levels are lower than prevailing EU-determined levels for both species. In addition, as the social discount rate increases and, therefore society's preferences in the near future, the biomass of both species decreases, while catches or potential landings increase.

**Keywords**: mixed fisheries management, predator-prey model, European fisheries, Southern hake, blue whiting

#### **INTRODUCTION**

The effects of fishing are reflected not only in the target species but also in the entire ecosystem that inhabit. There are scientific evidences that it is occurring in the marine ecosystems and this imposes to find alternative approaches to the current fisheries management scheme, so it has been expressed the need that fisheries research and management to move towards an ecosystem-based approach [1]. The introduction of ecological considerations in fisheries management looks like this as a strategy to ensure the sustainability of fisheries and marine ecosystems. More and more scientists are recommending multi-species approaches to fishery management, due to the complex series of interactions between a fishery's different species [1, 2]. And in practice, fisheries are exploited as a multi-species resource [3]. Biological interactions amongst fish stocks can play a dominant role in how marine ecosystems are structured, and they can have a significant impact on the fish populations' dynamics [2, 4]. More specifically, predation and cannibalism are sources of mortality that can regulate a population's size and recruiting [2, 5-7]. Therefore, fishery management can largely benefit from better comprehension of the role of biological interactions—including trophic relationships—in the resource's dynamics [8-26].

Within the context of ecosystem management, the multispecies approach occupies an important place in fisheries management, since biological species interactions regulate the recruitment and the size of the populations of the ecosystem. The study of trophic relationships as sources of mortality may improve the understanding of the population dynamics and the management of marine resources. Fish stock assessment methods have evolved from monospecific models, studying the population of a single species whose dynamics is affected only by its own biomass and the effect of fishing on the same, towards multispecies models. The multispecies models take into account ecological or technological interactions to optimize yields form the ecosystem as a whole. The multispecies models are in many cases extensions of monospecific models, as it is the case of the excess production models, aggregate production models, multispecies per recruit models, virtual population analysis model, and food and trophic network models. Ecological interdependence occurs when there is a certain relationship between two exploited stocks [16, 17] or between two different population segments of the same stock. From there, we can go on to define two types of ecological interactions: competition and predation. Competition is defined according to the negative effects that one organism exerts over another by consuming or interfering with its access to a resource that has a limited availability (supply) [18]. This interaction leads to a reduction in the survival, growth, and/or reproduction of competitors, particularly those that, hierarchically speaking, are subordinate [19, 20]. And predation is the consumption of one organism or species (prey) by another organism/species (predator) through carnivory, herbivory or omnivory [20]. On other hand, technological interaction occurs when two or more fishing gears are operating on the same population of fish.

Multispecies bioeconomic models arise from the extension of Gordon-Schaefer model for a single target stock, incorporating logistic equations predator-prey. Predator-prey models constitute a particular case within the multispecies models. They are based on the equations of Lotka-Volterra, describing the trophic interactions between the predator and the prey. The predator-prey basic model assumes exponential or Malthusian growth for the population of prey in absence of predators. This model incorporates the intrinsic growth rates of the predator and the prey and the carrying capacity of the ecosystem to each of the two species. The predator-prey model with capture poses a situation of commercial exploitation of the species and takes into account the discount rate of the fishery. This model aims to maximize the present value of the net benefit from the exploitation of both species: predator and prey.

This chapter deals with the management of a multispecies fishery (mixed fishery) with two target stocks that exhibit significant trophic interaction (ecological interdependence) as well as predation: the southern stock of European hake (*Merluccius merluccius*) and the blue whiting stock (*Micromesistius poutassou*). At this North Atlantic fishery, Southern hake is the predator and blue whiting the prey.

## **THE EUROPEAN HAKE AND BLUE WHITING MIXED FISHERY**

The European hake and blue whiting are two target species for the Spanish longline and trawl fleet in Iberian Atlantic waters, although the latter is also used for horse mackerel, Atlantic mackerel, and octopus. Both species are primarily distributed across the continental shelf, where they spawn during the winter months.

European hake is widely distributed throughout the north-eastern Atlantic Ocean [27]. It is a demersal benthopelagic species that can reach depths that vary from 30 to 1000 meters, although they generally dwell at depths ranging between 70 to 370 meters. They form schools that stick close to the coastline in the summer and keep a greater distance during the winter. They reproduce at depths of 100 to 300 meters. Egg-laying season runs from January to May in the Bay of Biscay. Juveniles live in the muddy depths until about three years of age, at which point they move closer to the coast. Adults can typically be found on the continental slope. The European hake is a predator at the top of the northeast Atlantic demersal trophic pyramid. It primarily feeds on other species of fish like the anchovies (*Engraulis encrasicholus*), sardines (*Sardina pilchardus*), and blue whiting (*Micromesistius poutassou*). According to the organization that analyses the fish stocks in the Northeast Atlantic grounds (ICES), there are two stock units for this species: the southern stock, in zones VIIIc and IXa, and the northern stock, in the remaining NE Atlantic zones.

Source: Authors compilation from International Council for Exploration of the Sea (ICES) [27].

Blue whiting is a demersal species from the gadidae family, and it can be found throughout the northern Atlantic [28]. Its habitat is the ocean, and as a benthopelagic species, it lives mainly along the continental shelf and slope, distributed vertically at depths of between 150 and 1000 meters, though it is most commonly found at 300-400 meters below the surface. Blue whiting spawns between February and June and reaches first maturity at three years of age. Growth is rapid, and females are typically larger than males. The blue whiting's diet consists primarily of various types of crustaceans.

A number of studies have confirmed the ecological interdependence of the hake and blue whiting populations in Iberian waters analyzing the diet of the European hake in the Cantabrian Sea (zone VIIIc), and based on a seasonal analysis of the stomach contents of the fish sampled [29-31]. They highlight the importance of the blue whiting as the hake's primary prey, particularly amongst the adult population, while most juveniles consume cupleoids, at more shallow depths, since at such depths there are fewer blue whiting. Other studies confirm the existence of a significant relationship between the size of the hake and the size of the blue whiting using statistical regression analysis [9, 32]. Likewise, hake is far more dependent upon blue whiting in Iberian fishing grounds (zone VIIIc) than in the northern part of the Bay of Biscay and the Celtic Sea [2, 9, 32]. Other authors studied the diet of the blue whiting, hake, horse mackerel and Atlantic mackerel in Portuguese waters (Zone IXa) and analyzed their stomach contents [8], and they concluded that in terms of percentage, occurrence, and weight, the blue whiting is the hake's most important prey.

Hake landings and biomass in ICES zones VIIIc and IXa are shown in Table 1 for period 1988-2014. These variables have changed over the past 25 years in zones VIIIc and IXa, as Figure 1 demonstrates. The landings, in general, exhibit a downward trend throughout most of this period, both in terms of the total catch for the industry overall as well as the Spanish fleet. However, beginning in 2007 there was significant recovery, though the numbers once again declined at the end of the period. Spawning stock biomass (SSB) also exhibited a downward trend up until 2006, at which point a notable recovery was made. Note that between 1994 and 1998, the landings surpassed the reproductive biomass; this scenario surfaced once again between 2007 and 2010.

As a result of the elevated hake landings, the species has been outside biosafety level limits since the 1990s [27]. This situation has created an incentive for implementing a recovery plan for the species aimed at recovering the stock and bringing it back within the established biosafety level limits, that is 35,000 tons of reproductive stock biomass (European Council-EC Regulation 2166/2005). According to that plan, in 2006 the European Commission (EC) applied an annual reduction of 10% to the total allowable catch (TAC) and fishing effort for the fishing fleets (measured as the sum of the engine power in kilowatt and the number of days fishing in the area). Over the last few years, the positive effects of this plan have started to become noticeable, to such an extent that the EC began increasing the TAC for this species in 2011.

Source: Authors compilation from Table 1.

Figure 1. Hake landings (tons) and estimated SSB (tons) in ICES zones VIIIc and IXa. 1988-2014.

As for the blue whiting, Table 2 shows the biomass and landings for this species in ICES zones VIIIc and IXa for period 1988-2014. The evolution of these variables is showed more clearly in Figure 2. Spanish landings in zones VIIIc and IXa have stayed relatively stable, at around twenty thousand tons since 2010, at which time a considerable decline was noted, due to the decreased TAC established for this species in 2010. The SSB demonstrates a sustained increase until the end of the 1990s, where a significant decrease is observed. Nevertheless, this variable shows signs of recovery in the last few years due to a drop in catches over the past decade, in combination with an increase in recruitment since 2009. It is estimated that in 2013, the SSB was already above the precautionary limits [28]. This has allowed European Council agreed a TAC higher in 2014 and 2015 than in previous years.

**Table 2. Blue whiting biomass and landings in in ICES zones VIIIc and IXa. 1988-2014**

Source: Authors compilation from International Council for Exploration of the Sea (ICES) [28].

The Spanish fishing fleet has also exhibited a downward trend over the past 25 years, going from 279 ships in 1988 to 180 in 2013 [28, 33]. As far as economic data for the fishing grounds is concerned, Table 1 shows a standard ship's average revenue and costs between 2010 and 2014. The largest segment of the costs corresponds to personnel expenses (48% of the ship's average revenue), while the gross cash flow is positive and accounts for approximately 18% of the total revenue.

Lastly, Table 3 also shows the technical characteristics and the main economic data for this Spanish fleet and, in particular, the unit costs and prices per landed tons for each species. Data are shown as an average for the period 2010-2014. Since we do not know the composition of the catches for the entire Spanish fleet in this fishery, the costs have been determined based on a representative sample. More specifically, the unit costs have been estimated using the weight that corresponds to each species (13.5% hake and 20.8% blue whiting) in the landings of vessels based in the Port of Vigo in 2010-2014 (these ships represent 37.8% of the total of the fishery's Spanish fleet), bearing in mind the average tonnage of each species that these ships landed. Additionally, the unit prices were estimated based on prices obtained in the Vigo market for each species.

#### **AN APPLIED MANAGEMENT MODEL**

The ecological interdependence between hake and blue whiting in this fishery, which in this case is a predatory relationship, influences the marine ecosystem structure and trophic chain. Increasing or decreasing the TAC for one of the two species will impact this structure and its sustainability in the long run and, ultimately, the sustainability of the industry in this multi-species fishery. Therefore, it is important to take a simultaneous decision regarding catch levels for both stocks, based on their ecological relationship.

To that end, based on [34], we propose the following net growth functions for each species, taking into account the ecological relationships between hake and blue whiting:

$$
\frac{dX}{dt} = r_X X \left[ 1 - \frac{X}{K_X} \right] - H_X + \alpha XY = F(X) - H_X \tag{1}
$$

$$
\frac{dY}{dt} = r_Y Y \left[ 1 - \frac{Y}{K_Y} \right] - H_Y + \beta XY = G(Y) - H_Y \tag{2}
$$

where *X* stands for hake spawning biomass; *Y* is for blue whiting spawning biomass; *r* and *K* are biological and ecological parameters and denote the intrinsic growth rate and the average load capacity corresponding to each species, respectively; *H* is for catches (or landings); and  $\alpha$  and  $\beta$  denote the co-efficient for ecological interaction between hake and blue whiting, respectively. According to the traditional notation in the bio-economic literature on fisheries, the function of net fishery benefits at moment  $t$  is determined by the sum of the net benefits generated by the catch for both species for that moment *t* (most commonly *t* is considered as a year). Formally, it is defined as the following expression [35]:

$$
\pi(t) = (p_X - c_X)H_X + (p_Y - c_Y)H_Y \tag{3}
$$

And where *p* and *c* stand for the catch unit price and cost of the corresponding species, both parameters are usually assumed constant along the period of study. The problem that the manager or regulator must solve is setting catch levels for each species that will yield greater potential benefits in the long term, given the biological relationships between both species and their net growth limits. Formally, this is expressed as follows [35, 36]:

$$
max_{H_X, H_Y} \int_0^\infty [(p_X - c_X)H_X + (p_Y - c_Y)H_Y] e^{-\delta t} dt
$$
  
s.t. 
$$
\frac{dX}{dt} = F(X) - H_X
$$
 (4)

$$
\frac{dY}{dt} = G(Y) - H_Y
$$

where  $\delta$  stands for the social discount rate. This parameter collects the preferences of the society (or country) by the time and the conservation of the living aquatic resources: the higher this parameter, the greater preference for the present moment and greater exploitation of marine resources; and the lower the discount rate, more preference for the future and sustainability of marine biological resources. The yield of government bonds to long-term (ten years) is often used as the discount rate in bio-economic models.

In order to apply the theoretical model to the case study (hake and blue whiting mixed Spanish fishery), we need to know the value of the parameters of the net growth functions in addition to parameters shown in Table 3 (unit price and cost for catches of both species). Econometric regressions were calculated based on the SSB and catch data for the 1988-2014 period gathered by ICES [27, 28] and shown in Tables 1 and 2. The results of these regressions can be seen in Table 4. These estimations indicate that increases in blue whiting biomass (prey) have generated a positive effect on hake biomass along that period 1988-2014 (a plus sign in the parameter for  $\alpha$  interdependence in the hake growth function). However, increases in hake biomass (predator) lead to a reduction in blue whiting biomass (a minus sign in the parameter  $\beta$  for interdependence in the blue whiting growth function). These results are consistent with a relationship of interdependence predator-prey; and they are, in general, in line with results from other studies that have also showed this relation analyzing the stomach contents of the fish sampled [2, 8, 9, 29-32].

By adding the value of the parameters shown in Tables 3 and 4 to the above management problem and applying the theory of optimal control [37], we can obtain the optimal SSB values for both species and the corresponding catch values. The results for different discount rate values are shown in Table 5.

As the social discount rate increases—and, therefore, society's preferences in the near future—the biomass of both species decreases, while catches (or potential landings) increase. In 2015, the TAC was set at 13,826 tons for hake and 1,260,000 tons for blue whiting by European Council. These fishing opportunities are slightly higher than they would be if catches for both species were estimated jointly by incorporating their trophic interaction (see Table 5).

Notes: *p*-values are reported in parentheses. Coefficient estimates are statistically significant at \*\*\*1%, \*\* 5% or \*10% level.

Discount rate	<b>SSB</b>		<b>TAC</b>		
	Hake	Blue whiting	Hake	Blue whiting	
3%	40499	3016874	10915	670808	
4%	38951	2834582	11213	856307	
5%	37392	2636035	11344	1020481	
6%	35954	2459279	11467	1139988	

**Table 5. Estimated tons of spawning stock biomass (SSB) and total allowable catch (TAC) for different discount rates**

#### **CONCLUSION**

The rapid growth of the world population is generating a strong pressure on the marine resources as a source of food. Not only overfishing has impact on the target species, but also on the whole of the ecosystem where these species live. It is necessary to use multispecies approaches in fisheries management due to the complex set of interactions among species that occurs in the marine ecosystems. The ecological or biological interactions between species can play a key role in the structuring of the marine communities, and can significantly affect the dynamics of fish populations. Specifically, predation and cannibalism are sources of mortality that can regulate the recruitment and the size of the population. This chapter has developed a multispecies bio-economic model of predator-prey type applied to the mixed fishery for hake and blue whiting in European waters. Both species have a significant trophic interaction, as well as commercial importance for the Spanish fishing fleet which makes them suitable for applying a model of this type.

Hake and blue whiting stocks caught by the Spanish fleet in domestic fishing grounds exhibit significant prey-predator interaction, where hake is the predator and blue whiting the prey. By developing a multi-species bio-economic model for managing both populations in a mixed fishery, instead of contemplating two single-species fisheries, this biological interdependence can be considered as a biological technical externality. When this externality is positive, the optimal stock levels for predator and prey alike are greater than if they were independent populations. More specifically, increases in blue whiting biomass have a positive effect on hake biomass and vice-versa. Similarly, optimal populations of both species increase when the discount rate decreases, while catches would increase if this parameter were increased. The results obtained demonstrate that catches—where the existing trophic interaction is factored into the estimation thereof—are below the TAC levels established by the European Council.

In particular, Spanish fishing boats are currently responsible for 64% and 3% of the TAC established by the European Council for both species in ICES zones VIIIc and IXa. That is, the fleet would bring in approximately 7,000 and 30,000 tons of hake and blue whiting, respectively, if the catches for both stocks were determined in light of their ecological interaction (and while using the 5% discount rate typical of bio-economic studies). However, the TAC established for the Spanish fleet in 2015 was about 9,000 tons of hake and 38,000 tons of blue whiting, or amounts in excess of those that would be allowed had the TAC for both species had been estimated while factoring in their ecological interdependence. Although the 2015 TAC for both species is slightly greater than the fishing opportunities actually
obtained for these species, we remark that excess blue whiting catches could well lead to a reduction in the biomass of this species and could therefore—given the species' trophic relationship—also reduce the long-term biomass of hake, which is one of the Spanish fleet's primary target species.

In short, in mixed fisheries where there is an ecological interdependence between species, when the TAC for a given species is estimated on its own, it could have a greater impact on other target species that are not factored into in the management problem. Therefore, it is a good idea to determine the TAC jointly for the species involved and thus internalize the effect of their trophic interaction. This study has provided a very simple example of two stocks, but it is one that is quite relevant to the Spanish fleet, as hake is one of its primary target species. We must continue to gather information on trophic relationships in order to fine tune EU fishery policy recommendations and generate the least impact possible on marine ecosystems, thereby helping to ensure the conservation and sustainability of marine biodiversity as well as sustainability of the fishing activity.

# **MARINE SPONGE COMPOUNDS WITH ANTI-INFLAMMATORY ACTIVITY IN 2012–2016; AND THEIR MECHANISM OF ACTION**

## *Maushmi Kumar\**

SVKM'S NMIMS, Shobhaben Pratapbhai Patel School of Pharmacy and Technology Management, Mumbai, India

## **ABSTRACT**

This chapter presents an overview of the development and study of marine sponge's bioactive compounds for anti-inflammatory activity for last four years i.e., 2012-2016. Marine pharmacology during 2009–2011 remained a global enterprise contributing to the preclinical pharmacology of 262 marine compounds which are in pharmaceutical pipeline. There is no updated review for the studies done on marine sponge's compounds showing anti-inflammatory activity after 2011. This chapter is a sincere effort to present a systematic review of the preclinical pharmacology of marine sponge and its associated microbes/symbionts compounds for potential activity in inflammation.

**Keywords:** porifera, inflammation, inflammatory mediators, IL-1, IL-6, TNF-α, PGE2

## **1.INTRODUCTION**

An inflammatory response is a natural defensive mechanism triggered by body tissues on being damaged by invading pathogens, physical stress, injury, persistent foreign bodies and by autoimmune reactions. Depending on the stimuli and the causative agents, it can be short or long lasting. Chronic inflammation involves the release of a number of mediators such as monocytes, macrophages, lymphocytes, plasma cells and fibroblasts that are not prominent in the acute response (Beg et al., 2011). The defence elements of body is found majorly in blood

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: maushmiskumar@gmail.com.

and during inflammation these cells and chemicals leave the blood and enter the tissue around the injured or infected site to protect and fight damage. Any type of infection caused by a bacterium, virus or fungus, commonly causes inflammation; while inflammation is the body's own response to it. It is part of many other common acute and chronic diseases. The therapeutic strategy for the treatment of patients with inflammation has been first, the relief of symptoms and the maintenance of function; and second the slowing or arrest of the tissuedamaging process. Nonsteroidal anti-inflammatory drugs (NSAIDs) relieves pain for significant periods, nonopioid analgesics are appropriate for the treatment of both acute and chronic inflammatory conditions. The glucocorticoids also have powerful anti-inflammatory effect but their toxicity limits their use mostly in cases of rheumatoid arthritis. The identified targets for inflammation are the pro-inflammatory mediators cyclo-oxygenase 1 and 2 (COX-1/-2), mitogen-activated protein kinases (MAPKs), janus protein tyrosine kinases (JAKs), nuclear transcription factor (NF-κB) and signal transducers and activators of transcription (STAT) which all directly or indirectly lead to the production of a vast number of proinflammatory cytokines and regulatory proteins such as IL-1/6, TNF-α, MIF, IFN-γ, MMPs (Kulkarni et al., 2006).

The role of natural products as therapy in inflammation has been recognized since ancient ages, and major progress has been done using combinatorial chemistry. Natural products with anti-inflammatory activity have been traditionally used for inflammatory conditions such as fevers, pain, migraine and arthritis (Yuan et al., 2006). Many such natural products and their derivatives with anti-inflammatory activity have been studied in detail like curcumin, parthenolide, resveratrol, cucurbitacins, 1, 8-cineole, salicylate, epigallocatechin-3-gallate, pseudopterosins, quercetin, lyprinol, bromelain, flavonoids, saponins and *Boswellia serrata* gum resin. Recently there is also lot of interest in multi-target drug concept to use the huge array of natural products with privileged scaffolds for developing safe anti-inflammatory multi-target drugs (Koeberle et al., 2014). In investigation of extracts from a marine organisms- sea urchin, *Echinus esculentus* for anti-inflammatory activity, UPLC-ToF-MS and NMR analysis concluded the purified compound with a phosphocholine group with an unknown side chain. A bryozoan, *Eucratea loricata*'s organic extract revealed antiinflammatory activity in NF<sub>K</sub>B, TNF- $\alpha$  and IL-1 $\beta$  screening (Do Thuy, 2012). There are many anti-inflammatory natural compounds reported from marine sponge, varying widely in both chemical structure and biological activity. The anti-inflammatory compounds from marine sponge are dominated by terpenoid compounds, especially sesterterpenes (Keyzers and Davis-Coleman, 2005).

In this chapter we review the development of marine sponge's anti-inflammatory compounds for last four years i.e., 2012-2016. A systematic review of the preclinical pharmacology of marine sponge and its associated microbes/ symbionts compounds for potential activity in inflammation is discussed.

## **2. MARINE SPONGE'S ANTI-INFLAMMATORY ACTIVITY**

Twenty four anti-inflammatory compounds were reported during the year 2008-11, which may be classified into diverse structural types: terpenes, non-terpenes, alkaloids and peptides. Marine sponges are the richest source of anti-inflammatory compounds among other marine

invertebrates such as ascidian, soft coral, cnidarians and gorgonian. The anti-inflammatory sponge natural product is dominated by isoprenoid derived metabolites, especially sesterterpenes followed by nitrogenous compounds- alkaloids, peptides etc. (Keyzers and Davis-Coleman, 2005). New treatment approaches for acute and chronic inflammation is investigating novel anti-inflammatory molecules which can target Toll-like receptor (TLR) signaling pathways. Fung et al. (2014) worked on crude marine sponge extracts and identified compound Girolline which targeted TLR5 signalling. It inhibited signaling through both MyD88-dependent and independent TLRs (i.e., TLR2, 3, 4, 5, and 7) and reduced cytokine (IL-6 and IL-8) production in human peripheral blood mononuclear cells and macrophages. In other study, *Geodia cydonium* extract induced a reduction in VEGF (vascular endothelial growth factor) and proinflammatory cytokines (CCL2, CXCL8, CXCL10, IFN- $\gamma$ , and TNF- $\alpha$ ) levels in human breast cancer cell line MCF-7 cells, indicating an anti-inflammatory effect (Costantini et al., 2015). *Spongia officinalis* was investigated for in vivo anti-inflammatory activity using the carrageenan-induced paw edema model in rats. The methanol extract (25, 50 and 100 mg/kg) produced a significant reduction of the edema and the semi-purified fraction F3 from methanol extract exhibited significant activity at the dose of 50 mg/kg, at the third hour after carrageenan injection, with 72.85% reduction in paw volume (Dellai et al., 2012). The methanolic extract of the Red sea marine sponge *Xestospongia testudinaria* prevented carrageenan-induced acute local inflammation in rats. Methanolic extract (100 mg/kg) of red sea sponge *Xestospongia testudinaria* decreased % increase in paw weight measured at 1, 2, 3 and 4 h after carrageenan injection. The extract decreased paw malondialdehyde (MDA) and nitric oxide (NO) and decreased the inflammatory cytokines, tumor necrosis factor-α (TNF-α), interleukin-1  $\beta$  (IL-1β) and IL-6 (El-Shitany et al., 2015). Phorbaketal A, a tricyclic sesterterpenoid was isolated from the marine sponge *Phorbas* sp. It significantly inhibited the production of nitric oxide (NO), by showing suppression in the expression of inducible NO synthase at both the mRNA and protein levels in LPS- induced RAW 264.7 cells. Further, it also reduced production of inflammatory cytokines such as tumor necrosis factor-alpha, interleukin (IL)-1beta, IL-6, and monocyte chemotactic protein-1 (Seo et al., 2015). The ethanol extract of the demosponge *Homaxinella* cf. *balfourensis* showed activity by reducing the release of  $IL-1\beta$  and PGE2 only at the highest, but not cytotoxic concentration of 250μg/mL significantly. The extract of *Isodictya erinacea* inhibited the release of IL-1 $\beta$  and PGE2, although not affecting LTB4in a dose dependent manner. The extracts of the sponge *Isodictya toxophila* and *Mycale* (Oxymycale) *acerata*'s decreased the release of IL-1β, LTB4 and PGE2 release at the lower concentration of 50μg/mL, which was not cytotoxic (Moles et al., 2014). Solomonsterol A, a selective pregnane X receptor (PXR) agonist was isolated from the marine sponge *Theonella swinhoei*. It exerted anti-inflammatory activity along with attenuation of systemic inflammation and immune dysfunction in a mouse model of rheumatoid arthritis. It reduced the degree of joint damage by inhibiting the expression of pro-inflammatory mediators. (Mencarelli et al., 2014). In another study on the anti-inflammatory effect of compound 11-oxoaerothionin isolated from the Verongida sponge *Aplysina fistularis*, a concentration-dependent inhibition of iNOS (inducible nitric oxide synthase) protein, NO-<sup>2</sup> (nitrite), proinflammatory cytokines and PGE2 (prostaglandin E2) production was observed, when RAW264.7 cells and primary macrophages were preincubated with the compound after stimulation with lipopolysaccharide (Medeiros et al., 2012).

Aeroplysinin-1 is a secondary metabolite isolated from marine sponge *Aplysina* genus with a wide spectrum of bio-activities. It is a chiral, optically active molecule. The enantiomer (-)-aeroplysinin-1 was isolated from *Ianthella ardis* and (+)-aeroplysinin-1 was the first brominated derivative from *Aplysina aerophoba* isolated by Fattorusso & Minale (1972). The dextrorotatory enantiomer has been investigated extensively. It has potent antibiotic effects on gram-positive bacteria and several dinoflagellate microalgae. In preclinical studies, (+)-aeroplysinin-1 have shown promising anti-inflammatory, antiangiogenic and anti-tumor effects. Due to its versatility, it is of pharmaceutical interest for treatment of different pathologies (Garcia-Vilas et al., 2015). Another marine sponge *Neopetrosia* (order Haploscleridae, family Petrosiidae) whole crude extract and its isolated compounds revealed antimicrobial, anti-fouling, anti-HIV, cytotoxic, anti-tumor, anti-oxidant, anti-protozoal, anti-inflammatory activities. Total extracts of *N. proxima* (100 mg/Kg) and *N. rosariensis* (100 mg/kg) significantly inhibited the paw edema of rats 60% and 72% resp. Dichloromethane and methanol fractions of *N. proxima* reduced myeloperoxidase activity and dichloromethane fraction of *N. rosariensis* significantly inhibited nitric oxide (66%), prostaglandin E2 (30.5%) and tumor necrosis factor alpha production (72%) (Franco et al., 2012; Qaralleh 2016). The crude extract of sponge *Reniera sarai*, also displayed antiinflammatory activities (Dhinakaran et al., 2014). Red sea sponges *Scalarispongia aqabaensis* and *Callyspongia siphonella* are poorly investigated genera for their compounds and biomedicinal value. Sterols scalaristerol (5α, 8α- dihydroxycholest-6-en-3β-ol) from *Scalarispongia aqabaensis*, and callysterol (ergosta-5, 11-dien-3β-ol) from *Callyspongia siphonella* were isolated for its anti-inflammatory activity in rat-hind paw edema. The results indicated that callysterol has a strong anti-inflammatory activity, which was comparable to cortisone, while compound scalaristerol showed moderate anti-inflammatory activity. Callysterol affected the release of superoxide anion and thromboxane B2 in a concentrationdependent manner. It showed close to 50% inhibition at approximately 10 μM (Youssef et al., 2010).

## **3. CHEMICAL STRUCTURES OF COMPOUNDS ISOLATED AND THEIR MECHANISM OF ACTION**

A wide range of chemical compounds from various marine invertebrates have been investigated for their anti-inflammatory properties (Table 1). Most of them exhibit phospholipase A2 inhibitory activity. They also control nuclear factor-B activation and inflammatory gene expression (Alcaraz & Paya, 2006). Some sesquiterpenes were found to inhibit human neutrophil degranulation, superoxide generation, leukotriene B4 production (variabilin), TPA (12-o-tetradecanoylphorbol-13-acetate)-induced ear oedema (variabilin, bolinaquinone, topically) as well as carrageenan induced paw oedema (variabilin, petrosaspongiolide M and bolinaquinone, p.o.) in mice (Giannini et al., 2001; Haefner 2003).

Table 1. Compounds isolated from marine sponge and fungus and their mechanism of action **Table 1. Compounds isolated from marine sponge and fungus and their mechanism of action**

## **4. ANTI-INFLAMMATORY ACTIVITIES OF BACTERIA ASSOCIATED WITH MARINE SPONGES**

Anti-inflammatory activity of secondary metabolites produced by *Theonella* sp. was studied using RAW 264.7 macrophages. Inhibition of nitric oxide (NO) production in lipopolysaccharide stimulated RAW 264.7 cells is a well-established assay to screen antiinflammatory activity. The inhibition level of NO released by RAW 264.7 was estimated from nitrate standard curve. Two isolates TM 1.8 and TM 1.9 possessed anti-inflammatory activities of 112.06% and 109.7% respectively for every 1ug/L sample. The result was compared in inhibiting NO production compared to positive control N-Monomethyl-Larginine Monoacetate (L-NMMA) which showed an inhibitory activity at 87.41% for every 1ug/L sample (Radzi et al., 2015). New tanzawaic acid derivative tanzawaic acid Q, and four known analogues, tanzawaic acids A, C, D, and K were investigated from a marine-derived fungus *Penicillium steckii* 108YD142. These compounds significantly inhibited nitric oxide production and the new tanzawaic acid Q inhibited the lipopolysaccharide (LPS)-induced inducible nitric oxide synthase and cyclooxygenase-2 proteins and mRNA expressions in RAW 264.7 macrophages. The result of this study demonstrated that the new tanzawaic acid derivative inhibits LPS-induced inflammation (Shin et al., 2016).

## **5. SYNTHETIC COMPOUNDS FROM THE MARINE SPONGE COMPOUNDS LEAD**

Several inflammatory diseases most notably rheumatoid arthritis, is related to P2X7R activation, which has earned great attention and interests in the application of new treatments through the inhibition of this receptor (Toulme et al., 2010). The functional role of the P2X7R in the inflammatory event is well known as an important mediator in the expression and release of important cytokines and inflammatory mediators. Because of its significant role, it is recently considered as an important anti-inflammatory and pain target, and it has received lot of attention from pharmaceutical companies for evaluating clinical trials based on it (Soares-Bezerra et al., 2013**)**.

		and A804598	2006
3.	Anti-inflammatory action in	Carteramine A	Kobayashi et al.,
	human neutrophils		2007

**Table 2. Synthetic compounds from the marine sponge compounds as a lead**

Several new synthetic compounds have been developed for both the P2X3R and P2X2/3R and P2X7 receptors. AF-353 is the most notable synthetic compound developed by Roche Pharmaceuticals (Gever et al., 2006) and A-317491 developed by Abbott Laboratories

for P2X3R (Gunosewoyo & Kassiou, 2010). Disubstituted tetrazoles, the cyanoguanidines A-438079, A-740003 and A804598 with action on hP2X7R (human)/mP2X7R (mouse) and rP2X7R (rat) are the candidates for a potential antagonist for P2X7R (Nelson et al., 2006). The compounds are listed in Table 2. TerraMarine Pharmaceuticals, New Zealand has already identified two promising anti-inflammatory compounds from marine organisms. The first one was patented in September 2005, and is now being improved for its effectiveness and usability. Further, they also plan to study the compound's action in the body and its pharmacokinetic properties. The study will help to determine the correct dosage of the compound and also its development into a usable drug. TerraMarine is also in process to file the provisional patent for the second compound. Owning a patent will achieve TerraMarine the rights to use the chemical structure of the compound as an anti-inflammatory drug or any other for 16 years (Proffitt 2006).

#### **CONCLUSION**

Research work summarized in this chapter highlights the ongoing search and development in the field of marine sponge's bioactive compounds and their extraordinary potential as a source of novel bioactive compounds and drugs. In the meantime, much work is in progress with reference to the clinical trials and bringing the drug in the market. However, this ultimate step is dependent on the extent to which the pharmaceutical industry shows its preparedness to grasp such opportunities. The recent policy adopted by most governments worldwide is encouraging and aims at funding basic research, clinical and the manufacturing industry. There is need of continuous effort in preclinical and clinical studies of the marine anti-inflammatory compounds to be tested so that more and more marine drugs are launched. The continuous search for marine sponge leads, and its transformation into a drug with such financial support will ensue good results.

# **TROPHIC ECOLOGY OF THE SHORTFIN MAKO**  *ISURUS OXYRINCHUS* **(LAMNIFORMES: LAMNIDAE) IN THE EASTERN PACIFIC OCEAN**

## *Rigoberto Rosas-Luis\* , Jonathan E. Pincay-Espinoza, Peggy Loor-Andrade and Maribel Carrera-Fernández*

Departamento Central de Investigación, Universidad Laica "Eloy Alfaro" de Manabí, Ciudadela Universitaria vía San Mateo, Manta, Manabí, Ecuador

## **ABSTRACT**

Shortfin mako sharks *Isurus oxyrinchus* are important organisms in the pelagic ecosystem. In spite of their vulnerable status, they are captured by fishermen in the Eastern Pacific Ocean. The proper management and conservation of this population in the Pacific is critical and thus, more biological knowledge of this species is needed. In this work, the trophic habits and consumption of key prey by *I. oxyrinchus* were studied through stomach content analysis of samples collected off the coast of Ecuador, and a literature review of its feeding habits was conducted for the eastern Pacific. The index of relative importance of prey items, and the consumption of key prey were calculated for the three areas. The diet was composed of 78 prey taxa, and cephalopods were the main prey items in the north and central areas, with the jumbo squid *Dosidicus gigas* being the most important prey. For the southern area, *I. oxyrinchus* fed on fish with the bigeye cigarfish *Cubiceps pauciradiatus* being the most important prey species. The trophic niche of *I. oxyrinchus* was composed of squids and fish as the main prey items. The niche breadth for the three areas was reduced, and the trophic level calculated with stomach contents and stable isotopes of  $\delta^{15}N$  showed values of 3.68 to 4.44 suggesting that this shark is a tertiary predator in the ecosystem. The jumbo squid *D. gigas* and fish of the family Scombridae were described as key species in the diet of *I. oxyrinchus*. The consumption estimate from 2000 to 2013 was 39 128 tons, with 55.8% of this consumption represented by *D. gigas*. These results demonstrate that *I. oxyrinchus* is an

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: riroluis@yahoo.com.mx.

active and top predator in the trophic webs of the Eastern Pacific, with opportunistic feeding habits on the more available and abundant prey species.

**Keywords:** *Isurus oxyrinchus*, shortfin mako, trophic ecology, Eastern Pacific Ocean

#### **1.INTRODUCTION**

The shortfin mako shark *Isurus oxyrinchus* (Rafinesque, 1810) is a species of the family Lamnidae, which inhabits the waters of tropical and subtropical oceans (Compagno, 2001; Compagno et al. 2005; Nelson, 2006), with a distribution in the Atlantic, Indic and Pacific Oceans (Nelson, 2006). Sharks have a slow growth rate, late maturity, and long gestation period, biological characteristics that are sensitive to marine changes (Cortés, 2000; Frisk et al. 2001; Frisk et al. 2005).

In the early 1920s, the shark fisheries showed an increase in captures (Barker and Schluessel, 2005). As a result of this fishery activity, ocean shark populations have been declining (Dulvy et al. 2008; Ferreti et al. 2008; Mucientes et al. 2009; Dulvy et al. 2014). In spite of the fisheries regulation, the over-fishing continues as the main factor influencing the decline of sharks (Ferrati et al. 2010). According to the Food and Agriculture Organization of the United Nations (FAO, 2015), in the Eastern Pacific Ocean *I. oxyrinchus* is an important species in the total catches of sharks, and according to the International Union for the Conservation of the Nature (IUCN), it is considered a vulnerable species (Polidoro et al. 2012).

Sharks, such as *I. oxyrinchus*, are key top species that regulate the food webs in the ecosystems (Motta and Wilga, 2001; Navia et al. 2010; Bornatowski et al. 2014). *Isurus oxyrinchus* is an active predator of bony fishes and cephalopods in the Atlantic Ocean and in the south Pacific off the coast of Chile (Stillwell and Kohler, 1982; Vaske-Júnior and Rincón-Filho, 1998; Cortés, 2000; Maia et al. 2006; Mucientes-Sandoval and Saborido-Rey, 2008; Lopez et al. 2009; Wood et al. 2009). Its diet may include other sharks, dolphins and marine mammals (Cliff et al. 1990; Velasco-Tarelo, 2005; Mucientes-Sandoval and Saborido-Rey, 2008; Lopez et al. 2009; Lopez et al. 2012; Preti et al. 2012; Biton-Porsmoguer et al. 2015). As *I. oxyrinchus* is a top predator, its depletion from the oceans promotes changes in topdown control (Ferreti et al. 2008; Ferreti et al. 2010), and modifies the structure and flux of biomass and energy in the ecosystems (Ferreti et al. 2008; Heupel et al. 2014). Thus, it is necessary to identify their food sources and feeding habits at a local and regional scale, and perform a global analysis to identify trends in the trophic ecology of this shark.

Research on the diet and feeding behavior, as well as the predation strategy, of sharks has been conducted in the North and South Pacific Ocean (Yatsu, 1995; Mucientes-Sandoval and Saborido-Rey, 2008; Vetter et al. 2008; Lopez et al. 2009). In the central Pacific off the coast of Ecuador, greater knowledge of *I. oxyrinchus* and other sharks is needed. Trophic ecology studies are conducted to determinate the function and position of species in the food web, and are important to understanding the impacts of predators on the abundance and biomass of trophic levels (Motta and Wilga, 2001; Aguiar and Valentin, 2010; Hussey et al. 2014). Thus, the objective of this research was to investigate biological aspects and the trophic ecology of *I. oxyrinchus* caught in the Ecuadorian Pacific and compare these results with those from the

North and South Eastern Pacific Ocean, identifying key prey species, and inferring the biomass consumption of key prey species.

## **2. METHODS AND STATISTICAL ANALYSES APPLIED IN THE TROPHIC ECOLOGY OF** *ISURUS OXYRINCHUS*

#### **2.1. Stomach Content Analysis Applied to the Trophic Ecology of**  *Isurus oxyrinchus*

#### *2.1.1. Prey Identification*

The stomach contents of sharks have generally been collected from the by-catch of the artisanal or industrial fleets (Stillwell and Kohler, 1982; Vaske-Júnior and Rincón-Filho, 1998; Cortés, 2000; Maia et al. 2006; Mucientes-Sandoval and Saborido-Rey, 2008; Lopez et al. 2009; Wood et al. 2009; Galván-Magaña et al. 2013). Fishing methods used by fishermen are long-line and surface and middle water gillnet. The stomachs are extracted and their fullness is estimated as a percentage of stomach capacity. The stomach content is placed in a labeled bag, then keep on ice for transfer to the Laboratory, and frozen directly for later analysis. Prey are separated and identified to the lowest taxonomic level using different keys of identification and weighted with a precision of 0.1 g. For the identification of complete bony fishes, squids and cartilaginous fishes, the keys of Fischer et al. (1995a, b), and Jered and Roper (2010) are used. Fish remains are identified using the skeleton according to Clothier (1950), and the reference collection of fish skeletons of each institution. Hard structures such as otoliths and squid beaks are identified according to Wolff (1984), North et al. (1984), Clarke (1986), García-Godos (2001) and Xavier and Cherel (2009). Additional, the total length or fork length with precision in centimeters and the sex of each shark are recorded.

#### *2.1.2. Cumulative Prey Curves*

Cumulative prey curves have been constructed to determine if an adequate number of stomachs had been analyzed. These curves are constructed at all taxonomic levels and excluded those prey that occurred only once (Preti et al. 2012). A vegan package (Oksanen et al. 2010) of the statistical software R (R Development Core Team, 2010) is used for this analysis. When the curve reached the asymptote, the sample size is considered sufficient to describe the diet (Hurtubia, 1973). When the asymptote is not evident a straight line to the last 4 points is fitted and compared the slope of the line with a line of slope zero, with the asymptote indicated when the lines did not differ significantly (Bizzarro et al. 2007).

#### *2.1.3. Diet Analysis*

To evaluate the feeding rate, vacuity index has been used (Consoli et al. 2008), with the following equation  $V = N_e/N_s * 100$ , where,  $N_e$  = number of empty stomachs and  $N_s$  = total number of stomachs analyzed.

Stomach contents have been analyzed by frequency of occurrence, and numeric and gravimetric methods to quantify the diet. Frequency of Occurrence (%FO) is calculated as the percentage of predators that fed on a certain prey. The number of individuals of a certain prey

relative to the total number of individual prey is represented by Number (%N), and the weight of a certain prey relative to the total weight of all prey is calculated as Weight (%W) (Cailliet, 1976). The percentage of the Index of Relative Importance (%IRI) is calculated to describe the contribution of each prey in the diet (Pinkas et al. 1971), as follows %IRI =  $((IRI*100)/\Sigma IRI)$ . Graphics of the most important prey items by area have generally been plotted.

Comparisons between groups have been tested using contingency tables and by estimating G statistics (Crow, 1981). This statistic has a  $\chi$ 2 distribution.

$$
G = 2 \cdot \sum_{i,j} X_{ij} \ln \left( X_{ij} / (X_i X_j / N) \right)
$$

Where Xij is the FO of prey of the i category ingested by the j predator category, Xi is the FO of prey of the i category ingested by all predators, Xj is the total FO of prey ingested by the j predator category, and N is the total number of prey items ingested by all predators.

#### *2.1.4. Trophic Overlap*

The index of Morisita-Horn has been used to calculate the trophic overlap between the food and feeding habits, as follow,  $C\lambda = 2\sum (Pxi^*Pyi)/(\sum Pxi^2 + \sum Pyi^2)$  where  $C\lambda$  is the Morisita-Horn index between the *x* and *y* predators, *Pxi* is the proportion of prey *i* in the total prey consumed by predator *x*, *Pyi* is the proportion of prey *i* in the total prey consumed by predator *y*, *n* is the number of total prey (Smith and Zaret, 1982). Values of this index vary from 0 to 1, where values >0.6 indicate high overlap, 0.3 to 0.6 indicate a medium overlap, and 0.0 to 0.29 indicate low overlap (Langton, 1982).

#### *2.1.5. Niche Breadth and Trophic Level*

The %IRI has been used to obtain the niche breadth (*Bi*) by calculating the standardized Levin's index (Hurlbert, 1978; Krebs, 1999), as follows  $Bi = ((1/\sum Pij^2))$ -1)/(*n*-1), where *Bi* is the Levin's index of predator *i*, *Pij* is the diet proportion of predator *i* that uses prey *j* and *n* is the number of prey categories. This index takes the values of 0 to 1; when  $Bi < 0.6$  the niche breadth is narrow, and when *Bi* > 0.6 the niche breadth is wide (Krebs, 1999).

The trophic level has been calculated with the following equation:  $TL_k = 1 + (\sum P j^* T L j)$ , where  $TL_k$  is the trophic level,  $P_j$  is the proportion of the prey category in the predator diet, *TLj* is the trophic level of the prey categories (bony fishes  $TLj = 3.24$ , cephalopods  $TLj =$ 3.20, crustaceans *TLj* = 2.52, invertebrates *TL j* = 2.5, seabirds *TLj* = 3.87, chondrichthyan fishes  $TLj=3.65$  and marine mammals  $TLj = 4.02$ ) (Cortés, 1999).

#### *2.1.6. Feeding Strategy*

The feeding strategy of *I. oxyrinchus* has been described using the method of Amundsen et al. (1996). This is a two-dimensional method based on the specific abundance of prey (%SAP) and the frequency of occurrence (%FO). Results of this method describe the prey importance as rare or dominant, the feeding strategy as a generalist or specialist predator, and the inter- and intra-specific components of the niche breadth. The values are calculated with the following equation:  $Pi = (\sum S_i / \sum S_i t_i)^* 100$ , where *Pi* is the specific abundance of prey *i*, *Si* is the weight in grams of prey *i*, and *Sti* is the total weight of all stomach contents of stomachs with prey *i*. It was not possible to apply this method to the other two areas because there were no data on individual feeding.

#### *2.1.7. Consumption by Sharks of Key Prey Species*

Estimates of consumption by sharks have been calculated using catches as a measure of abundance in the ocean because biomass estimates of sharks are not available. The analysis assumes that the proportion of each prey species does not vary over time. The consumption equation is represented as follows:  $Qi = \sum Fj^*(Q/B)^*DCij$ , where  $Q_i$  is the consumption of prey species, *Fj* represents fishery catches of sharks in tons, (*Q*/*B*)*j* is the Consumption/ Biomass relationship of sharks, and  $(DCij = % IRI)$  is the diet proportion of each prey species *i* in the diet of sharks *j*.

#### **2.2. Stable Isotopic Analysis**

#### *2.2.1. Sampling and Isotopic Analysis*

A small portion of muscle (dorsal portion of the head, or caudal portion) is cleaned with distilled water and lipids are extracted with chlorophorm and methanol (Bligh and Dyer 1959). Samples are freeze-dried and powdered, and 0.285-0.315 mg of each sample is packed into tin capsules. Isotopic analyses are performed at different laboratories (Laboratory of Stable Isotopes at the Estación Biológica de Doñana, Plant Science Department at University of California, Laboratorio de Isótopos estables UNAM, Laboratorio de Isotópos Estables CICIMAR-IPN). Samples are generally heated to  $1020^{\circ}$ C using a continuous flow isotoperatio mass spectrometer (Thermo Electron) by means of a Flash HT Plus elemental analyser interfaced with a Delta V Advantage mass spectrometer. Stable isotope ratios are expressed in the standard δ-notation (‰) relative to Vienna Pee Dee Belemnite ( $\delta^{13}$ C) and atmospheric N<sub>2</sub> ( $\delta^{15}$ N). Based on laboratory standards, the measurement error is  $\pm$  0.1 and  $\pm$  0.2 for  $\delta^{13}$ C and δ <sup>15</sup>N, respectively. The C:N ratio of tissues has to be always lower than 3‰. ANOVA tests have been used when comparing isotope values between groups.

#### *2.2.2. Trophic Level Based on Isotope Values*

The trophic level position of each species has been calculated according to Kim et al. (2011) and Carlisle et al. (2012), using the following equations:

$$
TL = [(\delta^{15}N_{\text{predator}} - \delta^{15}N_{\text{base}})/\text{TEF}] + 3,
$$

where TL is the trophic level of that consumer,  $\delta^{15}N_{\text{predator}}$  represents the values of the consumer's muscle tissue;  $\delta^{15}N_{base}$  is the mean  $\delta^{15}N$  of *Benthosema panamense* (9.9‰; for the Pacific off Ecuador; Calle, 2010, with a trophic level of 3; Dambacher et al., 2010), and *Pleuroncodes planipes* (12.3‰; for the north Pacific with a trophic level of 2.6; Madigan et al., 2012) as reference species that share the same habitat as predators, and TEF =  $3.7$  is the transfer energy factor of each predator (Sweeting et al. 2007).

#### **2.3. Trophic Ecology of** *Isurus oxyrinchus* **in the Eastern Pacific**

#### *2.3.1. Feeding Habits of Isurus oxyrinchus*

For description of the feeding habits of *I. oxyrinchus* off Ecuadorian waters (central Pacific), samples were collected in the fishing port of Santa Rosa, Santa Elena, Ecuador 02°13´S; 80°58´W, from July 2013 to April 2015, (Figure 1). For the north and south Pacific, reports of the food and feeding habits of *I. oxyrinchus* were reviewed. For the northern area of Eastern Pacific Ocean, the reports of Vetter et al. (2008) and Preti et al. (2012) were consulted, and for the southern area, the reports of Yatsu, (1995), Mucientes-Sandoval and Saborido-Rey, (2008), Lopez et al. (2009), Lopez et al. (2012), and Rosas-Luis et al. (2016) were consulted. To perform an adequate comparison of the prey items of *I. oxyrinchus*, the diet values reported off the coast of United States of America by Lopez et al. (2009), and off the coast of Chile by Preti et al. (2012) and the present study (Figure 1) were used to compare and estimate the feeding habits and consumption of sharks.

Figure 1. Eastern Pacific Ocean. Gray dark polygons represent the northern (Off the coast of the United States of America), central (off the coast of Ecuador), and southern (off the coast of Chile) areas where stomach content analyses were reported for *Isurus oxyrinchus*.

The consumption by *I. oxyrinchus* of the jumbo squid *D. gigas* and fishes of the family Scombridae (all scombrid fishes were unified into a single group; species included were *K. pelamis*, *T. albacares*, *Auxis* spp., *Scomber japonicus*, *Sarda chiliensis*, and unidentified scombrid fishes) were calculated for the period 2000 to 2013 based on the available fishery data of each area. The Q/B value was taken from Rosas-Luis et al. (2008).

#### *2.3.2. Stable Isotopic Analysis of Isurus oxyrinchus*

Stable isotopic analysis of  $\delta^{15}N$  and  $\delta^{13}C$  was applied to muscular samples collected in the fishing port of Santa Rosa, Santa Elena, Ecuador 02°13´S; 80°58´W, from July 2013 to April 2015. Reported data of Malpica-Cruz et al. (2013) and Maya-Meneses et al. (2016) for the North Pacific, and Clarian et al. (2016) for the south Pacific, were consulted and compared with those of the central area. Three size groups were used in the comparison, small sharks <112 cm total length, medium sharks 112-196 cm, and large sharks >196 cm.

Figure 2. Size distribution of the shortfin mako *Isurus oxyrinchus* in centimeters (cm) caught off the coast of Ecuador. Black bars represent males and dark gray bars represent females.

Figure 3. Cumulative curve of prey (black line) and standard deviation (gray) calculated for *Isurus oxyrinchus* caught off the coast of Ecuador. (A) represents the curve when all stomachs analyzed with all prey items were included, and (B) represents the curve calculated when uncommon prey were deleted (prey that occurred once in the stomachs).

## **3. FEEDING DESCRIPTION OF** *ISURUS OXYRINCHUS* **IN THE EASTERN PACIFIC OCEAN**

#### **3.1. Results of Stomach Content Analysis**

#### *3.1.1. Central Area "Ecuadorian Pacific"*

#### **General Description of** *I. oxyrinchus* **Caught in the Central Area**

The feeding habits of 281 shortfin mako sharks were analyzed from the Ecuadorian Pacific Ocean: 134 were males, 129 females and 18 undetermined, with a sex proportion of 1.04M:1H ( $\chi^2$  = 0.095; p = 0.75). The size of males ranged from 106 to 257 cm total length (Mean = 174.51  $\pm$  23.60) and females from 105 to 267 cm total length (Mean = 176.16  $\pm$ 25.40) (Figure 2). The undetermined individuals ranged from 108 to 213 cm total length, and no size differences were observed among males and females ( $t = -0.54$ ;  $p = 0.58$ ). Figure 3 shows the cumulative prey curve. When all the prey items were included, the curve did not reach the asymptote ( $\mathbb{R}^2 = 0.95$ , p = 0.01), but did when prey that occurred once were excluded ( $R^2 = 0.85$ ,  $p = 0.05$ ).

#### **Prey Identification**

Forty taxa were identified in the stomach contents of *I. oxyrinchus* caught in the Ecuadorian Pacific (Table 1). Cephalopoda was the main prey group (%IRI =  $58.28%$ ), with squids of the family Ommastrephidae being the most important in the diet (%IRI =  $48.36$ ). The second most important group in the diet was Osteichthyes (% $IRI = 41.07%$ ), with fishes of the family Scombridae being the most important (%IRI =  $20.62$ ) (Figure 4, Table 1). The jumbo squid *D. gigas* was the main prey species in the diet (%IRI = 48.28), followed by the skipjack *K. pelamis* (%IRI = 11.39), the scombrid *Auxis* spp. (%IRI = 7.47), and finally, the squid *Ancistrocheirus lesueurii* (%IRI = 7.26) (Figure 4 and Table 1).

#### *3.1.2. Northern and Southern Pacific Areas*

#### **Prey Identification**

Values of %IRI, %FO, %N from the north and south Pacific areas are shown in Table 1. For the northern area, 42 taxa have been reported in the diet of *I. oxyrinchus*. Cephalopods have been reported as the main prey items, with squid *D. gigas* of the family Ommastrephidae being the most important, followed by the group composed of Osteichthyes, with the fish *Cololabis saira* of the family Scomeresocidae and the chub mackerel *Scomber japonicus* of the family Scombridae being the most important. Other prey groups such as Chondrichthyes, mammals, and marine birds have also been reported (Figure 4, Table 1).

Twenty-two prey taxa have been reported in the diet of *I. oxyrinchus* in the southern area (Table 1). Osteichthyes have been reported as the main prey group, with the fish *Cubiceps puciradiatus* of the family Nomeidae being the most important. The second most important group was Cephalopoda, with the jumbo squid *D. gigas* of the family Ommastrephidae being the most important. Other groups of less importance such as Chondrichthyes, Mammalia and Crustacea have also been reported in the diet (Table 1, Figure 4).

Figure 4. Diet composition of the main prey found in the stomach contents of *Isurus oxyrinchus* in the Eastern Pacific Ocean, North (A), Central (B) and South (C), expressed in the percentage of Number (%N) and Weight (%W) (vertical axis) and the Frequency of Occurrence (%FO) (horizontal axis).

Table 1. Index of Relative Importance (%IRI), Frequency of Occurrence (%FO), Number (%N) and Weight (%W) of prey<br>in the stomach contents of shortfin mako *Isurus oxyrinchus* in the Eastern Pacific Ocean. Un = Unidentified **Table 1. Index of Relative Importance (%IRI), Frequency of Occurrence (%FO), Number (%N) and Weight (%W) of prey in the stomach contents of shortfin mako** *Isurus oxyrinchus* **in the Eastern Pacific Ocean. Un = Unidentified.**  Northern and southern areas values were calculated based on Preti et al. (2012) and Lopez et al. (2009) **Northern and southern areas values were calculated based on Preti et al. (2012) and Lopez et al. (2009)**

# Table 1. (Continued) **Table 1. (Continued)**

Bel: Belonidae, Car: Carangidae, Cor: Coryphaenidae, Ech: Echeneidae, Hae: Haemulidae, Mer: Merluciidae, Mon: Monacanthidae, Mug: Mugilidae, Nom: Nomeidae, Pri: Priacanthidae, Reg: Ragalecidae, Sco: Scombridae, Tet: Tetraodontidae. Anc: Ancistrocheiridae, Gon: Gonatidae, His: Histioteuthidae, Mas: Mastigoteuthidae, Oct: Octopoteuthidae, Omm: Ommastrephidae, Ony: Onychoteuthidae, Opi: Opistoteuthidae, Thy: Thysanoteuthidae. Mob: Mobulidae. Del: Delfinidae.

#### *3.1.3. Trophic Overlap*

Prey items, found in the stomach contents of sharks from the Ecuadorian Pacific and those reported for the northern and southern Pacific, overlap with five specific prey (*Katsuwonus pelamis, Auxis* sp., *S. japonicus*, *D. gigas*, *Histioteuthis* sp.). Based on these prey items, a high trophic overlap was found between the northern and central areas  $C\lambda$  = 0.87, while between the central and southern areas, and the northern and southern areas, trophic overlap was moderate ( $C\lambda = 0.52$ , and  $C\lambda = 0.48$  respectively).

#### *3.1.4. Niche Breadth and Trophic Level*

The niche breadth for *I. oxyrinchus* in the north was  $Bi = 0.06$  with 42 prey taxa. In the central area, it was  $Bi = 0.07$  with 40 prey taxa, and for the south it was  $Bi = 0.14$  with 21 prey taxa. The trophic level calculated for *I. oxyrinchus* in the northern area was 4.22, and for the central and southern areas, the trophic level was 4.23.

#### *3.1.5. Feeding Strategy*

The Amundsen graphical analysis, considering 24 prey families, indicated that most of the families found in the stomach contents, such as Echeneidae, Mugilidae, Gonatidae, Mastigoteuthidae, Octopoteuthidae and Onychoteuthidae, were consumed as rare items. The families Ommastrephidae and Scombridae showed the greatest abundance and frequency of occurrence in the Ecuadorian Pacific Ocean.

Figure 6. Total consumption of *Isurus oxyrinchus* in the Eastern Pacific Ocean: black area represents the consumption of fish, and gray area represents the consumption of cephalopods. Cephalopod Consumption in the Eastern Pacific Ocean: black area represents the total consumption, and gray area is the consumption of *Dosidicus gigas*. Consumption of fish in the Eastern Pacific Ocean: black area represents the total consumption, and gray area represents the consumption of Scombrid fish. Consumption of fish and cephalopods in the Eastern Pacific, North (United States of America), Central (Ecuador) and South (Chile): black area represents fish, and gray area represents cephalopods.

#### *3.1.6. Consumption of Fish and Squid by Isurus oxyrinchus*

Figure 6 shows the consumption by *I. oxyrinchus* of specific prey. The total consumption of fish in the three areas during the period analyzed was 39 128 tons. For squid, consumption was calculated to be 21 839 tons. The consumption of scombrid fishes was 6 657 total tons, and this value represented 17.01% of the total fish consumption. The total consumption of the jumbo squid *D. gigas* was 19 299 representing 88.37% of the total consumption of squids.

#### **3.2. Results of Stable Isotope Analysis**

δ <sup>15</sup>N values of *I. oxyrinchus* of the central area (own unpublished data) were higher for sharks of medium size than larger size (one-way ANOVA,  $F_{19} = 4.67$ ,  $P < 0.05$ )(Figure 7). Results of the comparison between N values of all size groups in the three areas showed no difference (one-way ANOVA,  $F_6 = 2.46$ ,  $P > 0.05$ ).

Trophic position of *I. oxyrinchus* based on δ <sup>15</sup>N isotopes showed the highest values for medium sharks, and the lowest values for small sharks in the central and north areas (Table 2). The highest value of the trophic position was calculated for the south area, but no size class was reported. The trophic position values varied around 1 unit when the prey at the base of the food web changed (Table 2).

Figure 7.  $\delta^{15}$ N and  $\delta^{13}$ C values (mean  $\pm$  s.d.) for *Isurus oxyrinchus* of the eastern Pacific ocean.

**Table 2. Trophic position (TP) of** *Isurus oxyrinchus* **by size interval and studied areas. TP-1 was calculated by using the pelagic red crab** *Pleuroncodes planipes* **as base of the trophic web, and TP-2 was calculated by using the myctophid** *Benthosema panamense***. \* no size reported** 

Pacific area	<b>Size</b>	Number of samples	$TP-1$	$TP-2$
North	small	15	3.84	4.89
	medium		4.12	5.17
	large	6	3.68	4.73
Central	medium	41	4.37	5.42
	large		3.97	5.02
South	$\ast$	50	4.44	5.49

Values of  $\delta^{13}$ C between medium and large sharks for the central area (own unpublished data) did not vary (one-way ANOVA,  $F_{19} = 1.78$ ,  $P > 0.05$ ). Results of the comparison of  $\delta^{13}$ C values between the three areas did not vary (one-way ANOVA, F<sub>6</sub> = 0.54, P > 0.05) (Figure 7).

#### **4. DISCUSSION**

The high metabolic rates of Lamnid sharks (Newton et al. 2015) make the identification of food items difficult. However, this can be mitigated if sharks are feeding when they are caught. The stomachs analyzed in each study showed that the sharks fed actively before they were caught, and it was confirmed with the low vacuity percentage of stomachs for the three areas of the Eastern Pacific Ocean. Moreover, the feeding behavior of *Isurus oxyrinchus* is characterized by the consumption of complete or large pieces of prey (Wood et al. 2009), further improving the identification of stomach contents. In this case, prey species were wellpreserved and in earlier digestion stages, improving the identification of ingested species. The number of stomachs was adequate to describe the diet in the three areas: the United States of America, the South Pacific off the coast of Chile, and the Central Pacific Ocean off the coast of Ecuador.

#### **4.1. Feeding Habits in the Eastern Pacific Ocean**

The diet of *I. oxyrinchus* from different regions was composed of a similar number of prey items. Forty prey items were identified in the stomachs of sharks from the central area and 42 were reported for sharks off the coast of the United States (Preti et al. 2012). These may indicates the availability and abundance of similar prey in these areas, such as squids and fish (Clarke, 1996; Ebert and Stehmann, 2013; Galván-Magaña et al. 2013).

The feeding habits of *I. oxyrinchus* showed that these sharks are predators of fishes and squids, in agreement with the results previously reported for this species in the Pacific Ocean (Stillwell and Kohler, 1982; Velasco-Tarelo, 2005; Mucientes-Sandoval and Saborido-Rey, 2008; Lopez et al. 2009, 2012; Preti et al. 2012; Galván-Magaña et al. 2013). High consumption of bony fishes by *I. oxyrinchus* in the Ecuadorian Pacific and similar feeding behavior in the southern area suggests that these prey are abundant in the ecosystems and available to sharks (Stillwell and Kohler 1982; Lopez et al. 2009, 2012; Gorni et al. 2012, 2013). Nevertheless, as indicated by our results, the FO of squid was similar to fish, suggesting that these cephalopods are also important in their diets (Preti et al. 2012). The importance of fish and squid appears to vary between sampled areas and among seasons. There are reports showing fishes as the most important food source, indicating a feeding strategy based on ichthyophagous habits (Stillwell and Kohler, 1982; Velasco-Tarelo, 2005; Mucientes-Sandoval and Saborido-Rey, 2008, Lopez et al. 2009, 2012; Preti et al. 2012). In other areas, teutophagous habits are suggested (Galván-Magaña et al. 2013).

There is evidence of a trophic overlap between the food sources used by *I. oxyrinchus* since the squid *D. gigas* and the fishes *K. pelamis* and *Auxis* spp. were the most important prey in the Ecuadorian Pacific and in the northern area off the US coast (Velasco-Tarelo, 2005; Mucientes-Sandoval and Saborido-Rey, 2008; Vetter et al. 2008; Lopez et al. 2009; Preti et al. 2012). Squids are consumed by other sharks such as *Alopias pelagicus*, *Alopias superciliosus*, and *Prionace glauca* in Ecuadorian waters, and three species have been reported in their diet: *D. gigas* and *Sthenoteuthis oualaniensis* of the family Ommastrephidae, and *Ancistrocheirus lesueurii* of the family Ancistrocheiridae (Galván-Magaña et al. 2013; Rosas-Luis et al. 2016). The use of *D. gigas* as prey by *I. oxyrinchus* may be a result of the sharks´ vertical migration to deep waters during the day, which can be up to 800 m deep (Bress, 1993; Abascal et al. 2001; Loefer et al. 2005; Field et al. 2008). These deep waters are where *D. gigas* is found (Nigmatullin et al. 2001; Bazzino et al. 2010). On the other hand, the use of scombrid fishes such as *K. pelamis* and *Auxis* spp. may be a result of their high abundance and distribution in the Pacific (Allen and Robertson, 1998). Contrary to the results for the northern and central areas where cephalopods are the most important prey, in the southern area the bigeye cigarfish *Cubiceps pauciradiatus* was reported as the main prey source (Lopez et al. 2009). However, as presented in this work, the second most important prey was *D. gigas*. The inclusion of cephalopods in the diet of *I. oxyrinchus* in the southern

area varies year to year, as they were reported as the main prey item in 2008 (Mucientes-Sandoval and Saborido Rey, 2008), and were not important in 1995 (Yatsu, 1995). The important prey species in the diet suggests that *I. oxyrinchus* is an opportunistic feeder, and that its diet may change as a consequence of movements and abundance of prey.

#### **4.2. Variation in Diet in the Three Areas of the Eastern Pacific Ocean**

Crustaceans, marine birds, rays, sharks, and marine mammals are uncommon prey species in the diet of *I. oxyrinchus*. Crustaceans and birds have been reported as prey sources of this shark for the southern and northern areas (Vetter et al. 2008; Lopez et al. 2009; Preti et al. 2012), but they were not found in the stomachs analyzed for the central area. It is known that crustaceans, such as the pelagic red crab *Pleuroncodes planipes* in the north Pacific and *Pleuroncodes monodon* in the southern hemisphere, are abundant (Aurioles-Gamboa 1992; Roa et al. 1995; Robinson et al. 2004) and preyed upon by large predators such as *D. gigas* (Rosas-Luis et al. 2008). Thus, these prey are indirectly consumed by *I. oxyrinchus* via squid predation. Birds as food sources are preyed upon in the southern hemisphere by sharks such as *Galeocerdo cuvier* (Cliff and Dudley, 1991; Heithaus, 2005), but for *I. oxyrinchus* these prey sources may be ingested when they are dead and floating on the surface waters.

The presence of uncommon prey species in the diet of *I. oxyrinichus* in each area suggests that the primary distribution of these prey species overlaps with that of *I. oxyrinchus*. A large manta ray *M. japonica* was found in the stomach contents of a shark, and some large sharks had consumed small marine mammals. However, as our results and those previously reported by Lopez et al. (2009) and Preti et al. (2012) showed, these prey were consumed primary by large sharks. The consumption of these prey types by *Carcharodon carcharias*, *Carcharhinus leucas*, *Galeocerdo cuvier*, *Hexanchus sixgill* and *Notorynchus cepedianus* suggests that these species are active predators of marine mammals and birds (Lowe et al. 1996; Heithaus, 2002; Moteiro et al. 2006; Bornatowski et al. 2012). Considering that marine mammals and large fish were consumed in low proportions by *I. oxyrinchus*, we cannot conclude that this shark is an active predator of this kind of prey in the eastern Pacific Ocean. Finally, the consumption of other sharks by *I. oxyrinchus* was found in the three studied areas in agreement with similar reports in the Atlantic and Indian Oceans (Cliff et al. 1990; Maia et al. 2006).

#### **4.3. Niche Breadth and Trophic Level**

Measures of trophic position and niche breadth are essential in the interpretation of trophic ecology (Hussey et al. 2014). These results demonstrated that *I. oxyrinchus* in the Eastern Pacific Ocean has a narrow niche breadth, as a result of a selectivity for prey of the families Scombridae and Ommastrephidae. Its estimated trophic level (4.23) reflects its high level of predation activity in the ecosystem. This is a value similar to other Lamnidae species such as *Carcharodon carcharhias* and *Lamna nasus* with high trophic levels of 4.5 and 4.2, respectively (Cortés, 1999), that indicates, *I. oxyrinchus* is a top predator and a tertiary consumer in the ecosystem (Cortés, 1999; Estrada et al. 2003).
#### **4.4. Feeding Strategy**

The feeding strategy of *I. oxyrinchus* has been conditioned by prey availability, as this shark is a highly migratory species that exploits different areas and consumes a wide range of prey (Lopez et al. 2009). In the north (Velasco-Tarelo, 2005; Preti et al. 2012) and central Pacific, *I. oxyrinchus* fed mainly on *D. gigas, Katsuwonus pelamis*, *Auxis* spp., *Thunnus albacares* and *Scomber japonicus*, coinciding with the high abundance and distribution of these species in the Pacific Ocean (Punsly and Deriso, 1991; Markaida and Gilly, 2016). Nevertheless, feeding habits differed in the southern area off the coast of Chile where this consumer showed a heterogeneous and generalized diet (Lopez et al. 2009, 2012). This suggests that the niche breadth may vary according to geographic area, and that this shark preys opportunistically on abundant and available prey species.

#### **4.5. Consumption of Fish and Squids by** *Isurus oxyrinchus*

*Isurus oxyrinchus* is a top predator in the eastern Pacific Ocean, with an active vertical and horizontal migration (Fowler, 2014) that determines its impact on the food web. Captures of this shark for the analyzed areas are the only indicators permitting calculations of the trophic consumption of prey (Rosas-Luis et al. 2016). Considering this indicator, the consumption of fish is higher than squid, but as our results showed, these values vary between northern, central and southern areas. We focused our study on the most important prey to demonstrate how the decline of this shark may affect the abundance of other marine organisms (Chang and Liu 2009; Ferreti et al. 2010). If the actual tendency in the decline of *I. oxyrinchus* continues, the population of *D. gigas* and other prey will be affected positively. On the contrary, if the prey populations increase, the population of sharks may be affected positively. It is known that the estimates of biomass between prey and predator are overestimates (Jennings and Collingridge, 2015), but these can be used to create models and measurements for the management and conservation of endangered species.

The high consumption rates of the jumbo squid *D. gigas* by *I. oxyrinchus* suggests that this squid is an important component in the food web (Nigmatullin et al. 2001; Rosas-Luis et al. 2008; Alegre et al. 2014), and confirms its abundance and distribution patterns in the Eastern Pacific Ocean (Markaida and Gilly, 2016). On the other hand, the importance of scombrid fishes in the diet increases latitudinally, confirming their wide distribution in this region (Allen and Robertson, 1998), and its availability as a food source for *I. oxyrinchus*. So that, the trophic relationships between prey and predator are fragile, and small disturbances may affect both components in the ecosystem, resulting in disturbances throughout the trophic webs.

#### **4.6. Stable Isotopic Analysis of** *Isurus oxyrinchus*

Values of  $\delta^{15}N$  and  $\delta^{13}C$  of *I. oxyrinchus* in the central, north, and south eastern Pacific were interpreted in addition of the results of the analysis of stomach contents. Isotopes resulted in no difference between sharks sampled in the three areas. This result suggests that *I. oxyrinchus* has similar feeding habits in the whole area, being cephalopods and fish the

main prey groups (Stillwell and Kohler, 1982; Velasco-Tarelo, 2005; Mucientes-Sandoval and Saborido-Rey, 2008; Lopez et al. 2009, 2012; Preti et al. 2012; Galván-Magaña et al. 2013). Malpica-Cruz et al. (2013) and Maya-Meneses et al. (2016) mentioned that small and medium size *I. oxyrinchus*, caught off the coast of Mexico, had no variation in the δ<sup>15</sup>N values, contrasting with the result of the central area where medium and large *I. oxyrinchus* had significant variation. The difference in  $\delta^{15}N$  values for sharks in the central area results of the ontogenetic shift to a broader diet (Preti et al. 2012), and a more diverse feeding preferences of medium size sharks (Malpica-Cruz et al. 2013). The trophic position of *I. oxyrinchus*, based in δ<sup>15</sup>N values of *P. planipes* as the base of the food web, coincided with the trophic position calculated with the results of stomach content analysis and that reported by Cortés, (1999), but it was different when the myctophid *B. panamense* was used as the base of the food web. It suggest that the selection of the organism as base of the food web is determinant for the trophic position in the ecosystem, and that more research is needed in order to define similar organisms as key species for isotopic analysis in each studied area. Despite this, the trophic position of *I. oxyrinchus* vary according to size, habitat and availability of food, and caution must be consider when make conclusions of the trophic position of this species.

Regarding the  $\delta^{13}C$  values, no differences were found in comparison between size and areas, which confirms a same use of habitat of this species in the eastern Pacific. *Isurus oxyrinchus* are known to migrate between inshore and offshore environments (Stillwell and Kohler, 1982), this patters have been documented when sex segregation is present (Maya-Meneses et al. 2016). Unfortunately, our results and those reported for the south and north areas are not adequate to perform an analysis by sex, and nothing can be concluded. Thus, isotopic concentrations of muscular tissue of females and males are needed in order to prove the sexual segregation in and offshore of this species.

#### **CONCLUSION**

In conclusion, our results demonstrate that the short fin mako shark *I. oxyrinchus* feeds mainly on bony fishes and squids, but its trophic habits include other prey such as rays, sharks, marine mammals, marine birds and crustaceans. As described, *I. oxyrinchus* feeds on abundant and available prey sources, demonstrating its role as an opportunistic feeder in the studied areas. Variation in the prey items identified in the stomach contents is a result of the latitudinal distribution of sharks and the distribution areas of the potential prey, but as these results show, the jumbo squid *D. gigas* and fish of the family Scombridae are the most important food sources across the region. The squid *D. gigas* may be considered a key species in the development of *I. oxyrinchus* populations as this squid has shown demographic explosions and traverses both hemispheres having a positive impact on the populations of its predators.

Additional trophic ecology studies in the Pacific Ocean are necessary to identify the variation in the use of food sources by *I. oxyrinchus*. There are few studies on this shark in the north and south Pacific, and this is the first report with a full description of the feeding habits of this shark in the central Pacific. These results and those reported for the same species in the Atlantic Ocean increase our understanding of the importance of this species in the ecosystem. We suggest integrating this information into ecological models for the better management of the shark population.

#### **ACKNOWLEDGMENTS**

The authors thank the University Laica "Eloy Alfaro" of Manabí and its Central Department of Research for their support through the project "Trophic Ecology of the Large Pelagic Species of the Ecuadorian Pacific 2014-2015", of which this manuscript is a part. The authors would like to thank all the students who directly contributed to this project for their help collecting samples. An additional thanks to the fishermen of Santa Rosa, Salinas for granting us access to the sharks. Thanks to Sarah Young for her support and observations on the English version.

# **ABSTRACT**

Long-term and large-scale monitoring studies indicate the changes of anthropogenic impact on the water ecosystems, which can be chronically stressed by multiple environmental factors. Fish are very sensitive to anthropogenic pollution, and some of them may be tested as biomonitors for the evaluation of the ecological status and risk assessment of marine environments. Fish biochemical parameters could be directly related to the area the fish were collected. In polluted areas the exposure of fish to xenobiotics results to interaction between these compounds and biological systems which may give elevation to biochemical and physiological damage or/and adaptive mechanisms via the induction of defense immune and antioxidant systems. Biochemical and physiological parameters are used as biomarkers for contaminants and could be applied for the evaluation of environmental stress and its after-effects in fish. Biomarkers exposure to environmental stressors vary widely depending on the type of anthropogenic activity involved. Sewage and chemical pollution from industrial, agricultural, maritime transport and domestic effluents are the main sources of pollution in Black Sea ecosystem. Coastal waters are the main recipients of discharges and combine effects of the various kinds of contaminants result dramatic ecological consequences such as eutrophication, biodiversity loss, elimination of some species, worsening of their health and decline the population size. Biochemical biomarkers variables seem to be useful indicators of the health status of fish and their habitats in monitoring studies. Scorpion fish (*Scorpaena porcus*) is among the most common fish species in Black Sea coastal waters, and it was selected as biomonitor species. The biomarker response in scorpion fish from several Sevastopol bays characterizing different level of pollution was studied

related to anthropogenic impact. Selected biomarkers of exposure and effect, including parameters of oxidative stress and oxidative damage, were good tools for the evaluation of fish health and ecological status of their habitats.

**Keywords**: Black Sea, bays, pollution, biomarkers, oxidative stress, monitoring

# **1.INTRODUCTION**

Marine environment and especially the coastal waters play an important role in human activity, because more than 2 000 000 000 people live in the coastal part of the sea and ocean and use their resources directly (The World Health Report, 2002). However, despite marine coastal ecosystems are extremely productive areas, they are impacted by great anthropogenic pressure, namely from pollutants, containing in domestic, agricultural, maritime transport and industrial effluents, entering marine water. Aquatic organisms, and especially fish are very important for commercial purposes, including fishery and aquaculture. Additionally, they play the key role in ecosystem, because they belong to the vertebrates, which are at the top of the food chain. Fish health characteristics, and their responses to unfavorable living conditions, have been extensively used as indicators of habitat quality in assessment tools developed for scientific and management purposes.

Fishes' response to environmental changes is complex, depending on the intricate relations between environmental conditions and the individual ability to adapt, which depends on their life history, age, physiological status, taxonomic position (Martinez-Alvarez et al., 2005; Fonseca et al., 2011a). Usually the investigators report the elevated levels of the manmade pollution and its deleterious effects on marine organisms in all levels of their biological organization. Long-term and large-scale monitoring studies indicate the changes of anthropogenic impact on the water ecosystems, which can be chronically stressed by multiple environmental factors. Environmental pollutants transfer to fish organism and accumulate in it, caused early biological effects, especially in cell and molecular levels. Accumulation of these alterations provokes damage of organ structure, tissues and systems disfunction, biochemical changes, including ROS generation (Gillis, 2012; Gillis et al., 2014; Grinevicius et al., 2009; Kaptaner et al., 2014).

For analysis of negative factors effects on fish many different criteria are used. Fish behavior, morphological characteristics, physiological and biochemical responses to specific and multiple stressors have been extensively used to determine individual health and population status, and to assess habitat quality (Fonseca et al., 2011b; Serafim et al., 2012). A multi-biomarker approach was applied in a dynamic environment with a significant chemical contamination. Moreover, biochemical responses in natural populations of different fish species depend on their ecological and biological features, which can result from different physiological processes in them (Solé et al. 2009; Rudneva, 2012).

The present multi-biomarker approach identified of anthropogenic pollution, including industry, agriculture, fishery, aquaculture, tourism, petroleum and gas production, coastal domestic infrastructure, maritime transport impact on marine environment in Black Sea. The specificity of Sevastopol bays including their geographical position, geomorphological structure, hydrological fluctuations and different level of pollution allow to understand the main trends of anthropogenic impact on fish health and to establish the biomarkers response on stress living conditions.

In the present work the level of several biomarkers was assessed in highly distributed in Black Sea fish species *Scorpaena porcus*. For assessment of multiple biomarker responses in fish we determined the biomarkers of exposure: (1) antioxidants level in the form of enzymes activity, that reflects the response on the toxicity of reactive oxygen species (ROS): superoxide dismutase (SOD), catalase (CAT), peroxidase (PER), glutathione reductase (GR); (2) biotransformation enzyme, phase II glutathione S-transferase (GST), which metabolizes and conjugates xenobiotics; effect biomarkers: (1) lipid peroxidation (LPO) in the form of TBARS and chemiluminescence parameters; (2) level of oxidized proteins, measured as carbonyl groups concentration; (3) aminotransferase activity, which attributed with liver function. These biochemical responses were determined in scorpion fish *Scorpaena porcus*, sampled in four Sevastopol bays. It is resident species and it is also abundant in numerous other bays and coastal waters in Black Sea coast line.

The main objective of the present study was to evaluate the potential of fish biochemical response as indicators of habitat quality in marine bays, considering both natural and anthropogenic stressors.

# **2. MATERIALS AND METHODS**

#### **2.1. Materials**

Scorpion fish *Scorpaena porcus* is highly distributed benthic species in Black Sea (Figure 1). Because this fish is among the most common fish species in Black Sea coastal waters, it was selected as biomonitor organism. It is demersal form, inhabiting benthic biotops, its abundance is at the depth of 1-40 m. However, sometimes it is found at the depth of 1-10 m. Scorpion fish is a settled form, however, it migrates at the bottom of the sea and its activity is high at night. Spawning time begins at the end of May and finish is at the middle of September. Female spawns the eggs in twin sacks, which dissolve in marine water, and the embryos in the eggs develop in pelagic zone. Scorpion fish is a batch spawner, individual female spawns many portions and the eggs hatch every 1-2 day. Individual spawning portion contains 1100-27200 eggs (Svetovidov, 1964).

Figure 1. Scorpion fish *Scorpaena porcus.*

Figure 2. Sampling sites of *Scorpaena porcus* in Sevastopol bays, Black Sea.

Fish were caught in spring period of 2014 in four Sevastopol bays Streletskaya Bay (n = 17), Aleksandrovskaya Bay (n = 18), Karantynnaya Bay (n = 20) and Kazach'ya Bay (n = 10), characterizing different level of anthropogenic impact and pollution (Figure 2). The animals were immediately placed in the aerated tank, transfer in the laboratory and anesthesy. For biochemical determinations liver samples were washed several times by cold 0.85% solution of NaCl, homogenized and centrifuged at 8000 g during 15 min at cool conditions. In obtained extracts biomarkers were determined.

#### **2.2. Biochemical Assays**

#### *Antioxidant Enzyme Activities*

Antioxidant enzyme activities in the scorpion fish liver in this study were determined according to methods described previously (Rudneva, 2012), with a few minor modifications. *Superoxide dismutase* (SOD) was assayed on the basis of inhibition of the reduction of nitroblue tetrasolium (NBT) with NADH mediated by phenazine methosulfate (PMS) under basic conditions (Nishikimi et al., 1972).All measurements were performed in 0.017 M sodium pyrophosphate buffer pH 8.3 at  $+ 25^{\circ}$ C. The reaction mixtures contained 5  $\mu$ M NBT, 78 µM NADH, 3.1 µM PMS, and a 0.1 ml sample; the final volume was 1.5 ml. The reaction was carried out in the cuvette of spectrophotometer at 560 nm. *Catalase* (CAT) was measured by the method involving the reaction of hydroperoxide reduction. *Peroxidase* (PER) activity was detected by spectrophotometric method using benzidine reagent (Litvin, 1981). The reaction mixture contained 1 ml acetate buffer pH 5,4, 0.4 ml 0.09% benzidine, 0.2 ml 0.03%  $H<sub>2</sub>O<sub>2</sub>$ , and 0.2 ml sample. The reaction followed in a spectrophotometer for 1 min at 20 $^{\circ}$ C and at 600 nm. *Glutathione reductase* (GR) activity was assayed spectrophotometrically using a method modified after Goldberg and Sparner (1987). The reaction mixture contained 0.1 ml mM NADPH, 0.5 ml 7.5 mM oxidized glutathione, 0.2 ml mM EDTA, and 2 ml 0.05 M phosphate buffer pH 8.0. After incubation for 10 min, the extinction of the mixture was determined at 340 nm. *Glutathione-S-transferase* (GST) activity was determined by the method of Habig et al. (1974) by following the increase in absorbance at 340 nm due to the formation of the conjugate 1-chloro-2,4-dinitrobenzene (CDNB) using as substrate at the presence of reduced glutathione (GSH). The reaction mixture was prepared by mixing 1.5 ml sodium phosphate buffer 0.1 M pH 6.5, 0.2 ml GSH 9.2 mM, 0.02 ml CDNB 0.1 M and 0.1 ml of the sample. The absorbance was measured at 340 nm and at the temperature  $+25^{\circ}$ C spectrophotometrically using Specol-211 (Germany). The increase in absorbance was recorded for a total 3 min. The reaction solution without the hepatic homogenates was used as blank.

#### *Aminotransferases Activity*

Aminotransferases (ALT and AST) activity was also determined spectrophotometrically with 2,4-dinitrophenylhydrazine using the standard kit (Filicit - Diagnosis, Ukraine). Specifically, 0.2 ml substrate-buffer solution was added to 0.04 ml of liver extract or serum and incubated at room temperature for 1 h. The reaction was stopped by 0.2 ml 1,4 dinitrophenylhydrazine and the solution was incubated for 20 min. Then 2 ml 0.4 N NaOH was added to the mixture and the OD of the sample was measured at 500-530 nm. The ratio AST/ALT (de Rytis coefficient) was calculated also.

#### *Cholinesterase (ChE) Activity*

Cholinesterase (ChE) was measured on the basis on hydrolysis of acetylcholinchloride to acetic acid and choline. The alterations of pH changes the colour of the mixture which was determined spectrophotometrically used the standard kit (Felicit - Diagnosis, Ukraine).

#### *Oxidized Proteins (OP) Concentration*

The analysis of the concentration of was processed according the method of Dubinina et al. ( 1995). Optical density of carbonyl groups reacted with 2,4-dinitrophenil hydrazones was assayed at the following wave length 346, 370, 430, 530 nm used the spectrophotometer Specol-211 (Carl Zeiss, Iena, Germany).

#### *TBARS Level*

In obtained extracts thiobarbituric acid (TBA)-reactive substances concentration was determined spectrophotometrically, according the standard procedure (Stalnaya & Garishvily, 1977), the optical density was measured at 535 nm, as we described previously (Rudneva et al., 2012).

#### *Chemiluminescence Analysis*

Parameters of spontaneous hemiluminescence (SChL) and inducible by  $H_2O_2$  and FeSO<sub>4</sub> chemiluminescence (IChL) were measured used Luminometer 2010 (LKB, Sweden) (Vladimirov, 2001). The value of hemiluminescence was estimated in arbitrary units per protein concentration.

#### *Total Soluble Protein Concentration*

Total soluble protein concentration was quantified spectrophotometrically used the kits of the Filicit-Diagnosis (Ukraine). The enzyme activities were calculated per mg protein in the liver extracts.

#### **2.3. Statistical Analysis**

Biochemical measurements were detected in duplicate for each sample. Simple, descriptive statistics were performed using an ANOVA to determine means (+/- SEM) (Halafyan, 2008). *P* value of 0.05 was used for determination of statistical significance in all cases. The graphs were made using the computer program EXELL. Statistical correlations between studied biochemical parameters in tested animals and tissues were calculated by the least-squares method using the computer program CURVEFIT (Version 2.10-L).

## **3. RESULTS**

#### **3.1. Ecological Characteristics of Tested Sites**

Tested Sevastopol bays have significant anthropogenic influence from multiple sources (industrial, agricultural, shipping activities, domestic, recreation), which was evident from sediment chemical characterization. The bays are differed each from other by hydrological characteristics, hydrochemical parameters and the level of anthropogenic impact and pollution.

Figure 3. Streletskaya Bay.

For the purpose of the study of pollution effects on *Scorpaena porcus* we collected fish from four Sevastopol bays, which were ranked from most (Streletskaya Bay) to medium (Aleksandrovskaya Bay and Karantinnaya Bay) and least impacted (Kazach'ya Bay).

*Streletskaya Bay* (Figure 3) is the most susceptible to human impacts, because of the intense navigation and recreation that occurs there. Fuel docks and shipyards are located on its coasts; their drainage, along with the discharges of two municipal treatment enterprises and two storm water sewer systems, considerably pollute the marine environment (Ovsyanyi et al., 2001; Sergeeva, et al., 2010). According to several authors (Kiryukhina and Mironov, 2004), water and sediments in Streletskaya Bay contain considerably greater amounts of oil, heavy metals, chlorinated hydrocarbons, nutrients and suspended matter than the other three bays. The level of petroleum hydrocarbons at the bottom sediments was estimated as 705 mg/100 g wet weight, which was in 10-fold higher than in Karantynnaya Bay (Eremeev et al., 2008). The mean concentration of chlorinated hydrocarbons and petroleum hydrocarbons in the bottom sediments was estimated as  $1.33 \text{ u } 715.5 \text{ mg}/100 \text{ g}$  wet weight (Osadchaya, 2013). To this connection the level of petroleum hydrocarbons elevated during of 2003-2009 in 1,2- 1,5-fold as compared to 1990s (Osadchaya, 2013). Concentration of 6 indicative congeners of PCBs ( $\Sigma$ PCB<sub>6</sub>) and  $\Sigma$  DDT in bottom sediments in Streletskaya Bay was estimated as 121 and 51 ng/g respectively (Malahova & Malahova, 2009), while mercury level was higher in 5- 10-fold than the legal levels and ranged from 460 to 1063 ng/g dry weight (Kostova  $\&$ Plotitcina, 2011). However, in the recent decade a change of the "quality" of the anthropogenic load was recorded in Streletskaya Bay, due to intensive building of tourist hotel complexes and shipyards on its coast.

*Aleksandrovskaya Bay* is involved in the great Sevastopol Bay and it is located before the pier, which separates Sevastopol Bay from the open part of the sea (Figure 4). The sediments of Aleksandrovskaya Bay were contaminated to a greater extent and they classify as the third level of oil contamination (Rubtzova, et al., 2013). Level of  $\Sigma PCB_6$   $\Lambda \Sigma$  DDT in the bottom sediments in this bay was estimated as 97,4 ng/g dry weight and 14,8 ng/g dry weight respectively (Shcurova & Malahova, 2012). At the period of 1985 to 2009 concentration of petroleum hydrocarbons (PAH) in bottom sediments tended to increase in Sevastopol Bay, including Aleksandrovskaya Bay also, which is located at the entrance of Sevastopol Bay (Оsadchaya, 2013).

Figure 4. Aleksandrovskaya Bay (1) and Karantinnaya Bay (2).

*Karantinnaya Bay* is located near Sevastopol Bay. They are separate each from other by the pier (Figure 4). In this bay the level of chlorinated hydrocarbons and petroleum hydrocarbons in the bottom sediments is estimated as  $165,0 \text{ u } 65,0 \text{ mg}/100 \text{ g}$  wet weight respectively (Eremeev et al., 2008). However, water in this bay contains  $NO<sub>3</sub> - 17-116\mu g/l$ and  $N_{\text{org.}}$  – 552 µg/l, which was greater than in the other Sevastopol bays (Kuftarkova et al., 2008). That was due to the different locations of the areas and the discharges of domestic wastewater in Karantinnaya Bay.

Figure 5. Kazach'ya Bay.

*Kazach'ya Bay* is located at 15 km from the center of the city Sevastopol between the Kamyshovaya Bay and the cape Phiolent (Figure 5). Kazach'ya Bay is recognized as reference site in the systems of Sevastopol bays, because the level of toxicants in its sediments is less then in other sampling sites. For instance, the level of mercury was estimated as 33.7 ng/g dry weight and PCB content was 152.0 ng/g wet weight (Malahova et al., 2003). Concentration of chlorinated hydrocarbons and petroleum hydrocarbons was estimated as 157.0 mg/100 g and 36.0/mg/100 g (Eremeev et al., 2008) respectively, which is the evidence of its low polluted status as compared with the other tested sites (Rubtzova et al., 2013). According the data of the chemical analysis, concentration of  $NO<sub>2</sub>$  in the water was estimated as 1,0  $\mu$ /L, NO<sub>3</sub> 6  $\mu$ /L, NH<sub>4</sub> 11-14  $\mu$ /L, and N<sub>org</sub>. 447  $\mu$ /L, that is the evidence of the least anthropogenic press on the ecosystem of Kazach'ya Bay as compared to the other tested sites (Kuftarkova et al., 2008).

Despite of the additional non-persistent source of pollution, which is dolphinarium, located in the bay, according the chemical characteristics of the water and sediments, we suggest that Kazach'ya Bay can be used as reference area in comparative studies of biomarkers in scorpion fish for the evaluation of pollution effects caused anthropogenic activity. Moreover, the processes of the self-cleaning in this site are very intensive, which provides to save natural environment in general (Moiseenko, 2012).

Therefore, based on the analysis of the published data, we can conclude that among the tested Sevastopol bays Streletskaya Bay is the most negatively affected environmentally, Karantinnaya Bay and Aleksandrovskaya Bay are less contaminated, and Kazach'ya Bay is

least pressed. To the other hand, according the data of Kiryukhina and Mironov (2004), sediments in Aleksandrovskaya Bay were contaminated to a greater extent than those in Karantinnaya Bay, and the surface layers of the water, in contrast, were not polluted. That was due to the different locations of the areas and the discharges of domestic wastewater in Karantinnaya Bay.

#### **3.2. Biomarkers Response**

#### *Antioxidant Enzyme Activity*

High SOD activity ( $p < 0.05$ ) was indicated in the liver of fish from Streletskaya Bay and Aleksandrovskaya Bay in comparison to the values of the individuals from the other sampling sites (Figure 6). No significant differences were found in SOD activity in fishes from Karantinnaya Bay and Kazach'ya Bay. Enzymatic level was the similar in the animals, caught in Streletskaya Bay and Aleksandrovskaya Bay. The greatest CAT activity ( $p < 0.05$ ) was measured in the fish from Streletskaya Bay. The lowest activity ( $p < 0.05$ ) was observed in the animals from Karantinnaya Bay, while no significant differences were shown between the CAT level in scorpion fish inhabiting Aleksandrovskaya Bay and Kazach'ya Bay. PER activity was more, than in 10-fold greater ( $p < 0.01$ ) in the liver of fish from Kazach'ya Bay, the lowest value was shown in fish caught in Aleksandrovskaya Bay, no significant differences were indicated in the animals from Karantinnaya Bay and Streletskaya Bay. High GR activity was shown in the fish from Streletskaya Bay and Karantinnaya Bay, the lowest value was indicated in the animals from Kazach'ya Bay, while GR activity in the fish from Aleksandrovskaya Bay was greater in 2-fold ( $p < 0.05$ ). The highest GST activity was shown in the individuals from Streletskaya Bay ( $p < 0.05$ ), enzyme activity was the similar in the fish from Kazach'ya Bay and Karantinnaya Bay, while the value of the individuals from Aleksandrovskaya Bay was higher ( $p < 0.05$ ). No relationships were observed between antioxidant enzyme activities in tested fish.

#### *Cholinesterase Activity*

ChE activity was significant higher ( $p < 0.05$ ) in the liver of fish from Kazach'ya Bay as compared to the values of the animals from the other tested bays (Figure 7). No significant differences were observed in ChE level in the fish from Streletskaya Bay, Karantinnaya Bay, and Aleksandrovskaya Bay.

#### *Aminotransferase Activity*

Aminotransferase activity is present in Figure 8. The lowest ALT activity was indicated in the fish from Karantinnaya Bay ( $p < 0.05$ ), while no differences were observed between enzyme activities in the liver of the fish from the other tested bays. High AST activity was shown in the scorpion fish caught in Kazach'ya Bay and Aleksandrovskaya Bay ( $p < 0.05$ ), the lowest value was measured in the fish from Streletskaya Bay, hepatic AST activity in the individuals from Karantinnaya Bay was intermediate as compared with the values of the fish from the other tested sites.

#### *TBARS Concentration*

The greatest TBARS level was indicated in the liver of fish, collected in Streletskaya Bay  $(p < 0.01)$ , while no significant differences were observed between the values of the individuals from the other examined bays (Figure 9).

#### *Chemiluminescence Level*

The values of spontaneous chemiluminescence (SChL) level was significantly greater (p < 0.05) in the hepatic extracts of the fish, caught in Streletskaya Bay and Aleksandrovskaya Bay, as compared with the values of the individuals from Kazach'ya Bay and Karantinnaya Bay (Figure 10). The response of inducible chemiluminescence (IChL) varied widely in hepatic extracts of fish in tested bays: it was the highest in the fish from Streletskaya Bay and progressively decreased in the individuals as following: Kazach'ya Bay  $\rightarrow$  Karantinnaya Bay  $\rightarrow$  Aleksandrovskaya Bay.

Figure 6. Antioxidant enzyme activities in the liver of scorpion fish, mean  $+$  SEM (1 – Kazach'ya Bay, 2 – Karantinnaya Bay, 3 – Aleksandrovskaya Bay, 4 – Streletskaya Bay; \* – significant differences between fish from Streletskaya Bay and the values in fish from another bays;  $\bullet$  – with Aleksandrovskaya Bay, ▪ –with Kazach'ya Bay).

Figure 7. Cholinesterase activity in the liver of scorpion fish, mean  $\pm$  SEM, 1-4 - bays, see Figure 6 (\* - significant ( $p < 0.05$ ) difference with the values of the fish captured from tested bays).

Figure 8. Aminotransferase activity in the liver of scorpion fish, mean  $+$  SEM,  $1 - 4$  bays, see Figure 6. \* – significant differences between fish from Streletskaya Bay with another bays; ● – Aleksandrovskaya Bay, ▪ – Kazach'ya Bay).

Figure 9. Concentration of TBA-reactive substances in the liver of scorpion fish, mean + SEM. 1-4 bays, see Figure 6.  $*$  - significant ( $p < 0.05$ ) difference with values of the fish captured from tested bays).

#### *Oxidized Proteins (OP) Concentration*

Concentration of oxidized proteins (OP) in the liver of scorpion fish from checked bays is present in the Figure 11. Level of oxidized proteins, measured in all tested wave length (OD346, OD370, OD430, and OD530) was the greatest in the fish from Streletskaya Bay, high values were shown in the fish from Karantinnaya Bay and Aleksandrovskaya Bay, and the lowest level was found in the individuals caught in Kazach'ya Bay.

Figure 10. Chemiluminescence level in the liver of scorpion fish, mean  $\pm$  SEM. SChL – spontaneous, IChL – inducible ChL.  $1 - 4$  – bays, see Figure 6.  $*$  – significant differences between fish from Streletskaya Bay with the values in fish from another bays; ● – with Aleksandrovskaya Bay, ▪ – with Kazach'ya Bay.

Figure 11. Concentration of oxidized proteins in the liver of scorpion fish, mean + SEM. 1-4 bays, see Figure 6. \* – significant differences between fish from Streletskaya Bay and the values in fish from another bays; ● – with Aleksandrovskaya Bay, ▪ – with Kazach'ya Bay.

Therefore, we could conclude the different response of the hepatic biomarkers in scorpion fish, caught in examined Sevastopol bays.

#### **4. DISCUSSION**

The ecological characterization of examined bays in the coastal part of Sevastopol city showed the presence of diverse contaminants in the sediments and in the water, which are the result of human activities. The main anthropogenic sources of these pollutants are attributed with industrial and agricultural discharges, domestic effluents, shipping and recreation activities. High concentration of xenobiotics in the bottom sediments and in the water in the biotops of scorpion fish causes oxidative stress in fish resulted their transfer via water and food in the organism.

In polluted areas the exposure of aquatic organisms to xenobiotics results to interaction between these compounds and biological systems which may give elevation to biochemical and physiological damage or/and adaptive mechanisms via the induction of defense immune and antioxidant systems (Goksoyr et al., 1996). Therefore, biochemical and physiological characteristics are used as biomarkers for contaminants and could be applied for evaluation of environmental stress and its after-effects. However, biomarkers exposure to environmental stressors vary widely depending on the type of anthropogenic activity involved (Adams, 2005). Biomarkers response depends on tissues and organs specificity and functions. In this context, liver is the main organ of pollutants accumulation and biotransformation, generating ROS production and its metabolites (Sole et al., 2009; Grinevicius et al., 2009; He et al., 2012; Morachis-Valdez et al., 2015).

For the evaluation of oxidative stress in fish caught in different bays, we used various parameters, and among them we studied the biomarkers of exposure - the activities of antioxidant enzymes namely SOD, CAT, PER, GR and GST, which was also recognized as phase II biotransformation enzyme (Livingstone, 2001; Van der Oost et al., 2003). Enzymatic antioxidant response in the liver of scorpion fish was characterized by a higher variability of SOD and GR activities among tested bays, while CAT, PER and GST values were more constant. In this case our results agree with the data of other researchers, who also reported the similar trends of antioxidant enzymatic response in the liver of *Dicentrarchus labrax,*  caught in the estuaries, impacted by human activity (Fonseca et al., 2011a).

Antioxidant enzyme activity in the liver of fish from the most contaminated Streletskaya Bay was significantly higher as compared with the values of the animals, caught in other tested sites, with the exception of PER. Furthermore, antioxidant enzyme activity had positive correlation (with the exception of PER) with the level of anthropogenic impact in the examined bays, suggesting that pollution level increases the ROS production in fish liver and the antioxidant enzymatic system responds to an increase of environmental stress. At the other hand, increase of antioxidant enzyme activities in the fish from the most polluted bay demonstrated their ability to resist against oxidative stress and to adapt to the unfavorable living conditions. The similar responses of enzyme antioxidant system were documented in the tissues of fish affected different levels of pollutants in the laboratory and field conditions: heavy metals (Cao et al., 2010, 2011), petroleum and oil compounds resulting oil spills (Martinez-Gomez et al., 2009), organic chemicals (Al-Mamoori et al., 2014), complex urban effluents (Hansson et al., 2006), etc. We could note the specificity response of antioxidant enzymes in fish liver to different toxicants and their mixture, containing in the water and sediments as well as synergic and antagonistic effects at the case of interactions between xenobiotics and water. However, extremely high level of hepatic PER activity in scorpion fish from free contaminated Kazach'ya Bay could be attributed with the presence of short term local pollution source, which induced enzyme activity in the hepatocytes of the animals in the least impacted site.

GST activity was significantly higher (approximately in 4.5-5-fold) in the liver of fish from the most impacted Streletskaya Bay, while no significant differences were observed among the values of the individuals from less polluted and reference sites. We also noted high

positive correlation between CAT and GST activity  $(r = 0.87)$ , while no relationships were observed between the other examined antioxidant enzyme values. GST plays an important role in the detoxification of lipid peroxides and demonstrates the functions such as glutathione peroxidase activity towards reactive oxygen species in the cells under oxidative stress. Induction of GST activity in some aquatic organisms such as mussels has been also found in high polluted marine environments (Hansson et al., 2006), after the wreckage and oil spills of the tankers (Martinez-Gomez et al., 2009). Increase of GST activity was documented in some fish species and invertebrates collected in environments impacted by complex discharges of contaminants and accidents (Hamed et al., 2004). Because enzyme plays an important role in biotransformation of xenobiotics, it may be used as a valid bioindicator for evaluation of pollution level. GST clearly responds on the pollution level and its response is linked with the antioxidant enzyme activities and induction of biotransformation processes in the hepatocytes. At the other hand, different factors both biotic, abiotic and anthropogenic may be determined GST activity and in our previous study we described the fluctuations of GST level in several fish species, inhabiting different biotops in the coastal waters of Black Sea (Rudneva et al., 2010). The researchers reported also, that the spatial patterns in GST activity were complex, given that high enzyme activity was observed in the liver of teleost species in highly polluted sites and in the least polluted site. The investigators suggest a strong GST inhibition by organic compounds in the liver of two species *S. senegalensis* and *P. microps* from the site, where the highest PAH concentrations were measured (Fonseca et al., 2011b).

Oxidative damage in scorpion fish liver measured as effect biomarkers, namely TBARS, oxidized proteins and chemiliuminescence level both spontaneous and inducible, showed the variability for between tested bays. Our findings indicated significant increasing (more than in 2-fold) the level of TBARS in the liver of scorpion fish caught in the most polluted Streletskaya Bay, than the corresponding values of the animals from the less polluted sites, which were comparable. High positive correlation was observed between CAT activity and TBARS level  $(r = 0.89)$  and GST activity and TBARS  $(r = 0.98)$ . Therefore, we suggest, that TBARS level is a good biomarker for the evaluation of fish response to pollution. The researchers also reported the increase of LPO values in the aquatic animals exposed to pollutants (Javed et al., 2015; Jiang et al., 2011).

Similar trends were shown in chemiluminescence levels, which were attributed with the increasing of lipid peroxidation in the liver of fish, inhabiting polluted environment (Vladimirov, 2001). Both IChl and SChL values were significantly greater in the liver of the animals from the most impacted Streletskaya Bay. We found high positive correlation between ChL values in fish hepatocytes and TBARS concentration  $(r = 0.51)$  and between ChL level and CAT activity  $(r = 0.67)$ . However, we measured high IChL level in the fish from the reference site Kazach'ya Bay, which could be explained for the complex influence of biotic and abiotic factors on the ROS production. Different food spectra, hydrochemical and hydrological fluctuations may be the reasons of high level of inducible chemilumioniscence in the liver of scorpion fish from Kazach'ya Bay, while the spontaneous (SChL) was lower as compared with the values of the fish from less impacted sites Aleksandrovskaya Bay and especially high polluted Streletskaya Bay. Therefore, we could conclude that ChL level in hepatocytes is also good biomarker in the procedure of the evaluation of fish health in examined sites.

Concentration of oxidized proteins (OP) in tissues is an indicator of the chronic pollution impact on fish organism resulted oxidative stress also. Oxidative stress caused unfavorable living conditions is an imbalance toward the pro-oxidant side of the pro-oxidant/antioxidant homeostasis. The content of protein carbonyl groups are good biomarker of oxidative stress because they have some advantages in comparison with the measurement of other oxidative products: they are the relative early formation and the relative stability of carbonylated (oxidized) proteins (Dalle-Donne et al., 2003; Luschak, 2007). Carbonyl (CO) groups (aldehydes and ketones) are produced on protein side chains when they are oxidized. These moieties are chemically stable, therefore protein carbonyl content is the most general indicator of protein oxidation. The accumulation and increase of carbonyls in proteins has been observed in several human diseases (Dalle-Donne et al., 2003; Luschak, 2007). Oxidative damage of proteins may result negative consequences because among proteins there are enzymes, hormones, mediators and other biomolecules, which play an important role in the metabolism and homeostasis of the organism.

In our studies we showed significant increase of oxidized proteins concentration in the liver of fish from the most contaminated Streletskaya Bay. The total level of oxidized proteins increased progressively in the hepatocytes of the individuals from Kazach'ya Bay  $\rightarrow$ Karantinnaya Bay  $\rightarrow$  Aleksandrovskaya Bay  $\rightarrow$  Streletskaya Bay (0.127  $\rightarrow$  0.226  $\rightarrow$  0.16  $\rightarrow$ 0.313 correspondingly). We found high direct correlation between TBARS level and oxidized proteins concentration  $(r = 0.63)$ . However, high correlations between GR, GT and OP were shown also ( $r = 0.76$  and  $r = 0.61$  respectively), which could reflect the interactions between the antioxidant enzyme activities and OP production. Growth of LPO parameters and oxidized proteins level in tissues of the animals in contaminated habitats are postulated as the non-specific response of the organism to the stress effects, and it was documented at the case of environment pollution by various chemical agents and their complex (Martinez-Porchas et al., 2011; Liu et al., 2006; Kaptaner et al., 2014).

Oppositely, we found that hepatic ChE activity progressively decreased in fish as following Kazach'ya Bay  $\rightarrow$  Karantinnaya Bay  $\rightarrow$  Aleksandrovskaya Bay  $\rightarrow$  Streletskaya Bay. Inhibition of enzyme activity may reflect the pollution of biotope of organophosphate chemicals, metals, detergents which were recognized in domestic sewage and maritime effluents entering in Streletskaya Bay. Our results agree with the data of several researchers, who documented the inhibition of ChE activity in tissues of fish in polluted locations (Van der Oost et al., 2003; Napierska et al., 2009). ChE inhibition by organophosphorus (OP) compounds follows different behaviors depending on pesticide chemical structure. Ions can alter ChE activity inhibiting or activating so that it was proposed that enzymes could be used as biomarkers of heavy metals pollution. Another concern about application fish ChEs as biomarker of pesticides is that in eutrophed sites some species of cyanobacteria produce anticholinesterasic metabolites such as anatoxin-a which can be considered natural OP compounds and which toxicity can be approximately in 1000-fold higher than that of the insecticide paraoxon (Assis et al., 2011). Cholinesterases may reflect the disturbance of neural functions of the organism in stress conditions. Monitoring of ChE inhibition has been measured in the tissues of marine fish seems to be a valid indicator for chemical pollution of the marine environment as well (Kirbi et al., 2000). In our previous study we described the differences of ChE activity in the blood of scorpion fish caught in different polluted areas, and we also showed significantly decrease of the enzymatic activity in the blood serum of the individuals in the most impacted site (Rudneva et al., 2012).

AST is used as clinic diagnostic tool and it is attributed with cell necrosis of the liver and skeletal or cardiac muscle, starvation and lacking of vitamin E. ALT is an acute hepatic damage good marker (Coppo et al., 2001-2002). Hepatic ALT activity in scorpion fish varied less, than AST. The lowest ALT activity was indicated in the fish in Karantinnaya Bay without further site variability. AST activity varied independently and the lowest value was shown in the animals in the most polluted Streletskaya Bay. Both ALT and AST activities were lower in fish caught in Karantinnaya Bay. Therefore, at present study we reported significantly decrease of AST activity in the liver of fish in Streletskaya Bay, which can be attributed with the great intoxication, caused accumulation in the organ high concentration of toxicants. Enzyme activity could be inhibited by the complex mixture of environmental contaminants in Streletskaya Bay. In our previous study we also reported that aminotransferase activities (both ALT and AST) were lower in blood serum of fish in polluted sites (Streletskaya Bay and Karantinnaya Bay) than those in the samples, collected in free polluted areas (Rudneva et al., 2012). We propose that the reason of this phenomena was attributed with the damaged of hepatocytes in the liver of fish from highly impacted sites. To the other hand, aminotransferases are the organ-specific indicators for toxic effects and determination of transaminases in the liver has proved in diagnosis of liver damage (Van der Oost et al., 2003). Thus, the response of hepatic transaminases is not uniform and could be used as indicator of fish physiological status and health.

Therefore, we can conclude, that tested biochemical parameters in scorpion fish are good biomarkers for the evaluation of oxidative stress, caused anthropogenic pollution. However, they respond clearly at the case of the strong differences in pollution level between examined sites. Oppositely, the response was not uniform in fish from both less polluted bays and, probably, it depends on various xenobiotic combinations in them. Additionally, in these sites we could have so-called "mask effect" of pollutants which was associated with the complex effects of pollutants mixture on fish enzymatic activities. Some of toxicants induce oxidative stress and increase the level of antioxidant enzyme activities, while the others (heavy metals) bind with protein amino acids, SH-groups, carbonyls and other reactive groups, damage enzyme structure and inhibit its activity. We observed this effect in fish blood from highly polluted area, where lack or so-called "normal" enzyme activities were the result of summary effects of combinations of pollutants and their interactions (Rudneva et al., 2012). These interactions could modulate organism response and lead not only adaptive effect, but toxic one, characterizing the inhibition of defense systems, including immune and antioxidant components. Thus, in some cases in tissues of fish inhabiting high polluted water bodies the researchers observed the decrease of the activity of antioxidants and other key enzymes, which characterized clearly toxic effect caused high level of heavy metals and chlororganic compounds accumulation.

### **CONCLUSION**

Biomarkers variables in the liver of scorpion fish from different sites of Sevastopol coastal waters, reported in this study, seem to be useful indicators of the health status of fish and water quality in monitoring studies. The best biomarkers are the following: ChE activity and GST activity, TBARS, oxidized proteins and chemiluminescence level, which are highly

sensitive to anthropogenic pollution and reflect the response of the organism on stressful environment. Antioxidant enzyme and aminotransferase activities response was not uniform and depends on examined sites and the combinations of pollutants in them. The obtained results can be applied for development monitoring management and for perspectives of conservation ecology and fish status in impacted aquatic ecosystems. The analysis of the hepatic biomarkers is important for the evaluation of fish health in human impacted water bodies and their abilities to protect against chemical pollution and keep their life in the pollute environments. As the response of biomarkers are not uniform and only measuring a battery of bioindicators can provide insight into the fish health and ecological status of their habitats.

#### **ACKNOWLEDGMENTS**

The authors wish to thank fishermen of IMBR, to all involved in fish sampling and laboratorial procedures, Mr. Alex Jurkov and Mr. Oleg Shaida for the pictures of the Sevastopol bays in this paper.

# **AQUATIC INVASIVE SPECIES: ADDITIONAL STEPS COULD HELP MEASURE FEDERAL PROGRESS IN ACHIEVING STRATEGIC GOALS\***

# *United States Government Accountability Office*

# **WHY GAO DID THIS STUDY**

Aquatic invasive species—harmful, nonnative plants, animals, and microorganisms living in aquatic habitats—damage ecosystems or threaten commercial, agricultural, and recreational activities. The Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990 created the Task Force and required it to develop an aquatic nuisance (which GAO refers to as invasive) species program. The Water Resources Reform and Development Act of 2014 includes a provision that GAO assess federal costs of, and spending on, aquatic invasive species.

This chapter examines (1) how much Task Force member agencies expended addressing aquatic invasive species for fiscal years 2012-2014; (2) activities conducted by Task Force member agencies and challenges in addressing aquatic invasive species; and (3) the extent to which the Task Force has measured progress in achieving the goals of its 2013-2017 strategic plan. GAO sent a questionnaire to member agencies to obtain expenditures for fiscal years 2012-2014; interviewed member agency officials; and analyzed laws and strategic planning documents.

# **WHAT GAO RECOMMENDS**

GAO recommends that the Task Force develop a mechanism to measure progress toward its strategic goals and help meet certain statutory requirements. Most member agencies

<sup>\*</sup> This is an edited, reformatted and augmented version of a United States Government Accountability Office, Publication No. GAO-16-49, dated November 2015.

generally concurred or had no comments, but NOAA disagreed. GAO believes its recommendation is valid as discussed further in this chapter.

### **WHAT GAO FOUND**

The 13 federal member agencies of the Aquatic Nuisance Species Task Force (Task Force) estimated expending an average of about \$260 million annually for fiscal years 2012 through 2014 to address aquatic invasive species. However, several member agencies identified in their questionnaire responses challenges in developing their estimates. For example, some member agencies reported that their activities to address aquatic invasive species were often integrated into larger projects, making it difficult to isolate the portion of expenditures specific to aquatic invasive species out of total expenditures for the projects. As a result, expenditure information reported by GAO generally reflects member agencies' best estimates of total expenditures, rather than actual expenditures.

Task Force member agencies conducted a wide range of activities and identified several challenges in addressing aquatic invasive species. Member agencies reported conducting activities across several activity categories, including taking actions to prevent introductions, control the spread of existing invaders, and research ecological impacts of aquatic invasive species. For instance, most conducted prevention activities—such as constructing a series of electric barriers to prevent the entry of Asian Carp from the Mississippi River Basin into the Great Lakes—recognizing that prevention activities may be the most cost-effective method of addressing aquatic invasive species. Additionally, officials from several member agencies expressed concern that their activities, though numerous, may not be adequate relative to the growing magnitude and impacts of aquatic invasive species amid decreasing or constrained agency resources.

The Task Force—which is co-chaired by the U.S. Fish and Wildlife Service and National Oceanic and Atmospheric Administration (NOAA)—developed a 2013- 2017 strategic plan to guide its member agencies but has not taken key steps to measure progress in achieving the goals laid out in its strategic plan. As called for in its strategic plan, the Task Force in 2012 planned to develop an operational plan to track and measure aquatic invasive species activities and progress. However, the Task Force did not develop an operational plan because of constrained funding and limited resources, according to Task Force representatives. The Task Force also did not meet several of the 1990 Act's requirements including describing its members' roles and activities and reporting annually to Congress on the program's progress. The representatives agreed that a mechanism to track activities and measure progress is important and said they plan to discuss the possibility of doing so at their November 2015 meeting. Task Force representatives, however, had not established a time frame or specifics for their approach. Developing and regularly using a tracking mechanism could help the Task Force measure progress in achieving its strategic goals, as well as help the Task Force meet the 1990 Act's requirements to describe its members' roles and specific activities and to report annually to Congress on the program's progress.

#### Congressional Committees

Invasive species<sup>1</sup>—harmful, nonnative plants, animals, and microorganisms—are pervasive throughout the United States and cause major economic losses to segments of the economy and significant environmental damage each year to crops, rangelands, waterways, fisheries, and ecosystems. 2 Invasive species, called a national crisis by the Department of the Interior, $3$  number in the thousands and are expected to increase, with about 250 new species having invaded the United States since 2011 and more than 750 invasive species expanding their range since that time.<sup>4</sup> As we have found, the impact of invasive species in the United States is widespread, and their consequences for the economy and the environment are profound, although this can be difficult to measure.<sup>5</sup> A widely cited academic study from 2005—the most recent comprehensive study of its kind—estimated that the environmental impacts and economic costs associated with invasive species amount to almost \$120 billion per year.<sup>6</sup>

Addressing aquatic invasive species is a complex, interdisciplinary issue with the potential to affect many sectors and levels of government operations. Multiple federal agencies, often in coordination with state and local governments, industry, international parties, and nongovernmental agencies, work to prevent, manage, eradicate, and raise awareness about invasive species. The National Invasive Species Council, which was established by an Executive Order in 1999 to, among other things, coordinate federal agencies' activities concerning invasive species,<sup>7</sup> reported that estimated expenditures for invasive species activities by more than 20 federal agencies were over \$2 billion dollars in fiscal year 2014.<sup>8</sup> This estimate encompasses expenditures for all invasive species, however, and does not separate out expenditures specific to aquatic invasive species—species found in marine, freshwater, estuarine, and riparian areas, such as fish, mollusks, snakes, plants, and pathogens or parasites of aquatic animals and plants. Aquatic invasive species, which are one type of invasive species, harm native ecosystems or commercial, agricultural, or recreational activities dependent on these ecosystems, such as by threatening commercially or recreationally important fish species, according to the National Invasive Species Council. Officials from National Oceanic and Atmospheric Administration (NOAA) and the Department of the Interior have likened aquatic invasive species to an oil spill that will

continue to spread unless promptly and completely contained—once they have arrived and become established, aquatic invasive species are difficult to eradicate.<sup>9</sup>

The Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990, as amended (the 1990 Act), was enacted to, among other things, prevent the unintentional introduction and dispersal of nonindigenous (which we refer to as nonnative) species into waters of the United States through the management of ballast water (water in a ship's holding tank used for stability and safety that may be taken on in one location and discharged in another) and other requirements, and to understand and minimize economic and ecological impacts of nonnative aquatic nuisance species that become established in the United States.<sup>10</sup> The 1990 Act notes that, if preventive management measures are not taken nationwide to prevent and control unintentionally introduced nonnative aquatic species in a timely manner, further introductions and infestations of destructive species may occur. The 1990 Act created the Aquatic Nuisance Species Task Force (Task Force), which coordinates governmental efforts dealing with aquatic invasive species in the United States through regional panels, special committees, and work groups. The Task Force consists of 13 federal member agencies along with state, regional, and nongovernmental organizations.<sup>11</sup> Each of the Task Force's federal member agencies has a different set of responsibilities related to aquatic invasive species.<sup>12</sup>

The 1990 Act requires, among other things, the Task Force to develop and implement an aquatic invasive species program for waters of the United States. Specifically, the 1990 Act requires the Task Force to develop a program that identifies the goals, priorities, and approaches for aquatic invasive species prevention, monitoring, control, education, and research to be conducted or funded by the federal government. The act requires the Task Force to (1) describe the specific prevention, monitoring, control, education, and research activities to be conducted by each Task Force member; (2) describe the role of each Task Force member in implementing the elements of the program; and (3) include recommendations for funding to implement elements of the program.<sup>13</sup> The act also requires that the Task Force report to Congress annually on the progress of its program.<sup>14</sup> In 1994, The Task Force developed a program overview that established the core elements of its aquatic invasive species program and served to guide the work of the Task Force. The Task Force subsequently developed a series of strategic plans starting in the early 2000s to further guide its membership—the federal, state, regional, and nongovernmental organizations that conduct aquatic invasive species activities—in implementing the aquatic invasive species program. In 2012, the Task Force developed its most recent strategic plan, covering 2013 through 2017, which identified eight goals for the program.

The Water Resources Reform and Development Act of 2014 includes a provision in section  $1039(a)(2)$  that GAO conduct an assessment of the federal costs of, and spending on, aquatic invasive species.<sup>15</sup> We briefed your offices on our preliminary results on June 3, 2015. This report transmits our final results related to this review. This report examines (1) how much Task Force member agencies expended addressing aquatic invasive species for fiscal years 2012 through 2014; (2) activities conducted by Task Force member agencies and challenges in addressing aquatic invasive species; and (3) the extent to which the Task Force has measured progress in achieving the goals of its 2013-2017 strategic plan.

For all three objectives, we reviewed aquatic invasive species-related laws, regulations, and academic studies. To determine how much Task Force member agencies expended addressing aquatic invasive species and to obtain information on activities conducted, we conducted interviews with, and obtained documentation from the Task Force and its 13

federal member departments and agencies (member agencies) regarding any expenditure information they maintain related to aquatic invasive species. We also interviewed staff from the National Invasive Species Council to learn about their efforts to collect information on federal expenditures for invasive species activities. We then developed and disseminated a questionnaire to the 13 Task Force member agencies to obtain each member agencies' estimated annual expenditures to address aquatic invasive species for fiscal years 2012 through 2014 (the most recent years for which reliable data were available) and examples of these activities.<sup>16</sup> The expenditures reflect the agencies' best estimates of how much they spent on aquatic invasive species activities during these years. Based on our assessment of the estimated annual expenditures reported by Task Force member agencies, we found the estimates for fiscal years 2012 through 2014 were sufficiently reliable for purposes of this report—to provide general estimates of total annual expenditures by these agencies on activities related to aquatic invasive species.

To further describe activities conducted by Task Force member agencies and any challenges in addressing aquatic invasive species, we built on the information gathered through our questionnaire and conducted a series of interviews with officials from the 13 member agencies; the federal ex-officio member of the Task Force, the Smithsonian Environmental Research Center; and each of the Task Force's six regional panels. Through these interviews, we collected information and documentation on the agencies' aquatic invasive species activities and any challenges they face in addressing aquatic invasive species. Many of the activities reported by agencies were ongoing or span multiple fiscal years, and thus, the information we collected often highlights, but is not limited to, fiscal years 2012 through 2014. We also conducted site visits in Southern Florida, Northern California, and Western Washington to observe activities and interview local federal officials at the sites. We selected these locations based on the number and variety of aquatic invasive species present and federal agencies involved, as well as the types of activities conducted in those locations.

To determine the extent to which the Task Force has measured progress in achieving the goals of its 2013-2017 strategic plan, we conducted interviews with and obtained documentation from Task Force representatives, officials from the 13 Task Force member agencies, and officials representing the six regional panels. We reviewed the Task Force's 2013-2017 strategic plan and other documentation related to its strategic plan. We then compared this information to program requirements identified in the 1990 Act, our previous reports on leading practices provided by the Government Performance and Results Modernization Act of 2010, and our executive guide on strategic planning,  $17$  as appropriate. Appendix I presents a more detailed description of our objectives, scope, and methodology.

We conducted this performance audit from November 2014 to November 2015 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

#### **BACKGROUND**

Aquatic invasive species can be found in all U.S. states and territories. They can enter and travel in aquatic habitats by several common pathways, including through the discharge of ships' ballast water; hull fouling, such as barnacle growth, on commercial vessels and recreational boats; and accidental or intentional release of organisms into aquatic habitats through aquaculture, bait, aquaria (fish tanks), or the pet trade. Once established in a particular location, an aquatic invasive species can spread to other locations and ecosystems. Scientists and officials from several federal agencies said that the presence and impacts of aquatic invasive species are, and are likely to continue, growing, such as from the warming of ocean waters and the opening of shipping channels through the Arctic, allowing new species to potentially thrive in habitats previously too cold or inaccessible.

*See Appendix II for more information on species examples, their known locations, and invasion pathways.*

The Task Force, created by the 1990 Act, is co-chaired by the U.S. Fish and Wildlife Service (FWS) and NOAA. FWS provides funding for the administration of the Task Force, including conducting annual meetings, publishing *Federal Register* notices, and supporting an Executive Secretary and other FWS staff that work as regional coordinators.<sup>18</sup> To implement its aquatic invasive species program, the Task Force relies on its 13 member agencies—each of which has a different set of responsibilities related to aquatic invasive species, based on their overall mission and areas of programmatic responsibility (see table 1). These member agencies conduct aquatic invasive species activities and commit resources to achieve the goals of the aquatic invasive species program.<sup>19</sup> According to the Task Force's 1994 program overview, implementation of the program is a cooperative effort that will build on and fill gaps in existing activities and programs, and individual agencies will implement the program in line with their specific authorities, priorities, expertise, and funding. In addition, the Task Force is advised by six regional panels— consisting of representatives of state, tribal, and nongovernmental organizations, commercial interests, and neighboring countries—that help identify regional priorities and coordinate regional activities.<sup>20</sup> Some funding is provided to each regional panel as well as to state governments and other entities to support implementation of species- or region-specific aquatic invasive species management plans and other activities.<sup>21</sup> Together, these federal, state, and nonfederal agencies and organizations work to prevent and control aquatic invasive species and implement the 1990 Act.

Activities to address aquatic invasive species can be categorized using the seven general activity categories developed by the National Invasive Species Council. These categories reflect common activities agencies conduct along the continuum of an invasion of a species, from preventing the arrival or spread of an invading species to controlling or eradicating that species from the ecosystem. Table 2 describes each activity category.

## **Table 1. Aquatic Nuisance Species Task Force Member Agencies' key roles and responsibilities**

Sources: Draft, Aquatic Nuisance Species Task Force 2014 Report to Congress (information); GAO (analysis). | GAO-16-  $\overline{A}$ 9

Note: This list of agency roles and responsibilities for aquatic invasive species is not comprehensive; it is intended to illustrate key roles and responsibilities of each agency as they relate to aquatic invasive species.

- <sup>a</sup>The Plant Protection Act authorizes the Secretary of Agriculture, who has delegated this authority to the Animal and Plant Health Inspection Service to publish, by regulation, a list of noxious weeds and to prohibit or restrict their importation, exportation, or movement in interstate commerce if necessary to prevent the introduction into the United States or the dissemination of a noxious weed within the United States (7 U.S.C. § 7712). Noxious weeds are any plant or plant product that can directly or indirectly injure or cause damage to crops, livestock, poultry, or other interests of agriculture, irrigation, navigation, the natural resources of the United States, the public health, or the environment.
- <sup>b</sup>Among other things, the Lacey Act, as amended, prohibits the importation into the United States and interstate transport of certain animals, including aquatic invasive species listed as injurious wildlife.

Activity category	Definition	
Prevention	Actions taken to prevent the entry, establishment, dispersal, and dissemination of	
	invasive species.	
Early detection and rapid	Actions taken to detect incipient invasions and assess the current and potential impact	
response	of invasions; to eradicate, contain, or control a potentially invasive nonnative species	
	introduced into an ecosystem while the infestation of that ecosystem is still localized,	
	and to eradicate or contain invasive species populations while they are still localized.	
Control and management	Actions taken to lessen and manage the impact of invasive species within their	
	established ranges and limit their spread.	
Restoration	Actions taken to assist the recovery and reestablishment of plant and animal	
	communities that have been overwhelmed by invasive species.	
Research	Actions taken to identify, evaluate, control, and understand invasive species and their	
	interactions with the biotic (i.e., living things that shape an ecosystem) and abiotic	
	(i.e., not derived from living organisms) elements of the environment.	
Education and public	Actions taken to maintain and increase public awareness of invasive species and	
awareness	related programs and to promote public activities that reduce the spread and impact of	
	invasive species.	
Leadership and international	Actions taken to provide leadership, oversight, and coordination to maintain and	
cooperation	enhance the capabilities to prevent, control, manage, and understand invasive species	
	and invasion pathways with relevant state, local and international partners, and	
	provide for public input and participation.	

**Table 2. Categories of activities to address invasive species**

Sources: The National Invasive Species Council Invasive Species Interagency Crosscut Budget Summary (2014); GAO questionnaire of 13 Task Force member agencies. | GAO-16-49

Note: These activity categories apply to all invasive species, including both aquatic and terrestrial species.

Figure 1. Invasive species invasion curve.

Preventing the introduction of aquatic invasive species into ecosystems is generally the most effective means of avoiding their establishment and spread, according to numerous academic reports, as well as the Task Force and several of its member agencies.<sup>22</sup> According to a 2006 study, the difficulties and expense of reversing biological invasions means investment in prevention is likely to be the most successful and cost-effective response to biological invasions.<sup>23</sup> Further, eradication (the elimination of an invading species from the ecosystem) and control (limiting an invasive species to a specific ecosystem) becomes increasingly difficult and costly as a species becomes established and spreads, as shown in figure 1. 24

# **TASK FORCE MEMBER AGENCIES ESTIMATED EXPENDING AN AVERAGE OF ABOUT \$260 MILLION ANNUALLY TO ADDRESS AQUATIC INVASIVE SPECIES IN FISCAL YEARS 2012 THROUGH 2014**

Task Force member agencies estimated expending an average of about \$260 million annually for fiscal years 2012 through 2014 to address aquatic invasive species. Several of the member agencies identified challenges and limitations associated with the expenditure information they provided in response to our questionnaire. As a result, the information reported by Task Force member agencies on annual expenditures through our questionnaire generally reflects the agencies' best estimates, rather than actual expenditures. Table 3 provides the estimated annual expenditures for each Task Force member agency during fiscal years 2012 through 2014.

Based on information reported through our questionnaire, estimated expenditures by Task Force member agencies for fiscal year 2014 ranged from a high of about \$149 million by the U.S. Army Corps of Engineers (Corps) to a low of \$70,000 by the Bureau of Land Management. Specifically, the Corps reported that the majority of its estimated annual expenditures were for controlling and managing existing aquatic invasive species at multiple projects it manages, and mostly came from the respective project's operations and maintenance funding. The Bureau of Land Management's estimates for fiscal year 2014 comprised the annual cost to develop and place aquatic invasive species awareness advertisements in print materials focusing on outdoor activities such as hunting, fishing, and boating. Also, for fiscal year 2014, the Bureau of Land Management reported that it did not have funding to provide to its state offices to coordinate or carry out aquatic invasive species activities in their local areas, as it did in fiscal years 2012 and 2013. Estimates for Task Force member agencies generally reflected a variety of activities undertaken or funded by the respective agency spanning multiple species and regions within their areas of programmatic responsibility. In contrast, estimates for some agencies reflected efforts specific to a particular region or activity. For example, the Environmental Protection Agency (EPA) reported that its estimates mostly reflected expenditures of funding transferred to other agencies to carry out activities in support of the Great Lakes Restoration Initiative—a program launched in 2010 to protect and restore the Great Lakes ecosystem. One of the Initiative's main focus areas includes prioritizing efforts to prevent the introduction of new invasive species into the Great Lakes.<sup>25</sup>

## **Table 3. Estimated annual expenditures to address aquatic invasive species, by Task Force Member Agency, Fiscal Years 2012 through 2014**

Sources: GAO questionnaires of 13 Task Force member agencies. I GAO-16-49

Note: The data in this table were provided by Task Force member agencies and reflect their best estimates of annual expenditures to address aquatic invasive species for fiscal years 2012 through 2014.

<sup>a</sup>The U.S. Forest Service reported that it was unable to develop estimated annual expenditures for its aquatic invasive species activities. The agency cited several reasons, including that its program management and financial accounting systems do not separately track aquatic invasive species expenditures.

<sup>b</sup>The Department of State estimates reflect amounts mostly provided to the Great Lakes Fishery Commission, largely for Sea Lamprey control and research efforts. The Great Lakes Fishery Commission provided financial resources to other Task Force member agencies and therefore to minimize double-counting, we have to the extent possible, excluded this funding from the estimates reported by the other Task Force member agencies.

<sup>c</sup>The Environmental Protection Agency's estimates reflect amounts for the Great Lakes Restoration Initiative (a program launched in 2010 to protect and restore the Great Lakes ecosystem), most of which was provided to other Task Force member agencies. To minimize double-counting, we have, to the extent possible, excluded this funding from the estimates reported by the other Task Force member agencies.

In responding to our questionnaire, several of the Task Force member agencies identified challenges and limitations in collecting information on how much they estimated expending to address aquatic invasive species. These included the following:

 **Expenditures on aquatic invasive species activities are not specifically tracked.**  Seven of the 13 Task Force member agencies reported that their budget structures and financial accounting systems were not designed to specifically track expenditures on aquatic invasive species activities. For instance, the U.S. Forest Service reported that many aquatic invasive species related activities are conducted throughout the agency, but the agency's program management and financial accounting systems do not separately track aquatic invasive species expenditures. Specifically, U.S. Forest Service officials said they could not identify the portion of funding expended directly for aquatic invasive species because these activities were often integrated into larger projects—such as inspecting and cleaning equipment used in fighting wildfires. For

example, the agency has developed specific protocols to inspect, assess, and decontaminate equipment, such as the inside of a fire pump, to help make sure it is clear of any invasive algae or mussels that may be unintentionally transferred to a new watershed when moving water between areas to fight fires. U.S. Forest Service officials further explained that this is one step of many in cleaning and preparing the equipment for its next use, and its management and financial accounting systems are not set up to capture or break out activities to this level of detail. Similarly, the Bureau of Reclamation reported that expenditures for aquatic invasive species activities at its water projects—such as clearing water control structures to maintain water delivery through pipes and canals—are funded mostly through the operations and maintenance budget for each project and are not tracked as expenditures specific to aquatic invasive species.

 **Decisions on expenditures for aquatic invasive species are made at the local or regional level.** Four of the 13 member agencies reported that decisions on expenditures for aquatic invasive species activities are delegated to a regional or local level and are not tracked at the national level. For example, the National Park Service reported that once funding is provided to a national park, headquarters management does not generally direct how the funding is expended at that park. Instead, park management generally determines how the funding will be used to accomplish park objectives, including whether and how to prioritize funding for aquatic invasive species activities. Similarly, the Bureau of Land Management reported that numerous decisions and activities take place at its local or state office level that are not tracked by headquarters, including expenditures on aquatic invasive species, and, therefore, annual expenditures on aquatic invasive species across the agency are unknown. The U.S. Forest Service also reported in its questionnaire that many of its aquatic invasive species activities are conducted through cooperative partnership agreements at the local and regional level and expenditures for these activities are not reported at the national level.

# **TASK FORCE MEMBER AGENCIES CONDUCTED A WIDE RANGE OF ACTIVITIES AND IDENTIFIED SEVERAL CHALLENGES IN ADDRESSING AQUATIC INVASIVE SPECIES**

Through our questionnaire and interviews with officials from the Task Force and its member agencies, we found that member agencies conducted a wide range of activities and faced several challenges in addressing aquatic invasive species. Most member agencies reported conducting activities across the seven general activity categories developed by the National Invasive Species Council, including taking actions to prevent introductions of new aquatic invasive species and control the spread of existing ones (see app. III). Task Force member agencies also identified several challenges in addressing aquatic invasive species. Some of these challenges are overarching, and others relate to how member agencies plan or conduct aquatic invasive species activities specific to the activity categories.

Regarding overarching challenges, several Task Force member agencies—including officials from the Departments of the Interior and Agriculture, the Corps, and NOAA—

expressed concern that their activities, though numerous, may not be adequate relative to the growing magnitude and impacts of aquatic invasive species amid decreasing or constrained agency resources. Task Force representatives further said that many of the member agencies have faced competing priorities in carrying out aquatic invasive species-related activities, with some member agencies having limited flexibility to conduct work in multiple areas. According to officials from the U.S. Geological Survey (USGS), for example, much of the agency's aquatic invasive species activities have been focused on identifying methods to treat and control Asian Carp in accordance with the Great Lakes Restoration Initiative and other funding for this work. USGS officials said that though their work on Asian Carp has been critical, it has sometimes meant that they have not been able to prioritize other needs, such as identifying marine invaders from nonballast water sources or new marine and arctic threats given the warming of ocean waters.

The following are examples of activities Task Force member agencies conducted to address aquatic invasive species along with challenges they identified related to specific activity categories, based on the responses we received to our questionnaire and interviews with officials from the Task Force and its member agencies. These examples include activities from each of the seven activity categories—(1) prevention, (2) early detection and rapid response, (3) control and management, (4) restoration, (5) research, (6) education and public awareness, and (7) leadership and international cooperation. These examples do not represent all activities conducted or challenges identified by member agencies, but rather they illustrate the nature and type of activities and challenges discussed.

#### **Prevention**

Eleven of the 13 Task Force member agencies reported conducting a range of prevention activities, often related to managing specific pathways to help prevent the introduction of aquatic invasive species into new aquatic habitats. Task Force member agencies repeatedly highlighted the importance of conducting prevention-oriented activities as a cost-effective means of addressing aquatic invasive species. Officials from some member agencies also said that they would like to conduct more prevention-oriented activities, but that they have faced challenges in doing so, in part because of policy or funding decisions within their respective agencies.<sup>26</sup> For example, Corps officials said they believed that it would be most costeffective to treat certain aquatic invasive plants upstream from project boundaries before the species spreads downstream and potentially threatens project infrastructure; however, it is generally the agency's policy to treat areas within rather than outside project boundaries.<sup>27</sup> Some Task Force member agencies also told us that prevention activities cannot be conducted at the expense of activities aimed at controlling aquatic invasive species already established, and that a more balanced approach between prevention and control activities may be warranted.

Examples of prevention activities include the following:

 **Regulations.** The U.S. Coast Guard and EPA regulate the management of ballast water—a primary pathway for the introduction of new aquatic invasive species into and within the United States— and other vessel discharges into waters of the United States. In 2012, the Coast Guard updated its ballast water regulations to include a

standard for the allowable concentrations of living organisms allowed in a vessel's ballast water discharged in waters of the United States. In 2013, EPA issued a general permit that contains numeric technology-based limitations on acceptable concentrations of living organisms in ballast water discharge.<sup>28</sup>

- **Inspections.** FWS's Office of Law Enforcement inspects certain wildlife shipments to help ensure that prohibited species, including certain aquatic invasive species, do not enter the country. FWS's has about 120 inspectors at 49 ports of entry nationwide that review import documentation and conduct visual inspections of some shipments to help prevent species listed as injurious wildlife under the Lacey Act from being illegally brought into the country or across state lines. $29$
- **Physical barriers.** The Corps operates a series of electric barriers in the Chicago Area Waterway System located approximately 25 miles from Lake Michigan to prevent the entry of Asian Carp and other aquatic invasive species from the Mississippi River Basin into the Great Lakes. These barriers send out pulses to form an electric field in the water that discourages fish from crossing.

#### **Prevention Efforts to Control the Spread of Quagga and Zebra Mussels**

Several Task Force member agencies are involved in activities to prevent the spread of invasive Quagga and Zebra Mussels throughout the western United States. For example, U.S. Fish and Wildlife Service (FWS) and the National Park Service support implementation of the Quagga-Zebra Mussel Action Plan, which was developed by several state and federal agencies, as well as nongovernmental organizations in the western United States. This plan serves as a road map for identifying and prioritizing specific actions needed to prevent the further spread of Quagga and Zebra Mussels, respond to new infestations, and manage existing ones. FWS has installed signs at National Wildlife Refuges to alert boaters about the risk of these species and has funded training in 18 states on inspecting boats and other watercraft to identify and remove the mussels. The National Park Service expended approximately \$2 million in fiscal year 2014 on mussel prevention and control and monitoring at nine western parks. In addition, the Bureau of Reclamation has conducted a series of public education and outreach efforts, including the dissemination of informational pamphlets at boat shows, designed to educate the public on practices they can follow to help prevent the spread of Quagga and Zebra Mussels.

Source: Bureau of Reclamation. | GAO-16-49 Quagga Mussels covering infrastructure.

#### **Early Detection and Rapid Response**

Ten of the 13 Task Force member agencies reported conducting early detection and rapid response activities—activities to detect the presence of aquatic invasive species in an area and remove any newly detected species while they are localized and before they become established and spread to new areas. Aside from preventing introductions, the most costeffective way to address an invasive species is to detect and respond to invasions early, according to documents from the U.S. Forest Service and NOAA. However, coordinated rapid response efforts have been challenging to implement due, in part, to constraints in existing funding, according to officials from some agencies. Consequently, 11 Task Force member agencies are part of a federal work group, co-led by the Department of the Interior and the National Invasive Species Council, that in January 2015 started developing a framework for a national early detection and rapid response program and a plan for an emergency rapid response fund.<sup>30</sup> The work group reported in July 2015 that it plans to issue a report of recommendations to implement an early detection and rapid response framework, including mechanisms for funding, to the White House and the Council on Climate Preparedness and Resilience in the fall of 2015.

#### **Early Detection Technique Using Environmental DNA**

Detection methods such as the use of environmental DNA have become widespread among Task Force member agencies, such as the U.S. Geological Survey (USGS), the U.S. Army Corps of Engineers (Corps), the National Park Service, the Bureau of Reclamation, and the U.S Fish and Wildlife Service (FWS). Environmental DNA—genetic material shed into the environment by organisms that can be detected in samples of air, water, or soil—is a relatively new tool being used to detect invasive species, particularly in areas where the species is not abundant or is difficult to detect. For example, because they are well camouflaged in the environment, visual detection of Burmese Pythons in South Florida is difficult, with detection rates of less than 1%. Use of environmental DNA methods, however, can increase python detection rates to more than 90%, according to USGS officials. Since spring 2015, USGS researchers have been working with FWS to test water from the Loxahatchee National Wildlife Refuge in Florida to determine whether Burmese Pythons may have spread to the refuge. Although environmental DNA helps confirm the presence of an aquatic invasive species in an area, it neither confirms whether the species has become established in the area, nor does it provide information on the number or current location of any species detected.

Examples of early detection and rapid response activities include the following:

- **National early detection database.** The USGS maintains the Nonindigenous Aquatic Species Database, a publicly accessible database, to track information on the locations of aquatic invasive animals throughout the United States. Federal agencies, as well as state and local agencies and the public, can report aquatic invasive species sightings and when verified, the sightings are added to the database and updated daily by the USGS.<sup>31</sup>
- **Rapid response strike teams.** The FWS has five regional strike teams in place to help eradicate any new invasions as soon as possible after they are detected in the nation's 563 wildlife refuges. These strike teams survey a small portion of the acreage within national wildlife refuges when new invasions are suspected,

according to FWS officials, to determine the presence of any invasions and then take actions to eradicate or contain confirmed invasions before populations spread.

#### **Control and Management**

Eleven of the 13 Task Force member agencies reported conducting activities designed to lessen and mitigate the impact or spread of aquatic invasive species on the facilities or areas they manage. Such activities may be designed to eradicate an invading species, but where eradication is not deemed feasible, such activities are designed to manage the invader by controlling the impact of the species and its spread. Activities aimed at controlling or managing the impact and spread of invasions represent a substantial portion of overall aquatic invasive species-related activities conducted, in terms of both effort and funding, according to Task Force representatives and officials from several member agencies. Some of these officials stressed the importance of sustaining efforts to control and manage aquatic invasive species to avoid reintroductions or spread of the species. For example, Corps officials said that, after eliminating infestations of Melaleuca, an invasive wetland tree, over a prescribed 10- year treatment period, periodic treatments would still be necessary to ensure new populations do not become established. Officials from several member agencies including the Corps noted, however, that limited or inconsistent funding has, at times, made it challenging to consistently manage areas as prescribed—potentially leading to the reemergence of aquatic invasive species.

Examples of control and management activities include the following:

- **Biological controls.** To control and manage the spread of Alligatorweed, a leafy aquatic invasive plant found in the southeastern United States and California, officials from the Corps told us they are using a beetle that feeds and reproduces only on Alligatorweed. According to officials from the Corps and the U.S. Department of Agriculture, the beetle has been successful in controlling the weed, and the need for additional treatments, such as herbicide applications, has been nearly eliminated in Florida.
- **Chemical controls.** The Department of State, through the Great Lakes Fishery Commission, along with the Corps, FWS, USGS and other federal and state partners, are primarily using chemicals called lampricides to kill Sea Lamprey, an invasive fish, in their larval stage before they can attach and prey upon native fish. According to Department of State officials, as of 2015, chemical controls have led to a 90 percent reduction in the Sea Lamprey population over its historical high level.
- **Physical and mechanical controls.** The Bureau of Reclamation uses physical and mechanical control methods to remove Water Hyacinth, an aquatic invasive plant, from one of its California facilities. Bureau of Reclamation officials said that, if left untouched, Water Hyacinth clogs canals, pumps, and fish screens, which can kill the fish they are working to protect. Bureau of Reclamation officials told us that, between 2013 and 2015, they removed between 10,000 and 20,000 truckloads of Water Hyacinth from the area surrounding the facility—with a dump truck filled with

Water Hyacinth leaving the facility every 5 minutes during the height of its growing season.

#### **Multipronged Method to Control and Manage Melaleuca**

Melaleuca, an Australian tree that has destroyed many southern Florida wetlands, can be managed through a combination of biological, chemical, and physical and mechanical controls. For instance, through the introduction of weevils, a type of beetle that serves as a biological control, Melaleuca can be controlled. Researchers from the U.S. Department of Agriculture said, however, that the ability of Melaleuca trees to grow in various water depths has prevented the weevils— which require ground to burrow in—from successfully reproducing and eating the Melaleuca in swampy areas. According to National Park Service officials, Melaleuca can also be controlled if it is consistently treated over a 10-year period using the method in which the trees are first cut or hacked down with a machete or mechanical device and then sprayed with herbicides designed to kill them on the first, second, fourth, seventh, and tenth years of treatment. If this process is not followed as prescribed, however, the trees may regrow and spread. The National Park Service Exotic Plant Management Team and Everglades National Park have contributed to control of Melaleuca in South Florida, as shown in the photo below.

Source: National Park Service. | GAO-16-49 Partially treated Melaleuca forest.

#### **Restoration**

Ten of the 13 Task Force member agencies reported conducting a variety of activities to restore aquatic habitats adversely affected by aquatic invasive species. Officials from a few Task Force member agencies said that it may be possible to begin restoring habitats or ecosystems while control and management activities are under way, but in some cases aquatic invasive species may need to first be controlled or contained. According to a few member agencies, this creates a challenge in that restoration activities must wait until control activities are finished, meaning that restoration may be delayed.

Examples of restoration activities include the following:

 **Habitat restoration.** NOAA reported providing funding and technical expertise for community-based habitat restoration projects, such as providing about \$925,000 in 2012 for the Lower Black River Habitat Restoration Project in Ohio. The goal of this project is to restore fish and wildlife habitat in the lower Black River through actions such as the removal of aquatic invasive plants by chemical and manual techniques followed by the planting of native shrubs.

• **Native fish restoration.** The National Park Service reported removing nonnative fish from waters in a number of parks to restore native species and enhance natural aquatic biodiversity. Officials told us that they have been expending about \$1 million per year since 2013 at Yellowstone National Park on lake trout removal efforts in Yellowstone Lake. These efforts include contracting with commercial fishing crews to remove invasive lake trout that have caused a significant decline in populations of the native Yellowstone Cutthroat Trout.

#### **Research**

All 13 Task Force member agencies reported conducting or sponsoring research designed to support activities to help prevent, detect, or control the impacts or spread of aquatic invasive species, as well as determine their impacts on aquatic habitats. Research is critical to identify effective techniques for prevention, detection, control, and management of aquatic invasive species and to help clarify and quantify the effects aquatic invasive species have on native species and habitats, as well as economic costs and impacts to human health, according to Task Force documents. Officials from several member agencies and Task Force representatives noted that significant gaps in knowledge in certain areas related to aquatic invasive species is a challenge and, therefore, would like to see additional research, such as a comprehensive study to identify and assess the environmental impacts and economic costs associated with invasive species in the United States. Such information is critical to understanding the magnitude of the impacts from aquatic invasive species and for obtaining funding to address problems they are causing, according to these officials. In addition, limits in scientific knowledge about newly introduced species and the levels at which they may become established or harmful, especially in ballast water, affect member agencies' ability to manage the ballast water pathway, according to officials from NOAA and the Smithsonian Environmental Research Center. Officials from the U.S. Coast Guard said that it is difficult to set regulations or establish allowable concentrations of organisms that can be safely released in ballast water when the threshold for establishment of a new potentially invasive species may not be well understood.

#### **Federal Research on Hydrilla**

Federal research on Hydrilla, a submerged invasive plant that has clogged navigation channels and other water systems across the United States, involves efforts by several Task Force member agencies. For example, the U.S. Army Corps of Engineers (Corps) conducted research on the biology of Hydrilla during 2015 to provide a better understanding of the invasion ecology of this species in northern rivers and glacial lakes. The Corps has also researched chemical treatments and application strategies to control or alter the reproduction of Hydrilla. Chemical treatments developed through research have been successful in controlling some strains of Hydrilla, according to Corps officials. Aquatic herbicides developed through research have also been successful in controlling Hydrilla, but some strains have become resistant. In addition, the Animal and Plant Health Inspection Service, in collaboration with the Corps, is researching biological controls for Hydrilla, such as releasing insects that will eat the plant.

Examples of research activities include the following:

- **Species research.** The Corps is researching various types of invasive aquatic vegetation and options for managing such species through its Aquatic Plant Control Research Program, which is authorized by statute.<sup>32</sup> In 2014, Corps' researchers completed field studies in Montana that used selective management strategies to control Eurasian Watermilfoil, a plant that is invasive throughout most states, including Alaska.
- **Impacts research.** Officials from USGS and NOAA have conducted research aimed at improving scientific knowledge about how aquatic invasive species may be adversely affecting ecosystems. In 2015, USGS continued research to identify whether newly established nonnative species may warrant being considered "high priority invaders," such as the Burmese Python in the Everglades. Since 2009, NOAA has conducted research to determine how certain aquatic invasive species have affected endangered salmon feeding behavior and habitat in the Pacific Northwest as part of its effort to understand the impacts that aquatic invasive species have on these native species and the ecosystems upon which they depend.
- **Pathways research.** The Maritime Administration sponsors the operation of three research facilities—in California, Maryland, and Wisconsin—that are testing the capability of treatment systems for ballast water to determine whether those systems may be approved by the U.S. Coast Guard pursuant to its ballast water regulations.

#### **Education and Public Awareness**

Eleven of the 13 Task Force member agencies reported engaging in education and public awareness activities to increase awareness about aquatic invasive species and their impacts and help minimize or prevent further introductions. According to Task Force documents, the lack of public awareness about the impacts and threats posed by some invasive species and how they are introduced is a substantial challenge for Task Force member agencies in addressing aquatic invasive species.

#### **Lionfish Education and Public Awareness**

Several Task Force member agencies are involved in raising awareness about Lionfish, a highly invasive fish that has spread throughout coastal waters of the southeast and the Caribbean. To help raise awareness, the National Oceanic and Atmospheric Administration, along with nonprofit partners, has sponsored numerous Lionfish derbies since 2010, including 10 public tournaments in 2014 in which divers could hunt the edible fish with spears. The National Park Service produced a Lionfish Response Plan in 2012 that aims to help inform the public about the Lionfish invasion and prevent and mitigate impacts to parks. Biscayne National Park, in Florida, conducts an education program in which Lionfish removed from the park are sent to classrooms for safe dissection by students. National Park Service officials told us that concentrated education efforts like this have been effective in educating the public about Lionfish. In addition, the Department of State provided funding to work with partners in the Gulf of Mexico and the Caribbean to launch a web portal that provides managers and the public with access to the latest information on Lionfish and impacts in the Atlantic Ocean.

Examples of education and public awareness activities include the following:

- **National awareness campaigns.** The Task Force, Bureau of Land Management, FWS, U.S. Forest Service, and the U.S. Coast Guard are among the federal agencies that collaborate on the "Stop Aquatic Hitchhikers!" campaign. Since 2002, this multimedia campaign has used television, billboards, and social and print media to encourage users of outdoor recreational areas to help stop the transport and spread of aquatic invasive species by, for example, making sure they clean, drain, and dry their boats and boat trailers before transporting them to different aquatic areas.
- Local awareness events. The National Park Service, along with state agencies and nongovernmental organizations, hosted the inaugural 5K "Race Against Invasives" run through Everglades National Park in February 2015 to raise awareness about invasive species, especially those in Florida.

## **Leadership and International Cooperation**

Ten of the 13 Task Force member agencies have been involved in activities to provide leadership to the aquatic invasive species community—which includes federal and nonfederal as well as international agencies working on aquatic invasive species issues—and to enhance cooperation and collaboration, such as by participating and serving as members in a range of international, national, regional, state, and local task forces, councils, and other entities. Given the often complex and widespread nature of aquatic invasive species, working across jurisdictional boundaries is the most effective approach to combating aquatic invasive species, according to Task Force officials and documents. Moreover, working with other federal and nonfederal agencies and organizations helps the Task Force to identify areas where legislation may be needed to fill gaps in statutory authority, suggest priority policy issues, and define roles and responsibilities for managing aquatic invasive species, according to Task Force documents. Officials from the regional panels told us, however, that one challenge in such work is that constrained agency funding has meant that they have not been able to consistently attend Task Force, regional panel, or other cooperative meetings.<sup>33</sup>

Examples of leadership and international cooperation activities include the following:

- **Aquatic Nuisance Species Task Force activities.** The Task Force conducts semiannual meetings that provide an open and public forum for members to exchange information and coordinate their aquatic invasive species activities. For example, the Task Force's May 2015 meeting included presentations on a wide range of topics, from the adoption of species-specific national management plans to recommendations from its regional panels on issues of local significance.
- **International cooperation.** Officials from the Corps and the U.S. Department of Agriculture have collaborated with scientists in China, South Korea, and Switzerland to identify and develop insect biological control agents to target invasive aquatic plants such as Hydrilla and Eurasian Watermilfoil. For example, in fiscal year 2014, Corps officials reported expending about \$450,000 on developing such control agents, which included collecting 350 plant samples from more than 90 field sites to

help match invasive plants located in the United States with their countries of origin to improve the success of identifying insects to control these species.

# **THE TASK FORCE HAS NOT TAKEN KEY STEPS TO MEASURE PROGRESS IN ACHIEVING ITS STRATEGIC GOALS**

The Task Force has not taken key steps to measure progress in achieving the goals laid out in its 2013-2017 strategic plan.<sup>34</sup> In 2012, the Task Force developed its 2013-2017 strategic plan, which serves to guide Task Force member agencies in conducting aquatic invasive species-related activities to implement the aquatic invasive species program. The strategic plan identifies eight goals for the program—which generally align with the seven activity categories developed by the National Invasive Species Council—as well as a number of targeted action items for Task Force member agencies to achieve these goals (see table 4).<sup>35</sup>

The action items identified in the strategic plan were intended to be completed over the 5 year period of the plan, but the strategic plan also stated that accomplishing the items would be dependent upon the budgets of individual agencies. The strategic plan did not identify or describe roles or activities to be conducted by specific member agencies or measures to track progress in achieving its eight strategic goals. Rather, the strategic plan called for the Task Force to develop an operational plan to specify how Task Force member agencies would put the strategic plan into operation.<sup>36</sup> According to the strategic plan, the function of the operational plan was to ensure the strategic goals were measurable and accountable. Specifically, the operational plan was intended to contain the following elements: (1) a description of short-term efforts to support and implement the strategic plan and its goals; (2) the roles of Task Force member agencies; (3) when available, the time frames, lead agencies or groups, and funding; and (4) regular updates with its actions reported annually to measure progress toward accomplishing the goals of the strategic plan. The elements envisioned for the operational plan are also largely required by the 1990 Act.<sup>37</sup>

Before the strategic plan went into effect, however, the Task Force decided not to develop an operational plan as envisioned in the strategic plan. Instead, the Task Force decided to develop a reporting matrix in the form of a spreadsheet to collect information on member agencies' aquatic invasive species-related activities, according to the Task Force's autumn 2012 meeting minutes. This reporting matrix was designed to collect information on the aquatic invasive species activities that member agencies had planned to conduct related to the goals of the strategic plan. This reporting matrix was also designed to collect funding information associated with each of these activities, which could serve as a starting point for the Task Force to identify funding gaps and priorities and develop recommendations for funding to implement elements of its aquatic invasive species program as required by the 1990 Act. The reporting matrix was disseminated to Task Force member agencies in August 2012, but fewer than half (6 of 13) of the Task Force member agencies provided information to the Task Force.<sup>38</sup> According to Task Force representatives, the Task Force did not disseminate or collect additional information using the reporting matrix after 2012.

## **Table 4. Aquatic Nuisance Species Task Force's 2013-2017 strategic goals and examples of action items**

Source: Aquatic Nuisance Species Task Force Strategic Plan (2013-2017). | GAO-16-49.

Note: The action items included in this table are not comprehensive, but rather they serve as examples of the action items associated with each strategic goal and are intended to illustrate the types of actions that Task Force member agencies may take to implement the strategic plan.

<sup>a</sup>Among other things, the Lacey Act, as amended, prohibits the importation into the United States and interstate transport of certain animals, including aquatic invasive species listed as injurious wildlife.

According to Task Force representatives, the Task Force decided not to develop an operational plan or use the reporting matrix after 2012 because of constrained funding and limited resources. In particular, they said they were limited in their efforts because of the constrained funding environment that emerged from sequestration in 2013 and 2014.<sup>39</sup> According to Task Force representatives, the retirement in 2013 and the continued vacancy of its Executive Secretary has resulted in the Task Force being without dedicated staff to support updates to the reporting matrix. Task Force representatives further explained that, given the limited staff devoted directly to the Task Force, they rely on staff from member agencies to contribute to the administration of the program, but member agencies have had competing priorities and have not had the resources to contribute to developing an operational plan in the way that was originally envisioned when the strategic plan was developed. In addition, Task Force representatives said that, since 2014, the Task Force along with member agency staff, has been focused on drafting a report to Congress, an annual requirement under the 1990 Act.<sup>40</sup> Since its inception, the Task Force has provided one report to Congress, in 2004.

Task Force representatives said they expect to finalize and issue their draft report by the end of 2015. In reviewing a draft of the report, we found that the draft provided an overview and examples of aquatic invasive species activities conducted by the Task Force, member agencies, regional panels, and states since the Task Force's 2004 report, as well as some information on the role of Task Force member agencies in aquatic invasive species management. After they finalize the 2015 report, Task Force representatives have not indicated that they would begin submitting reports annually to meet this reporting requirement in the future.

Task Force representatives also said they have no plans to develop an operational plan, as called for in the strategic plan, but acknowledged the importance of developing a means to regularly track various member agencies' aquatic invasive species activities and measure progress toward meeting the strategic goals. Specifically, in response to our inquiry into the status of an operational plan, Task Force representatives told us in May 2015 that they planned to discuss the possibility of reviving or modifying the reporting matrix they had used in 2012. Task Force representatives subsequently told us that, during a June 2015 meeting, member agencies agreed that a tracking mechanism was important. However, they also told us that they did not determine what such a mechanism would look like, how it would be implemented and by whom, or how to address concerns expressed by some member agencies that the mechanism not burden agency staff already working at capacity in light of constrained funding. Task Force representatives said they plan to further discuss the idea of reviving or modifying the reporting matrix at their next semiannual Task Force meeting in November 2015. But, representatives could not tell us when they planned to make a decision on the approach they would take or provide specifics on what information they would collect or how they would measure progress in achieving their strategic goals.

By developing and regularly using a tracking mechanism—that would include the elements envisioned for an operational plan and required by the 1990 Act—the Task Force could better position itself to (1) measure progress in achieving its strategic goals and (2) comply with certain requirements in the 1990 Act for the aquatic invasive species program. Addressing aquatic invasive species is a complex, interdisciplinary issue with the potential to affect many sectors and levels of government operations. Strategic planning is a way to respond to this governmentwide problem on a governmentwide scale. Our past work on crosscutting issues has found that governmentwide strategic planning can integrate activities

that span a wide array of federal, state, and local entities, as well as provide a comprehensive framework for making resource decisions and holding agencies accountable for achieving strategic goals.<sup>41</sup> With its strategic plan, the Task Force has a framework in place to guide and integrate the numerous and varied aquatic invasive species activities spanning many member agencies. In addition to measuring progress in achieving the Task Force's strategic goals, developing and regularly using a tracking mechanism could also help the Task Force meet the 1990 Act's requirements to describe its members' roles and specific activities and to report annually to Congress on the program's progress.

#### **CONCLUSION**

Aquatic invasive species, a serious and growing problem affecting all states and U.S. territories, have been likened to a never-ending oil spill, given that they are notoriously difficult to eradicate once they become established. Though hard to calculate, the economic and ecological harm caused by aquatic invasive species is vast. Capturing how much federal agencies have expended—and will likely need to expend—to effectively address aquatic invasive species is also challenging. Consequently, it is not possible to identify how much may be needed to fully address aquatic invasive species, both in terms of current invasions or measures to prevent future invasions. Capturing how much progress federal agencies have made in combatting aquatic invasive species is similarly challenging.

The Task Force and its member agencies have taken significant steps— including conducting a wide array of activities and developing a strategic plan to guide their efforts—to address the threats and impacts of aquatic invasive species. However, the Task Force has not met several of the 1990 Act's requirements, including reporting annually to Congress on the program's progress, or developed a mechanism to ensure its strategic goals are measurable and accountable, such as through an operational plan, as called for in its strategic plan, because of constrained funding and limited resources. Task Force member agencies agreed that a mechanism to track activities and measure progress was important, but the Task Force has not decided what the mechanism would look like, how it would be implemented and by whom, or how to address concerns that it not burden agency staff already working at capacity. Developing and regularly using a tracking mechanism could help the Task Force measure progress in achieving its strategic goals, as well as help the Task Force meet the 1990 Act's requirements to describe its members' roles and specific activities and to report annually to Congress on the program's progress. Moreover, such a mechanism could provide a starting point for identifying funding gaps and priorities, better positioning the Task Force to meet the 1990 Act's requirement to include recommendations for funding to implement elements of its aquatic invasive species program.

## **RECOMMENDATION FOR EXECUTIVE ACTION**

As the Aquatic Nuisance Species Task Force considers how to measure progress toward accomplishing its strategic goals, we recommend that the Task Force develop and regularly use a tracking mechanism, to include elements envisioned for an operational plan and to largely meet requirements in the 1990 Act, including:

- specifying the roles of member agencies related to its strategic plan,
- tracking activities to be conducted by collecting information on those activities and associated funding,
- measuring progress member agencies have made in achieving its strategic goals, and
- reporting to Congress annually on the progress of its program.

## **AGENCY COMMENTS AND OUR EVALUATION**

We provided the Secretaries of Agriculture, Commerce, Defense, Homeland Security, Interior, State, and Transportation and the Administrator of the EPA a draft of this report for their review and comment. Only the Department of the Interior and the Department of Commerce's NOAA provided written comments. Interior generally agreed with the report's findings and recommendation, and NOAA disagreed, as further discussed below. The Department of Defense's U.S. Army Corps of Engineers, the Department of State, and EPA indicated that they had no comments on our report through e-mail communications provided through departmental audit liaisons on October 19, October 21, and October 23, 2015, respectively. We also received e-mails provided through audit liaisons from the following departments that stated that the departments agreed with the report's findings and recommendation and had no other comments: The Department of Agriculture's Animal and Plant Health Inspection Service and U.S. Forest Service (dated October 29, and October 30, 2015, respectively); the Department of Transportation (dated October 26, 2015); and the Department of Homeland Security (dated October 15, 2015).

In its written comments, the Department of the Interior stated that it generally agreed with the findings of our report and concurred with our recommendation. Interior stated that it appreciated our review of the challenges faced by the Task Force in addressing and managing risks posed by the introduction and proliferation of aquatic invasive species. Interior stated that the Task Force, of which its FWS is a co-chair, is currently evaluating the reporting matrix to improve its utility as a tracking mechanism. Additionally, Interior stated that, at its November 2015 meeting, the Task Force agreed to track accomplishments using a modified activity tracking tool while its members continue to evaluate how best to track their activities going forward. Interior also stated that the Task Force's report to Congress is undergoing final agency review, and it is expected to be delivered to Congress in the coming months, which, together with its tracking efforts, will help provide the Task Force with a mechanism to both measure and communicate progress toward its strategic goals, as called for in our report. We agree that using a modified activity tracking tool and completing the report to Congress will be positive first steps in the Task Force's measuring progress toward accomplishing its strategic goals and meeting requirements in the 1990 Act, in accordance with our recommendation. Interior also provided technical comments, which we incorporated, as appropriate.

In its written comments, NOAA disagreed with several aspects of our findings, conclusions, and recommendation. In addition, NOAA stated that our report did not sufficiently address certain aspects of the mandate to conduct the review contained in section 1039(a)(2) of the Water Resources Reform and Development Act of 2014. First, NOAA stated that the report did not mention future costs to mitigate the impacts of aquatic invasive species and that, although it may be difficult to give specific numbers, some information could be speculated upon. In the opening paragraph of our report, we state that the impacts of invasive species in the United States are widespread and expected to increase, with profound consequences for the economy and the environment. We cite a 2005 academic study—the most recent comprehensive study of its kind— that estimates the environmental impacts and economic costs associated with invasive species at almost \$120 billion per year. Additionally, through our questionnaire, we requested that federal member agencies provide planned activities and estimated expenditures for future years. However, as we describe in the scope and methodology appendix (app. I) of our report, we decided not to report future estimated expenditures given the limited information provided by some member agencies. We believe that reporting partial information could be misleading and could underestimate likely future expenditures.

Second, NOAA stated that our analysis could have gone into more detail about current federal spending on prevention activities. We limited our reporting of expenditures for fiscal years 2012 through 2014 to estimates of *total* annual expenditures for each Task Force member agency because many member agencies reported that they could not provide estimates of their expenditures by activity category, including prevention. Third, NOAA stated that we did not address whether federal spending is adequate for the maintenance and protection of services provided by federal facilities. As we note in our report, capturing how much federal agencies have expended—and will likely need to expend—to effectively address aquatic invasive species is challenging. Given the limited information available from the Task Force member agencies on current and planned expenditures related to aquatic invasive species, we determined we would not be able to reliably conduct an analysis of the adequacy of federal spending. Lastly, NOAA stated that we chose to focus on the Aquatic Nuisance Species Task Force and its strategic plan rather than documenting other legislative and programmatic efforts that target the prevention, control, and management of aquatic invasive species. The scope of our review includes all federal member agencies of the Task Force, and in discussing activities and challenges those member agencies face in addressing aquatic invasive species, our report highlights many of the legislative and programmatic efforts those agencies are undertaking, such as efforts by the U.S. Coast Guard and EPA to regulate and manage ballast water through updated regulations.

NOAA also stated that our report did not mention federal mandates intended to address aquatic invasive species other than the Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990, the National Invasive Species Act of 1996, and Executive Order 13112. NOAA stated that at its exit conference with us on July 14, 2015, it noted that many federal agencies receive additional directions or mandates to address or respond to aquatic invasive species and their impacts and that each agency must balance these mandates. We agree that federal agencies may have multiple responsibilities in addressing aquatic invasive species we outline many of these responsibilities in table 1 of the background of our report where we describe the key roles and responsibilities of Task Force member agencies under various federal laws. Also, in describing examples of the activities and challenges member agencies face in addressing aquatic invasive species in the second objective of our report, we identify and describe many of the requirements and mandates member agencies must follow. For example, we describe efforts of the FWS' Office of Law Enforcement to enforce the Lacey Act, which prohibits the importation and interstate transport of wildlife listed as injurious, among other things. NOAA also stated that balancing and responding to various requirements ultimately affects the agencies' ability to adequately respond to this national issue. We agree with this statement, and in our discussion of challenges faced by member agencies in addressing aquatic invasive species, we report that many of the member agencies have faced competing priorities in carrying out aquatic invasive species-related activities, with some member agencies having limited flexibility to conduct work in multiple areas.

In addition, NOAA stated that the reported presence of a species in USGS' Nonindigenous Aquatic Species database (one of two key sources we used to prepare species' location information for the map) does not mean that the species is established in a particular state's waters as the map portrays. In our draft report, in a note to the figure, we included a statement to clarify that species distributions in the map represent the reported presence of a species in at least one, but not necessarily all, bodies of water in the state, and do not necessarily indicate establishment of the species in any part of the state. To further clarify this point so as not to potentially mislead readers, in response to NOAA's comment, we have updated the figure title and note and also added a statement to this effect in the body of the report. Second, NOAA stated that Caulerpa, one aquatic invasive species we highlighted in the figure, had been eradicated. Upon receipt of this information from NOAA and in light of obtaining additional supporting data, we removed Caulerpa from the figure. Third, NOAA stated that providing points of pathways of invasion was confusing or inaccurate in some cases. We agree that the manner in which we linked our description of the pathways of invasion to the map in the draft report could be misinterpreted; consequently, in response to NOAA's comment, we disassociated the description of pathways from the map. We believe that providing a description of various pathways aquatic invasive species may use to enter and spread into new areas is important context for our report.

Furthermore, concerning our recommendation that the Task Force develop and regularly use a tracking mechanism, to include elements envisioned for an operational plan and to largely meet requirements in the 1990 Act, NOAA stated that it does not believe the recommendation can address problems faced by the Task Force. NOAA stated that, with respect to measuring progress, the Task Force agreed to use an activity matrix to compile information, but the matrix has not been updated since 2012 for several reasons, including because of uncertainties in funding, shifting priorities, and the loss of the Task Force Executive Secretary position, which has not been filled since the former Executive Secretary retired in 2013. NOAA further stated that the report does not address the underlying causes that have hindered Task Force efforts to track progress, including the limited budget under which the Task Force operates, which has been reduced significantly in recent years. Our recommendation was not intended to comprehensively address the problems faced by the Task Force, but rather was more narrowly focused. Specifically, the intent of our recommendation is to help the Task Force regularly track progress toward achieving its strategic goals in a manner that ensures it also largely meets requirements in the 1990 Act, such as reporting to Congress annually on the progress of its program. In our report, we discuss the constrained funding environment and limited resources the Task Force and its member agencies reported working under, including having limited staff devoted directly to the Task Force and facing the constrained funding environment that emerged from sequestration in 2013 and 2014. We believe that by implementing our recommendation—that

is, by developing and regularly using a tracking mechanism to include the roles of member agencies, activities conducted and associated funding, and progress made in achieving strategic goals—the Task Force would be in a better position to identify and communicate its progress, as well as funding or resource needs to address problems faced by the Task Force. As we note in our report, capturing how much federal agencies have expended—and will likely need to expend—to effectively address aquatic invasive species is challenging. But by developing and regularly using a tracking mechanism, we believe the Task Force would be better-positioned to assess funding gaps and priorities and begin to identify solutions to address the challenges member agencies face in addressing aquatic invasive species.

Finally, NOAA identified examples where it stated information portrayed in our report could have evolved into recommendations. For example, NOAA commented that a recommendation that calls for a more balanced approach in conducting prevention activities would be beneficial. In our report, we state that member agencies repeatedly highlighted the importance of conducting prevention-oriented activities as a cost-effective means of addressing aquatic invasive species. We also note that officials from some member agencies said they would like to conduct more prevention-oriented activities, but that prevention activities cannot be conducted at the expense of activities aimed at controlling aquatic invasive species already established, and that a more balanced approach between prevention and control activities may be warranted. We include this and the other examples NOAA references in our report to provide context on an issue, provide examples of activities being undertaken by member agencies, or describe challenges faced by member agencies in addressing aquatic invasive species—consistent with the objectives and scope of work conducted for this review. Consistent with government auditing standards, we are to have sufficient, appropriate evidence to provide a reasonable basis for findings and conclusions before we can develop recommendations. Based on our work, we did not have sufficient evidence to provide a reasonable basis for making recommendations on the examples NOAA identified. We encourage NOAA to continue to work with Task Force member agencies and others to pursue areas they identify as needing additional work, such as identifying ways to take a more balanced approach across prevention and control activities. We believe that by implementing our recommendation, NOAA, as one of the co-chairs of the Task Force, would be in a better position to identify funding gaps and priorities, and determine recommendations for funding based on emerging needs.

NOAA also provided technical comments, which we incorporated, as appropriate.

Anne-Marie Fennell Director. Natural Resources and Environment

## **APPENDIX I: OBJECTIVES, SCOPE, AND METHODOLOGY**

This report examines (1) how much the Aquatic Nuisance Species Task Force (Task Force) member agencies expended addressing aquatic invasive species from fiscal year 2012 through 2014; (2) activities conducted by Task Force member agencies and challenges in addressing aquatic invasive species; and (3) the extent to which the Task Force has measured progress in achieving the goals of its 2013-2017 strategic plan.

For all three objectives, we reviewed aquatic invasive species-related laws, including the Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990, as amended (the 1990 Act),<sup>1</sup> regulations, and academic studies. We conducted interviews with, and obtained documentation from, the co-chairs of the Task Force and other Task Force representatives; officials from the 13 Task Force federal member departments and agencies (member agencies);<sup>2</sup> and representatives from each of the Task Force's six regional panels to learn about their roles and responsibilities, aquatic invasive species-related activities, and any expenditure information they maintain related to those activities. In addition, we interviewed staff from the National Invasive Species Council to learn about their efforts to collect information on federal expenditures for invasive species activities.

To determine how much Task Force member agencies expended addressing aquatic invasive species for fiscal years 2012 through 2014 and obtain information on activities conducted, we developed and disseminated a questionnaire to the 13 Task Force member agencies, requesting information on their estimated expenditures and activities conducted to address aquatic invasive species. Specifically, the questionnaire requested member agencies to provide estimates of their expenditures for the activities they conducted in each of the following seven aquatic invasive species activity categories: (1) prevention, (2) early detection and rapid response, (3) control and management, (4) research, (5) restoration, (6) education and public awareness, (7) and leadership and international cooperation.<sup>3</sup> These were the same activity categories used by the National Invasive Species Council to collect and report information for its annual invasive species interagency "crosscut" budget summary. The council's annual budget summary includes estimates of federal agency expenditures and planned funding on activities to address all types of invasive species, but it does not include a breakdown of expenditure by type, including expenditures specific to aquatic invasive species. Therefore, the council's annual budget summary provided a framework for us to follow in developing our questionnaire, but we could not use information from the budget summary to obtain or report information on federal expenditures specific to aquatic invasive species. Several Task Force member agency officials recommended that we follow the council's framework for our questionnaire since many of the member agencies provide information to the council, and they suggested that following a similar framework would facilitate their ability to respond to our request. In developing our questionnaire, we worked with staff from the National Invasive Species Council and conducted pretests with three member agencies to obtain their comments, which were incorporated as appropriate.

In our questionnaire, we requested that each member agency provide (1) its estimated expenditures for fiscal years 2012 through 2014 (the most recent years for which member agencies reported reliable data were available), (2) examples of aquatic invasive species activities conducted during this time period, and (3) its planned activities and estimated expenditures for future years, which we defined as fiscal years 2015 and 2016. We also included questions about how the Task Force member agencies prepared their estimates, their sources of information, any challenges or limitations in preparing the estimates, and whether the estimates were reviewed by their budget or financial offices.

We received completed responses from all 13 of the Task Force member agencies. The member agencies provided information on their activities conducted to address aquatic invasive species, but member agencies varied in the level of detail they provided about their estimated expenditures. Twelve of the 13 member agencies included at least some information on their estimated expenditures for fiscal years 2012 through 2014, but the U.S. Forest Service reported that it was unable to provide estimates. For the other 12 agencies, they varied in their ability to provide consistent and complete information on their estimated expenditures at the level of detail we requested in our questionnaire. With respect to the expenditure information for fiscal years 2012 to 2014, some agencies were able to provide estimates of their expenditures by activity category, but many reported that they could not provide estimates at this level of detail. For example, the Environmental Protection Agency reported its expenditures supported activities for five of the seven activity categories, but because it could not provide separate estimates for each of these categories it reported all of its expenditures under the prevention category. Similarly, the National Park Service reported conducting activities in all seven activity categories in fiscal years 2012 and 2013, but provided estimates for two activity categories (research and restoration) and reported that it was unable to determine how much of its estimated expenditures went toward the other five activity categories in these years. Based on inconsistencies and incomplete responses across the 13 member agencies, we decided to limit our reporting for fiscal years 2012 through 2014 to estimates of total annual expenditures for each Task Force member agency.

With respect to future expenditures for fiscal years 2015 to 2016, a few member agencies indicated they did not have estimates of expenditures for future years, though others had partial estimates. To avoid reporting potentially misleading information that could underestimate likely future expenditures compared to amounts reported for fiscal years 2012 through 2014, we decided not to report the future expenditure estimates provided to us. Similarly, 9 of the 13 member agencies reported that they were not able to provide estimates for how much they expended addressing specific aquatic invasive species, citing reasons such as expenditures being tracked at a project level rather than by a specific species. Therefore, we do not include species-specific expenditure information in our report.

After receiving completed questionnaires, we followed up with Task Force member agency officials to obtain clarification or additional information, as needed. We did not independently verify the accuracy of the estimated expenditures reported by the member agencies, which likely include some over- and some under-estimates. For example, in its response, the U.S. Fish and Wildlife Service (FWS) described various activities that were implemented through projects supported with grant funding from the Wildlife Sport Fish Restoration Program.<sup>4</sup> But, FWS did not include expenditure estimates for these project activities because it could not reliably estimate how much of the grant funding should be attributed to the aquatic invasive species component of the grant-funded projects. We asked each of the Task Force member agencies for their assessment of whether their estimated expenditures for fiscal years 2012 to 2014 were an underestimate, overestimate, or about right. Ten of the member agencies responded that their estimates were "about right," and two indicated they were underestimates (one member agency did not provide estimates). Accordingly, the expenditures reflect the agencies' best estimates of how much they expended on aquatic invasive species activities during these years. Based on our assessment of these responses, along with the responses provided through the questionnaire, we determined that the expenditure estimates for fiscal years 2012 through 2014 were sufficiently reliable for purposes of this report—to provide general estimates of total annual expenditures by Task Force member agencies on activities to address aquatic invasive species.

To describe the activities conducted by Task Force member agencies and any challenges in addressing aquatic invasive species, we built on the information gathered through our questionnaire and conducted a series of interviews with officials from the 13 member agencies, the federal ex-officio member of the Task Force (the Smithsonian Environmental Research Center), and each of the Task Force's six regional panels. Through these interviews, we collected information and documentation on aquatic invasive species activities conducted and any challenges agencies identified in addressing aquatic invasive species. Many of the activities and challenges relate to ongoing activities that span multiple fiscal years and thus the information we collected often highlights, but is not limited to, fiscal years 2012 through 2014. We also conducted site visits in Southern Florida, Northern California, and Western Washington to interview local federal officials and observe activities at the sites, such as inspections of shipments of live fish to search for aquatic invasive species and research being conducted at research facilities. We selected these locations based on the number and variety of aquatic invasive species and federal agencies, as well as the types of activities conducted in those locations. Information we obtained from our interviews and site visits on activities conducted and challenges identified are not generalizable, but we believe the examples we obtained provide important insights into the wide array of aquatic invasive species activities being undertaken across the 13 Task Force member agencies and the challenges agencies face in conducting those activities.

To determine the extent to which the Task Force has measured progress in achieving the goals of its 2013-2017 strategic plan, we conducted interviews with and obtained documentation from Task Force representatives, officials from the 13 Task Force member agencies, and officials representing the six regional panels. We reviewed the Task Force's 2013-2017 strategic plan, its 2012 reporting matrix, and other documentation related to the Task Force's efforts to collect information related to its strategic plan. We then analyzed and compared this information to program requirements identified in the 1990 Act, $5$  our previous reports on leading practices provided by the GPRA Modernization Act of  $2010<sup>6</sup>$  and our executive guide on strategic planning, $<sup>7</sup>$  as appropriate.</sup>

We conducted this performance audit from November 2014 to November 2015 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

# **APPENDIX II: EXAMPLES OF AQUATIC INVASIVE SPECIES AND THEIR REPORTED PRESENCE BY STATE, AND COMMON PATHWAYS**

Table 5 provides descriptions of the aquatic invasive species used as examples, and table 6 provides descriptions of common pathways of invasion.

Species	States affected	Species description
Common Water Hyacinth <b>Chinese Mitten</b>	Alabama; Arizona; Arkansas; California; Colorado; Connecticut; Delaware; Florida; Georgia; Hawaii; Illinois; Kentucky; Louisiana; Massachusetts; Mississippi; Missouri; New Jersey; New York; North Carolina; Oregon; South Carolina; Tennessee; Texas; Virginia; Washington California; Connecticut;	A free-floating flowering plant that forms dense colonies that block sunlight and crowd out native species, and can clog water intake structures, canals, and irrigation systems, therefore damaging ecosystems, raising operation costs, and impacting navigation of waterways. Common Water Hyacinth has become established in the Southeast, Northeast, and along the Pacific Coast of the United States after being introduced from South America through the ornamental aquarium trade. Crustaceans that threaten fisheries and aquatic ecosystems,
Crab	Delaware; Louisiana; Maryland; Michigan; New Jersey; New York; Ohio; Oregon; Washington	cause clogging at water intake structures, and have the potential to transport disease to humans. Chinese Mitten Crabs are native to the Pacific Coasts of China and Korea. They were introduced to California, the Great Lakes, and the Mid-Atlantic Coast through ballast water discharge and the intentional or accidental release of these crabs purchased as food. Chinese Mitten Crabs are listed as an injurious species under the Lacey Act, making it illegal to import or transport them between states.
Sea Lamprey	Illinois; Indiana; Michigan; Minnesota; New York; Ohio; Pennsylvania; Wisconsin	Fish that prey on native fish by attaching to the outside of a native host fish and draining its nutrients, often killing the host fish. Sea Lamprey can devastate native fish populations and harm fishing industries. They are native to the Atlantic Ocean, but invaded the Great Lakes by passing through canals.
Asian Carp	Every state but Alaska, Montana, and Rhode Island	Collectively refers to four species: Grass Carp, Bighead Carp, Black Carp, and Silver Carp. These fish harm ecosystems, threaten native species, and are also a danger to human health when they jump out of the water, which can injure or distract recreational boaters. Found naturally in Russia and China, each species of Asian Carp was intentionally introduced in the United States to improve water systems. Specifically, Grass Carp were intended for vegetation control, Bighead and Silver Carp for water quality improvement, and Black Carp for aquaculture-related work on parasite control. However, these fish escaped their introduction areas and, as a group, Asian Carp have invaded lakes in nearly all U.S. states, including the invasion of Grass Carp into the Great Lakes. Bighead Carp, Black Carp, and Silver Carp are listed as injurious species under the Lacey Act, making it illegal to import or transport them between states.
Zebra and Quagga Mussels	Alabama; Arizona; Arkansas; California; Colorado; Connecticut; Delaware; Georgia; Illinois; Indiana; Iowa; Kansas; Kentucky; Louisiana; Maryland; Massachusetts; Michigan; Minnesota; Mississippi; Missouri; Nebraska; Nevada; New Jersey; New York; North Dakota; Ohio; Oklahoma; Pennsylvania; South Dakota; Tennessee; Texas; Utah; Vermont; Virginia; West Virginia; Wisconsin	Distinct species of mussels that cause similar types of damage to native ecosystems by destroying native fish habitat and food webs. Both species of mussels colonize on water supply pipes, which can impact hydroelectric and nuclear power plants, public water supply plants, and industrial facilities. These mussels also affect navigation and boating by increasing the weight on vessels and sinking navigation buoys. They arrived in the United States from the Black, Caspian, and Azov Seas through ballast water discharge and have spread across much of the continental United States from recreational boats and fishing gear. Zebra Mussels (but not Quagga Mussels) are listed as an injurious species under the Lacey Act, making it illegal to import or transport them between states.

# **APPENDIX III: AQUATIC INVASIVE SPECIES ACTIVITIES CONDUCTED BY TASK FORCE MEMBER AGENCIES**

Through our questionnaire to the 13 federal member agencies of the Aquatic Nuisance Species Task Force (Task Force), we requested that member agencies identify the types of aquatic invasive species activities they conducted during fiscal years 2012 through 2014, including how those activities fell within the seven general activity categories developed by the National Invasive Species Council. The Task Force member agency responses are summarized in Table 7.

# Table 7. Aquatic invasive species activities conducted by task force member agencies, by activity category, **Table 7. Aquatic invasive species activities conducted by task force member agencies, by activity category,**  Fiscal Years 2012 through 2014 **Fiscal Years 2012 through 2014**

## **END NOTES**

- <sup>1</sup> For the purposes of this report, we define an invasive species as a nonnative species—to include all taxa of animals, plants, and microorganisms—the introduction of which does or is likely to cause economic or environmental harm or harm to human health.
- <sup>2</sup> GAO, *Invasive Species: Clearer Focus and Greater Commitment Needed to Effectively Manage the Problem*, GAO-03-1 (Washington, D.C.: Oct. 22, 2002); *Invasive Species: Cooperation and Coordination Are Important for Effective Management of Invasive Weeds*, GAO-05-185 (Washington, D.C.: Feb. 25, 2005); CRS, Invasive Non-Native Species: Background and Issues for Congress (Washington, D.C.: Nov. 25, 2002); and the Department of the Interior's *National Invasive Species Council Five-Year Review of Executive Order 13112 on Invasive Species* (Washington, D.C.: 2005).
- <sup>3</sup> The Department of the Interior's 2014 Invasive Species Action Plan states that invasive species pose one of the greatest threats to the ecological, economic, and cultural integrity of U.S landscapes. The plan also states that the number and impacts of aquatic invasive species are expected to escalate in the coming decade due to, among other things, the global movement of people and materials from increased tourism and trade that will further disperse species around the world.
- <sup>4</sup> EDDMapS. August 2015. The University of Georgia, Center for Invasive Species and Ecosystem Health. Available online at www.eddmaps.org/tools/query.
- <sup>5</sup> GAO-05-185; GAO-03-1; and GAO, *Invasive Species: Federal and Selected State Funding to Address Harmful, Nonnative Species*, GAO/RCED-00-219 (Washington, D.C.: Aug. 24, 2000).
- <sup>6</sup> D. Pimentel, R. Zuniga, and D. Morrison, "Update on the environmental and economic costs associated with alieninvasive species in the United States," *Ecological Economics* 52 (2005). This study is the most recent comprehensive assessment of the costs associated with invasive species on a national scale available, according to officials from several federal agencies that work on invasive species issues.
- <sup>7</sup> 64 Fed. Reg. 6183 (Feb. 8, 1999). National Invasive Species Council, Invasive Species Interagency Crosscut Budget (May 27, 2015). In 1999, Executive Order 13112 established the National Invasive Species Council, to, among other things, provide national leadership regarding invasive species and coordination of federal agency activities concerning invasive species relying to the extent feasible and appropriate on existing organizations. As part of this effort, the National Invasive Species Council has been identifying funding sources and spending by federal agencies on invasive species activities through an annual "crosscut" budget summary.
- <sup>8</sup> Expenditures are the actual spending of money; an outlay. GAO, *A Glossary of Terms Used in the Federal Budget Process*, GAO-05-734SP (Washington, D.C.: September 2005).
- <sup>9</sup> As we have previously found, a fundamental concept to invasiveness is that invasive species have been introduced into an environment in which they did not evolve, and they usually have no natural predators to limit their spread. GAO-03-1.
- <sup>10</sup> 16 U.S.C. § 4701(b).
- <sup>11</sup> 16 U.S.C. § 4721(b).The Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990, as amended, designated the following as Task Force members: the Director of the U.S. Fish and Wildlife Service, the Undersecretary of Commerce for Oceans and Atmosphere, the Administrator of the Environmental Protection Agency, the Commandant of the U.S. Coast Guard, the Assistant Secretary of the Army (Civil Works), the Secretary of Agriculture, and the head of any other federal agency the Task Force chairpersons deem appropriate. As of July 2015, the Task Force was co-chaired by representatives from the U.S. Fish and Wildlife Service and the National Oceanic and Atmospheric Administration, and membership consists of the following 13 federal agencies and departments: (1) Animal and Plant Health Inspection Service, (2) U.S. Forest Service, (3) National Oceanic and Atmospheric Administration, (4) U.S. Army Corps of Engineers, (5) U.S. Coast Guard, (6) Bureau of Land Management, (7) Bureau of Reclamation, (8) National Park Service, (9) U.S. Fish and Wildlife Service, (10) U.S. Geological Survey, (11) Department of State, (12) Department of Transportation's Maritime Administration, and (13) Environmental Protection Agency. In addition, the act, as amended, authorized the chairpersons to invite representatives from state agencies and other governmental entities to participate as ex-officio members of the Task Force. As of 2015, the Task Force included 13 state, regional, and nongovernment entities as ex-officio members, along with six regional panels.
- $12$  The Task Force uses the terms "aquatic invasive species" and "aquatic nuisance species" interchangeably. The 1990 Act uses the term "aquatic nuisance species." For purposes of this review, we use the term "aquatic invasive species." According to the definition we used in our questionnaire, aquatic species include all animals and plants as well as pathogens or parasites of aquatic animals and plants totally dependent on aquatic

ecosystems for at least a portion of their life cycle. Bacteria, viruses, parasites and other pathogens of humans are excluded.

<sup>13</sup> 16 U.S.C. § 4722(b).

<sup>14</sup> 16 U.S.C. § 4722(k)(2).

<sup>15</sup> Pub. L. No. 113-121, § 1039(a)(2), 128 Stat. 1193, 1237 (2014).

<sup>16</sup> We also requested that Task Force member agencies provide us with details about their aquatic invasive species related expenditures, such as expenditures by categories of activities and specific aquatic invasive species of concern. The agencies varied in the level of detail they were able to provide to us. Because of the incompleteness and inconsistency of the data reported across the Task Force member agencies, we did not include this information in our report.

- <sup>18</sup> According to Task Force representatives and FWS officials, in fiscal year 2014, about \$260,000 in funding was provided through the FWS' Branch of Aquatic Invasive Species program budget to support administration of the Task Force.
- <sup>19</sup> Several agencies have included addressing invasive species (or aquatic invasive species in particular) as part of their strategic planning efforts that guide agency activities and resource expenditures. Specifically, the Department of the Interior, with five member agencies on the Task Force, includes addressing invasive species as a stated goal as part of its departmentwide goals contained in its 2014-2018 strategic plan. Similarly, in its 2015-2020 strategic plan, the U.S. Forest Service includes addressing invasive species as part of its goal to sustain the nation's forests and grasslands. In addition, in September 2015, FWS's Fish and Aquatic Conservation Program released its 2016-2020 strategic plan in which managing aquatic invasive species is identified as one of seven goals. This plan described specific challenges related to aquatic invasive species that program staff plan to conduct over the 5-year period to accomplish the plan's goals.
- $20$  Each of the six regional panels meets at least once a year to share information and coordinate activities, among other things, and each panel is responsible for reporting back to the Task Force on its progress in implementing aquatic invasive species activities and to provide recommendations. The 1990 Act directed the Task Force to establish two of the six regional panels and to encourage development of additional regional panels.
- <sup>21</sup> According to Task Force representatives and FWS officials, in fiscal year 2014 FWS provided over \$3 million in funding, including approximately \$1 million to support implementation of 40 state and interstate aquatic nuisance species plans with Task Force approved management plans; \$240,000 to six regional panels; \$1 million for the Quagga-Zebra Mussel Action Plan; \$300,000 for the National Asian Carp Management and Control Plan; and \$700,000 for expenditures on other national species management and control plans.
- <sup>22</sup> David M. Lodge, et al., "Biological Invasions: Recommendations for U.S. Policy and Management" in *Ecological Society of America*, 16(6) (Washington, D.C., 2006); Brian Leung et al., "An ounce of prevention or a pound of cure: bioeconomic risk analysis of invasive species" in *The Royal Society*, DOI 10.1098/rspb.2002.2179; and David Finnoff et al., "Take a risk: Preferring prevention over control of biological invaders," *Ecological Economics* 62 (2007) 216-222; U.S. Environmental Protection Agency, Office of Wetlands, Oceans, and Watersheds, "Overview of EPA Authorities for Natural Resource Managers Developing Aquatic Invasive Species Rapid Response and Management Plans" (Washington, D.C.: December 2005).
- <sup>23</sup> David M. Lodge, et al., "Biological Invasions: Recommendations for U.S. Policy and Management" in *Ecological Society of America*, 16(6) (Washington, D.C., 2006).
- <sup>24</sup> See also G.M. Ruiz and J. T. Carlton, *Invasive Species: Vectors and Management Strategies*, chapter 5, 2nd ed. (2003); and Daniel Simberloff, "How Much Information on Population Biology Is Needed to Manage Introduced Species?," *Conservation Biology* 17, no. 1 (February 2003). "The most effective way to deal with invasive species, short of keeping them out, is to discover them early and attempt to eradicate or at least contain them before they spread."
- <sup>25</sup> Great Lakes Interagency Task Force, *Great Lakes Restoration Initiative Action Plan Fiscal Years 2010-2014*, 09- P-0231 (Washington, D.C.: Feb. 21, 2010.) The plan includes a "zero tolerance policy" for invasive species. We recently reported on information available about the Initiative's activities and results, including those addressing invasive species, see GAO, *Great Lakes Restoration Initiative: Improved Data Collection and Reporting Would Enhance Oversight*, GAO-15-526 (Washington, D.C.: July 21, 2015).
- $^{26}$  The preference to do more prevention-oriented activities, according to officials from several member agencies, includes activities under both the *prevention* and *early detection and rapid response* activity categories.
- $^{27}$  To treat aquatic invasive species outside project boundaries in the past, the Corps partnered with state and local agencies. Specifically, the River and Harbor Act of 1958, as amended, authorizes a comprehensive U.S. Army

<sup>17</sup> GAO/GGD-96-118.

Corps of Engineers program to provide for the prevention, control, and progressive eradication of noxious aquatic plant growths and aquatic invasive species from navigable and other waters of the United States. The law requires a cost share from local interests for the program's projects (known as the Aquatic Plant Control program). Before 1996, the Corps utilized this authority to fund aquatic invasive plant control projects with local and state governments. According to Corps officials, Corps management stopped requesting funding for this control program in 1996 based on a determination that the local and state governments receiving the benefits of this work should be responsible for paying all of the costs. From fiscal year 1998 through fiscal year 2012, the Corps conducted limited activities under this Aquatic Plant Control program when Congress would appropriate or direct funds for it, according to Corps officials.

- <sup>28</sup> 78 Fed. Reg. 21938 (Apr. 12, 2013). In October 2015, the United States Court of Appeals for the Second Circuit ruled that EPA acted arbitrarily and capriciously with respect to five aspects of the permit and remanded these aspects to EPA to adequately address them; however, the permit remains in force while EPA does so.
- $29$  A species can be added to the list of injurious wildlife by statutory amendment or by FWS rulemaking. The most recent listings were in March 2015, when FWS added four reptiles to the list. See 80 Fed. Reg. 12702 (Mar. 10, 2015). As of April 2015, there were about 240 mammals, birds, reptiles, fish, crustaceans, and mollusks of which about 150 are considered aquatic invasive species—that were listed as injurious wildlife. This includes species of walking catfish (100), snakeheads (28), zebra mussels (6), carp (4), mitten crab (3) and snakes (9). In addition, FWS officials indicated that all salmonids (approximately 170 species) are listed due to their pathogen risk, which renders them injurious. In October 2015, FWS finalized a change to the process by which it adds new species to its list of injurious wildlife to make it more efficient and allow the agency to better prevent the introduction of species that are injurious. 80 Fed. Reg. 66554 (Oct. 29, 2015).
- <sup>30</sup> This work was initiated in response to the October 2014 Priority Agenda Enhancing the Climate Resilience of America's Natural Resources, issued by the White House Council on Climate Preparedness and Resilience.
- <sup>31</sup> USGS officials told us that, before 2012, the Nonindigenous Aquatic Species Database also included data on aquatic invasive plants, but that they stopped including plant data in the database because of funding constraints at the time. In June 2015, USGS officials told us that an increase in funding to their Invasive Species Program in fiscal year 2015 has allowed them to resume their efforts to collect and report data on aquatic invasive plants as part of this database, and that adding plant information back to the database was a high funding priority for the agency partly due to requests from other federal agencies and partners to do so. <sup>32</sup> 33 U.S.C. § 610(a)(1).
- $33$  Some regional panel representatives told us that it has been difficult for them to fully conduct activities, including attending semiannual Task Force meetings, due to decreased funding provided to the panels. Beginning in fiscal year 2012, funding for the regional panels decreased from \$300,000 to \$240,000 annually, which represents a decrease from \$50,000 to \$40,000 per panel. Similarly, Task Force representatives said that funding to support implementation of state and interstate management plans has remained level at about \$1 million annually, but that the number of approved plans eligible for assistance has increased each year, resulting in less funding being awarded per state plan.
- <sup>34</sup> For the Task Force's 2013-2017 strategic plan, see http://anstaskforce.gov/Documents/ ANSTF%20Strategic% 20Plan%202013-2017.pdf.
- <sup>35</sup> We have previously found that, though a legal requirement specific to federal agencies and departments, the Government Performance and Results Modernization Act of 2010 serves to guide executive federal agency planning and provides leading practices for strategic planning at agencies and entities that work closely with or are a part of the federal government, including task forces. (See GAO, *Environmental Justice: EPA Needs to Take Additional Actions to Help Ensure Effective Implementation*, GAO-12-77 (Washington, D.C.: Oct. 6, 2011.) The identification of goals in the Task Force's Strategic Plan is consistent with such leading practices.
- <sup>36</sup> We have previously found that the Government Performance and Results Modernization Act of 2010—which calls for a performance plan to implement an agency's strategic plan—provides leading practices for strategic planning for task forces. The operational plan described in the Task Force's Strategic Plan is consistent with such leading practices.
- <sup>37</sup> The 1990 Act requires the Task Force to submit a report to Congress annually detailing the progress of its program, as well as to develop a program that (1) describes the specific prevention, monitoring, control, education and research activities to be conducted by each Task Force member; (2) describes the role of each Task Force member in implementing the elements of the program; and (3) includes recommendations for funding to implement elements of the program.
- <sup>38</sup> All six regional panels also provided information to the Task Force for the reporting matrix in 2012.
- <sup>39</sup> As a result of sequestration in 2013 and 2014, federal agencies reduced or delayed some services and disrupted agency operations. For information on 2013 sequestration, see GAO, *2013 Sequestration: Agencies Reduced Some Services and Investments, While Taking Certain Actions to Mitigate Effects,* GAO-14-244 (Washington, D.C.: Mar. 6, 2014).
- <sup>40</sup> The 1990 Act requires the Task Force, beginning in 1992, to submit a report to Congress annually detailing the progress of its program.16 U.S.C. § 4722(k)(2).
- <sup>41</sup> GAO, *Climate Change: Adaptation: Strategic Federal Planning Could Help Government Officials Make More Informed Decisions*, GAO-10-113 (Washington, D.C.: Oct. 7, 2009).

#### **End Notes for Appendix I**

<sup>1</sup> 16 U.S.C. §§ 4701-4751.

- <sup>2</sup> We defined our scope to include the 13 federal department and agencies that are the federal members of the Aquatic Nuisance Species Task Force, as established by the 1990 Act. Other federal agencies may also conduct aquatic invasive species-related activities.
- <sup>3</sup> We also included an eighth category labeled "other" for member agencies to report any activities they determined did not fit within any of the seven categories.

*Chapter 45* 

 $\overline{a}$ 

# **AQUATIC NUISANCE SPECIES TASK FORCE STRATEGIC PLAN (2013-2017)**

## *Aquatic Nuisance Species Task Force*

## **EXECUTIVE SUMMARY**

Aquatic nuisance species (ANS) are nonindigenous species that threaten the diversity or abundance of native species, the ecological stability of infested waters, and/or any commercial, agricultural, aquacultural, or recreational activities dependent on such waters. ANS include nonindigenous species that may occur within inland, estuarine, or marine waters and that presently or potentially threaten ecological processes or natural resources. The term ANS is often used interchangeably with aquatic invasive species, the preferred term of Federal and State managers. An aquatic invasive species is defined as a species not native to the ecosystem under consideration whereby introduction of this species does or is likely to cause economic or environmental harm or threaten human health.

ANS are one of the largest threats to the ecosystems and economies of the United States. Approximately 49% of the species on the threatened or endangered species lists are at risk primarily because of predation or competition with exotic species. In fact, impacts of invasive species are second only to habitat destruction as a cause of global biodiversity loss. ANS such as snakehead fish, sea lamprey, hydrilla, and the New Zealand mudsnail may prey upon, displace, alter habitat, or otherwise harm native species. Other ANS may reduce production of fisheries, decrease water availability to residential and commercial users, block transport routes, choke irrigation canals, foul industrial and public water supply pipelines, degrade water quality, accelerate filling of lakes and reservoirs, and decrease property values. The damages to human enterprises caused by ANS results in enormous economic costs. The United States invests more than \$120 billion per year in damage and control costs to combat invasive species. As the world trade network continues to grow, the number and frequency of introduced species are expected to increase. Additionally, climate change may also allow

This is an edited, reformatted and augmented version of a document approved by the ANS Task Force, May 3, 2012.

increased introductions. This plan presents the strategic priorities designed to address ANS in the United States under current and future conditions.

In 1990, Congress passed the Nonindigenous Aquatic Nuisance Prevention and Control Act to establish a broad national program to prevent introduction and control the spread of introduced ANS; this legislation was reauthorized and furthered with the National Invasive Species Act in 1996. The Aquatic Nuisance Species Task Force (ANSTF) is an intergovernmental organization dedicated to preventing and controlling aquatic invasive species and implementing these Acts. The ANSTF, co-chaired by the U.S. Fish and Wildlife Service and National Oceanic and Atmospheric Administration, consists of 13 Federal agency representatives and 13 *ex-officio* representatives. These members work in conjunction with Regional Panels and issue-specific committees to coordinate efforts amongst agencies as well as efforts of the private sector and other North American interests.

The ANSTF serves to develop and implement a program for waters of the United States to prevent introduction and dispersal of ANS, monitor, control, and study such species, and disseminate related information. In 1994, the *Aquatic Nuisance Species Program* document was drafted to guide the work of the ANSTF, establishing the core elements of the Task Force. A broader focus was established with the 2002-2007 and 2007-2012 Strategic Plans, placing more emphasis on prevention strategies. This *Aquatic Nuisance Species Task Force Strategic Plan 2013- 2017* (Strategic Plan) carries through many of the goals and objectives established in previous plans by remaining focused on prevention, monitoring, and control of ANS as well as increasing public understanding of the problems and impacts associated with invasive species. The Strategic Plan also calls attention to other areas of management including habitat restoration and research. The Strategic Plan establishes eight goals, each with objectives and action items to be completed in the next 5 years.

*Coordination*: The ANSTF was created to facilitate cooperation and coordinate efforts between Federal, State, tribes, and local agencies, the private sector, and other North American interests. The objectives for the coordination goal include strengthening cooperation at both national and regional levels within the ANSTF and the Regional Panels and encouraging the development and implementation of ANS plans and regulations.

*Prevention*: Prevention is the first-line of defense against ANS. This goal calls for developing strategies to identify and reduce the risk of ANS introduced by increasing development and use of risk assessments, Hazard Analysis and Critical Control Point programs (HACCP), and pathway assessment and interdiction options.

*Early Detection and Rapid Response*: Early Detection and Rapid Response programs are designed to monitor habitats to discover new species soon after introduction, report sightings of previously unknown species in an area, and work quickly to keep the species from becoming established and spreading. Objectives for the ANSTF include improving detection and monitoring programs and facilitating development and implementation of rapid response contingency plans.

*Control and Management:* Control and management tools are needed to assess, remove, and contain ANS populations as well as to guide management decisions. The ANSTF will implement this goal by evaluating and providing support to management plans, increasing training opportunities, and encouraging the development of management techniques.

*Restoration:* Habitat restoration is an essential to guard against future invasions and to minimize harm from invasive species. This goal focuses on restoring impacted ecosystems
and consideration of potential ANS during planning and implementation of restoration activities.

*Education/Outreach:* The lack of awareness concerning ANS impacts is one of the largest management obstacles. Few people understand the threat some nonindigenous species pose and how their actions might introduce them. Objectives by the ANSTF for education and outreach include reaching out to the general public, providing technical guidance to targeted audiences, and raising awareness among legislators and decision makers.

*Research:* Research supports all facets of the Strategic Plan and is necessary to increase the effectiveness of prevention, detection, response, and control and management of invasive species. To help ensure that research addresses critical needs, this goal focuses on coordination among government agencies, academia, and other participating entities.

*Funding:* Securing dedicated long-term and emergency funding is necessary to achieve the goals laid out in the Strategic Plan. The actions outlined by the ANSTF focus on coordinating Federal agency budgets to support ANSTF priorities, develop partnerships, and seek opportunities to leverage funds within Federal and State agencies, local governments, tribal entities, industry, as well as other entities including non-governmental organizations.

The Strategic Plan should not be considered a comprehensive list of all ANS strategic actions; it does contain a targeted set of priority strategic goals, objectives, and associated action items that are intended to be completed in the next 5 years**.** The accomplishment of specific objectives and action items will be dependent upon budgets of individual agencies and the Regional Panels; and in some cases, legal or regulatory changes as well as enforcement of these changes. An Operational Plan will be composed to depict short-term efforts to achieve the actions in the Strategic Plan to ensure the goals and objectives of the Strategic Plan are measurable and accountable. The Operational Plan will be completed by the ANSTF members working together and separately with support of the Regional Panels and committees. The actions in the Operational Plan will be updated regularly and reported on to measure the progress towards meeting the goals of the Strategic Plan.

Management of ANS is challenging; however, considerable success is being achieved in the prevention, detection, eradication, control, and outreach efforts of ANS along with increased emphasis for the restoration of ecosystems that have been impacted by ANS. Additional research and information exchange, new detection and eradication techniques, and innovative control methodologies are increasing our capacity to address invasive species problems. The *Aquatic Nuisance Species Task Force Strategic Plan 2013–2017* takes a deliberate, cooperative approach and builds on existing programs. The Task Force will strive to maximize efforts over the next 5 years to prevent and control invasive species with the purpose of protecting our environment, economy and human health.

### **INTRODUCTION**

Aquatic nuisance species (ANS) are nonindigenous species that threaten the diversity or abundance of native species, the ecological stability of infested waters, and/or any commercial, agricultural, aquacultural, or recreational activities dependent on such waters. ANS include nonindigenous species that may occur within inland, estuarine, or marine waters and that presently or potentially threaten ecological processes or natural resources. In addition

to the severe and permanent damage to the habitats they invade, ANS may also adversely impact society by hindering economic development, preventing recreational and commercial activities, decreasing the aesthetic value of nature, and serving as vectors<sup>1</sup> of human disease. The table below provides a list of the three classes of adverse impacts caused by ANS.

The term ANS is often used interchangeably with aquatic invasive species (AIS), the preferred term of Federal and State managers. An aquatic invasive species is defined as a species not native to the ecosystem under consideration whereby introduction of this species does or is likely to cause economic or environmental harm or threaten human health.

#### *Environmental Harm*

In the United States, approximately 49% of the species on the threatened or endangered species lists are at risk primarily because of predation or competition with exotic species<sup>2</sup>. In fact, impacts of invasive species are second only to habitat destruction as a cause of global biodiversity loss<sup>3</sup>. ANS impact the habitats they invade by reducing the abundance of native species and altering ecosystem processes. They can impact native species through predation, competition for food and space, hybridization, as well as the introduction of pathogens and parasites. Normal functioning of the ecosystem, including hydrology, nutrient cycling, or productivity, may also be altered by ANS. Aquatic weeds provide an excellent example of the severe impact an exotic organism may have on the environment. Non-native aquatic plants including Eurasian water-milfoil (*Myriophyllum spicatum*), hydrilla (*Hydrilla verticillata*), and water hyacinth (*Eichhornia crassipes*) can negatively impact the diversity of native aquatic plants and invertebrates, the efficiency for large predator fish to obtain prey, water quality, and aquatic recreational activities including swimming, fishing and boating. Invasive fish species also have the ability to alter aquatic ecosystems. For example, the common carp (*Cypinus carpio*) is capable of reducing native vegetation and increasing turbidity. These types of habitat alterations are responsible for the extinction of several native fish species<sup>4</sup>.

#### *Economic Harm*

ANS are seen as a threat not only to native biodiversity and ecosystem functioning, but also to economic development. They can reduce production of fisheries, decrease water availability to residential and commercial users, block transport routes, choke irrigation canals, foul industrial and public water supply pipelines, degrade water quality, accelerate filling of lakes and reservoirs, and decrease property values. The damages to human enterprises caused by ANS result in enormous economic costs.

Over the past 200 years, more than 50,000 non-native plant and animal species have become established in the United States. Approximately one in seven has become invasive<sup>5</sup>,

with damage and control costs estimated at more than \$120 billion per year<sup>6</sup> - a cost higher than the total of all other natural disasters combined<sup>7</sup> . Zebra and quagga mussels (*Dreissena polymorpha, D. rostriformis bugensis*) alone cause one billion dollars per year in damages.<sup>8</sup> Another 100 million is spent annually in the United States to control nonnative aquatic weeds.<sup>9</sup> In two California lagoons, more than \$5 million was spent in the first 3 years of an ongoing eradication program for the seaweed *Caulerpa taxifolia*. <sup>10</sup> As a final example, the Great Lakes States invested over \$26.7 million toward prevention and control of aquatic invasive species in just 2 years, of which almost \$900,000 was committed to Asian carp<sup>11</sup> control efforts. <sup>12</sup> These numbers are likely underestimated as they do not consider ecosystem health or the aesthetic value of nature, which can influence tourism and recreational revenue. Estimating the economic impact associated with ANS is further confounded as monetary values are difficult to estimate for the extinction of species or loss of native biodiversity and ecosystem services.

#### *Harm to Human Health*

Throughout history, epidemic diseases such as malaria, yellow fever, typhus, and bubonic plague have spread using organisms as vectors and reservoirs. Further, there has been conjecture that the ballast water of ships may transport waterborne pathogens and diseases<sup>13</sup> as well as causative agents of harmful algal blooms (HABs)<sup>14, 15</sup>, however, additional study is needed to link the transport of microorganism to outbreaks of human disease. The effect of ANS on public health extends beyond the immediate effects of disease and parasites; human injury may also result from ANS. For instance, hazards may occur from collisions between boaters and jumping silver carp (*Hypophthalmichthys molitrix) or* from the sharp-edged mussel shells found in recreational areas. Additional risk to human is perceivable as chemicals used to control invasive species can pollute soil and water. Other ANS, such as invasive mussels, may increase human and wildlife exposure to organic pollutants such as polychlorinated biphenyls (PCBs), as these toxicants accumulate in their tissues and are passed up the food chain.

### **ANS - What Can Be Done?**

Prevention is the most cost effective and environmentally protective tool to control ANS. Preventative measures include decontaminating boats and gear that could transport ANS and restricting the importation or release of potentially harmful species. However, even the best prevention efforts may not stop all invasions. When a new species is introduced, the best strategy is early detection and rapid response. This includes monitoring habitats to discover new species soon after introduction, reporting sightings of previously unknown species in an area, and working quickly to keep introduced species from becoming established and spreading. Once established, invasive species can be difficult to control and nearly impossible to eradicate. Control methods include mechanical, chemical, and biological approaches. The methods used will vary dependent upon the species and location; however, control efforts are typically costly, labor intensive, and indirectly affect native species. Furthermore, control efforts often create disturbance, which may render the habitat vulnerable to subsequent

invasions. Accordingly, habitat restoration is necessary following eradication or control efforts to minimize the chance an area will be reinvaded.

Education and outreach are critical tools to prevent and manage the impacts of ANS. The public must understand the problems and impacts associated with ANS so they can be active partners in solving the problem. More importantly, people need to know what they can do to help prevent the introduction and spread of ANS. Federal, State, and local programs and legislation have implemented regulations to prevent the introduction and reduce the spread of invasive species. These regulations include mandatory boat inspections at public boat ramps, live species prohibitions and restrictions, and ballast water regulations at shipping ports. To successfully address ANS issues collaboration, cooperation, and coordination are necessary among and between Federal and State agencies, local governments, tribal entities, industry, as well as other entities including non-governmental organizations.

#### *Future Challenges*

Global trade and intercontinental travel have been cited as major causes of biological invasion. For example, it has been estimated that 10,000 marine species are transported around the world in ballast water every day<sup>16</sup>. As the world trade network continues to grow, new markets and trade routes continually open. This growth will increase the number of new species that are introduced and the frequency with which such introductions are repeated. Managing this increased rate of aquatic bioinvasion will require the United States and other counties to strengthen approaches for preventing introductions while maintaining trade.

Additional challenges to ANS management result from changes in the Earth's climate that will likely continue, or even accelerate, over the next century. Very little is known of the impacts from ANS in relation to climate change, yet models suggest that the economic, energy, social, and environmental impacts may be profound. Fast growth, rapid reproduction, and the ability to survive in a wide range of environmental conditions are among some of the life history traits shared by ANS that may allow them to capitalize on the biotic and abiotic changes generated by global climate change. Furthermore, species that have long been "in motion," but failed to establish and reproduce in hostile conditions, may soon be able to invade these once "off limit" thermal regimes. Other species will migrate to maintain the temperature conditions needed for reproduction, growth, and feeding. There is a growing concern that these shifting species will begin to function as invasive species, disrupting the structure and function of their new communities. Many communities have already experienced the impacts of warming coastal waters and have shown subsequent alterations in species proportions as well as changes to community structure and dynamics. Predictions of how species will respond to climate change will help guide conservation decisions and management of natural resources. Future ANS managers will need to develop tools that include both invasion biology and climate change impacts.

# **STRUCTURE** O**F THE AQUATIC NUISANCE SPECIES TASK FORCE**

The Aquatic Nuisance Species Task Force (ANSTF) was established by Congress with the passage of the Nonindigenous Aquatic Nuisance Prevention and Control Act (NANPCA) in 1990 and reauthorized with the passage of the National Invasive Species Act (NISA) in

1996 (collectively, the Act). The ANSTF is an interagency committee established by Section 1201 of the Act and serves to develop and implement a program for waters of the United  $State<sup>17</sup>$  that:

- Prevents the introduction and dispersal of ANS;
- Monitors, controls and studies such species;
- Conducts research on methods to monitor, manage, control and/or eradicate such species;
- Coordinates ANS programs and activities of ANSTF members and affected State agencies; and
- Educates and informs the general public and program stakeholders about the prevention, management, and control of these species

### **Federal and Ex-Officio Members**

The ANSTF's charter is authorized by the Federal Advisory Committee Act (FACA) of 1972. The charter provides the ANSTF with its core structure and ensures an open and public forum for its activities. To meet the challenges of developing and implementing a coordinated and complementary Federal program for ANS activities, the ANSTF members include 13 Federal agency representatives and 13 representatives from ex-officio member organizations. These members work in conjunction with Regional Panels and issue-specific committees to coordinate efforts amongst agencies as well as efforts of the private sector and other North American interests.

The Act designated the Director of the Fish and Wildlife Service and the Undersecretary of Commerce for Oceans and Atmosphere as the ANSTF Co-chairpersons. It specified six Federal agencies<sup>18</sup> that would constitute the ANSTF, but also gave the co-chairs legal authority to include other Federal agencies as members of the ANSTF, as appropriate. Members of ANSTF are responsible for committing resources to achieve the goals of the Strategic Plan and reporting annually on their progress. At the time of Plan adoption (May 3, 2012), the following were ANSTF member departments and agencies:

- United States Fish and Wildlife Service (USFWS)—co-chair
- National Oceanic and Atmospheric Administration (NOAA)—co-chair
- Army Corps of Engineers (ACOE)
- Bureau of Land Management (BLM)
- Bureau of Reclamation (BOR)
- Department of State (DOS)
- Environmental Protection Agency (EPA)
- United States Forest Service (USFS)
- Department of Transportation (DOT), Maritime Administration (MARAD)
- National Park Service (NPS)
- United States Coast Guard (USCG)
- United States Department of Agriculture, Animal and Plant Health Inspection Service (USDA-APHIS)
- United States Geological Survey (USGS)

The Act also named four organizations<sup>19</sup> to be included in the base ANSTF membership, yet authorized the co-chairs to invite representatives of specific regional organizations, State agencies, and other governmental entities to participate as *ex-officio* members of the ANSTF. At the time of Plan adoption (May 3, 2012), the following were ex*-officio* members of the ANSTF:

- Great Lakes Commission
- Lake Champlain Basin Program
- Chesapeake Bay Program
- San Francisco Estuary Project
- American Public Power Association
- American Water Works Association
- Association of Fish and Wildlife Agencies
- Gulf States Marine Fisheries Commission
- Mississippi Interstate Cooperative Resources Association
- Native American Fish and Wildlife Society<sup>20</sup>
- National Association of State Aquaculture Coordinators
- Smithsonian Environmental Research Center
- *Fisheries and Oceans Canada (invited observer)*

# **ANSTF Regional Panels**

The ANSTF focuses its work on ANS issues of national concern that require or could benefit from collaborative solutions. It strives to create opportunities and synergies among members and participants to work collaboratively by sharing resources, expertise, and ideas across agency and organizational lines. While the ANSTF has a national focus, it recognizes the tremendous importance of actions taken at the regional and local level to achieve national ANS solutions. Section 1203 of NANPCA created the Great Lakes Regional Panel to identify priorities, to coordinate ANS program activities, and to advise public and private interests on control efforts in their region. The 1996 amendment required the ANSTF to encourage the development of additional regional panels to provide an intergovernmental mechanism for the development of a coordinated Federal program to prevent and control nonindigenous ANS as authorized by the Act. The Regional Panels are responsible for implementing actions that assist in achieving the Strategic Plan's goals and reporting annually on their progress $^{21}$ . At the time of Plan adoption (May 3, 2012), the ANSTF had established six Regional Panels:

- Great Lakes Regional Panel
- Western Regional Panel
- Gulf and South Atlantic Regional Panel
- Northeast Regional Panel
- Mississippi River Basin Regional Panel
- Mid-Atlantic Regional Panel

Regional Panel membership is composed of Federal, State, intergovernmental, tribal, industry, and environmental non-governmental organization representatives. In addition, some panels may include international representation (e.g. Canadian Federal and Provincial representatives) as observers.

The Regional Panels make a concerted effort to involve a broad spectrum of stakeholders in order to provide balanced advice to the ANSTF on regional priorities and issues of local significance.

### **ANSTF Committees**

To obtain the necessary technical coordination of various ANS efforts, the ANSTF has established several issue- and/or species-specific standing and ad hoc committees to carry out the Act. Committee membership includes all affected entities, such as Federal and State agencies, tribes, non-governmental organizations, industry groups, and academia. Committees are made up of member agency representatives and subject matter experts. Committee activities include the development of public awareness/action campaigns, species-specific control and management plans, standardized scientific protocols, research priorities, theoretical frameworks to screen organisms prior to their entry to the United States., and providing technical advice to the ANSTF. Committees, both standing and ad hoc, are responsible for reporting to the ANSTF on goal attainment under this Plan. At the time of Plan adoption (May 3, 2012), the ANSTF had established three standing committees that oversee related working groups: the Communication, Education and Outreach Committee, Research Committee, and Prevention Committee (the latter is a joint committee with the National Invasive Species Council (NISC)). In addition, ad hoc committees are formed as needed to focus on a specific discipline or issue that warrants the attention of the ANSTF.

### **ANSTF Strategic Plan**

Section 1202 of the Act authorized the ANSTF to develop and implement a program for waters of the United States to prevent introduction and dispersal of ANS, to monitor, control, and study such species, and to disseminate related information. The *Aquatic Nuisance Species Program* document guided the work of the ANSTF from 1994 to 2002. The document tracked the requirements outlined in the NANPCA (1990). It established the core elements of the ANS program (prevention, detection and monitoring, control) and support elements (research, education, and technical assistance), provided for prioritization of activities, and charted a course for implementation of the Act.

The ANSTF Strategic Plans for 2002–2007 and 2007- 2012 maintained the key elements of the ANS Program, but provided a broader focus for activities consistent with provisions of NISA (1996). These plans provided more emphasis on prevention strategies, particularly for intentional introductions.

The ANSTF Strategic Plan for 2013 – 2017 (hereafter, the Strategic Plan) carries through many of the goals and objectives established in previous plans by remaining focused on prevention, monitoring, and control of ANS as well as increasing public understanding of the problems and impacts associated with invasive species. The Strategic Plan also calls attention to other areas of ANS management, including habitat restoration and research. The Strategic Plan establishes eight goals:

- 1. Coordination Maximize the organizational effectiveness of the Aquatic Nuisance Species Task Force
- 2. Prevention Develop strategies to identify and prevent the establishment of new and slow the spread of existing ANS in the waters of the United States
- 3. Early Detection and Rapid Response Identify and respond to aquatic nuisance species within a timely manner following introduction in order to prevent their establishment and/or spread
- 4. Control and Management Control established aquatic nuisance species when feasible and when the benefits of managing the established species outweigh the costs of removing them with respect to harm to the environment, the economy, and public health
- 5. Restoration Protect and rehabilitate native species and ecosystems by conducting habitat restoration efforts on multiple scales
- 6. Education / Outreach Increase awareness concerning the threats of aquatic nuisance species, emphasizing the impacts, importance of prevention and containment, and recommendations for appropriate domestic and international actions
- 7. Research Facilitate research to address environmental, economic, and human health risks and impacts associated with aquatic nuisance species
- 8. Funding Coordinate Federal agency budgets to support Aquatic Nuisance Species Task Force priorities and establish a clear process that links State and regional needs in their areas of responsibility

The strategic goals serve as a blueprint and coordination tool for the ANSTF. The order in which the goals are presented in the Plan represent the logical arrangement determined by the ANSTF; accordingly, the hierarchy of the goals do not represent individual importance or priority level. Under each goal, objectives describe what is to be accomplished over the next 5 years. Action items listed under the objectives describe how ANSTF expects to accomplish the goals and objectives. The accomplishment of specific objectives and action items will be dependent upon budgets of individual agencies and the Regional Panels; and in some cases, legal or regulatory changes as well as enforcement of these changes. The Strategic Plan should not be considered a comprehensive list of all ANS strategic actions; it does contain a targeted set of priority strategic goals, objectives, and associated action items that are intended to be completed in the next 5 years.

# **ANSTF Operational Plan**

In addition to its Strategic Plan, the ANSTF will compose a separate Operational Plan. Its function is to ensure the goals and objectives of the Strategic Plan are measurable and accountable. In contrast to the action items in the Strategic Plan that outline long-term or continual actions, the actions listed in the Operational Plan will depict short- term efforts used to support and implement the Strategic Plan. The Operational Plan will be completed by the ANSTF members working together and separately with support of the Regional Panels and committees. To the greatest extent possible, implementation of the actions within the Operational Plan will build on and fill gaps in existing activities and programs rather than supplanting them. Responsibilities will be assigned to specific agencies, Regional Panels, or committees. Implementation will be assumed by those specified in line with their specific mandates, priorities, expertise, and funding. The Operational Plan will include, when available, the time frame, lead and supporting agencies or groups, and allocated funding. Further, the Operational Plan will be regularly amended to reflect changes in circumstances, plans, or priorities. The actions listed in the Operational Plan will be reported annually to measure the progress towards accomplishing the over-arching goals and objectives identified within the Strategic Plan.

# **COORDINATION WITH OTHER FEDERAL AND STATE INVASIVE SPECIES MANAGEMENT PLANS**

The ANSTF recognizes that many Federal and State agencies, interagency groups, and local entities contribute to the management of invasive species. The largest and most comprehensive invasive species-focused committees and working groups are the National Invasive Species Council (NISC), Federal Interagency Committee for the Management of Noxious and Exotic Weeds (FICMNEW), and the Federal Interagency Committee on Invasive Terrestrial Animals and Pathogens (ITAP). As described below, these working groups facilitate communication and collaboration at all levels of the Federal government and with State, local and private partners by focusing on particular taxa and pathways.

The National Invasive Species Council (NISC) was established by Executive Order 13112 (Order). NISC is co-chaired by the Secretaries of Agriculture, Commerce, and the Interior and includes 10 member departments and their constituent agencies as well as a small staff assigned specifically to the Council. The Order directs the Secretary of the Interior to establish an Invasive Species Advisory Committee (ISAC) composed of nonfederal experts and stakeholders to provide advice and recommendations to NISC on invasive species-related issues. NISC provides national leadership and oversight on both terrestrial and aquatic invasive species and ensures that Federal programs and activities to prevent and control invasive species are coordinated, effective, and efficient. NISC has specific responsibilities including promoting action at State, tribal, local, and ecosystem levels; identifying recommendations for international cooperation; facilitating a coordinated network to document, evaluate, monitor invasive species' effects; developing a web-based information network on invasive species; and developing guidance on invasive species for Federal agencies to use in implementing the National Environmental Policy Act. NISC is also responsible for preparing a National Invasive Species Management Plan which directs Federal efforts to prevent, control and minimize invasive species and their impacts.

The Federal Interagency Committee for the Management of Noxious and Exotic Weeds (FICMNEW) was established through a Memorandum of Understanding signed by agency leadership in August 1994. FICMNEW represents an unprecedented formal partnership between 16 Federal agencies with direct invasive plant management and regulatory responsibilities spanning across the United States and territories. FICMNEW members interact on important national and regional invasive plant issues and share information with various public and private organizations participating with the Federal sector to address invasive plant issues. FICMNEW's charter directs the committee to coordinate, through the respective Secretaries, Assistant Secretaries, and Agency heads, information regarding the identification and extent of invasive plants in the United States and to coordinate Federal agency management of these species. FICMNEW accomplishes these portions of its charter by developing and sharing scientific and technical information, fostering collaborative efforts among Federal agencies, providing recommendations for national and regional level management of invasive plants, and sponsoring technical and educational conferences and workshops concerning invasive plants.

ITAP is the Federal Interagency Committee on Invasive Terrestrial Animals and Pathogens. ITAP's mission is to support and facilitate more efficient networking and sharing of technical information for program planning and coordination among Federal agencies and departments involved with invasive species research and management. ITAP focuses on several major taxonomic groups of invasive species for which improved technical coordination is essential to facilitate effective Federal responses.

Invasive species management plans prepared by these groups and others provide an opportunity to identify priorities and establish cooperative, well-coordinated approaches to invasive species management. Invasive species issues are significant in their breadth and scope; as this area involves all taxa of life and threatens natural ecosystems around the globe. A variety of pathways are capable of transporting species into new environments including ballast water and hulls of ships, materials associated with the trade of nursery stock, importation of fruits and vegetables, and the international movement of people. Furthermore, multiple efforts are necessary to encompass the various components of invasive species management, including prevention, monitoring, removal, restoration, research, and education. The great extent needed to manage invasive species and their impacts infers that one agency, task force, or work group cannot tackle it alone. Work can be done with greater effectiveness and efficiency if it is focused on specific taxonomic, ecosystem, or regional priorities. To ensure that redundancy and overlap does not occur while addressing invasive species-related issues, the ANSTF communicates with Federal and State agencies and interagency groups to create a big picture framework for existing management plans. Working with other agencies and organizations allows the ANSTF to identify areas where legislation is needed to fill gaps in statutory authority, suggest priority policy issues, and define roles and responsibilities for managing invasive species.

States also play a critical role in preventing and controlling the spread of invasive species and have numerous programs relating to the wide variety of invasive species found within their borders. ANSTF encourages State and interstate planning entities to develop management plans describing detection and monitoring efforts of ANS, prevention efforts to stop their introduction and spread, and control efforts to reduce their impacts. In addition, these plans serve to coordinate efforts between State agencies, local governments, tribal entities, industry, as well as other entities including nongovernmental organizations. Consequently, they are a valuable and effective tool for identifying and addressing ANS problems and concerns in a climate of many jurisdictions and other interested entities. Once a State or interstate ANS management plan is approved, the ANSTF monitors the activities of the planning entity to ensure the plans are implemented. This monitoring process allows the ANSTF to evaluate the capacity and capability at State and local levels to coordinate, detect, and respond to invasive species. This information allows the ANSTF to better identify strategies for monitoring, containment, outreach, and other ANS activities. It also allows for identification of priority activities and species, obstacles to fully implementing the ANS State management plans, and cooperative partnerships that exist among entities managing ANS. This information is critical for recognizing the amount and type of data and management methods available, which allows for an assessment of gaps, redundancies, and opportunities for collaboration among agencies that are not being realized. It is clear that actions and goals performed at the Federal level will not will not succeed unless they are undertaken in cooperation with stakeholders; for that reason, coordination and joint action with State partners is critical for addressing invasive species problems within the United States.

### **CONCLUSION**

Management of ANS is challenging; however, considerable success is being achieved in the prevention, detection, eradication, control, and outreach efforts of ANS along with increased emphasis on the restoration of ecosystems that have been impacted by ANS. Additional research and information exchange, new detection and eradication techniques, innovative control methodologies, and collaborative models are increasing our capacity to manage ANS. Since the establishment of the ANSTF, awareness of the problems caused by ANS has dramatically improved, as evidenced by increased activity at Federal, State, and local levels. Despite the significant increase in activity and awareness, much remains to be done to prevent and mitigate the impacts of ANS. The intent of the ANSTF Strategic and Operational Plans is to create a strategic approach to minimize harm to the environment, economy, or human health that results from ANS. This involves taking advantage of what has been learned and creating next steps that are well planned and coordinated.

### **Goal 1: Coordination - Maximize the Organizational Effectiveness of the Aquatic Nuisance Species Task Force**

The scope and complexity of ANS management summons the strengths of different government agencies and private organizations in different ways. A primary objective of the ANSTF is to facilitate cooperation and coordinate Federal government efforts relating to ANS in the United States with those of the private sector and other North American interests by utilizing Regional Panels and issue-specific committees and including bi-national bodies where applicable. The Regional Panels established by the ANSTF are a critical and effective mechanism for achieving the goals and objectives established by the ANSTF Strategic Plan. The memberships within each of the panels include representatives of States, Indian tribes, non-governmental organizations, commercial interests, and neighboring countries. The roles of each panel include, but are not limited to, identifying regional ANS priorities, coordinating ANS program activities in the region, making recommendations to the ANSTF, and providing advice to public and private interests concerning methods of ANS management and control.

To further increase coordination, the ANSTF encourages State and interstate planning entities to develop management plans describing detection and monitoring efforts of ANS, prevention efforts to avert their establishment and spread, and control efforts to reduce their impacts. In addition, management and control plans have been developed or are under development by the ANSTF and other partners for several species. Under Section 1204 of the Act, management plan approval from the ANSTF is required for both State and species plans to obtain funding. Regardless of financial incentives, plans are a valuable and effective tool for identifying and addressing ANS problems and concerns in a climate of many jurisdictions and interested entities.

Fulfilling Goal 1 requires ongoing cooperation, communication, and dialogue as well as an understanding of the views and roles of all agencies and organizations involved. The actions suggested below will allow the ANSTF to lower institutional barriers to efficiency and effectiveness, beginning with enhanced Federal agency collaboration. The actions also include a thorough analysis of the roles, responsibilities, and supporting legislation involving

ANS so gaps in authority can be identified. Further, strong monitoring and evaluation of the ANSTF Strategic and Operational Plans are encouraged to provide measures of success toward reaching goals and providing information for future revisions of the plans.

### *Objective 1.1: Strengthen the Coordination Capacity of the ANSTF*

- a) Increase communication among the members, Regional Panels, and committees of the ANSTF to prioritize issues and activities
- b) Continue to build capacity within and among the Regional Panels in order to increase regional and international coordination, identify needs and emerging issues, and communicate recommendations to ANSTF members
- c) Provide technical guidance and resource assistance to States though a coordinated effort by the Regional Panels
- d) Strengthen the working relationship with NISC, working cooperatively to implement ANS activities identified in the ANSTF Strategic Plan and NISC National Management Plan
- e) Identify, increase communication, and encourage participation with other interagency organizations dedicated to invasive and nuisance species
- f) Identify, increase communication, and encourage participation with industry, tribes, and other stakeholders affected by ANSTF and Regional Panel activities
- g) Annually report on the ANSTF Operational Plan; when warranted, utilize this information to update and amend the ANSTF Operational Plan

### *Objective 1.2: Evaluate the Ability of Statutory Authorities, Regulations, and Programs Necessary to Implement ANSTF Goals and Objectives*

- a) Identify gaps in statutory authorities, regulations, and programs necessary to meet ANSTF goals and objectives
- b) Recommend revisions to statutory authorities, regulations, and programs when needed to meet ANSTF goals and objectives

### *Objective 1.3: Facilitate the Development and Continued Effectiveness of State and Interstate ANS Management Plans*

- a) Encourage plan development and provide technical drafting assistance to States without an ANS management plan
- b) Encourage State and interstate ANS management plan review and revision every 5 years to reflect completed goals and objectives, new goals and objectives, new species and pathways, and management priorities
- c) Seek opportunities to leverage funds to fully support implementation of ANSTFapproved State and interstate ANS management plans
- d) Report on the number of State and interstate ANS management plans in place and under development
- e) Review guidelines for the preparation of State and interstate ANS management plans
- f) Annually summarize and report on State and interstate ANS management plan accomplishments and expenditures; utilize this information to compose a national assessment of ANS activity

*Objective 1.4: Coordinate the Development and Implementation of ANSTF- Approved Species Control and Management Plans and Pathway Management Plans*

- a) Encourage the development of pathway management plans
- b) Coordinate discussions on species and pathways for which plans may be needed; determine a lead entity for development of such plans
- c) Distribute ANSTF-approved species management and control plans to State, tribal agencies, and relevant stakeholders to encourage State and tribal-level action
- d) Monitor the development, evaluate the effectiveness of implementation, and report on the progress of ANS plan implementation
- e) Report annually on the progress of existing ANSTF-approved species control and management plans
- f) Support the implementation and long-term efforts of ANSTF approved plans

*Objective 1.5: Cooperate with Nations That Have Neighboring Waters and Shared Pathways with the United States to Prevent, Detect, and Control ANS*

- a) Broaden involvement with international ANS activities and organizations
- b) Continue and expand cooperation between ANSTF, Regional Panels, and foreign entities concerning the planning and implementation of prevention, monitoring, research, education, and control programs related to ANS that infest waters of the United States and neighboring nations

# **Goal 2: Prevention - Develop Strategies to Identify and Prevent the Establishment of New and Slow the Spread of Existing ANS in the Waters of the United States**

Prevention is the first line of defense against ANS. Once a species becomes established, control efforts require significant and sustained resources. Since eradication may not be feasible, prevention is the most cost-effective means to avert the risk of harmful introductions. Investment in prevention avoids many of the long-term economic, environmental, and social costs associated with ANS. New species can arrive through many different ways, but most species that are considered to be invasive are a direct result of human activity. The movement of ANS may utilize pathways including, but not limited to, ballast water and hulls of ships, canals and waterways, aquaculture, the aquarium and pet trade, the bait industry, recreational activities, biological research, and habitat restoration projects.

Long-term success in prevention will reduce the rate of introductions, the rate of establishment, and the damage from additional ANS. One example of this success can be found in the Great Lakes. Beginning in 1970, one invader on average was recorded every 8 months in this region<sup>22</sup>; in 2006 more stringent measures were taken to regulate ballast water discharges, and since that time no new invasive species attributed to ballast water release and transoceanic shipping in general have been reported in the Great Lakes<sup>23</sup>. Additional successes in prevention will require Federal agency support and cooperation with State agencies and private organizations. Implementation of preventative measures may require broadening legislative mandates, strengthening the capacity of some departments, and refining or consolidating legislative and regulatory tools. The actions suggested below

identify the most efficient way to reduce ANS risks by supporting authorities and programs that address intentional and unintentional introductions from all pathways. The joint ANSTF and NISC Prevention Committee via the Pathways Work Team has completed a report on major invasive species pathways (*Training and Implementation Guide for Pathway Definition, Risk Analysis and Risk Prioritization*) as well as a *Pathways Ranking Guide*. These documents will be used to guide ANSTF efforts in pathway management.

*Objective 2.1: Take Steps to Interdict Specific Pathways by Developing and Implementing Guidance and Appropriate Measures*

- a) Develop and implement risk mitigation measures to prevent introductions through priority pathways
- b) Evaluate risk mitigation measures to prevent introductions to ensure they are effective and environmentally sound
- c) Encourage State and Federal agencies to incorporate invasive species management into emergency response and contingency plans (e.g., wildfire management and spill response plans)
- d) Recommend amendments to the injurious wildlife provisions of the Lacey Act (18 U.S.C. § 42) to allow a proactive approach for preventing the establishment of new invasive species through the trade of live organisms
- e) Recommend amendments to legislation to ensure prevention of the establishment of nonnative aquatic plants though trade is addressed
- f) Encourage improved implementation and enforcement of the Lacey Act provisions on injurious wildlife and other regulations relevant to the transport, propagation, sale, collection, possession, importation, purchase, cultivation, distribution, and introduction of ANS

*Objective 2.2: Facilitate Use of Science-Based Risk Assessment and Screening Procedures to Assess and Prioritize Pathways for the Introduction of ANS or Potential Species of Concern*

- a) Identify authorities and regulations to carry out screening of specific pathways or species; recommend improvements based on identified gaps
- b) Support continued application of pathway ranking tools and related management guidance
- c) Develop and maintain a priority list for ANS pathways

*Objective 2.3: Expand Training and Use of the Hazard Analysis and Critical Control Point (HACCP) Program into Work Conducted by Natural Resource Managers*

# **Goal 3: Early Detection and Rapid Response - Identify and Respond to Aquatic Nuisance Species within a Timely Manner Following Introduction in Order to Prevent Their Establishment and/or Spread**

Despite the best preventive efforts, new ANS are certain to be introduced into waters of the United States. When a new species is introduced, the best strategy is early detection and rapid response (EDRR). This includes monitoring habitats to discover new species soon after introduction, reporting sightings of previously unknown species in an area, and working quickly to keep the species from becoming established and spreading. EDRR increases the likelihood that localized ANS populations will be found, contained, and eradicated before they become widely established. EDRR can slow range expansion of ANS, and avoid the need for costly long-term control efforts. Several States including Minnesota, Wisconsin, Indiana, and Virginia have successfully eradicated infestations preventing the establishment and spread of ANS. Moreover, novel approaches to enhance early detection, including genetics-based methods, are being actively developed. These methods have strong potential to improve the ability to identify likely invaders and susceptible habitats.

Providing fast access to information on taxonomy, control methods, and subject matter experts can allow new and existing ANS to be readily recognized and managed. EDRR must be supported with emergency funding and guided by contingency plans coordinated by Federal, State, and local agencies as well as other entities, including tribes and nongovernmental organizations. Goal 3 also supports several other needs: it evaluates prevention and control programs, provides information on invasion patterns and future management needs, and emphasizes the value of taxonomic expertise as an essential component of EDRR efforts. The actions suggested below identify environmentally sound methods that can prevent further spread and minimize harm to public interests. In addition to increasing ANS monitoring efforts, actions include the development of rapid response capabilities as well as research and education programs specifically related to the early detection of and rapid response to ANS.

#### *Objective 3.1: Facilitate Surveys and Monitoring to Detect ANS*

- a) Assess existing early detection monitoring programs; identify gaps and recommend improvements for a more integrated approach
- b) Develop model protocols for universal or common practices for early detection monitoring
- c) Work with agencies and organizations to incorporate invasive species monitoring into existing survey work
- d) Identify high-priority areas for targeted monitoring efforts; develop new early detection and surveillance programs as needed, including monitoring the impact of climate change on the distribution of ANS
- e) Further develop, refine, and support genetic and emerging tools based on novel approaches to improve early detection of ANS

### *Objective 3.2: Make Taxonomic and Ecological Information and Expertise Readily Available*

- a) Update the ANSTF Expert Database on a regular basis
- b) Identify gaps in available expertise
- c) Support establishment of new taxonomic expertise to identify native and exotic species

*Objective 3.3: Increase Public and Industry Involvement in Early Detection and Rapid Response Programs*

- a) Increase public volunteer training opportunities utilizing existing programs and infrastructure
- b) Promote use of the ANS National Hotline and USGS Online Reporting Form to report sightings of non-native species
- c) Develop additional tools to encourage reporting of suspicious sightings

#### *Objective 3.4: Facilitate Development of Rapid Response Contingency Plans*

- a) Review and make accessible existing model rapid response plans for aquatic invasions
- b) Support development of additional model rapid response plans for aquatic invasions based on both taxonomic groups and jurisdictional authority where invasion occurred
- c) Identify authorities and regulations to carry out emergency response actions
- d) Support implementation of the National Incident Management System (NIMS) to prevent, protect against, recover from, and mitigate the effects of ANS incidents as mandated by Homeland Security Presidential Directive (HSPD)-5<sup>24</sup>

### *Objective 3.5: Build Capacity to Respond Rapidly to Invasions*

- a) Synthesize lessons learned from previous rapid response attempts to new ANS invasions and make it readily available
- b) Make species-specific control and management information readily available
- c) Develop a rapid response technical support network that that can provide resources and technical support in response to newly detected species
- d) Increase training opportunities of the NIMS protocol
- e) Increase number of mock-NIMS based rapid response exercises to identify additional steps needed for rapid response preparedness
- f) Explore opportunities and identify obstacles for establishing an emergency rapid response fund

### **Goal 4: Control and Management - Control Established Aquatic Nuisance Species When Feasible and When the Benefits of Managing the Established Species Outweigh the Costs of Removing Them with Respect to Harm to the Environment, the Economy, and Public Health**

Once ANS are established, under most conditions complete eradication is usually not feasible. A more realistic approach for established populations is using control measures to slow the rate of range expansion and lessen the impacts to public interests. Management objectives may include eradication within an area, suppressing a population, limiting spread, and reducing impacts. Control measures may include mechanical, chemical, biological, and integrated pest management strategies. Adequate funding, public awareness, and management expertise are critical to success, particularly because ANS can span geographic and jurisdictional boundaries and do not recognize political boundaries or agency jurisdictions.

Therefore, Federal and State agencies, Indian tribes, and private organizations should coordinate an ecosystem-level approach to managing ANS.

Multiple control and management tools are needed to assess, remove, and contain ANS populations as well as to guide management decisions. The actions suggested below seek to identify, improve, and execute these tools. Further, the Strategic Plan actions require interjurisdictional communication and regionally coordinated action through the continued development and implementation of control and management plans.

*Objective 4.1: Support and Evaluate ANSTF-Approved Control and Management Plans*

- a) Identify gaps in control efforts and tools
- b) When warranted, develop or broaden existing control methods and programs to achieve the target level of control

*Objective 4.2: Increase Invasive Species Training for Natural Resource Managers and Leverage Participation*

- a) Increase the number of training workshops and total number of personnel and volunteers trained in control measures for ANS
- b) Review and, as needed, develop ANS training materials used by natural resource managers

*Objective 4.3: Evaluate the Benefits and Risks Associated with the Commercial Harvest of ANS as a Means of Control or Eradication*

- a) Develop guidelines to assist States and tribes in determining when commercial harvest may be beneficial for control of ANS
- b) Develop guidelines to assist States and tribes in developing policies for new or existing commercial harvest programs for ANS
- c) Encourage long-term monitoring and evaluation of commercial harvest activities

*Objective 4.4: Encourage an Integrated Pest Management (IPM)<sup>25</sup> Approach to Manage Existing ANS Populations*

### **Goal 5: Restoration – Protect and Rehabilitate Native Species and Ecosystems by Conducting Habitat Restoration Efforts on Multiple Scales**

Habitat restoration is an essential part of the control and management efforts used to guard against future invasions or to minimize harm to native ecological communities and other public interests. Restoration of the natural habitat should be addressed whenever the control or eradication of ANS is planned since habitat rehabilitation is often necessary to avoid the replacement of one invasive species with another, control flooding, or avoid other problems associated with the absence of biological organisms. Restoration activities may also include planting or stocking organisms or improving predator-prey relationships to attain food webs more similar to pre-invasion conditions. ANS can be transported by materials, equipment, vehicles, or personnel used to conduct restoration activities; accordingly all habitat restorations, even those not focused on ANS control, should call attention to actions

that prevent establishment of invaders not yet present within the project site. Restoration efforts should make use of plant and animal species that are native to the particular habitat. One of the benefits of using native species includes their ability to thrive under the local conditions while being less likely to invade new habitats. Consequently, native species reduce maintenance costs and produce healthy natural communities, thus providing a practical and ecologically valuable option for restoration projects.

The actions suggested below focus on ANS concerns during habitat restoration efforts by targeting consideration of potential ANS during planning and implementation of restoration activities and encouraging post-restoration monitoring to ensure that any ANS introduced as a result of restoration are responded to in a rapid and efficient manner.

### *Objective 5.1: Restore Impacted Ecosystems*

- a) Identify and support agencies or programs that can assist in restoring areas impacted by ANS
- b) Provide technical assistance on the species and methods to use in restoring native species, including means to enhance resilience against re-invasion, climate change, and other drivers of change
- c) Compile, highlight, and share lessons learned for both restoration successes and failures within the United States

### *Objective 5.2: Address and Provide Technical Assistance for Invasive Species Management before, during, and after Habitat Restoration Projects*

- a) Ensure that Federal land and water management field and guidance manuals consider ANS issues during the planning and development of habitat restoration projects
- b) Review and make accessible existing restoration project standards to mitigate impacts of ANS during restoration activities. Develop new guidelines when warranted
- c) Encourage application of adaptive management principles and assessment of treatment regimes to improve and sustain restoration efforts over time
- d) Encourage the development of Hazard Analysis and Critical Control Point (HACCP) plans for all federally funded or authorized restoration projects
- e) Support the development and expansion of markets that supply native plants and certified weed-free materials; encourage use of these materials by agencies and other organizations Encourage post-restoration monitoring for ANS by agencies and other organizations conducting habitat restoration or landscaping projects
- f) Encourage restoration of areas following ANS eradication or control efforts

# **Goal 6: Education and Outreach - Increase Awareness Concerning the Threats of Aquatic Nuisance Species, Emphasizing the Impacts, Importance of Prevention and Containment, and Recommendations for Appropriate Domestic and International Actions**

The lack of awareness concerning ANS impacts is one of the largest management obstacles. Few people understand the threat some nonindigenous species pose and how their

actions might introduce them. Many ANS have been introduced through the actions of uninformed people; for example, disposing of bait, launching a boat, or stocking a private pond can each lead to the introduction of ANS if precautions are not taken. Further, the importation of organisms through trade has allowed species to spread by the receipt of unwanted organisms that hitchhike with the intentionally imported ones. Many policy makers, natural resource administrators, and private interest groups have facilitated the intentional introductions of species for certain economic or recreational purposes without understanding the effects these species may have on native species. These intentional and unintentional methods of introduction can be eliminated or curtailed by educating people about their potential to transfer ANS into new habitats.

Robust public awareness and action programs will help the public understand the impacts associated with invasive species so they can be partners in solving the problems. More importantly, people need to know what they can do to help prevent the introduction and spread of ANS in waters of the United States. ANSTF agency and *ex-officio* members, Regional Panels, States, tribes, and other entities have conducted workshops, created exhibits, pamphlets, information sheets, wallet identification cards, videos, websites, traveling displays, and other public education materials for distribution across the country. In recent years, many States have focused efforts on educating non-English speaking communities about ANS issues in general, and in respect to their culture. The actions suggested below focus on continuing to develop, review, and disseminate information to the general public as well as targeted user groups and businesses that may be potential vectors of ANS. Support and collaboration are necessary at many levels among and between Federal and State agencies, local governments, tribal entities, public and non-public sectors to successfully address ANS. As such, the actions below also focus on education of ANS threats and solutions for legislators and other decision makers.

### *Objective 6.1: Increase Understanding Among the General Public of the Problems and Impacts Associated with ANS and Actions That Can Be Taken to Prevent and Control ANS in Waters of the United States*

- a) Promote and expand new and existing national campaigns (e.g., Stop Aquatic Hitchhikers and Habitattitude<sup>TM</sup>) with a proven track record of raising awareness and fostering behavior change among target audiences
- b) Utilize the internet and social media as well as traditional media sources to disseminate information and promote awareness of ANS
- c) Develop educational activities and products aimed at the general public regarding specific actions that can be taken to prevent, detect, and control ANS
- d) Cooperate with media outlets to reach a broad range of the public with ANS messages
- e) Participate in public affairs activities (e.g., conferences, shows, tournaments) to reach a broad range of the public with ANS messages
- f) Raise the level of understanding and expertise on ANS worldwide by encouraging technical information exchange with other countries
- g) Participate in international conferences and workshops

*Objective 6.2: Disseminate ANS Outreach and Technical Guidance Materials to Target Audiences*

- a) Identify and prioritize targeted user groups and businesses that may be potential vectors of ANS.
- b) Maintain and promote the ANSTF Recreational Guidelines
- c) Leverage opportunities with relevant user groups and businesses to ensure awareness of the threats of ANS and reduce the risk of spread via emerging pathways

*Objective 6.3: Promote the Use of Guidance Documents, Best Management Practices (Bmps)<sup>26</sup> , and Other Outreach Materials Related to ANS*

- a) Encourage ANSTF member agencies, Regional Panels, and other stakeholders to submit guidance documents, BMPs, and other outreach materials to the ANSTF for review and endorsement
- b) Identify gaps in outreach materials. Develop or update these materials when needed
- c) Utilize the ANSTF website as a clearinghouse for guidance documents, BMPs, and other outreach materials endorsed by ANSTF

*Objective 6.4: Promote Awareness of the ANSTF and Its Activities and Provide Educational Briefings on ANS Threats and Solutions and to Legislators and Other Decision Makers*

- a) Provide timely advice to the appropriate agencies concerning ANS that have been detected in waters of the United States, as well as waters of neighboring nations
- b) Provide educational briefings and materials to Federal, State, tribal legislators and their staff members
- c) Provide educational briefings and materials to Federal and State agency decision makers to build support for and incorporation of ANS programs into agency activities
- d) Participate in and assist NISC with the national expansion of National Invasive Species Awareness Week

# **Goal 7: Research - Facilitate Research to Address Environmental, Economic, and Human Health Risks and Impacts Associated with Aquatic Nuisance Species**

Information and research is needed to quantify and clarify the effects that ANS are having on native species and habitat as well as to socio-economics and human health. Although much research has been conducted for some aquatic invasive species, there are many species for which little is known. Increased knowledge of the biology, potential impacts, associated control methods, and interaction with climate change and other major drivers of change will allow for the most effective management of ANS. Research supports all facets of this Strategic Plan and is necessary to increase the effectiveness of prevention, detection, response, and control and management of invasive species. To help ensure that research addresses critical needs, the actions suggested below focus on coordination among Federal, State, and tribal governments; academia; and other participating entities. Economic research is also highlighted in this section. There is a lack of knowledge on a worldwide scale of the economic impacts of ANS. In many cases, it is the economic impacts that will be the driving force in effecting change in personal and business actions, management, and policy.

Many of the actions below encourage the continued development of risk analysis $27$  tools to characterize the likelihood and severity of potential ANS to the environment, the economy, and human health and the means and methods to manage identified risks<sup>28</sup>. Science-based risk analysis is needed to evaluate invasive species before they reach the jurisdiction of the United States and to prioritize appropriate responses once they do. Risk analysis requires a methodology that integrates environmental, economic, social, and human health considerations. The principal role of ANSTF will be to provide guidance to these institutions on research, monitoring, and risk analysis needs and to provide feedback to researchers on the effectiveness of the management tools they develop.

*Objective 7.1: Develop and Maintain a List of ANS Research Priorities; Communicate This List to the Scientific Community*

*Objective 7.2: Develop and Maintain Guidance Documents, Protocols, and Best Management Practices (BMPs) Related to ANS*

- a) Maintain and promote the Federal Aquatic Nuisance Species Research Risk Analysis Protocol<sup>29</sup>
- b) Evaluate effectiveness and identify gaps in guidance documents and BMPs. Develop or update these documents when needed

*Objective 7.3: Track the Progress of Research Activities Funded or Prioritized by the ANSTF*

- a) Utilize the research page on the ANSTF website as a clearinghouse for research activities funded or prioritized by the ANSTF
- b) Share information on Federal invasive species grant opportunities and programs by linking this information from agency web pages to the ANSTF website

*Objective 7.4: Support Development of Socio-Economic Research and Methods to Quantify the Economic Impact of ANS*

*Objective 7.5: Support Research on Interdiction Methods for Specific Pathways of ANS<sup>30</sup>*

- a) Facilitate the development of technologies and practices used for ballast water treatment and vessel hull fouling
- b) Support development and implementation of fully effective ANS barriers between the Mississippi River and Great Lakes Basin and other infested natural waterbodies

*Objective 7.6: Support Efforts to Identify Gaps and Expand Research Relevant to Control and Eradication Measures to Address ANS That Have Become Established in Waters of the United States*

*Objective 7.7: Encourage Research to Develop Species Invasion-Risk Forecast Tools*

- a) Develop and implement risk analyses and forecast models to evaluate invasiveness of high priority species, taking into account climate change and other drivers of change
- b) Improve data collection at ports of entry so numbers and identification of species entering the United States through commerce in living organisms are available and accessible
- c) Support development of a Risk Analysis Clearinghouse based on the outcome of species invasion-risk forecast analyses

*Objective 7.8: Support Existing Databases and Global Database Networks So National and Worldwide Decision-Support Information for Invasive Species Management Is Accessible, Transparent, and Accurate*

### **Goal 8: Funding - Coordinate Federal Agency Budgets to Support the Aquatic Nuisance Species Task Force's Priorities and Establish a Clear Process That Links State and Regional Needs in Their Areas of Responsibility**

The ANSTF operates within a limited budget to conduct semiannual meetings and provides a fraction of the support needed to achieve goals identified by the Regional Panels and ANSTF-approved management plans. It is the cornerstone of the ANSTF to provide resources that will allow the States, Regional Panels, and tribes to implement programs that reflect the goals within the Strategic Plan. The actions suggested below focus on obtaining dedicated, long-term funding for the ANSTF by developing partnerships, and seeking opportunities to leverage funds within State and Federal agencies, Indian tribes as well as public and private interests. The actions also encourage Federal agencies to continually review ANS priorities to find opportunities where agency authorities align with priority needs to create funding opportunities that can be met or communicated to the Office of Management and Budget.

*Objective 8.1: Secure Dedicated, Long-Term Funding for the ANSTF Strategic Plan Actions*

- a) Compose an annual report focused on ANS and use it as an opportunity to reach decision makers and other leaders on the need for proper policies and funding for ANS efforts
- b) Encourage Federal agencies to take ANSTF-approved Regional Panel recommendations into consideration as budgets are developed and to provide feedback
- c) Encourage Federal agencies to continually review regional priorities for opportunities where agency authorities align with priority needs in order to create funding opportunities that can either be met or communicated to the Office of Management and Budget
- d) Coordinate with NISC to ensure ANS priorities are recorded in the Interagency Invasive Species Performance Budget and communicated to the Office of Management and Budget
- e) Seek opportunities to leverage funds for ANS activities from Federal agencies and additional partners.

*Objective 8.2: Optimize Use of Current Funding for ANS Activities by Engaging Potential Resources and Programs Within Federal Agencies and Additional Partners*

### *Objective 8.3: Develop a List of ANS Funding Priorities*

- a) Prioritize actions based on anticipated efficacy, threat level, and costs / benefits to natural resources
- b) Annually assess the funding needs of the Regional Panels as well as species-specific and State ANS management plans

# **APPENDIX 1: LIST OF ACRONYMS**

# **END NOTES**

- <sup>1</sup> The term "vector" is continues to vary among agencies and organizations and is commonly confused with "pathway". The ANSTF defines a vector as the physical means or agent causing a species to translocate or spread (e.g. ship, car, waders).Pathway is defined as an activity or process through which a species may be transferred to a new location (e.g. shipping, animal trade, recreational activities).

- $17$  The term "waters of the United States" is defined by the Clean Water Act 40 CFR 230.3(s)
- <sup>18</sup> Federal agencies specified within the Act include the U.S. Fish and Wildlife Service, National Oceanic and Atmospheric Administration, Environmental Protection Agency, United States Coast Guard, Army Corps of Engineers, United States Department of Agriculture.
- <sup>19</sup> Organizations specified within the Act include the Great Lakes Commission, Lake Champlain Basin Program, Chesapeake Bay Program, and San Francisco Bay-Delta Estuary Program.
- <sup>20</sup> Two members co-represent the Native American Fish and Wildlife Society
- $21$  Section 1202(k) (2) of NANPCA, requires the ANSTF to submit, on an annual basis, a report to Congress focusing on progress in carrying out the provisions of the Act. Under the Act, the Regional Panels are required to submit an annual report to the ANSTF describing activities in their regions related to ANS prevention, research and control activities. Additionally, contracts for funding the panels require an annual report.
- <sup>22</sup> Ricciardi A. 2001. Facilitative interactions among aquatic invaders: is an "invasional meltdown" occurring in the Great Lakes? Can Canadian Journal of Fisheries and Aquatic Sciences 58: 2513–2525.
- <sup>23</sup> Bailey SA, Deneau MG, Jean L, Wiley CJ, Leung B, MacIsaac HJ. 2011. Evaluating efficacy of an environmental policy to prevent biological invasions. Environmental Science and Technology 45: 2554–2561.
- <sup>24</sup> Homeland Security Presidential Directive 5 (HSPD-5) required all Federal agencies and departments to adopt the National Incident Management System (NIMS) to coordinate emergency preparedness and incident management and response among the public and private sectors.
- <sup>25</sup> Integrated pest management (IPM) is a broad based ecological approach that utilizes a range of practices to maximize control of a species. In IPM, one attempts to prevent introduction, to observe patterns of spread, and control as necessary by the most economical means, and with the least possible hazard to people, property, and the environment.
- <sup>26</sup> The phrase "Best Management Practice" (BMP) was originally used in the U.S. Clean Water Act and associated Federal regulations to refer to procedures used for industrial wastewater control and stormwater management. Although the term was defined by the Environmental Protection Agency as a regulatory tool used to implement Federal wastewater permit regulations, it is now commonly used in the language of environmental management. The Aquatic Nuisance Species Task Force uses the term BMP in the Strategic and Operational Plans to describe any method or technique found to be the most effective and practical means in achieving an objective while making optimum use of resources.
- <sup>27</sup> The term "Risk analysis" in this document includes both risk assessment and risk management. Risk assessment measures the likelihood of an event occurring and the severity of negative impacts from such an event. Risk management is the process of identifying, evaluating, selecting, and implementing actions to reduce risk and includes more subjective elements including risk prioritization, risk tolerance, and associated decisions that weigh the benefits and costs of risk minimization options.
- <sup>28</sup> Additional information on ANS risk analysis methodology can be found within 1) National Research Council. 1983. Risk Assessment in the Federal Government: Managing the Process. National Academy Press, Washington DC. 2) National Research Council. 1993. Issues in Risk Assessment. National Academy Press, Washington DC. 3) Stern, P.C. and H.V. Fineberg (eds). 1996. Understanding Risk: Informing Decisions in a Democratic Society. National Academy Press, Washington DC. 4) National Research Council. 2009. Science and Decisions: Advancing Risk Assessment. National Academy Press, Washington DC.
- <sup>29</sup> The ANSTF developed a research protocol as is required by the Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990 (NANPCA, 101, 104 STAT. 4671, 16 U.S.C. 4701-4741), as amended by the National Invasive Species Act, 1996. Section 1202(f) (2) of NANPCA directs the ANSTF to establish a protocol "to ensure that research activities carried out under [NANPCA] do not result in the introduction of aquatic nuisance species to waters of the United States."
- <sup>30</sup> The action items listed for Objective 7.5 are included in this document as they are mandated by the Nonindigenous Aquatic Nuisance Prevention and Control Act (NANPCA). Additional actions taken to support this objective will be included in the ANSTF Operational Plan.

*Chapter 46*

# **A NEW LATE TRIASSIC (WAREPAN: MIDDLE TO LATE NORIAN) ORTHOCONIC NAUTILOID FROM NEW ZEALAND AND NEW CALEDONIA**

# *J. A. Grant-Mackie*

School of Environment, University of Auckland, Ponsonby, Auckland, New Zealand

# **ABSTRACT**

*Stipamonotis herangiae* n. gen. et sp. is described from the Murihiku Terrain, mainly the Kawhia Regional Syncline, New Zealand, and the Téremba Terrain of New Caledonia. It is a small, cylindrical, unornamented michelinoceratine, a rare accompaniment to the bivalve monotis ubiquitous in these rocks, ranging through all zones of the Warepan Stage (Middle to Late Norian) at the very end of the time-range of the Order Orthocerida.

The topmost, previously unnamed zone of the Warepan Stage is here named the Cotterallae Zone, characterised by the presence of the bivalve *Makoiamya cotterallae*  Grant-Mackie, 2013 and the absence of species of monotis. Its fauna includes the last members of the new species.

**Keywords**: orthocerida, *Stipamonotis herangiae* new genus and species, Late Triassic, Norian, Warepan Stage, New Zealand, New Caledonia

### **INTRODUCTION**

During fieldwork on the Kiritehere coast, southwest Auckland (Figure 1), I collected examples of a small orthoconic nautiloid not previously recorded in the fauna. I regarded it then (Grant-Mackie 1975) as related to the Timor Permian genus *Bitaunioceras* Shimizu & Obata, 1936 (v. also Campbell, in Spencer et al. 2009). The same taxon has since been found also in the South Island (Nelson) and New Caledonia (Figure 2) (Appendix 1). The purpose of

 $\overline{a}$ 

Corresponding Author's Email: grant-mackie@xtra.co.nz.

this chapter is to document its distribution in the Late Triassic (Warepan Stage of the local chronostratigraphic scheme - Figure 3) and describe the species.

Figure 1. Locality maps. A. outline map of New Zealand showing collection sites of *Stipamonotis* in the Nelson area and the location of Map 1B. B. map of the coast SW of the mouth of the Kiritehere River (after Grant-Mackie 1981).

Figure 2. Outline map of New Caledonia showing *Stipamonotis* collections sites.

Figure 3. Divisions of the Late Triassic Warepan Stage (after Grant-Mackie 2015, with the Warepan-Otapirian boundary age adjusted according to Raine et al. 2015, and the zonal scheme altered as herein).

Orthoconic nautiloids are important elements of Paleozoic molluscan faunas. They appeared in the Early Ordovician, reached their acme in the Devonian, and four genera survived the Permo-Triassic extinction event (Bizzarini & Gnoli 1991, Gradinaru & Sobolev 2007), before finally succumbing at about the Norian-Rhaetian boundary c. 208.5 million years ago (Raine et al. 2015), except for an unconfirmed record of an Early Cretaceous genus, *Zhuravlevia* Doguzhaeva, 1994 from the Caucasus (Fam. Geisonoceratidae, otherwise Middle Ordovician - Early Triassic) (shown also in Ponder & Lindberg 2008, Figure 8.7, p. 178).

Doguzhaeva (1994) also recorded the orthoconic genus *Trematoceras*, without documentation, as occurring in the New Zealand Triassic, but a literature search has not provided any evidence for this claim, unless the record by Trechmann (1918) of *Orthoceras*  sp. from the Southland Late Triassic was regarded as a *Trematoceras* by Doguzhaeva. Begg (1981) reported the presence of four species of *Michelinoceras* and one of *Orthoceras* from the Malakovian, Etalian and Oretian (Anisian-Early Norian) of the Wairaki Hills, Southland. None of these fits the generic characters outlined below for the Kiritehere material, the *Orthoceras* having a marginal siphuncle and the michelinocerids possessing episeptal or endosiphuncular deposits. Collections examined in GNS Science, Lower Hutt, included some 20 Triassic orthocone specimens (Etalian – Otapirian; Anisian-Rhaetian), some of which are of the coleoid *Aulacoceras.* Apart from determining that these are probably not congeneric with the Kiritehere specimens described herein, because of lacking any of their characteristic features, they are not further considered here.

### **SYSTEMATICS**

Orthocerids have been subject to many classification schemes (v, e.g., Zakharov 1996) and that followed here is from Sweet (in Teichert et al. 1964) who also emphasised that any scheme of suprageneric classification of this group must so far be suspect and highly provisional because of the rarity of complete specimens and the inadequate state of current knowledge concerning their relationships.

The classification advocated by Zakharov (1996) has two subclasses of cephalopod, Nautilomorphi (or Nautiloda) and Coleoidea, with Superorder Pseudorthoceratoidea in the former, with a large embryonic shell, and Michelinoceratoidea in the latter, with a small embryonic shell. Both have a central or subcentral siphuncle; the Pseudorthoceratoidea possess various types of intracameral deposits and range Ordovician-Triassic whereas the Michelinoceratoidea are Paleozoic only.

This classification is radically different from that of the Treatise (Sweet 1964), and means that previously-identified '*Orthoceras'* sp. and *'Michelinoceras'* sp. are divided between two subclasses, calling for a more careful assessment of material before generic assignment. Furthermore, cephalopod classification probably continues in a fluid state and further changes are likely to be proposed. The more traditional/conservative scheme used in the Treatise (Sweet 1964) is for this reason followed here.

Class Cephalopoda Cuvier, 1798 Subclass Nautiloidea Agassiz, 1847 Order Orthocerida Kuhn, 1940 Superfamily Orthocerataceae M'Coy, 1844 Family Orthoceratidae M'Coy, 1844 Subfamily Michelinoceratinae Flower, 1945

*Michelinoceras* Foerste, 1932, (type *Orthoceras michelini* Barrande, 1966) is the most abundant and widespread of the Triassic orthoceratids and includes long slender nearly cylindrical orthocones with circular cross section, long camerae, central or nearly central siphuncles free of organic deposits, straight septal necks, thin cylindrical connecting rings, and well developed hyposeptal and episeptal cameral deposits (Sweet 1964).

#### **Genus** *Stipamonotis* **Grant-Mackie, n. gen.**

#### *Type*

S*tipamonotis herangiae* Grant-Mackie, n. gen. et sp., Late Warepan Stage (Late Norian), Late Triassic, New Zealand, New Caledonia.

#### *Derivation of Name*

Latin 'stipare', to accompany, emphasising the association of these orthocones with the abundant co-occurring pterioid bivalves, collectively monotis (see Grant-Mackie 2015).

#### *Diagnosis*

Unornamented longiconic michelinoceratine with straight transverse sutures, long chambers, centrally located orthochoanitic siphuncle with no endosiphuncular deposits, and episeptal and mural cameral deposits taking campanulate form.

#### *Comments*

In terms of Zakharov's (1996) scheme, the new genus would belong to the Superorder Pseudorthoceratoidea Barskov, 1963, Order Pseudorthocerida Barskov, 1963, and probably Family Trematoceratidae Zakharov, 1996. Unfortunately, specimens to hand do not include early ontogenetic structures, so that differences between Pseudoceratoidea and Michelinoceratoidea are not preserved, but the age strongly suggests location in the former superfamily if that classification were to be preferred.

The type species of *Stipamonotis* is known only from conch fragments of up to 11 chambers with no indication of curvature, and the juvenile portion of the phragmocone is unknown. The other common Triassic michelinoceratine, *Trematoceras* Eichwald, 1851 (type *Orthoceras elegans* Münster, 1841), and the only other genus known in the Late Triassic, possesses mural and episeptal deposits within the camerae but the latter produce stellate or petaloid impressions on internal molds of septal faces, and none was seen in specimens of the new material. In addition, some species show significant taper of the phragmocone and others possess annular ridges. Of the other genera included in this subfamily none possesses the combination of characters seen in the new genus, and most have a middle Paleozoic (Ordovician-Devonian) range. The other Triassic orthoceroid genera, *Paratrematoceras* Schastlivtseva, 1981, *Pseudotemperoceras* Schastlivtseva, 1986 and *Romanorthoceras* Gradinaru & Sobolev, 2007, are so far all of Early to Middle Triassic age (Schastlivtseva 1988, Gradinaru & Sobolev 2007, Sobolev & Gradinaru 2008); none of the three possesses any cameral deposits, *Pseudotemperoceras* also shows a much more distinct taper of the phragmocone and swelling of the siphuncle tube between septa, and *Romanorthoceras* (so far not fully described) possesses shorter camerae and is a faintly curved brevicone.

### *Stipamonotis herangiae* **Grant-Mackie, n. sp. (Figure 4)**

1975. aff. *Bitaunioceras* sp. Grant-Mackie: un-numbered page in Table 2.1., Vol. 2. 2009. aff. *Bitaunioceras* sp., Campbell, in Spencer et al., in Gordon (ed.): p. 224.

#### *Derivation of Name*

To honour the late well-known and highly respected Princess Te Puea Herangi, a past leader of the Tainui people of the Waikato, whose wider influence extended to the type area of Kiritehere. In addition, the rarity of *Stipamonotis* is complementary with the widely held opinion that Princess Te Puea was a leader of notably rare quality.

#### *Holotype*

C871, partial phragmocone of eight chambers in longitudinal section, showing siphuncle tube and cameral deposits, from collection AU1421, R16/f8625, Arawi Shellbed, cliff and shore platform, 310 m west of southern end of Kiritehere Beach; JAG-M, DCL, 1/61.

#### *Paratypes*

C 2137, AU11038; C2138, AU11940; C2139, AU12062; C2140, AU12085; C2141, AU12285; all from the Kiritehere area, southwest Auckland, in the Kawhia Regional Syncline, Murihiku Terrain; and C2136, AU7201 from the Téremba Terrain, New Caledonia (v. Appendix 1).

#### *Additional Material*

The new species is represented by 14 additional specimens from Kiritehere localities, and one or two specimens at each of two sites in the Nelson Regional Syncline, Murihiku Terrain, and three on Ile Ducos, Baie de St-Vincent, Téremba Terrain, New Caledonia (all listed in Appendix 1). It has not been recorded from the Southland Regional Syncline of the Murihiku Terrain.

#### *Diagnosis*

Unornamented michelinoceratine longicones of small diameter, with straight transverse sutures, long chambers, centrally located orthochoanitic siphuncle lacking endosiphuncular deposits, and mural and episeptal cameral deposits that become campanulate in shape.

#### *Description*

Known so far only from conch fragments with no certain apical or apertural portions preserved and unornamented exterior. Fragments up to 46 mm long, straight, longiconic, subcylindrical; up to 17 mm diameter (range from 3.3 mm), with subcentral orthochoanitic siphuncle  $\sim 0.1$ -0.12 mm diameter, lacking siphuncular deposits; sutures straight, transverse; chambers relatively long (range 3.1-6.3 mm), generally longer than conch diameter at that stage. Cameral deposits generally obscure due to recrystallisation but better preserved specimens (e.g., Figure 4C) show variation in form according to location along conch, with youngest having no deposits and oldest with episeptal and mural deposits which are bellshaped, mouth of 'bell' being adoral in position; intermediate camerae with deposits thinner than but generally conforming to shape of those of oldest camerae; constriction of bell shape

'behind' mouth of bell located slightly behind mid-height of each chamber. Body chamber not certainly known; no fragment shows evidence of conch curvature. Juvenile portion of shell seems to have been shed in at least some specimens (Figure 4A, B, C, E): earliest septum of holotype (a in Figure 4C) evenly curved, with no indication of septal neck, with septum discontinuous in siphuncular region and with cameral deposits continuous across (these features lost during specimen preparation); next-youngest septum (b in Figure 4C) clearly showed short backwardly-directed septal neck (as thin black lines continuous from septum, now also largely lost in preparation). Two oldest septa very thin, represented by curved black lines; septum no. 3 (c in Figure 4C) twice to 3X thickness of first two (perhaps due to incipient separation along this septum); septa d-f like first two.

### *Comments*

The new species is characterised by its long unornamented cylindrical form, circular section, subcentral empty siphuncle tube, in the campanulate form of its cameral deposits, and in the apparent shedding of the juvenile shell. Although no specimen certainly shows the body chamber, it may be at least partially preserved in one specimen (C2137 - Figure 4D) with a sediment-filled terminal chamber  $\sim$  8mm long which may represent part of the body chamber.

 $L =$  overall length of preserved phragmocone, D. max = maximum diameter of fragment, D. apic = diameter of adapical end of fragment, No. cham = number of preserved chambers, L. cham = length of longest chamber, D. siph = external diameter of siphuncle. In addition to those specimens listed here there are four more in AU8367, with L varying between 19.1 and 21.1 mm and D. max. varying between 4.6 and 17.0 mm. but with no other dimensions obtainable.

Specimen C2141 (Figure 4B) is the only one to show obvious taper, from 4.2 mm to 7.0 mm over 42 mm length. Shorter fragments show less obvious taper.

Figure 4(A-I). *Stipamonotis herangiae* n. gen. et sp. All images are X 4, except D, which is X 2. (A) paratype C2140, AU12085, Arawi Shellbed; cut section. (B) paratype C2141, AU12285, Arawi Shellbed; external view. (C) holotype C871, AU1421, Arawi Shellbed; longitudinal section, with septa (a-f) and camerae (I-VII) indicated. (D) paratype C2137, AU 11038, Arawi Shellbed; longitudinal section of bent or broken phragmocone, X 2. (E) paratype C2136, AU7201, Leprédour Shellbed; natural longitudinal section of partial phragmocone. (F) paratype C2141, AU12285, Arawi Shellbed; cast of oldest preserved septum. (G) paratype C2138, AU11940, Arawi Shellbed; partial external longitudinal view. (H) paratype C2138, AU11940, Arawi Shellbed; partial view of fragments of earliest preserved septum (x) and partial cast of remainder. (I) paratype C2139, AU12062, Arawi Shellbed; partial phragmocone showing both external and broken internal views.

The likelihood of the early-formed portion of the phragmocone being dehisced is seen also, with enough specimens showing features suggestive of moulting of the juvenile shell comparable to those described above for the holotype, so it may have been a common event in this species, occurring so as to improve mobility.

Cameral deposits in the holotype specimen vary along the conch in the following way: the first-formed three chambers of the type specimen (I-III in Figure 4C) seem wholly or mainly filled with cameral deposits. In subsequent chambers episeptal and mural deposits are apparent but do not completely fill them; in chambers IV and V internal spaces lacking cameral deposits are filled with sediment between the episeptal deposit and the succeeding septum and each set of deposits has a rounded base conforming to the curvature of the adapical septum, and the abapical septum is about half covered by cameral deposit. In camerae VI and VII cameral deposits are thinner but generally similar in form to those in IV and V. Deposits in the last-formed chamber are less well exposed or preserved but similar to those of VI. Chamber VII is the last-formed amongst those present and, although also poorly preserved, shows deposits similar to those in VI. Other specimens also show aspects of the above features, but less complete and less well preserved than in the type (e.g., C2136, C2137 - Figure 4D, E) but most are thoroughly recrystallized. C2136 shows banding of the cameral deposits indicative of depositional layering (Figure 4E), probably of post-mortem origin.

Species of *Trematoceras* show, inter alia, star- or petal-shaped impressions radiating across the septal surfaces from the septal foramen (Sweet 1964), a feature difficult to see in most specimens but clearly absent from two specimens of the new species (C2138 and C2141 - Figure 4F, H). This emphasises again that this genus seems to be absent from New Zealand Triassic faunas, despite Doguzhaeva's (1994) claim.

Initial superficial study suggested a relationship with *Bitaunioceras* Shimizu & Obata (Grant-Mackie 1975, Campbell 2009), but while this Permian genus does have a cylindrical form, straight transverse sutures and a subcentral siphuncle, it also possesses transverse constrictions and lirae on the phragmocone, both lacking in *Stipamonotis.* 

Presently the genus is monotypic. No other Triassic orthocones seen in either GNS Science or University of Auckland collections can be associated with *S. herangiae* n. sp. In particular, most display no cameral deposits, but in addition some have a significantly larger diameter than in that species and/or are of a different age. *Michelinoceras* sp. B (Begg 1981, unnumbered Figure, p. 180) has hyposeptal deposits and other cameral deposits are of a different form from that in *Stipamonotis.* Begg's *Michelinoceras* sp. A (1981, pl. 4, Figure b) has mural and episeptal deposits not comparable with those of the new genus. The coleoid *Prographularia otapiriensis* (Hector), which occurs close by in adjacent Otapirian strata, is also orthoconic but the guard is more strongly tapered and has longitudinal ridges and grooves.

#### *Associated Biota*

As the generic name emphasises, the new species is found generally as rare specimens in the monotis beds (v. Appendix 1). It accompanies *Eomonotis rauparaha* (Grant-Mackie)*, E. kiritehereensis* (Grant-Mackie)*, E. marwicki* (Grant-Mackie)*, E. murihikuensis* (Grant-Mackie), *Entomonotis richmondiana* (Zittel), *E. acutecostata* (Trechmann), *Pacimonotis discordans* (Grant-Mackie), *Maorimonotis maniapotoi* (Grant-Mackie), *M. routhieri* (Avias), *M. calvata* (Marwick). There are in addition a variety of other bivalves, diverse but rare brachiopods and occasional cephalopods, etc. (v. Appendix 1).

*Age*

All occurrences of *Stipamonotis herangiae* so far known are in Warepan strata. Grant-Mackie (1986) has provided a detailed correlation and biostratigraphic subdivision of strata of this age (Figure 3). N28/f7472 in part comes from the Rauparaha Zone at the base of the Warepan, NC/f051, NC/f524 and NC/f546 from the Murihikuensis Zone, N28/f7472 (part) and N28/f7868 from the Acutecostata Zone, R16/f8625, R16/f8726 and R16/f8748 from the Richmondiana Zone, and R16/f8528 from the Calvata Zone. It has thus been recorded in all monotis zones, and the occurrence in R16/f8723 is believed to belong to the Cotterallae zone, pre-Otapirian but lacking monotis, on the grounds that a few of the other packets in the Kiritehere slump (Grant-Mackie & Lowry 1964) were also judged to be from that zone. The time-range of the new taxon is thus the full Warepan Stage.

In 1986 I (Grant-Mackie 1986) proposed subdivision of the Warepan Stage into zones based on their varying content of monotis species. The topmost zone was left un-named, lacking monotis and Otapirian species. With the description of *Makoiamya cotterallae*  (Grant-Mackie 2013) we now have a species that can be used to characterise this part of Norian time, so I here define the Cotterallae Zone as that part of Warepan and Marokopan time lacking species of monotis and any indicators of the Otapirian Stage and chacterised by the presence *inter alia* of the bivalve *Makoiamya cotterallae* Grant-Mackie (Figure 3).

#### **ACKNOWLEDGMENTS**

D. Hikuroa, Nga Pae o te Maramatanga, University of Auckland, provided valuable advice on the derivation of the new names herein. DAB MacFarlan, New Plymouth, assisted with a computer search, John Simes and John Begg, GNS Science, Lower Hutt, assisted with locality data and publication references, and Andres Arcilla and Louise Cotterall, both of the School of Environment, University of Auckland, assisted respectively with specimen preparation and illustrations. ES Sobolev, AA Trofimuk Institute of Petroleum Geology & Geophysics, Novosibirsk, generously provided figures and data concerning the incompletely formalised genus *Romanorthoceras.* My wife, Diana, thankfully was able to assist me when I needed some coaching in computer technology.

### **APPENDIX 1**

Locality data for specimens of *Stipamonotis herangiae* n. gen. et sp. Full data are given in the first entry and indicators are omitted in subsequent entries, with the same order being preserved for all entries. Collectors, including the author, are shown by their initials ( $DCL =$ DC Lowry,  $FH = F$  Hasibuan,  $HJC = HJ$  Campbell,  $JAB = JA$  Bartrum,  $LX = Li X-C$ ,  $MM =$ M Manceñido,  $SD = S$  Damborenea,  $YJ = Yu J-S$ ,  $ZW = Zhang W-P$ ; the usual initials are used for compass points;  $Bw = W$ arepan Stage.

## **ABSTRACT**

Chemoreception is crucial to marine scavengers in food acquisition. The combined effect of salinity (10 psu, 30 psu) and ocean acidification (380 μatm, 950 μatm and 1250 μatm) on food detection at three foraging distances (20 cm, 40 cm and 60 cm) was studied in a marine scavenging gastropod *Nassarius festivus* over an exposure period of seven days. Time and percentage of individuals reaching the bait (excised clams) were recorded. Lower salinity increased food searching time at all distances away from the bait on both Day 1 and Day 7. Higher pCO<sub>2</sub> levels increased food searching time at 20 cm and 60 cm on Day 1, but 40 cm and 60 cm on Day 7. The interactive effect between  $pCO<sub>2</sub>$ and salinity was only significant on Day 1 at 20 cm. Lower salinity reduced percentage of individuals engaged in foraging at all distances away from the bait on both Day 1 and Day 7. The effect of  $pCO<sub>2</sub>$  was significant at 60 cm on Day 1, but at all distances on Day 7. The interactive effect between  $pCO<sub>2</sub>$  and salinity was only significant on Day 1 at 20 cm. In conclusion, food detection ability was negatively affected by low salinity and high  $pCO<sub>2</sub>$  with the inhibitory effect of  $pCO<sub>2</sub>$  being stronger as the time of exposure increased.

#### **INTRODUCTION**

Animal behaviour is complicated and generally includes how organisms search for food, store their food resources, exhibit aggression and defense, protect their territories, locate their mating partners, etc. All these kinds of behaviour are adaptations to a variable environment and shaped by evolution (Tuomainen and Candolin, 2011). Since behaviour mediates interactions between an individual and the environment, the ability of an organism to respond appropriately under new conditions is crucial for determining their immediate success or failure in the face of environmental changes.

Recent studies have shown that animal behaviour is affected by low oceanic pH that is predicted to occur in the future with sensory impairment such as auditory and olfactory functions. These disturbances eventually lead to problems in decision making. For example, the ability to respond to olfactory cues has been lost in clownfish for navigation (Mundy et al., 2009) and predator detection (Dixson et al., 2010; Ferrari et al., 2011). Munday (2010) also found that the larvae of damselfish *Pomacentris wardi*, when exposed to 850 μatm pCO2, seem to have lost the ability to differentiate predators and showed 5-9 times higher mortality than the control group without predators. Similar results were reported by Ferrari et al. (2011) regarding the coral reef fish *Pomacentris chrysurus* around 1000  $\mu$ atm pCO<sub>2</sub>. High pCO<sub>2</sub> levels could harm the auditory sense of marine fish (Simpson et al., 2011) and induce the lateralization capacity (Domenici et al., 2012). Ocean acidification could also impair the visual recognition and risk assessment. For example, anti-predation responses to the spiny chromis damselfish *Acanthochromis polyacanthus* were observed in juveniles of the Ambon damselfish *Pomacentrus amboinensis* upon exposure to 440 – 700 μatm pCO2; this ability, however, was lost when the  $pCO<sub>2</sub>$  level increased to 850  $\mu$ atm (Ferrari et al., 2012).

Food detection is crucial to animals' survival and success. This is particularly true for scavengers owing to sporadic food supply and intense competition (Morton and Yuen, 2000). Better food detection ability not only allows individuals to have access to carrion earlier, but they can also enjoy its most nutritious part. For example, marine gastropod *N. festivus* would choose soft tissues that are of higher energy content (Cheung et al., 2006). In a marine scavenging community, ocean acidification can be a selective force, as responses to ocean acidification are species-specific. Even closely related species may respond differently to acidification (Dupont et al., 2010; Logan, 2010). More sensitive species with greater impairment of chemosensory functions will be less competitive and eventually outcompeted by less sensitive ones.

Salinity has a significant effect on marine animals as they can only survive within a salinity range which is species-specific and life stage-specific (Willmer et al., 2000). Reduced salinity, in particular, affects ion and acid-base regulation and modifies responses to ocean acidification (Dickinson et al., 2012). While Dickinson et al. (2013) showed that moderate hypercapnia increased the shell and tissue growth of the hard shell clam, *Mercenaria mercenaria*, low salinity tended to abolish such growth response. The synergistic effect of salinity and ocean acidification was found in the eastern oyster, *Crassostrea virginica,* with lower salinity weakening the shell and enhancing oxygen consumption under high  $pCO<sub>2</sub>$ (Dickinson et al., 2012). In addition, the larval mortality of nassariid gastropods *Nassarius festivus* and *N. conoidalis* was greatly affected by high pCO<sub>2</sub> level (1250 μatm) when salinity was reduced from 30 psu to 10 psu (Zhang et al. 2014). Ko (2013) observed that the early

growth phase from hatching to the 5-day-old veliger stage of the Portuguese oyster, *Crassostrea angulata* showed high tolerance to pH 7.6 at 27 psu, but the larval shell area was significantly smaller at pH 7.4 when the salinity was reduced to 24 psu. Although low salinity (10 psu) reduced the scope for growth in *N. festivus* at elevated  $pCO<sub>2</sub>$  levels for 31 days, elevated *p*CO<sub>2</sub> levels had no effects in isolation on all other physiological parameters and only weak interactions with salinity for excretion and scope for growth (Zhang et el., 2016).

*Nassarius festivus* is the most competitive scavenger on the sandy shores of subtropical Hong Kong (Morton and Yuen, 2000). Its success relies on its excellent chemoreception, rapid feeding rate, and high tolerance to environmental stresses including starvation, temperature, salinity, and hypoxia. According to Cheung (1997), the salinity tolerance of *N. festivus* ranged from 15 psu to 35 psu. Morton and Yuen (2000) also showed that *N. festivus* is able to detect and move fast towards carrion from a distance of  $> 80$  cm in laboratory conditions. In this study, the foraging behaviour of *N. festivus* was investigated upon exposure to the combined effects of ocean acidification and low salinity.

#### **MATERIALS AND METHODS**

#### **Study Organisms**

*Nassarius festivus* (shell length 13 – 15 mm) were collected from Starfish Bay (22º48′N, 114º24′E), Hong Kong, in July 2014 and acclimated to laboratory conditions for two weeks before experimentation (temperature: 24°C, salinity: 30 psu, light-dark cycle: 12 hours: 12 hours). Excised clams *Ruditapes philippinarum* were offered as food twice a week at intervals of three to four days (Cheung, 1994), and seawater was changed immediately after feeding to avoid waste accumulation.

#### **Experimental Setup**

A full factorial experiment ( $3 \times 2$ ) with three pCO<sub>2</sub> levels (low: 380 µatm, medium: 950 μatm, and high: 1250 μatm) and two salinities (low: 10 psu, high: 30 psu) was set up, i.e., six treatments with different combinations of  $pCO<sub>2</sub>$  level and salinity. 10 psu represents the lowest salinity *N. festivus* experiences in summer due to rainfall, and 30 psu is the normal salinity in Hong Kong waters (Environmental Protection Department, 2012). Since carbon chemistry conditions vary with space and time, for experiments to be ecologically relevant, local scenarios should be taken into account (McElhany and Busch, 2013). The  $pCO<sub>2</sub>$  level of 380 μatm (LC) was the estimated current global level, while 950 μatm (MC) and 1250 μatm (HC) are the respective predicted levels for the years 2100 and 2300 according to the IPCC (Intergovernmental Panel on Climate Change, PCR8.5 scenario, Collins *et al*., 2013). Although a large fluctuation in pH is commonly observed on sandy shores, the pH levels *N. festivus* exposed to in this experiment (7.25 – 8.26) were beyond the range experienced in the field. According to Hong Kong government's report, the sampling site's pH varied between 7.75 and 9.00 (Environmental Protection Department, 2012), while pH values below 7.50 were recorded only 3 times in the last 17 years (1986 - 2013). Various  $CO<sub>2</sub>$  partial pressures were prepared by mixing air and industrial  $CO<sub>2</sub>$  gas (with a purity of 99.5%, Hong Kong Oxygen & Acetylene) at certain ratios (Findlay et al., 2008). Gases, well-regulated by digital flow meters (GCR-B9SA-BA15, Vogtlin, Sweden), were mixed in sealed bottles containing water, and then dried in conical flasks with silica gel balls. The gas mixture was bubbled into different treatments accordingly (Zhang et al., 2015). The control group was bubbled with ambient air only, while its temperature was kept at 24°C, with salinity at 30 psu. A carbon dioxide online analyzer (LI-260, Li-Cor Company, Switzerland) was used to measure the real time  $pCO<sub>2</sub>$  levels. Temperature, pH (NBS scale),  $pCO<sub>2</sub>$ , and salinity were recorded on a daily basis. The software CO2SYS (Stumpp et al., 2011) was used to calculate the saturation state of calcite ( $ΩCa$ ) and aragonite ( $ΩAr$ ), total alkalinity (At), and the relationship between these parameters. Total alkalinity was also double checked every week using an alkalinity titrator (HANNA, HI 84431, Germany). Table 1 shows the environmental parameters of the 6 treatments.

#### **Food Detection Experiment**

Each treatment had three replicates, with 120 individuals of *N. festivus* randomly assigned to each replicate. As  $pCO<sub>2</sub>$  has only a short-term effect on the ingestion rate and scope for growth in *N. festivus* (Zhang et al., 2016), therefore, the experiment lasted 7 days. The food detection experiment was conducted in a plastic swimming pool with a radius of 60 cm. Individuals were arranged in a circle at three distances (20, 40, and 60 cm) away from the bait (an excised short-necked clam *Ruditapes philippinarum*) at the centre of the pool. To achieve similar density at different distances, 20, 40, and 60 individuals were placed at 20 cm, 40 cm, and 60 cm, respectively.

The experiment was performed three times with different durations: 2 hours (acute exposure), 1 day, and 7 days. The hunger level was standardized by offering food every 3 days. For instance, in the acute exposure experiment (2 hours of exposure) gastropods were fed on Day 1. They were then exposed to the experimental conditions on Day 4, and food detection was studied 2 hours after exposure.

A video camera was set up above the swimming pool to record gastropod activities. The number of individuals foraging and the time each individual spent searching for food were recorded. Individuals that did not reach the bait within 60 minutes were identified as nonfeeding and were not included in the analysis. A plastic sheet was used to cover the swimming pool to ensure there was no gaseous exchange between the experimental setup and outside. An air tube was used to supply the desired concentration of  $CO<sub>2</sub>$  to each treatment. Salinity, pH, and temperature were kept constant during the experiment.

#### **STATISTICAL ANALYSIS**

Two-way ANOVA was performed with distance from bait and time of exposure to  $pCO<sub>2</sub>$ as fixed factors. When there was an interaction between the two factors, the effects of salinity and  $pCO<sub>2</sub>$  were analyzed separately at each level of the other factor by one-way ANOVA, followed by the multiple comparison Tukey test. For percentage of individuals engaged in feeding, percentage data were arcsine-transformed before the analysis. Normality and equal variance of the data were checked using Shapiro–Wilk and Hartley tests separately before ANOVA tests were conducted. All statistical analyses were performed using statistical software SPSS 20.0.

#### **RESULTS**

#### **Food Detection Time**

At 20 cm from the bait, no individuals of *N. festivus* exposed to 10 psu approached the bait after 2 hours of exposure, irrespective of  $pCO<sub>2</sub>$  level and distance from the bait (Figure 1). In contrast, food detection time increased significantly with  $pCO<sub>2</sub>$  ( $p < 0.01$ ) at 30 psu. After one day of exposure, food detection time varied significantly with salinity ( $F = 156.40$ ,  $df = 1$ ,  $p < 0.001$ ),  $pCO<sub>2</sub>$  (F = 8.78, df = 2,  $p < 0.01$ ), and the interaction between salinity and  $pCO<sub>2</sub>$  (F = 4.25, df = 2, p < 0.05) with the food detection time increased at lower salinity and higher pCO<sub>2</sub> (Table 2). On Day 7, the effect of elevated pCO<sub>2</sub> became insignificant (F = 3.31,  $df = 2$ ,  $p = 0.07$ ) but a longer detection time was observed at 10 psu (F = 104.90, df = 1, p < 0.001) (Figure 1). There was no interaction between  $pCO<sub>2</sub>$  and salinity (F = 1.88, df = 2, p = 0.20).

#### **Table 2. Results of the pairwise Tukey's test of food detection time at 20 cm away from the bait after 1 day of exposure to the combined effect of salinity and ocean acidification. Values in the same row with different letter designations indicate**  that they are statistically significant  $(p < 0.05)$

**1 0** effects of pCO<sup>2</sup> (380 μatm, 950 μatm, and 1250 μatm) and salinity (10 psu and 30 psu) at a distance of Figure 1. *N. festivus.* Food detection time after 2 hours, 1 day, and 7 days of exposure to the combined 20 cm from the bait.

after 2 hours of exposure, whereas at 30 psu elevated pCO<sub>2</sub> levels had no effect on the food **0** At 40 cm from the bait, no *N. festivus* individuals exposed to 10 psu approached the bait detection time ( $p = 0.052$ ). Food detection time increased at the lower salinity on both Day 1 and Day 7 (Figure 2) (Day 1: F = 71.48, df = 1, p < 0.001; Day 7: F = 34.11, df = 1, p < 0.001) but an increase in food detection time at higher  $pCO<sub>2</sub>$  was only observed on Day 7 (Day 1: F = 3.61, df = 2, p 0.06; Day 7: F = 22.34, df = 2, p < 0.001) with that at 1250  $\mu$ atm being significantly longer than that at 380  $\mu$ atm (F = 6.54, df = 2, p < 0.01).

At 60 cm from the bait, no individuals exposed to 10 psu approached the bait after they were exposed to the experimental conditions for 2 hours, whereas at 30 psu, elevated  $pCO<sub>2</sub>$ levels had no effect on the food detection time ( $p = 0.428$ ). On both Day 1 and Day 7, food detection time increased at both the lower salinity (Day 1:  $F = 37.16$ , df = 1, p < 0.001; Day 7: F = 29.85, df = 1, p < 0.001) and higher pCO<sub>2</sub> (Day 1: F = 8.35, df = 2, p < 0.005; Day 7: F  $= 13.21$ , df  $= 2$ , p  $< 0.001$ ) but there was no interactive effect between salinity and pCO<sub>2</sub> (Day 1:  $F = 1.62$ ,  $df = 2$ ,  $p = 0.24$ ; Day 7:  $F = 0.65$ ,  $df = 2$ ,  $p = 0.54$ ) (Figure 3). The food detection time at 1250 μatm was significantly longer than that at 380 μatm on both Day 1 ( $F = 2.39$ , df  $= 2$ , p < 0.05) and Day 7 (F = 4.39, df = 2, p < 0.05).

Figure 2. *N. festivus.* Food detection time after 2 hours, 1 day, and 7 days of exposure to the combined effects of  $pCO<sub>2</sub>$  (380 µatm, 950 µatm, and 1250 µatm) and salinity (10 psu and 30 psu) at a distance of 40 cm from the bait.

#### **Percentage of Individuals Engaged in Foraging**

Individuals exposed to 10 psu for 2 hours did not engage in foraging irrespective of distance from the bait, so only data from 30 psu were analyzed. The level of  $pCO<sub>2</sub>$  had no effect on the percentage of individuals engaged in foraging after they were exposed to the experimental conditions for 2 hours.

At 20 cm from the bait, both salinity ( $F = 488.00$ , df = 1, p < 0.001) and pCO<sub>2</sub>-salinity interaction (F = 4.74, df = 2,  $p < 0.05$ ) had significant effects on foraging after 1 day of exposure, with a much lower percentage of individuals engaged in feeding under 10 psu and/or at elevated pCO<sub>2</sub> levels (Table 3). After 7 days of exposure, lower pCO<sub>2</sub> (F = 8.93, df  $= 2$ ,  $p < 0.005$ ) or salinity (F = 424.90, df = 1,  $p < 0.001$ ) significantly reduced the percentage of individuals engaged in foraging, but there was no interaction between  $pCO<sub>2</sub>$  and salinity (F  $= 0.93$ , df  $= 2$ , p  $= 0.42$ ). The percentage engaged in foraging at 380 µatm was significantly higher than that at 950 μatm and 1250 μatm (Figure 4).

Figure 3. *N. festivus.* Food detection time after 2 hours, 1 day, and 7 days of exposure to the combined effects of  $pCO<sub>2</sub>$  (380 μatm, 950 μatm, and 1250 μatm) and salinity (10 psu and 30 psu) at a distance of 60 cm from the bait.

At 40 cm, the percentage of individuals engaged in foraging (at 30 psu) was not affected by pCO<sub>2</sub> after 2 hours ( $p = 0.824$ ) or 1 day ( $F = 3.17$ , df = 2, p = 0.078) of exposure but a lower percentage was observed after 7 days ( $F = 27.15$ ,  $df = 2$ ,  $p < 0.001$ ) with that at 380 μatm being significantly higher than that at 950 μatm and 1250 μatm. Salinity reduced the percentage of individuals engaged in foraging on both Day 1 ( $F = 376.04$ , df = 1, p < 0.001) and Day 7 ( $F = 470.45$ ,  $df = 1$ ,  $p < 0.001$ ), but there was no interaction between salinity and  $pCO<sub>2</sub>$  (Day 1: F = 0.91, df = 2, p = 0.43; Day 7: F = 0.05, df = 2, p = 0.95) (Figure 5).

At 60 cm from the bait, the percentage of individuals engaged in foraging was reduced significantly after 2 hours of exposure to 950  $\mu$ atm ( $p < 0.050$ ) and 1250  $\mu$ atm pCO<sub>2</sub> ( $p <$ 0.05). Both elevated  $pCO<sub>2</sub>$  and low salinity reduced significantly the percentage engaged in foraging after 1 day (pCO<sub>2</sub>: F = 27.72, df = 2, p < 0.001; salinity: F = 133.89, df = 1, p < 0.001) and 7 days (pCO<sub>2</sub>: F = 36.27, df = 2, p < 0.001; salinity: F = 98.46, df = 1, p < 0.001) of exposure, but there was no interaction between salinity and  $pCO<sub>2</sub>$  (Day 1: F = 3.50, df = 2,  $p = 0.06$ ; Day 7: F = 3.55, df = 2, p = 0.06). The percentage was significantly higher at 380 μatm than at 950 μatm and 1250 μatm (Figure 6).

**Table 3. Results of the multiple comparison Tukey's test on the percentage of individuals engaged in foraging at 20 cm from the bait upon exposure to the combined effects of salinity and ocean acidification for 1 day. ## **DISCUSSION**

The present study has demonstrated that elevated  $pCO<sub>2</sub>$  and low salinity reduced the percentage of individuals engaged in foraging and prolonged the food detection time in *N. festivus*. Behaviour or performance may be disrupted by reduced functional mechanisms (Briffa et al., 2012). For instance, significant physiological costs for coping with extra copper ions in ambient sea water could reduce the metabolic rate and therefore constrain activities with high energy demand, for instance, aggression (Rovero et al., 2000). The alteration of energy allocation in marine organisms by ocean acidification is well-known (Pörtner et al., 2004; Orr et al., 2005). As a consequence of internal hypercapnia compensation, energy will shift to maintaining an acid-base balance and constrain other behaviours. Dissanayake and Ishimatsu (2011) found that a shallow-water decapod *Metapenaeus joyneri* showed a 30% reduction in swimming activities at a high  $pCO<sub>2</sub>$  level (1 Kpa), which might be the result of reduced metabolic scope. As detection of carrion in *N. festivus* requires rapid movement which is energy demanding, a shift in energy allocation towards maintaining an acid-base balance will inevitably affect foraging.

Behaviour and chemoreception restrained under low salinity have been reported in various taxa. For instance, the movement of the marine isopod *Gnorimosphaeroma oregonensis* was reduced significantly at a salinity of 20 psu when compared to that at 30 psu. The Dungeness crab, *Cancer magister*, did not feed when exposed to 3.5 psu (Curtis et al., 2010). The dendrites of olfactory receptor neurons are responsible for receiving odour cues. Exposing the dendrites to an external environment in which ion concentrations are low, however, presents a challenge because low salinity seawater cannot provide the appropriate ionic and osmotic transmembrane gradients required to sustain neural function (Gleeson et al., 2000).

The second reason why the behaviour of animals in polluted environments might change is due to a disruption in the ability to gather ('perception') and assess information for making decisions ('cognition'). Exposure to elevated  $CO_2$ /reduced pH caused a shift in the predatory reef fish *Pseudochromis fuscus* from preference to avoidance of the smell of injured prey, with CO2 (950 μatm)-treated predators spending approximately 20% less time in a water stream containing prey odour compared with controls (Cripps et al., 2011). The impairment to the nervous system of larvae of the coral reef fish *Neopomacentrus azysron* under ocean acidification (880 μatm) may give support to the cognition impairment theory (Domenici et al., 2012). The impaired olfactory ability of the Clownfish (*Amphiprion percula*) larvae at high CO<sub>2</sub> was restored by an antagonist of the GABA-A receptor (Nilsson et al. 2012), a major neurotransmitter receptor in both vertebrates and invertebrates (Tsang et al., 2007). This indicates that the alteration of chemosensory functions is associated with the interference of neurotransmitter function. Under normal circumstances, opening of the GABA-A receptor causes an inflow of Cl<sup>−</sup> , leading to hyperpolarization and inhibition of the neuron. Upon exposure to high  $CO<sub>2</sub>$ , marine organisms regulate their acid–base balance to avoid acidosis by accumulating HCO<sub>3</sub><sup>-</sup> with compensatory reductions in Cl<sup>-</sup> which render some GABA-A receptors excitatory, thereby impairing sensory functions (Nilsson et al., 2012). Chung (2014) also found that a  $pCO<sub>2</sub>$  level around 900  $\mu$ atm can influence chemoreception, auditory sense, and visual sense of the damselfish *A. polyacanthus* through interference of the GABA-A neurotransmitter. In addition to changing the charge distribution at odour molecule receptor sites, reduced pH could disrupt chemosensory behaviour by causing a change in the ionic state of the odour molecules themselves (Brown et al., 2002; Leduc et al., 2004), making them unrecognizable or preventing them binding with the receptor sites.

Reduced ability in foraging decreases the chance of success in energy acquisition in *N. festivus* as the occurrence of carrion is sporadic and the competition among scavengers is intense, resulting in long-term effects on population growth. A longer food detection time may indicate a weak sensory ability or confusion in processing olfactory cues. This explains why individuals much further away from the bait (60 cm) were greatly affected by  $pCO<sub>2</sub>$  as the concentration of chemical cues from the bait was reduced. When food detection time increased, the chance that the prey was exposed to the predator also increased, a phenomenon commonly found in marine animals (Stein and Magnuson, 1976; Milinski and Heller, 1978). Nevertheless, this could be partially compensated for by a lower percentage of individuals engaged in foraging. This might be a strategy to avoid stress as shown in many other species (Briffa et al., 2012). The epaulette shark (*Hemiscyllium ocellatum*) tended to hide in corals in an attempt to escape from ocean acidification and its associated harmful effects (Heinrich et al., 2014). When animals cannot evaluate the potential risk due to cognitive defect, their behaviour will become circumspect and cabined (Nilsson et al., 2012).

*Nassarius festivus* and the hermit crab, *Diogenes edwardsii*, are scavengers sympatric on sandy shores in Hong Kong and undergo interspecific competition for carrion with *N. festivus* outcompeting *D. edwardsii* and dominating the feeding clusters. This is achieved by having an extendible proboscis allowing feeding at a distance, and chemoreceptors that permit long distance food detection (Morton and Yuen, 2000). However, the meta-analysis of Wittman and Pörtner (2013) has shown that in general molluscs are more sensitive to ocean acidification than crustaceans. Therefore, whether the competitive dominance of *N. festivus* in the scavenging community will change under ocean acidification deserves further investigations.

## **OXIDATIVE EFFECTS IN AQUATIC ORGANISMS EXPOSED TO LIPOPHILIC MARINE BIOTOXINS**

## *Carlos García1,2,\*, Javiera Oyaneder-Terrazas<sup>1</sup> and Hector R. Contreras<sup>3</sup>*

<sup>1</sup>Laboratory of Marine Toxins, Physiology and Biophysics Program, Institute of Biomedical Sciences, Faculty of Medicine, University of Chile, Santiago, Chile <sup>2</sup>Department of Environment, Foundation for Human and Environmental Sciences Research, Santiago, Chile <sup>3</sup>Department of Basic and Clinical Oncology, Faculty of Medicine, University of Chile, Santiago, Chile

Harmful algal blooms (HAB) on the coast of Chile are an ongoing problem and a challenge for producing seafood products from natural beds and from farming centers. Lipophilic marine biotoxins (LMB) are one of the groups of marine toxins, which in recent years, have been consistently identified in shellfish; its main characteristics are to have a latitudinal variability and species-specific assimilation/retention for each species.

Shellfish in the aquatic environment represent the best bio-indicator model to allow establishing levels of toxicities related to LMB and also represent an important tool for the constant monitoring of water pollution on the coasts of Chile. Antioxidant enzymes play an important role in the cellular antioxidant defense systems of all organisms and whose main task is to protect against oxidative damage caused by reactive oxygen species (ROS).

Bivalves from rocky strata, sandy bottoms and gastropods were extracted from areas exposed to lipophilic marine biotoxins (Aysén Region) and unpolluted areas (Los Ríos Region) to determine the levels of activity of antioxidant enzymes, superoxide dismutase (SOD), catalase (CAT), lipid peroxidation (LP), glutathione peroxidase (GPx) and glutathione reductase (GR), and to relate it to the concentrations of LMB in the visceral (hepatopancreas) and non-visceral tissues (mantle, gills, adductor muscle and foot) in shellfish.

Oxidative damage was detected in all evaluated species and significant differences were established with respect to those obtained from areas not polluted with LMBs. The species with the greatest oxidative damage were those related to the sandy bottom habitat (the Pacific clam and clam). LMB profiles detected in bivalves corresponded to okadaic acid (OA), dinophysistoxin-1 (DTX-1) and pectenotoxin-2 (PTX-2) in a ratio of 3:6:1, respectively. The variation of oxidative damage was related to decreased LMB toxicities in each species.

This study shows that variations in the activity of antioxidant enzymes are directly related to the concentration levels of LMB in shellfish, which could be used to explain the levels of mortality of some species (bivalves) during HAB events in the coast of Chile.

#### **OXIDATIVE STRESS AND ANTIOXIDANT RESPONSE**

Climate change has tended to transform seawater into a warmer and more saline environment in certain areas of the Earth, and the constant anthropogenic pollution is added to it. The increase in temperature on the planet tends to produce changes in the metabolic pathways in almost all species of sea creatures and it induces species, particularly those with shorter lifespans, to change their life cycle, thereby contributing to changes in the patterns of distribution of marine species (Ielmini et al., 2014). One of the most relevant effects of climate change at sea is the occurrence of events associated with algal blooms, in particular the proliferation of harmful algal blooms (HABs) associated with the production of toxins which are persistent in marine waters and that may enter into the trophic chain of hydrobiological organisms (EFSA, 2009; Glibert et al., 2014; Botana, 2016).

Hydrological changes, hydromorphological degradation and invasive species tend to contribute to the set of factors that generate stress in the marine environment (Amado et al., 2006). Marine, coastal and estuarine environments are subjected to changes due to natural (algal blooms) and non-natural chemical contamination associated with industrial production and high levels of urbanization. In this context, chemical monitoring programs have commonly used both marine organisms and sediments to identify chemical contaminants in these affected environments. Within these monitoring programs, shellfish are the organisms most widely used as bio-indicators due to their high filtration capacity, which allows them to accumulate and tolerate high concentrations of natural or non-natural contaminants in different geographical areas (Fernández et al., 2010).

However, the concentration of contaminants in their tissues does not provide any information on the biological importance and harmful effects that environmental pollution can cause in biological systems. Likewise, environmental surveillance allows for the protection of biological and ecological systems. With this purpose, general biological effects of exposure to potentially harmful substances in the environment are studied, such as the responses measured at subcellular level (oxidative stress and DNA adducts) and the determination of responses of the whole organism, for example, growth variables and disease occurrence indexes, which may indicate a relationship between pollutants and ecological damages produced (Thain et al., 2008; Fernández et al., 2010).

Acute or chronic exposure to environmental pollutants can produce a variety of alterations in aquatic organisms. Even though aquatic organisms can tolerate a certain amount of biological alteration induced by short-term pollutants, long-term exposure may deplete

repair and defense mechanisms, generating a negative impact on cellular organization, known as stress.

The sequence of biological events produced by stress and subcellular changes can provide evidence of damage before irreversible effects are evident in the organism. In this way, subcellular measurements can clarify the compromised physiological state of exposed organisms. Thus, some cellular components show exposure to a specific group of pollutants, while others, such as oxidative stress, can be used to indicate and establish the cumulative effects of exposure to complex mixtures of pollutants, such as those found in fjords or coastal waters (Gill et al., 2014).

Cell damage is the consequence of the accumulation of damage by oxidation on biomolecules caused by the high reactivity of free radicals and reactive oxygen species (ROS) produced in cells as a result of the necessary use of oxygen. Since oxygen is primarily used in respiration to support the life-sustaining metabolic processes, mitochondria, and specifically deoxyribonucleic acid (DNA), are the first target of oxidation. All aerobic organisms must cope with the need of dealing with reactive oxygen species (ROS).

ROS are chemically reactive molecules that contain oxygen, formed as a natural byproduct of normal oxygen metabolism, and play an important role in cell signaling and homeostasis. The generation of reactive oxygen species (ROS) is a condition inherent to aerobic life (Pamplona and Costantini, 2011). ROS have a dual role since they are involved in protective mechanisms of the cell and, at the same time, act as messengers in cellular signaling pathways (Cooke et al., 2003; Pamplona and Costantini, 2011). Reactive oxygen species (ROS) are unstable atoms or molecules that try to release electrons from other molecules to achieve greater stability, thus creating new radical species and causing chain oxidations (Vinagre et al., 2012). These include the superoxide anion radical  $(O_2^{\star})$ , hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), peroxyl radical (ROO'), nitrogen oxide (NO') and hydroxyl radical (HO') (Winterbourne, 2008). Some ROS contain unpaired electrons (free radicals) while others are non-radical species (e.g.,  $H_2O_2$ ) (Shehan and McDonagh, 2008) (Figure 1).

Figure 1. Metabolism of reactive oxygen species (ROS) (Guerreiro et al., 2014).

Many pollutants can exert harmful effects by catalyzing the ROS production. Nevertheless, the imbalance between pro-oxidants and antioxidants can induce harmful effects on macromolecules such as proteins, lipids and DNA (Rosenfeldt et al., 2013). It is well known that many xenobiotics can not only cause an overproduction of ROS, but also alter the levels of antioxidants, which can lead to an oxidative stress condition (Manduzio et al. 2005; Amado et al., 2009). In spite of this, we must consider that oxygen is essential for life and that ROS, in certain quantities, are necessary for many physiological processes that are essential for our survival (Vinagre et al., 2012).

Oxidative stress is an important component of the response to stress in marine organisms which are exposed to a wide variety of environmental stressors at varying time and space scales, for instance, variations in temperature, ultraviolet radiation and anthropogenic pollution (Vinagre et al., 2012). As such, oxidative stress occurs when the rate of production of reactive oxygen species (free radicals) exceeds the rate of clearance produced by endogenous antioxidant molecules (Adeyemi, 2014; Otunola et al., 2014). Therefore, during exposure to environmental stress, ROS levels may increase dramatically. Thus, when production and accumulation of ROS is beyond the ability of the body to treat these reactive species, the so-called oxidative stress is produced, which damages lipids, proteins and DNA (Vinagre et al., 2012).

A biomarker is defined as a variation occurring in cellular or biochemical components, measurable in a biological system and which may be indicative of xenobiotic exposure. In a broader perspective, an entire organism, population, community or ecosystem can be considered as a biomarker (Lam, 2009). Likewise, aquatic organisms present in rivers, lakes and sea are potentially useful as biomarkers of environmental pollutants (Ielmini et al., 2014).

Lipid Peroxidation (LPO) corresponds to the process in which reactive species (RSs) attack the polyunsaturated fatty acids of the cell membrane, inducing a chain reaction with lipid hydroperoxides as intermediates (Halliwell, 1987). This process can also result in the destabilization and disintegration of the cell membrane which causes serious problems to the biological system of the species (Valko et al., 2006). At the beginning of the LPO, peroxyl free radicals (ROO<sub>S</sub>) are formed which tend to be rearranged through an endoperoxide cycling reaction, producing or overproducing, as well as other end products of this process, such as malondialdehyde (MDA).

Malondialdehyde (MDA) is a natural biomarker produced in the lipid peroxidation reaction (LPO), which can be quantified and used for the evaluation of this process. MDA can be toxic to cells, causing an inhibition of protein synthesis, where some adducts may be formed with the DNA, leading to genotoxic, mutagenic and carcinogenic processes (Halliwell, 2007). Therefore, reactive oxygen species (ROS), including hydrogen peroxide  $(H<sub>2</sub>O<sub>2</sub>)$ , superoxide anion  $(O<sub>2</sub>.)$  and hydroxyl radical (OH), can cause damage to DNA, proteins and fatty acids, causing apoptosis and changes in cytoskeletal proteins (Melegari et al 2012).

The high levels of oxidative damage can result not only from oxidative stress, but also from the limitation of the cellular repair system, so that this dysfunction may cause a deregulation of the cellular defense system leading to cell death (Halliwell, 2007; Paskerova et al., 2012).

Biochemical modulations indicating the onset of oxidative stress are very complex, especially under exposure to an environment such as harmful algal blooms (HABs) (Shahraki et al., 2013; Pamplona and Costanini, 2011). The effects that may be observed are dependent

on the species, age, organ, type of exposure, type of material, duration of the dose and external environmental factors (Paskerova et al., 2012). Therefore, our bodies' functions are based on a perfect balance between ROS levels and those of antioxidants. The loss of this balance, due to an excess in ROS production or an insufficient availability of antioxidants, leads to oxidative stress underlying ROS-related diseases and cell damage (Figure 2).

Antioxidants are substances that retard and/or prevent the oxidation of the cellular substrate at low concentrations. Antioxidants are widely distributed in living organisms and are extremely important as representatives in the direct elimination of free radicals (Halliwell and Gutteridge, 2007). The main enzymatic antioxidants correspond to superoxide dismutase (SOD), catalase (CAT), ascorbate peroxidase (APX) and enzymes involved in the process of glutathione metabolism glutathione reductase (GR), glutathione transferase (GST) and glutathione peroxidase (GPx), which exert the primary defense in the destruction of ROS (Valko et al., 2006). Non-enzymatic antioxidants, such as reduced glutathione (GSH), tocopherol (vitamin E) and ascorbic acid (vitamin C), among others, help to combat reactive oxygen species (ROS) and reactive nitrogen species (Figures 1 and 2) (Halliwell and Gutteridge, 2007).

Among antioxidant enzymes, superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidases (GPxs) act together to destroy ROSs within the cell (Manduzio et al., 2005).

Figure 2. Major generative and eliminative reaction of free radical toxicity (Dickinson & Chang, 2011).

Glutathione-S-transferases (GSTs) represent an important group of detoxification isoenzymes whose natural substrates range from molecules of external origin to byproducts of cellular metabolism. GSTs mainly catalyze the conjugation of reduced glutathione (GSH) to various electrophilic compounds, but they can also act as isomerases or as binding proteins that sequester hydrophobic molecules (Figure 1)

Glutathione reductase (GR) does not play a direct role in the elimination of oxygen radicals; it can be considered as an essential antioxidant enzyme, since it reduces oxidized glutathione (GSSG) and maintains GSSG/GSH balance which is essential for cellular homeostasis and the functioning of other enzymes (Winston and Di Giulio, 1991, Figure 1). GSH plays a central role in the detoxification of ROS and also participates in the metabolism and detoxification of endogenous and exogenous substances (Yan et al., 1997). Therefore, the GR enzyme, which catalyzes the reduction of oxidized glutathione (GSSG), is essential for the maintenance of the GSH/GSSG ratio and the cellular redox state, protecting the cells against oxidative damage (Box et al., 2007).

Furthermore, SOD is a primary defense against oxygen toxicity by catalyzing the conversion of the superoxide anion into oxygen and hydrogen peroxide which can be sequentially removed by CAT or by the GSH-dependent pathway through GPxs (Manduzio et al., 2005, Figure 1). The positive correlation detected between SOD and GPxs indicates that GPxs are an important pathway of degradation of hydrogen peroxide and that the coordinated action of both enzymes acts against the oxidative attack induced by this compound (Bebianno et al., 2005).

The enzymes catalase (CAT) and glutathione peroxidase (GPx) are responsible for degrading or eliminating  $H_2O_2$ . The CAT reacts with  $H_2O_2$  molecules to form water and molecular  $O_2$ , using one molecule of  $H_2O_2$  as oxidizing molecule and another as reducing molecule (Hayes et al. 2007; Zamocky et al., 2008; Figure 2).

In addition, thiols correspond to compounds containing sulfhydryl groups (-SH) attached to a carbon atom. They are endogenous molecules that help aerobic cells maintain a reducing state, despite an oxidizing environment. They are efficient antioxidants that protect cells against the consequences of free radicals-induced damage. Thiol groups are found in all cells of the body and are indispensable for life (Da Costa et al., 2006).

In this way, biomarkers can provide an early warning indicator of exposure to toxic compounds, allowing changes in biological systems to be identified before the effects are evident at the community level (De machado et al., 2014).

The development of new strategies and methods for the discovery of biomarkers is essential to define early warning signals for the design of interventions and prevention strategies. Techniques such as genomics, transcriptomics, proteomics and metabolomics can provide new insights to develop tools for the identification of threshold values and exposure ratios against environmental pollutants (Lemos et al., 2010; Letendre et al., 2011).

## **HARMFUL ALGAL BLOOMS AND LIPOPHILIC MARINE BIOTOXINS**

The largest supply of nutrients in the sea for the development of life is the phytoplankton (biomass), which is beneficial for living organisms such as shellfish and fish (whether endemic or farmed). However, the contributions of nitrogen (N) and phosphorus (P) from anthropogenic resources (agricultural farmed and/or fish farmed) can alter the nutrients ratio (16:1) to very high levels (70:1), by altering the marine ecosystem (Hattenrath-Lehmann et al., 2015). This is how the organic imbalance (N:P), which is produced in some areas, creates a global variability in the communities of marine phytoplankton, resulting in an exponential growth of these species in many cases, which, although still a nutritional contribution to the many species of marine organisms, it generates a high trade and human impact since they are associated with the production of toxins capable of killing people (Figure 3) (Gerssen et al., 2010).

Figure 3. Summary of environmental impacts of Harmful Algal Blooms (HABs) on shellfish and miticulture (mussels) from the South Pacific Ocean.

To date, 5,000 phytoplankton species have been described, from which, under certain circumstances, 300 species have a high proliferation rate resulting in a high density of microalgae in the sea, a condition called "bloom". The circumstances or factors triggering these "blooms" are still not completely known, but what is certain is that specific changes of climatic and hydrobiological conditions play an important role in the conditions leading to a "bloom" (Hallegraeff, 2010; Picot et al., 2011). About 80 species, out of the 300 already mentioned found in phytoplankton, are dinoflagellates and diatoms that, under certain circumstances, produce phycotoxins (marine toxins). The abundance of this kind of toxic phytoplankton ranges from a few hundred of thousands to several million per liter in the sea, reaching maximum levels called "Harmful Algal Blooms" (HABs) (Anderson et al., 2012; Hallegraeff, 2014).

In order to determine the total toxicity of these toxin-producing dinoflagellates, both the absolute toxin concentration and the relative composition of them should be determined. These factors are directly related to local or regional parameters on which a bloom is developed (light, temperature, nutrients and salinity) (García et al., 2013; Nielsel et al., 2013). Thus, for a proper identification of a bloom, it is necessary to carry out two key processes:

plankton monitoring (stratification in the water column), and toxin monitoring (HPLC and LC-MS/MS) (Hess 2010; May et al., 2010).

In areas where toxic blooms occur, the main bodies affected are shellfish, which, by having high levels of water filtration (clearance rate), may accumulate high concentrations of nutrients and toxic phytoplankton in their tissues (visceral and non visceral tissues) (Navarro and Contreras, 2010; García and Lagos, 2013). This assimilation of toxins in shellfish leads to a variation in the assimilated toxic profiles (dinoflagellates) through different routes of biotransformation (enzymatic and non-enzymatic) present in the different species of shellfish affected by HABs, thus acting as powerful vectors (Rossini and Hess, 2010; Zamorano et al., 2013; García et al., 2015). The toxic variability produced can be enhanced through the transfer of toxins through the food chain, thus allowing for the accumulation of toxins in various organisms in the ocean (zooplankton, fish, sea lions and whales). This has been essential in determining the potential biotransformation forms and degrees of purification occurring in different marine species affected in a toxic bloom (Deeds et al., 2008; Lopes et al., 2013).

Thus, contamination of shellfish by HAB and other marine organisms generate annual economic losses for seafood, which are estimated to be over  $\epsilon$  700 million per year on miticulture in Europe (James et al., 2010; Glibert et al., 2012; Reguera et al., 2014). For this reason, in order to prevent intoxications caused by eating shellfish contaminated with phycotoxins, and to mitigate their harmful effects, international agencies have produced regulations, legislation and monitoring programs (EU, 2011). Several phycotoxin detection methods have been developed, many of which allow detection of phycotoxins within shellfish far below dangerous levels. Nevertheless, the challenge of each method is the detection and analysis of the available toxins from different biological matrices (shellfish tissues) and, at the same time, the identification of new toxic analogues that may result from the biotransformation of toxins (Picot et al., 2011; Paredes et al., 2011).

In the past 10 years, one of the most important group of blooms and identification of toxins has been the so-called lipophilic toxins. These are a group of marine toxins formed by the Okadaic acid-group (OA-group), Azaspiracid-group (AZA-group), Pectenotoxin-group (PTX-group) and Yessotoxin-group (YTX-group). It is noteworthy that in the mid-nineties, these toxin groups were part of a single group called diarrhetic shellfish toxins (DSTs). This, largely because the evaluation processes in shellfish (bioassay) and phytoplankton caused a simultaneous extraction of lipophilic toxins, therefore causing a tendency to associate the symptoms detected in bioassays or in human poisonings solely with the DST group. Thus, toxins that make up the AZA-group, PTX-group and YTX-group were excluded from DST group (Gerssen et al., 2010; Dominguez et al., 2010). It was further established in 2011 that the only suitable method for the identification of all lipophilic toxins was the LC-MS/MS (EU, 2011; Orellana et al., 2014; García-Mendoza et al., 2014).

On this basis, the European Union (EU) has established guidelines for maximum toxin lipophilic levels in shellfish for human consumption. The OA, DTXs and PTXs (combined or alone), in edible parts of seafood cannot exceed 160  $\mu$ g kg<sup>-1</sup> OA equivalent in shellfish, while maximum levels of YTX cannot exceed 3,75 mg kg-1 YTX equivalent in shellfish and 160 μg kg-1 AZA equivalent in shellfish for AZAs (EU, 2013; EURLMB, 2015).

Currently, it has been established that the distribution of most dinoflagellates producers of lipophilic toxins is found worldwide. OA-group toxins have been identified in Europe (U.K., Ireland, Denmark, Sweden, Norway, France, Spain, Italy, Portugal, Holland and Belgium); Canada; South America (Chile and Argentina), Japan, Australia and Africa (Morocco) (Gerssen et al., 2010; Rodrigues et al., 2010; García et al., 2015); AZA-group toxins have been identified in Ireland, UK, Norway, France, Portugal, North Africa (Morocco), Chile and USA (García and Contreras, 2014; Chevallier et al., 2015); PTX-group toxins have been identified in Ireland, Croatia, New Zealand, Portugal, Norway, Japan and Chile (Dominguez et al., 2010; Fux et al., 2011; Mackenzie et al., 2012) and YTX-group toxins, in Japan, Norway, Italy, New Zealand, Chile, Russia, Canada, United Kingdom and Spain (Tubaro et al., 2010; Dominguez et al., 2010; Pistocchi et al., 2012).

## **OKADAIC ACID-GROUP (OA-GROUP)**

Diarrhetic Shellfish Poisoning (DSP) is a gastrointestinal disease caused by ingestion of shellfish with accumulated fat-soluble polyether toxins (OA-group) produced by dinoflagellates of the *Dinophysis* and *Prorocentrum* genera. Dinoflagellates of the *Dinophysis* genre associated with the OA-group are: *Dinophysis acuminata*, *D. acuta*, *D. caudata*, *D. fortii*, *D. miles*, *D. ovum*, *D. sacculus*, *D. rotundata* and *D. tripos* (Naustvoll et al., 2012; Reguera et al., 2014).

In the South Pacific (Chile), blooms associated with the OA-group are usually produced in the spring-summer period (October to March) (García et al., 2013). The first record of poisoning associated with the OA-group dates from 1970 at the estuary of Reloncavi in Los Lagos Region (García and Contreras, 2014). The main groups that produce such type of toxins are: Okadaic acid (OA), dinophysistoxin-1 (DTX-1) and dinophysistoxin-2 (DTX-2) (Zamorano et al., 2013, Figure 4).

Figure 4. Chemical Structures Okadaic acid group (OA-group) and their chemical analogues identified in bivalve molluscs.

The variability of the toxic profile produced by dinoflagellate producers of OA-group depends on the species involved and the region in which the bloom occurs. As an example, the variability of the content of toxins in cells of *Dinophysis acuta* is 0-40 OA pg cell-1 /0-0.02 DTX-1 pg cell<sup>-1</sup>/0.3-0.6 DTX-2 pg cell<sup>-1</sup>, while for *Dinophysis acuminata* it is 0-160 OA pg cell<sup>-1</sup>/0-7.8 DTX-1 pg cell<sup>-1</sup>/0-169 DTX-2 pg cell<sup>-1</sup> (Lindahl et al., 2007). Within this group of toxins, toxic analogues resulting from the biotransformation of toxins in the digestive glands of bivalves have been identified; such biotransformation corresponds to the acylation of hydroxyl groups (-OH) with fatty acids of varying length and saturation (C-14 to C-22). The most identified is the 7-0-palmitoyl-dinophysistoxin-1 group (dinophysistoxin-3, DTX-3) (Rossignoli et al., 2011; Konoki et al., 2013, Figure 4).

The minimum dose required of OA and DTX-1 to produce toxic symptoms in people, has been estimated at 40 and 36 µg, respectively (Ferron et al., 2014; García et al., 2015). Death of intoxicated patients has not been reported, but okadaic acid (OA) and methyl-okadaic acid (DTX-1) have been shown to be potent tumor promoters in animals (Fujiki et al., 2013). Therefore, they might increase the risk of cancer among regular consumers (Lopez-Rodas et al., 2006; Valdeiglesias et al., 2013). This group also stands out as powerful cytotoxins that inhibit various types of serine/threonine phosphoprotein phosphatases  $2A$  (PP2A) (OA-IC<sub>50</sub>) 2.87 ng/ml and DTX-2-IC<sub>50</sub>5.96 ng/ml) (Smienk et al., 2013; Ehara et al., 2015).

## **YESSOTOXINS-GROUP (YTX-GROUP)**

Yessotoxins (YTXs) are a group of disulfated polycyclic polyether toxins. Dinoflagellates that are producers of this type of toxin are the species *Protoceratium reticulatum*, *Lingunodinium polyedrum* and *Gonyaulax spinifera* (Paz et al., 2008; Paz et al., 2013).

Most YTXs come from the *Protoceratium reticulatum* dinoflagellate; the first analogue identified was 45, 46, 47-trinor-YTX (norYTX); later, other toxic forms such as homo-YTX, noroxo-YTX, 40-epi-41-keto- YTX and 41-keto-YTXenon were identified (Dominguez et al. 2010). In molluscs, analogues of YTX have been identified, standing out the analogues of 45 hydroxy-YTX, 45, 46, 47-trinor-YTX, homoYTX, 45-hydroxyhomo-YTX, carboxy-YTX and carboxyhomo-YTX (Ciminiello et al., 2007; Dominguez et al., 2010, Figure 5).

The amounts of YTXs produced by each strain are variable, with values ranging from 0 to 71 pg cell<sup>-1</sup> (Paz et al., 2008). Therefore, the production of YTX toxins is directly influenced by the culturing, growth phase, nutritional and environmental conditions, as well as the type of extraction and/or analysis methods used for determining the toxicity profile (Guerrini et al., 2007). YTXs do not cause diarrhea in bioassays in mice nor cause inhibition of PP2A (Tubaro et al., 2010). Although YTX is known as a potent phosphodiesterase activator (PDE), the precise mode of action currently remains unknown (Paz et al., 2008; Korsnes, 2012). Symptoms caused by intoxication with YTX in humans are relatively unknown because no human poisoning has been reported to date (Franchini et al., 2010; Visciano et al., 2013). Their toxic evaluation in bioassays has determined that an intraperitoneal injection of approximate concentrations of 150  $\mu$ g kg<sup>-1</sup> produces dispersed mobility, dyspnea, jumps, tremors and cramps. These symptoms start 4 hours after the injection (Tubaro et al., 2008; Aasen et al., 2011).

Figure 5. Chemical Structure of Yessotoxins-group (YTX-group) and their chemical analogs identified in dinoflagellates and bivalve molluscs.

#### **PECTENOTOXINS-GROUP (PTX-GROUP)**

Pectenotoxins (PTXs) are a group of polyether macrolide toxins produced by dinoflagellates such as *Dinophysis fortii, D.* acuminata, *D.* acuta, *D. caudata*, *D. rotundata*, *D. norvegica* and in heterotrophic dinoflagellates such as *Protoperidinium divergens*, *P. depressum* and *P. crassipes* (Dominguez et al., 2010; Fux et al., 2011). Toxic levels of PTX-2 in Dinophysis cells identified in the fjords of Chile are  $\approx 180$  pg cell<sup>-1</sup> of PTX-2 (Blanco et al., 2007), while in New Zealand and in Norway, *Dinophysis acuminata* has been reported to be a producer of PTX-2 with levels  $\approx 25$  pg cell<sup>-1</sup> (Vale et al., 2008).

New isomeric forms of PTX-2 such as PTX-4, PTX-6 and PTX-7 have been identified in new natural blooms. Said varieties, when filtered and accumulated by shellfish, allow metabolization of toxins, producing new analogues of PTXs (Figure 6). Thus, to differentiate the nomenclature of toxic forms from dinoflagellates and those obtained from shellfish, the term PTX2-seco acid (PTX2-sa) has been assigned to the latter varieties. Among them, Pectenotoxin-2 seco acid (PTX2sa), 7-epi- Pectenotoxin-2 seco acid (7-epi-PTX2sa), 37-Oacyl-esters-PTX-2-SA, 11-O-acyl-esters-PTX-2-SA and 33-O-acyl-esters-PTX-2-SA stand out. Consequently, this way of toxic accumulation is an important element in the bioconversion of PTXs (Dominguez et al., 2010; Domenech et al., 2014).

Figure 6. Chemical Structure of Pectenotoxin-group (PTX-group) and their chemical analogs identified in dinoflagellates and bivalve molluscs.

To date, no case of intoxication by PTX-type toxins has been reported, although biotransformation of PTX-2 has been found in some shellfish species (MacKenzie et al., 2012). So, based on the association of the symptoms and the mussels' toxic capacity, it has been determined that the amount sufficient to produce a toxic condition is 48  $\mu$ g PTX-2 for a 60 kg person (Domínguez et al., 2010). PTX toxicity after intraperitoneal (i.p.) administration and after oral ingestion in mice is considered comparable. For example, hepatic damage in mice after i.p. administration and oral ingestion seem to be the same (Alfonso et al., 2014). In addition, PTX-2 has been found to be potentially citotoxic in the carcinogenic cell lines of the lungs, colon and kidneys. This effect cannot necessarily be extrapolated to its toxic forms, such as PTX-2-SA and 7-epi-PTX2-SA, demonstrating the importance of the initial structure of toxins that initiate citotoxic effects (Alfonso et al., 2014).

### **AZASPIRACIDS-GROUP (AZA-GROUP)**

Azaspiracids (AZAs) are toxins produced by the species *Azadinium spinosum*. This species has been identified by its production of Azaspiracid-1 (AZA-1), Azaspiracid-2 (AZA-2) (Twiner et al., 2014, Figure 7). Although AZA-1 is the predominant toxin in the shellfish samples, other analogues such as AZA-3, AZA-4, AZA-5 and hydroxyl analogues AZA6-11 have been identified (Kilcoyne et al., 2014; Kilcoyne et al., 2015). However, every year, new analogues of AZAs have been detected in different countries in Europe, which results in varying toxic profiles, depending on the species that accumulates them and their degree of biotransformation (De la Iglesia et al., 2014; Rúbies et al., 2015).

Figure 7. Chemical Structure of Azaspiracid-group (AZA-group) and their chemical analogs identified in dinoflagellates and bivalve molluscs.

 $CH<sub>3</sub>$ 

Η

H

Н

AZA6

The oral toxicity of AZA-1 at high doses (900 μg/kg) in mice produces significant damage to the small intestine, while a 500 μg kg-1 dose produces only hepatic damage, evidenced by a volume increase of the organ (38% post-ingesta increase). These data have established that chronic exposure of AZA can cause tumors in tissues (Initiator), and is also a great risk in simultaneous blooms with the OA-group (tumor promoter)(Ito, 2008; Aune et al., 2012). Parallel toxicological studies have established that the lowest observed effect level (LOEL) for AZA lies between 23 and 86 μg kg<sup>-1</sup> by person, even when levels of 80 μg kg<sup>-1</sup> AZA eq in shellfish could not produce AZA related intoxication symptoms. However, doses of 30 μg kg<sup>-1</sup> AZA eq in an ingested 400 g shellfish have produced intoxication syndromes in humans.

## **LEVELS OF OXIDATIVE STRESS IN MARINE ORGANISMS EXPOSED TO LIPOPHILIC MARINE BIOTOXINS**

Fjords and channels of southern Chile (Region of Aysen) are oceanically considered as a marine or estuarine transition system where fresh water from rivers and glacier melt is mixed with deep ocean waters, rich in nutrients and with a greater salinity (>30 psu) (Iriarte et al., 2010). Primary productivity is high (1-3 g C m<sup>-2</sup> d<sup>-1</sup>), with diatoms predominating throughout the year (Alves de Souza et al., 2008 a, b; Iriarte et al., 2010).

These characteristics have turned the area into an optimal zone for the culture of high added-value species such as Salmon Coho *(Oncorhynchus kisucht)*, Atlantic salmon (*Salmo salar*) and Rainbow Trout (*Oncorhynchys mykiss*), and have also responded to the sanitary crisis of the ISA virus, occurred in 2007 in the region of Los Lagos, and to the aquaculture industry by relocating the vast majority of farming centers established in the region of Los Lagos towards the regions of Aysén and Magallanes (Saavedro-Gallo, 2013; Gustafson et al., 2014; Sernapesca, 2014).

It should be noted that the highest percentage of salmon cultures is currently found in the region of Aysén, standing out for its demonstration of HABs associated with lipophilic toxins (Zamorano et al., 2013; García et al., 2015). These blooms show seasonal peaks, mainly between January and March; although, it is possible to observe vegetative cells throughout the year (Seguel and Sfeir, 2010). Such blooms would only affect shellfish coming from natural banks (e.g., mussels) (Zamorano et al., 2013; García et al., 2015), since all the reports associated with mortality of endemic fish and in farming centers (*S. salar*) worldwide, and which have not been associated with ichthyotoxins (*Karenia brevis, Prymnesium parvum* and *Hetrosigma akashiwo*)(Shen et al., 2010; Blossom et al., 2014), are only related to STXgroup toxins (Kwong et al., 2006; Bakke and Horsberg, 2010; Lage and Reis-Costa, 2013). The STX-group has been identified in the region and its bloom is associated with the dinoflagellate *Alexandrium catenella*; although these blooms have a seasonality of between 3 and 4 years (blooms of years 2009 and 2016) (Seguel and Sfeir, 2010; Varela et al., 2012), they do not significantly affect the salmon farming centers present in the region of Aysén.

The establishment of these farming centers with high added-value resources in areas with constant harmful algal blooms, and given the stages of development of cultured fish (periods from 12 to 14 months), allow for them to be exposed to at least 2 blooms associated with lipophilic toxins before the final product (*S. salar*) reaches its average harvest weight (3.5 to 4.5 kilograms). It is a relevant factor if we consider that HABs could not only affect filtered bivalves, carnivorous gastropods and crustaceans, but also predatory fish, wild fish and salmon in cultures. Therefore, through the feeding pathway and the constant exposure to lipophilic toxins produced by HAB, fish in cultures (*S. salar*) may accumulate lipophilictoxins (OA-group, PTX-group, AZA-group and YTX-group) in liver and muscle tissues, thus, affecting their basal metabolism, causing genetic damage and favouring a high retention of the lipophilic toxins in their tissues, which are characterized by having high contents of fatty acids in their tissues (muscles).

It is worth mentioning that numerous species of dinoflagellates associated with the production of lipophilic toxins have been identified in the región of Aysén, such as *D. acuta, D. acuminata*, *D. tripos*, *D. caudata*, *D. hastata* and *D. rotundata.* The first two species are associated with the production of lipophilic toxins (OA-group and PTX-group) and *P.*

*Reticulatum* is identified for producing YTX-group toxins (Seguel and Sfeir, 2010; García et al., 2013; García et al., 2015). Such species may even expand their bloom zones in the region through cultured fish since their production involves the relocation of live fish (wellboat) from different geographic areas (within the region), favoring the dissemination of toxic dinoflagellates described in the area (*Dinophysis sp., P. Reticulatum*) or, possibly, a new toxic species (*A. Spinosum*)(Zamorano et al., 2013).

Likewise, evaluations of enzymatic antioxidants and oxidative damage in fish (*S. salar*) and shellfish (*Mytilus chilensis*) have determined that, in the study area (region of Aysén), there is more relevant damage for filter-feeding species than for cultured fish.

The evaluation data on oxidative damage in tissues of bivalves (*Mytilus chlensis*) and Atlantic Salmon (*Salmo salar*) show that significant changes in the MDA from bivalves and fish exposed to blooms associated with *Dinophysis acuta* are evidenced ( $\approx 100$  cel  $1^{-1}$ ) if compared to the data obtained from the control group (region of Los Ríos). These data are correlated in all the bivalve's tissues studied (hepatopancreas, Figure 8). In addition, a longer exposure time (10 days) causes a significant increase of this biomarker in the hepatopancreas of bivalves and fish.

Regarding SOD activity, no significant changes were detected in any of the tissues evaluated in mussel and Atlantic salmon (Figure 9). Also, prolonged exposure does not establish any significant change in SOD activity in relation to the control group.

As for the basal level of CAT activity in the hepatopancreas of bivalves, this was higher than in the other evaluated tissues (mantle, hepatopancreas, foot and mantle), but its activity does not show significant changes during the evaluation period, while in fish, no alteration of its activity was detected (Figure 10).

Figure 8. Lipid peroxidation values in the fish gills and the hepatopancreas in the mussel of control and exposed to LMB cells (*Dinophysis acuta*  $\approx 100$  cel l<sup>-1</sup>). The values are expressed as mean  $\pm$  S.E. (*n* = 5). The significance levels observed are  $** p < 0.01$  in comparison to control group values.

Figure 9. Superoxide dismutase activity in the fish gills and the hepatopancreas in the mussel of control and exposed to LMB cells (*Dinophysis acuta*  $\approx$ 100 cel l<sup>-1</sup>). The values are expressed as mean  $\pm$  S.E.  $(n = 5)$ . SOD activity is expressed as U/mg protein.

Figure 10. Catalase activity in the fish gills and the hepatopancreas in the mussel of control and exposed to LMB cells (*Dinophysis acuta*  $\approx 100$  cel l<sup>-1</sup>). The values are expressed as mean  $\pm$  S.E. (*n* = 5). SOD activity is expressed as U/mg protein.

GPx activity maintains a basal level once the exposure period in fish is established, while after exposure, a significant induction of GPx activity in the hepatopancreas and mussel mantle was recorded (Figure 11). In turn, GR behaves just like the previous biomarkers and does not show any significant change in any of the species (mussel and Atlantic salmon) or in any of the assessed tissues (mantle, hepatopancreas, foot and mantle, Figure 12).

Figure 11. Glutathione peroxidase activity in the fish gills and the hepatopancreas in the mussel of control and exposed to LMB cells (*Dinophysis acuta* ≈100 cel l<sup>-1</sup>). The values are expressed as mean  $\pm$  S.E. (*n* = 5).

Figure 12. Glutathione reductase activity in the fish gills and the hepatopancreas in the mussel of control and exposed to LMB cells (*Dinophysis acuta* ≈100 cel l<sup>-1</sup>). The values are expressed as mean  $\pm$  S.E. ( $n = 8$ ).

In light of these results, we must consider that the aquatic environment is subject to temporal and spatial variations of quality. Indiscriminate dumping and release of waste containing hazardous substances can cause environmental imbalances that are considered a source of stress for the biotic community (Figure 3). Furthermore, toxicity in aquatic organisms caused by river and sea pollution tends to produce an increase in the production of "reactive oxygen species" (ROS), which causes the so-called oxidative stress. In the aquatic environment, in spite of the presence of constitutive antioxidant defense systems, higher levels of oxidative damage tend to be produced in organisms exposed to pollutants that stimulate the production of ROS (Figure 1). Thus, the use of biochemical or physiological analyses as indicators of toxicity is in constant development due to these analyses have the advantage of being able to outline the effects prior to the manifestation of diseases (Kurutas et al., 2009).

The toxicity of chemicals in the aquatic environment depends not only on their chemical and physical-chemical characteristics, but also on the biological processes in which they are involved. The bioavailability and spatial distribution of pollutants are highly regulated by hydrodynamics, biogeochemical processes and environmental conditions (e.g., redox, pH, salinity and temperature) prevailing in the ecosystem. Moreover, the accumulation of chemical substances depends on the chemical properties of the compound (e.g., polarity, lipophilicity and molecular weight) as well as on various biological processes that regulate food availability and metabolism and excretion efficiency (Dachs and Mejanelle 2010). Also, there are numerous factors that can influence the response of the antioxidant system in fish and bivalves to exposure to pollutants. This is due to the high seasonal variability in which aquatic organisms are frequently found as a result of their biotic regularities related to the environment, such as the reproductive and metabolic status of fish and environmental conditions such as food availability, oxygen level, temperature of water, salinity and photoperiod, among others (Da Rocha et al., 2009).

Nevertheless, the difference in antioxidant responses between species (fish and bivalves) depends on the quantitative distribution of the antioxidant defenses in the different tissues and subcellular compartments. Organ-specific responses to toxic levels of ROS may be related to anatomic location, pathways of exposure and distribution of pollutants, as well as to the defense capacity (Ahmad et al., 2006, Da Rocha et al., 2009 ), conditions of fasting (Ferreira et al., 2005) and location in the food chain (Solé et al., 2009). The differences of species in the efficiency of antioxidant defenses may partly explain the prevalence of oxidative damage observed in bivalve molluscs (Stoliar et al., 2012).

The main pathways of absorption of pollutants in marine fish and invertebrates (bivalves) correspond mainly to the gills and liver or digestive gland/hepatopancreas in bivalves. Through these pathways, chemicals cross cell membranes through passive or facilitated diffusion and active transport (Turja et al., 2015).

As LMBs are produced by dinofagellates, dominating a certain area in a maritime zone as a result of abiotic stimuli that promote a natural contamination, they act like an exogenous source of oxidative stress, producing ROS that will damage different aquatic species through the LPO of biological membranes. Therefore, as they are produced inside the cells, ROS are able to react with all types of biomolecules, organelles (mitochondria) and enzymes (cytochrome P450) (Inoue et al., 2003). Xenobiotics, such as LMBs, not only can cause ROS overproduction, but also alter the antioxidant levels which can lead to an oxidative stress condition (Amado et al., 2009). Some studies indicate that dinoflagellates, such as *Dinophysis*
sp., cause alteration of antioxidant enzymes and promote the induction of oxidative stress in different tissues of different bivalves species as well as in some fish (Clemente et al., 2010). Thus, LMBs can be bioaccumulated throughout the food chain by decreasing the activity of superoxide dismutase (SOD), GST, glutathione peroxidase (GPx) and causing oxidative stress in different biological structures such as proteins and DNA. However, this event would be likely associated with a more obvious damage in bivalves since the average blooms of *Dinophysis* sp.  $(100,000 - 200,000 \text{ cel } I^{-1})$ , to which fish are exposed in cultures, would allow an interaction with the toxins released from the dinoflagellates in the average range of  $\approx 5.0$ g l-1 , which does not produce any harmful effect on fish (*S. salar*).

Bivalve molluscs tend to be excellent biomonitors and bioindicators of pollution given their special characteristic as sessile benthic filter feeders, so they can accumulate and tolerate high concentrations of chemical pollutants, allowing them to provide reliable measurements over time of the bioavailable portion of total contaminants.

It should be noted that bivalve molluscs play a key role in the functioning of estuarine and coastal ecosystems since they are present in large geographic areas and, in general, are important commercial species worldwide (García et al., 2012; De machado et al 2014).

At a physiological level, exposure to harmful algal blooms that generate accumulation of toxins (LMB) and ROS toxins for bivalve molluscs implies a variability of the closure of shells, adductor muscle paralysis, retraction of the mantle and production of mucus (Perovic et al., 2000; Hegaret et al., 2012). Facing this event of algal exposure and LMBs, it has been possible to determine a positive correlation detected between SOD and GPxs, which indicates that GPxs are an important pathway of degradation of hydrogen peroxide and that the coordinated action of both enzymes acts against the oxidative damage induced by LMBs. Although, in the case of fish, there is a relationship between the temperature of water and antioxidant responses in the gills that can be detected (high levels of MDA). This is probably related to the fact that the gill epithelium is in direct contact with water and is, therefore, highly sensitive to its fluctuations, which tend to produce variable damages by ROSs. In fact, gills are more susceptible to changes in environmental parameters and more prone to oxidative stress than other tissues, which also implies that the antioxidant mechanisms have to be faster and more efficient in this tissue than in others (Fernandez et al., 2010).

Furthermore, it is described that the distribution of pollutants in organs of bivalves varies as a result of the differences in the surfaces in contact with pollutants, that is to say, by different affinities of pollutants with the binding sites and different rates of accumulation and excretion of the different bivalves species against pollutants (Yap et al. 2008; Fernandez et al., 2010). Thus, in some bivalves species inhabiting in areas constantly exposed to HABs, it is possible to observe a reduction of the antioxidant capacity and, therefore, a greater susceptibility to oxidative stress (Gill et al., 2014). In addition, the high summer temperatures cause increased values related to ROSs in the sea water (Keller et al., 2004). Therefore, antioxidant defenses of marine invertebrates and fish may vary according to their level of aerobic metabolism, exposure to cold environments and UV radiation (Maciel et al., 2004; Gouveia et al., 2005).

Nevertheless, because the oxygen dissolution is higher at lower temperatures, the response to oxidative stress could be expected to be inversely correlated with temperature, due to the increased oxygen availability to the ROS-generating processes at lower temperatures. Even though numerous studies show that the response to oxidative stress is not

directly correlated with temperature, ROSs are lower at the optimum temperature and increase at temperatures outside the upper and lower thermal limits than that constantly inhabited by the species (Vinagre et al., 2012).

In this way, the aquatic environment is an ideal medium for many environmental pollutants as they can be absorbed by aquatic organisms, altering the antioxidant/pro-oxidant balance in fish and bivalves (Lushchak, 2011). Moreover, depending on the source of the pollutant, the steady-state ROS concentration may be transiently or chronically increased, disrupting cellular metabolism and its regulation and damaging cellular constituents (Lushchak, 2011). Thus, some pollutants are substantially accumulated in specific tissues with no toxic effects recorded, while others demonstrate a high toxicity even at low levels (Jourmi et al. 2012).

Finally, stress responses induced by xenobiotics can be broadly classified as signs of intoxication and detoxification. Signs of intoxication may demonstrate debilitating phenomena, while detoxification signals are adaptive in nature and provide protection to biological systems when confronted with toxic xenobiotics (Bhattachary, 2001). This could explain why mortality is only related to some types of marine species affected by HAB or by effects of climate change, such as the El Niño Southern Oscillation (ENSO).

## **CONCLUSION**

The results of this study show that exposure to HABs associated with *Dinophysis* sp. does not cause significant damage in cultured fish (*Salmo salar*) considering the damages detected in the filter-feeding species *Mytilus chilensis*, even though both species were exposed to an equal number of cells ( $\approx$ 100 cel l<sup>-1</sup>) during the same period of time ( $\approx$ 10 days). Thus, it is established that the endogenous antioxidant defense system of both species is altered in a manner characteristic for each species, and independent of time. Simultaneously, the level of lipid peroxidation was the marker with the greatest alteration detected in the hepatopancreas of mussel, but it was not detected in fish. These results suggest that oxidative stress plays an important role in the *in vivo* toxicity that lipophilic toxins can produce in bivalves, which could explain, in some cases, the death of some species in areas with high cellular levels and high variables of abiotic conditions (variability of salinity and temperature) tending to produce oxidative stress to these filter-feeding species.

# **THE JUMBO FLYING SQUID (***DOSIDICUS GIGAS***) OFF OF COSTA RICA**

## *Bi Lin Liu , Xin Jun Chen, Jian Hua Li, Yi Gong and Jing Yuan Lin*

College of Marine Sciences, Shanghai Ocean University, Shanghai, China

## **ABSTRACT**

The fishery biology of jumbo flying squid (*Dosidicus gigas*) was studied based on squid resource surveys made by Chinese squid jigging vessels off the Costa Rica Dome in 2009 and 2010. The daily catch of *D. gigas* in two survey cruises ranged from 0 to 5.5 t and was mostly obtained from the areas bounded by  $6^{\circ}N-9^{\circ}N$  and  $91^{\circ}W-94^{\circ}W$  and by  $6^{\circ}30^\circ$ N $-7^{\circ}30^\circ$ S and  $96^{\circ}$ W $-97^{\circ}$ W. The sea surface temperature in the areas yielding the most catch ranged from 27.5 to 29°C. The sex ratio of the total catch was 3.75: 1 (female: male). Squid sizes ranged from 205 to 429 mm dorsal mantle length (ML) with ages no more than 10 months for females and 8 months for males. In the relationship of the mantle length (mm) and body weight (g) of the squid, there was no significant difference between sexes. The size (mantle length) and age at the first sexual maturity were 297 mm and 195 days in females, and less than 211 mm and 130 days in males. Growth in ML was best described by a linear function for both the sexes, while growth in body weight (BW) was best quantified by an exponential function for females and a power curve for males. The maximum absolute daily growth rates and instantaneous growth rate in ML were reached during 181-210 and 151-180 days for females and males, respectively. The Costa Rica Dome and its adjacent waters were considered to be a potential spawning ground. Most of the sampled stomachs (70.6%) had no food remains. The major prey of the squid were fish, cephalopods and crustaceans, with the most abundant being *Myctophum orientale* and *D. gigas*. The prey in more than 65% of the non-empty sampled stomachs evidenced cannibalism of *D. gigas*. The results improve current understanding of the fishery biology of *D. gigas* off the Costa Rica Dome, and may facilitate the assessment and management of related fishery resources.

## **INTRODUCTION**

Over the last two decades, the jumbo flying squid, *Dosidicus gigas* (d'Orbigny, 1835), has evolved as one of the most important species of cephalopod fisheries in the eastern Pacific. *D. gigas* is widely distributed in the eastern Pacific in the north from California (37°N), to the south in Chile (47°S) and east up to 125°W (Nesis, 1983; Nigmatullin et al., 2001). The highest abundance of *D. gigas* usually occurs off the Peruvian and Chilean coast in the southern hemisphere as well as in the Gulf of California and off the western coast of Baja, California in the northern hemisphere (Markaida and Sosa Nishizaki, 2003; Liu et al., 2010). Additionally, *D. gigas* is distributed in the water off the Costa Rica Dome where there is a strong upwelling. Japanese squid jiggers targeting *D. gigas* in this area obtained a high catch during the autumn of 1997 (El Niño) but poor catches during the fall of 1999 (La Niña) (Ichii et al*.*, 2002) in the waters off the Costa Rica Dome.

Many studies have been conducted on the fisheries biology of D. gigas in the Gulf of California, off the Peruvian coast (Masuda et al., 1998; Arguelles et al., 2001; Morales-Boj´orquez et al., 2001; Nigmatullin et al., 2001), and the high seas of the southeast Pacific Ocean (Ye, 2002; Ye and Chen, 2007; Liu et al., 2010; Chen et al., 2011). Three distinct groups were identified for *D. gigas* based on their difference in size at maturity (Nigmatullin et al., 2001): a small-sized group (mantle length (ML) 140-340 mm for females and 130- 260mm for males), a medium-sized group (ML 280-600 mm for females and 240-420mm for males), and a large-sized group (ML 550- 650 to 1000-1200 mm for females and >400-500 mm for males). D. gigas grow fast and do not live for more than 2 years with an average life span of ~1 year (Masuda et al., 1998; Arguelles et al., 2001; Chen et al., 2011).

At present, little information is available on the fishery biology of *D. gigas* in the waters off the Costa Rica Dome. Based on two scientific surveys of *D. gigas* by Chinese squid jigging vessels in the waters off the Costa Rica Dome undertaken in 2009 and 2010, the present study aimed to identify the environmental variables that influence the spatial distribution of *D. gigas* and to provide information on the population structure, maturity, and feeding characteristics of this squid species, further improving the understanding of the biology of *D. gigas* off the Costa Rica Dome. The information derived from this study is critical for quantifying the population dynamics of this squid and is of guiding significance to the assessment and management of this important marine resource.

## **RESULTS**

#### **1. Fishery**

#### *1.1. Catch and Its Relationship with Environmental Factors*

Ichill et al., (2002) reported that a fishery operation for *D. gigas* was conducted in waters of 7°-9° N and 92°-100°W from June through November in 1997, and the monthly average CPUE (tonnes per vessel per day) was 19.4 tonnes in August, 15.2 tonnes in September, and 8.5 tonnes in October of that year. In 1999, the fishery was only operational in the same fishing areas from August to September and the monthly average CPUE was low, 3.1 tonnes in August and 2.3 tonnes in September of that year. The abundance of jumbo flying squid within the 200 nautical miles exclusive economic zone of the Costa Rica Dome was unknown because fishery operation was not permitted.

The Chinese Government conducted two surveys off the Costa Rica Dome during 2009 to 2010 (Figure 1). The daily catch (CPUE) of *D. gigas* ranged from 0 to 5.5 t with no bycatch. The total catch was 95.5 t and the average CPUE reached 0.72 t. Overall, 75.7% of the fishing days had a CPUE lower than 1 t, and 17.4% of the fishing days had CPUE more than 2 t. The catch mainly came from the areas bounded by  $6^{\circ}$ -8°N and  $95^{\circ}30^{\circ}$ -97°W, and by 6°-9°N and 91°- 95°W (Figure 2). The high density of *D. gigas* appeared in the above two areas under different environmental conditions (Table 1).

Figure 1. The two survey areas covered by the Chinese squid jigger vessels off the Costa Rica Dome in 2009 (a) and 2010 (b).

In the fishing area of  $6^{\circ}$ -8°N and  $95^{\circ}30^{\circ}$ -97°W and during the period from July to September 2009, surface water temperature ranged from 27.5 to 29.0°C, at a depth of 50m the temperature ranged from 14.0 to 15.0°C and at a depth of 200m the temperature ranged from 13.0 to 13.7 °C. The corresponding water salinity ranged from 33.4 to 33.9 psu, from 34.8 to 34.9 psu and from 34.8 to 34.9 psu, respectively (Table 1). In the fishing area of 6°-9°N and 91°-95°W and during the period from February to March 2010, water temperature and salinity were  $28.0-29.0$ °C and  $33.8-33.9$  psu on the surface,  $24.0-25.0$ °C and  $34.3-34.4$  psu at the depth of 50 m, and 15.0–17.0  $^{\circ}$ C and 34.7–34.8 psu at the depth of 200 m, respectively (Table 1).

Figure 2. The spatial distribution of daily catch of *D. gigas* at 0.5°×0.5° latitude and longitude off the Costa Rica Dome in 2009 and 2010.

Date	Vessel	Survey area	Planned	Fishing	No. of	Range of ML

**Table 1. Summary of the survey areas and sample collection of** *D. gigas*

#### *1.2. Fishing Technology*

The fishery was predominantly operated by automated jigging using night lights to attract the squid. Experimental data showed when using high pressure sodium lamps the squid were attracted to shallower waters, which improved fishing efficiency, and the average product per hour was 1 to 6.5 times greater than in previous catches.

## **2. Hard Structure**

#### *2.1. Statolith*

Statolith length (SL) ranged from 1247 to 2249  $\mu$ m with a mean of 1846  $\pm$  140  $\mu$ m and statolith weight (SW) ranged from 1247 to 2249 µg with a mean of 816  $\pm$  161 µg. The relationship between statolith length and weight was best fitted by an exponential curve (Figure 3) showing no significant difference between sex (ANCOVA,  $F_{1,176} = 0.472$ , p =  $0.493 > 0.05$ ). The relationship between SL and Mantle length (ML) was best fitted by a logarithmic curve (Figure 3) showing no significant difference between sex (ANCOVA,  $F_{1,176} = 1.996$ ,  $p = 0.160 > 0.05$ ).

Figure 3. The relationship between statolith length and statolith weight and between statolith length and mantle length.

Three distinct growth zones, namely the postnuclear zone (PN), dark zone (DZ) and peripheral zone (PZ), could be identified based on incremental width from the focus to the edge of the dorsal dome on the statolith microstructure of all the individuals examined (Figure 4). Growth increments in the DZ were much wider than those in the PN and PZ. The first complete check is formed at the time of hatching and is referred to as the "natal ring" (NR; Figure 4A). The second complete check usually lies in the transitional area between the PN and DZ marking the end of paralarval stage (check 1; Figure 4A). The complete check on the outer boundary of the DZ (check 2; Figure 4A, B) and checks within the PZ were found in some statoliths (check 3; Figure 4A). The number of increments within the PN was  $26.2 \pm$  $3.7(n = 120)$  and within the DZ was  $86.1 \pm 11.5(n = 120)$ . Incomplete checks were occasionally observed in the lateral dome (See Figure 4 A check4). Second-order bands with fortnightly increments were observed within a few statoliths (check 5; Figure 4C). An additional center and rings were also revealed in several statoliths (See Figure 4D, E).

Figure 4. Light micrograph of *D. gigas* statolith caught off the EEZ of Costa Rica (A) an immature female of 179 days old and 251 mm ML; (B) a mature female of 216 days old and 310 mm ML; (C) an immature female of 165 days old and 246 mm ML; (D) a mature female of 205 days old and 331 mm ML; (E) a mature male of 197 days old and 325 mm ML; N is nuclear; NR is natal ring; PN is postnuclear zone; DZ is dark zone; PZ is peripheral zone; AC is additional center; AR is additional rings; Broken line shows the predicted normal outline of the lateral dome if the statolith does not have a check 4).

Laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS) analysis showed that calcium (Ca), sodium (Na) and strontium (Sr) are the major elements in the statolith of *Dosidicus gigas*. The Sr/Ca ratio is highest at the embryonic phase (Figure 5a) and declines with age, and its relationship with Sea surface temperature (SST) shows a reciprocal ratio. There is no significant difference of Sr/Ca ratio between different hatching months in every life stage. The Ba/Ca ratio shows a "U" form during the larva to adult stage (Figure 5c), and this could be seen as an indicator of vertical movement with larvae living on the surface and adults living in the deep layer. The nucleus is higher than the peripheral zone in the Mg/Ca ratio (Figure 5d) which presents a positive correlation with SST, and might possibly be due to the gradual decrease of growth rate in the statolith. *Dosidicus gigas*, in its embryonic phase, uses its own vitellicle as a nutrient substance, so the trace elements in this phase are related to the genetic factors of the parent rather than the water environment.

Figure 5. (Continued).

Figure 5. Element/Ca ratios measured with LA-ICP-MS in different growth zones of D. gigas statoliths from the nucleus to the edge. (1-4 represent: nucleus; postnuclear zone; dark zone and peripheral zone)

*2.2. Beak*

*D. gigas'* beak dimensions are best described by linear functions with mantle length but show a positive correlation by exponential equations with body weight. With squid ontogenetic growth, the size of each part of the beak becomes larger with the hood and crest growing faster but the rostrum and wing growing more slowly. The hood and crest of the upper beak grow faster than that of the lower beak.

After the upper beaks of *D. gigas* were regularly cut and ground, a pattern of bands could be seen on the medial surfaces of the rostrum sagittal section (RSS) across the rostrum tip to the joint of the hood (dorsal part) and crest (ventral part) (Figure 6). The anterior portion of the bands in both parts meet at the internal rostral axis in the shape of a  $\leq$ , and the posterior portions are parallel to the rostrum edges (Figure 6). These bands consist of a wider light increment and a thinner dark increment (Figure 7A, B), which in the hood is more discernable and clearer than in the crest (Figure 7C, D). The increments at the tip of the rostrum are narrowest (Figure 7A), gradually becoming wider at the anterior joint (Figure 7B), reaching to the widest at the medial part of the rostrum (Figure7C), and then become slightly narrower again at the posterior joint (Figure 7D).

Figure 6. Diagrams of upper beak of *D. gigas*. A: terms of upper beak; B: medial surface (dark) after sagittal sectioning; C: RSS show growth increments in the dorsal (hood) and ventral (crest).

Figure 7. Increments in the tip part of rostrum (A), the anterior joint part (B), medial part of rostrum (C) and posterior joint part (D) for one *D. gigas* showing the difference in the width of increments alone counting direction.

There was no significant difference in either  $\delta^{13}C$  and  $\delta^{15}N$  values between the upper and lower beak (P  $>0.05$ ), although the values in the lower beak were higher than in the upper beak. The  $\delta^{13}$ C in the upper and lower beaks had a relatively small range from -18.67 to -17.02% (-18.05  $\pm$  0.36%) and -18.36 to -16.69% (-17.81  $\pm$  0.35%) respectively, but the range for  $\delta^{15}N$  was much larger at 5.14 to 9.84‰ (6.77  $\pm$  1.09‰) and 5.94 to 10.04‰ (7.28  $\pm$ 1.02‰) respectively. Both  $\delta^{13}C$  and  $\delta^{15}N$  values in the upper and lower beaks increased with mantle length and age.

## *2.3. Gladius*

For *D. gigas*, a strong linear correlation was detected between gladius length and mantle length ( $r = 0.987$ , mantle length = 0.952 gladius length + 0.190, Figure 8), while a positive exponential relationship was found with body weight. In the vicinity of the Costa Rica Dome, water of a high temperature and sufficient food availability is appropriate to the longitudinal growth of the proostracum (Figure 9), thus the gladius is adequate to support the growth of mantle and internal organs. Moreover, a relatively short conus already provides sufficient reinforcement for fin locomotion to accommodate the low speed current field adjacent to the Costa Rica Dome. After gladii specimens are washed and wiped dry, the growth increments of the gladius can be observed directly on the edge of the lateral plates (Figure 10). These are roughly symmetrically distributed on both edges and are more discernable on the side of the body than on the dorsal surface.

Figure 8. Relationship between gladius length with mantle length of *Dosidicus gigas.*

Figure 10. Growth lines of gladius on the edge of lateral plate (marked with white arrows).

#### **3. Biology**

#### *3.1. Size, Age and Hatching Time*

For f the 281 collected statoliths, led males were all mature except for on specimens re mature, but fore sampled males only on the 281 squid sampled, ML ranged from 205 to 429 mm for females and 212 to 355 mm for males, and individuals with MLs between 290 and 350 mm dominated the sample (Figure 11). Of all the samples, 263 statoliths were successfully read from 211 females and 52 males. Estimated ages ranged from 130 to 289 days with dominant ages from 180 to 240 days, consisting of more than 75% of all the samples (Figure 12). The youngest female obtained was mature at 130 days and 218 mm ML, and the youngest male was mature at 130 days and 212 mm ML. The oldest female was mature at 289 days and 429 mm ML, and the oldest male was mature at 240 days and 352 mm ML. The hatching dates for squid collected during July and August in 2009 in this study ranged from November 2008 to April 2009 with a peak between January and February (winter), accounting for 72.2% of the total sample (Figure 13).

Figure 11. Mantle length (ML) frequency distribution by sex and maturity stage of *D. gigas* off the EEZ of Costa Rica Dome.

Figure 12. Age frequency distribution by sex and maturity stage of *D. gigas* off EEZ of Costa Rica Dome.

Figure 13. Back-calculated hatching frequency by month for *D. gigas* off EEZ of Costa Rica Dome.

#### *3.2. The Relationship between ML and BW*

The ML (cm)-BW (g) relationship of the samples collected were estimated as BW  $=$  $0.076186ML^{2.62945}$  (R<sup>2</sup> = 0.8868, n = 119) for males (Figure 14a), and BW = 0.100846ML<sup>2.5745</sup> ( $R^2 = 0.89233$ , n = 446) for females (Figure 14b). There was no significant difference in the BW-ML relationship between sexes  $(P > 0.05)$ .

Figure 14. The relationship between body weight and mantle length of male (a) and female (b) squid.

#### *3.3. Maturity*

In total, the sex ratio of the catch was 3.75: 1 (female: male), which was significantly higher than the expected  $(1: 1; P > 0.05)$ . The maturity of the squid was different between sexes (Table 2). In males, 81.4% of the total were at stage IV, 15.2% at stage III, and 3.4% at stage II. In females, 42.4% of the total were at stages I–II, 40.1% at stage III, and 26.6% at stage IV (Table 2). Only 0.9% of the females were at stage V (Table 2). For a given size, males were more likely to be mature than females (Table 2).

	N	Sexual maturity (%)						
<b>Sex</b>		Immature		Maturing	Mature	Spent		
				Ш				
Females	446	3.6	28.8	40.1	26.6	0.9		
Males	19		3.4	5.2	81.4			

**Table 2. Composition of the sexual maturity stages of female and male** *D. gigas*

Estimated female  $ML_{50\%}$  was 297 mm and Age $_{50\%}$  was 195 days. The change in the proportion of mature females with size and age (Figure 15) is described by the following equations:  $P_i = \frac{1}{1+e^{-0.024993 \times (ML_i - 297)}}$ 1  $p_i = \frac{p_i}{1+e^{-0.024993\cdot(ML_i-297)}}$  (R<sup>2</sup>=0.964) and  $p_i = \frac{p_i}{1+e^{-0.04035\cdot(Ag_e-195)}}$ 1  $p_i = \frac{1}{1 + e^{-0.04035 \times (Age_i - 195)}}$  (R<sup>2</sup>=0.985). For males, the relationship between the proportion of maturity with size and age could not be quantified with logistic models because there were too few immature males, so  $ML_{50\%}$  or Age<sub>50%</sub> were not estimated. However, we believe that the size and age at first maturity of males should be smaller or younger than those of the smallest specimen in this study (i.e., 211 mm and 130 days old) because only 2 immature males were found in the catch.

Figure 15. The size (a) and age (b) at first maturity of female squid.

#### *3.4. Growth and Growth Rates*

The age-ML data are best described by linear curves based on the AIC (Figure 16A) and no significant difference was found between females and males (ANCOVA,  $F_{1,260} = 0.004$ , P  $= 0.951$ ). The age-BW data are best described by exponential curves for females, but by power curves for males based on the AIC (Figure 16B)

For females, the maximum DGR  $(1.46 \text{ mm d}^{-1})$  and G  $(0.52)$  in ML occurred in 181-210 days, while the maximum values  $(2.07 \text{ mm d}^{-1} \text{ for DGR and } 0.85 \text{ for G})$  for males were reached at 151-180 days although small sample sizes in some age classes might influence the reliability of the estimated growth rates (Table 3). The DGR in BW for females increased with age and the maximum G  $(1.25)$  was reached in 181-210 days, but those for males decreased with age (Table 3).

## **Table 3. Absolute daily growth rates (DGR) and instantaneous growth rate (G) for mantle length (ML) and body weight (BW) for female and male squid off the Costa Rica Dome**

## *3.5. Diet*

The stomachs analyzed rarely contained food remains and on average 70.6% of the stomachs were empty. Regarding the fullness stages, 19.9% and 8.1% of the samples were graded to stage 1 and 2, respectively, while only 1.4% of the total samples were graded to stage 3.

The stomach contents included three major prey groups: fish, cephalopods and crustaceans, which represented 55.8%, 38.1%, and 6.1% of the stomach contents by weight, respectively. The species remains in the stomach contents were identified as Myctophidae, Sardinella, and *D. gigas*. Approximately 65% of the stomachs showed evidence of cannibalism. However, cannibalism was much greater for those squid caught in the light field around the survey vessel, and small squid (ML <10 cm) were often attacked by large-sized *D. gigas* around the squid jigging vessels in the fishing area of 6°-8°N and 95°30'-97°W during August to September in 2010.

Figure 16. Relationships between age and ML and between age and BW of *D. gigas* off the EEZ of Costa Rica Dome.

# **SPATIAL DISTRIBUTION AND SPECIES COMPOSITION OF ZOOPLANKTON IN THE EASTERN TROPICAL PACIFIC OCEAN WATERS OFF COSTA RICA**

*Bi Lin Liu, Jing Yuan Lin, Xin Jun Chen, Tao Jia and Gang Li*

College of Marine Sciences, Shanghai Ocean University, Shanghai, China

## **ABSTRACT**

An analysis of zooplankton species composition, abundance and spatial distribution was undertaken based on investigation data of zooplankton carried out by Chinese squid jigging vessels in the waters (4°30′N-10°24′N, 91°20′W-100°00′W) of the eastern tropical Pacific Ocean off Costa Rica from July to August in 2007 The analysis showed there to be 23 species 17 genus 10 family 8 order in the Coelentera; 74 species 43 genus 30 family 8 order in the Crustacea; 4 species 1 genus 1 family 1 order in the Chaetognatha; 5 species 5 genus 3 family 3 order in the Urochordata; 6 species 5 genus 3 family 1 order in the Annelida; and 3 species 3 genus 1 family 1 order in the Mollusca and other species, including paralarvae, juvenile fish and cephalopod, and pelagic larvae. The species of zooplankton with high abundance were Copepoda and Sagittoidea, while the species with high occurrence frequency were Copepoda, Sagittoidea, Macrura, paralarvae, juvenile fish and cephalopod. The average biomass and amount of zooplankton were  $124.78 \pm 176.83$  mg/m<sup>3</sup> and  $848 \pm 1219$  ind/m<sup>3</sup> respectively, in which Copepoda was the highest at  $727$  ind/ $m<sup>3</sup>$  and the next was Sagittoidea with an abundance of 373 ind/ $m^3$ .

**Keywords**: zooplankton, species composition, abundance, spatial distribution, eastern tropical Pacific Ocean waters off Costa Rica

## **1.INTRODUCTION**

The upwelling of the eastern tropical Pacific Ocean waters off Costa Rica is rich in species of zooplankton and biomass is high (Ferández-Álamo and Färber-Lorda 2006). Tuna, dolphins, blue whales and other large predators perennially prey on smaller fish and cephalopods in this area (Fiedler 2002). Zooplankton is an important part of the marine ecosystem, and the number and type of species directly impacts on the abundance of fish stock. Local studies have been undertaken to analyze the composition and distribution of zooplankton species in the northwestern Pacific, the *Ommatrephes bartramii* fishing ground and the Indian Ocean in the northwest ocean, and the results show that species composition and the distribution of zooplankton are important factors in the formation of fisheries (Xu et al. 2004; Qian et al. 2006). Wangelin and Wolff (1996), Bednarski and Morales-Ramírez (2004) studied species composition, biomass and spatial distribution of zooplankton in the Pacific coast bay of Costa Rica. The EASTROPAC program reported the distribution of zooplankton in the Costa Rican Pacific high seas. From July to August 2009, Chinese squid fishing vessels conducted a survey on the resources of the jumbo flying squid (*Dosidicus gigas*) in the eastern Pacific Ocean off Costa Rica, and collected zooplankton samples. Based on the survey data, this paper considers and analyzes the composition, biomass and spatial distribution of zooplankton species in the sea surface area, and provides basic data for further research on the formative mechanisms of cephalopod resources.

## **2. RESULTS**

#### **2.1. Total Biomass and Abundance**

The biomass of each site was  $2.2 \sim 1138$  mg/m3 with an average value of  $150.3 \pm 184.5$ mg/m3, and abundance ranged from  $18 \sim 7773$  ind/m3 with an average value of  $1030 \pm 1273$ ind/m3. About 40% of the site had a biomass greater than 100 mg/m3 and an abundance greater than 1000 ind/m3. These areas were mainly concentrated at  $8^{\circ}$  00'N  $\sim$  9° 30'N 98° 00'W ~ 100° 30'W, 9° 00'N ~ 10° 00'N 96° 00'W ~ 97° 00'W, 7° 30'N 95° 00'W and 8° 00'N, 92° 00'W (Figure 1, Figure 2).

#### **2.2. Composition of Zooplankton**

There was a variety of species in the collected zooplankton. The Cnidaria included 8 orders, 10 families, 17 genera and 23 species, and all of these were jellyfish. The Crustaceans included 8 orders, 30 families, 43 genera and 74 species (6 of which were identified only to the family) and were mainly copepods. The Chaetognatha comprised 1 order, 1 family, 4 genera, and these were all Sagittoidea. The Tunicata included 3 orders, 3 families, 5 genera 5 species and were mainly cysticercosis. The Annelida comprised 1 order, 3 families, 5 genera and 6 species. The mollusks included 1 order, 1 genus, 3 genera and 3 species. Other zooplankton included the larvae and eggs of cephalopods, the larvae of fish, and long tail,

short tail and oral foot type of floating larvae, etc. of which there were more than 15 (see Table 1).

Figure 1. The spatial distribution of zooplankton total biomass.

Figure 2. The spatial distribution of zooplankton total abundance.

## **2.3. Distribution and Frequency of Zooplankton**

The copepods and Sagittoidea were the most widely distributed species in the whole surveyed area. The second most widely distributed were the juvenile of cephalopods, paralarvae, and the juvenile and larvae of fish, Amphipoda, Brachyura and Oikopleuridae (Figure 3 - Figure 10). The average abundance of copepods was the highest with a value of 727 ind/ $m<sup>3</sup>$ , followed by Sagittoidea with a value of 373 ind/ $m<sup>3</sup>$  and an abundance of other species below 100 ind/m<sup>3</sup>. There was no obviously dominant distribution area for each group, although the spatial distribution of zooplankton abundance was different among the sampling sites (Figure 3 - Figure 10).

The copepods distributed in almost all surveyed waters and they were one of the dominant species with an occurrence of 82.7% (Table 1). Their abundance was about 22  $\sim$ 4789 ind/ $m<sup>3</sup>$  with an average value of 727 ind/ $m<sup>3</sup>$ . The sites where abundance was greater than 500 per/m<sup>3</sup> accounted for more than 50% of the total and were mainly distributed in  $7^{\circ}$  $00'N \sim 8^{\circ}$  00'N and 9° 00'N  $\sim 10^{\circ}$  00'N (Figure 4).

Figure 3. The abundance distribution of Copepoda.

Figure 4. The abundance distribution of Sagittoidea.

Sagittoidea were also distributed in most of the surveyed waters, and were one of the dominant species with a frequency occurrence of 82.7% (Table 1). Their abundance was about  $6 \sim 2002$  ind/m<sup>3</sup> with an average value of 373 ind/m<sup>3</sup>. The sites where abundance was more than 500 ind/m<sup>3</sup> accounted for about 25% of the whole area, and these sites were mainly distributed in 9° 00'N 98° 30'W ~ 99° 30'W, 7° 30'N ~ 10° 00'N 95° 00'W ~ 97° 00'W and 8° 00'N around 92° 00'W (Figure 5).

Figure 5. The abundance distribution of Macrura.

species	ď Amphipo	ura $\sigma$ Brachy vae ā	Sagittoidea	-a Copepo	Cephalopoda $\sigma$ Juvenile	and æ Juvenile Paralar	$\sigma$ Macrura vae ੜ੍ਹ ⊢	Oikopleuridae

(%)	24.0%	12.0%	82.7%	82.7%	62.7%	50.7%	77.3%	6.7%

**Table 1. The species composition of zooplankton**

Macrura were widely distributed in the study area with an occurrence of 77.3% (Table 1). Abundance in most sites was low, and there were only two sites where the abundance was about 500-1000 ind/ $m<sup>3</sup>$ , which accounted for 3.4% of the total area of the survey (Figure 6).

Figure 6. The abundance distribution of Cephalopod.

Cephalopods were also widely distributed in the study area with an occurrence of 62.7%. Abundance was  $2 \sim 16$  ind/m<sup>3</sup> with an average value of 5 ind/m<sup>3</sup>. The abundance in most sites was less than  $5 \text{ ind/m}^3$  (Figure 7).

The larvae of fish were widely distributed in the study area with an occurrence of 50.7%. Abundance was 2 to 52 ind/m<sup>3</sup> with an average value of 12 ind/m<sup>3</sup>. The abundance in most sites was less than 10 ind/m<sup>3</sup>. The larvae of fish in  $8^{\circ}$  30'N and  $96^{\circ}$  30'W had the highest abundance (Figure 8).

Amphipoda distributed in a few sites with a frequency of  $24.0\%$ . Abundance was  $4 \sim 239$ ind/m3 with an average value of 43 ind/m<sup>3</sup>. The species living in 3.9° 30'N, 99° 800'N had the largest abundance at  $200 \sim 300$  ind/m<sup>3</sup> (Figure 9).

Brachyura only distributed in 9 sites with an occurrence of 12.0%. Abundance was  $2 \sim 16$ ind/m<sup>3</sup> with an average value of 8 ind/m<sup>3</sup> (Figure 10).

The distribution of Oikopleuridae was very small, and appeared in only 5 sites, with a frequency of 6.7%. Abundance was  $6 \sim 54$  ind/m<sup>3</sup>, with an average value of about 25 ind/m<sup>3</sup>.

# **TURBOT AQUACULTURE IN SPAIN: AN OVERVIEW**

# *Marcos I. Pérez-Pérez, M. Dolores Garza-Gil\* and Manuel Varela-Lafuente*

Department of Applied Economics, University of Vigo, Vigo, Spain

#### **ABSTRACT**

Turbot (*Psetta maxima*) is one of the main species of farmed flatfish. Spain is by far the largest turbot producer in Europe and is the world's second-largest producer, with more than 99% of Spanish production concentrated in the Galicia region. Turbot aquaculture began in Scotland in the 1970s, after which it was introduced to France and Spain in the early 1980s. Spain expanded its production volume and number of farms, where improvements in juvenile production motivated construction of new installations. By the early 1990s, there were 16 turbot producers in Spain. This chapter addresses Spanish turbot aquaculture from 1983 – when the first industrial turbot farming company in Spain was set up in Galicia – to 2016. In that year, the turbot became the first vertebrate to be genetically sequenced in Spain; this breakthrough opened the way for further investigation into its resistance to various diseases and for the development of more efficient genetic selection projects to improve production. Here, the production and economic performance of Spanish turbot are analyzed in the local, European, and global context. Spain is the dominant market in Europe, but turbot farming was recently introduced to China and production levels are high there. In the coming years, Spanish turbot farming will face challenges that include advances in genetic engineering, a higher standard of research on fish meal substitutes, the development of vaccines for diseases to which turbot are prone, and preservation of the environment.

## **1.INTRODUCTION**

Flatfish have long been of interest to European aquaculture. Turbot (*Scophthalmus maximus* or *Psetta maxima*), sole (*Solea solea*), and halibut (*Hippoglossus hippoglossus*) are

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: dgarza@uvigo.es.

species viewed as candidates for commercial culture, but turbot is the only flatfish species to have made a significant step forward on that score (Varadi et al*.*, 2001). In 1968, Alan Jones was the first researcher to attain turbot larvae metamorphosis after 68 days of nursing. The potential for farming of Atlantic turbot has been under investigation since the early 1970s; researchers in Lowestoft (United Kingdom) reported on the first successful attempts to rear larval turbot in captivity in 1973. Significant research and development continued in the United Kingdom and France in the late 1970s, followed by more recent work on turbot cultivation in Spain, Holland, and (to a lesser extent) Chile.

Turbot farming began in the 1970s in Scotland, and it was then further developed in France and Spain. This farming required intensive culture systems with turbot juveniles supplied from the wild or by marine hatcheries. Starting in the late 1970s, the supply of juveniles from hatcheries was the industry's strategic bottleneck. While problems with hatcheries were being investigated, juvenile turbot continued to be obtained from the wild. This wild juvenile supply had traditionally come from northern Europe (United Kingdom, Germany) and been sent to production units on the Atlantic coast, usually in southern Europe. Hatcheries became effective suppliers of juvenile turbot by the mid- to late 1980s, and wild juvenile collection ceased at that time. Over subsequent decades, the production of hatcheryreared juvenile turbot has expanded rapidly, with most of the increase due to improvements in hatchery techniques for the large-scale rearing of turbot fry. Whereas 1984 saw the production of 4 tonnes of juvenile turbot, 5,000 t. were produced in 2004; here "t." abbreviates "tonnes" (a.k.a. "metric tons,"  $1 t = 1,000 kg$ ).

Turbot is currently produced in Scotland, France, Spain, Germany, Denmark, Ireland, the Netherlands, and Portugal. The main production centers are in southern Europe, especially Spain, because of the more suitable sea temperatures there. However, investment in recirculated turbot systems in northern Europe is continuing with mixed commercial success. Other technological improvements include feeds development and vaccines to combat disease. Most of the turbot produced in the European Union (EU) is also consumed there. The fish are generally sold whole, although they are gutted before sale in some countries. To satisfy market demand, Spain has begun selling filleted turbot. Predictions are for a gradual expansion of turbot production throughout Europe (Bjørndal and Øiestad, 2011).

Worldwide, Spain is the second largest producer of turbot (after China), and in 2016 it produced about 7,100 t. The waters and the environment make Spain, especially Galicia (northwestern Spain), an ideal location for turbot production. The temperature and environmental conditions of Galicia's estuaries are the main facilitators of turbot farming in the region. The Spanish Institute of Oceanography played an important role in the research and development that made possible one of the world's most thriving turbot industries.

## **2. BIOLOGY AND HABITAT OF THE TURBOT**

Turbot (*Scophthalmus maximus*, also known as *Psetta maxima*) is a flatfish species of the family Scophthalmidae. It is a demersal marine fish widely distributed in the eastern Atlantic Ocean, from Iceland and Norway to northern Africa – including the Baltic Sea, the North Sea, the Mediterranean, and the Black Sea. It has an asymmetric and almost round body, with both eyes on its left side. The skin is scaleless but with bony and irregularly distributed

protuberances. Turbot has a demersal lifestyle; thus it lives on sandy and muddy bottoms ranging in depth from shallow waters, where younger individuals tend to live, to 150 meters. It is carnivorous but with a narrow spectrum of prey: juveniles feed on mollusks and crustaceans, and adults feed mainly on other bottom-living fish (e.g., sandeels, gobies) and cephalopods yet also consume crustaceans and bivalves. Females reach maturity at 3 years of age and males at 2 years (and at respective lengths of about 46 cm and 30 cm). The maximum length is about 100 cm; the maximum published weight is 25 kg, and the maximum reported age is 25 years. Turbot exhibits one of the most rapid growth rates observed in flatfish (about 10 cm per year).

Spawning usually occurs from February through April in the Mediterranean and from May through July in the Atlantic. The natural sequence of spawning is every two to four days, and more than 5 million eggs are produced each spawning season. The eggs are pelagic in the Atlantic Ocean and demersal in the Baltic Sea. They are smooth and spherical, measure 1.1 mm in diameter, and contain a single oil globule (of diameter 0.18 mm). The larvae are initially symmetric but, at the end of the metamorphosis (day 40–50, 25 mm), the right eye moves to the left side and so loses its initial bilateral symmetry. The egg size is 0.9–1.2 mm, and the larval length at hatching is 2.7–3.1 mm (Fishbase, 2000).

## **3. TURBOT FARMING**

The turbot's rearing cycle begins in a hatchery, where the breeding specimens are housed. Turbot do not spawn spontaneously in captivity, so gametes are routinely handstripped. Starting in the third year of age, the breeders start laying gametes, which are carefully fertilized. Turbot females may produce  $1-10$  million eggs during the season, depending on fish size. The resulting spherical, pelagic eggs are incubated for four to five days at a controlled temperature. Once hatched, turbot larvae are more than 2.7 mm long. Larval rearing is typically intensive, with densities of about 20 million larvae per liter. They are fed daily with live food: rotifera, artemia, and phytoplankton. The ideal temperature for larvae nursing is from  $18^{\circ}$  to  $20^{\circ}$  (Celsius). Metamorphosis ends after 40–50 days, when larvae are about 25 mm long.

The 5–10-g turbot juveniles are then transported to a nursery section and stored in squareor round-shaped tanks (10–30 m<sup>2</sup>) with an open-circuit system for pumping seawater. Oxygen is often added to the tanks. The fry are fed manually or automatically with balanced dry feed. This stage of the rearing process, known as nursing, spans the fish's development from 10 g to 100 g and lasts for approximately five months. Once turbot juveniles weight 200–400 g, they are transferred to permanent land-based grow-out tanks that typically have a water surface area of 60–120 m<sup>2</sup> and a depth of 0.5–1.0 m. The initial density of 20 kg/m<sup>2</sup> will increase to  $50-70$  kg/m<sup>2</sup> for market-sized turbot. An open-circuit seawater system is used here, too, although some fisheries have experimented with closed-circuit systems.

The turbot are fed with extruded pellets, which are distributed manually or automatically. Water temperature is the key factor for optimal development. The ideal growth temperature is  $14^{\circ}$  to  $18^{\circ}$ , although turbot can tolerate temperatures as extreme as  $8^{\circ}$ – $24^{\circ}$ . The rearing period until the fish are ready to go to market, with an average weight of 1.8 kg, is 18 to 24 months (Fernández, 2013). Some 10% to 25% of the larvae survive to metamorphosis, and the

proportion of juveniles without deformities – and thus selected for continued cultivation – usually exceeds 90%. All juveniles are vaccinated against predominant fish diseases (Bjørndal and Øiestad, 2011).

Bjørndal and Palmieri (2008) used data from several fishing farms in Spain and Portugal to analyze the cost of producing turbot. Their base-case company has an annual output of 133 t., and its average cost is estimated to be  $\epsilon$ 7.54 per kilogram of turbot. If that company expanded its production capacity to an annual output level of 400 t., then it would enjoy a nearly 33% reduction (to  $\epsilon$ 5.07) in the average cost per kilogram. A turbot farm with production capacity of about 133 t. per year requires an investment totaling about  $64.3$ million; tripling the production capacity (to 400 t.) would require another  $\epsilon$ 1.8 million. Thus the additional investment costs are considerably less than the increase in output, which indicates that economies of scale are present. In addition, higher levels of output entail a more efficient use of both labor and management, which can be expected to reduce production costs even more (Bjørndal and Palmieri, 2008).

## **4. SPANISH RESEARCH ON TURBOT AQUACULTURE**

#### **4.1. Farming Research**

l

The research on turbot farming carried out since the early 1980s by the Instituto Español de Oceanografía<sup>1</sup> (IEO, the Spanish Institute of Oceanography), and specifically the IEO center in Vigo (Galicia), was fundamental for implanting and developing this industry in Spain. The first research project in Vigo that was funded by the IEO began in 1982 and is entitled "Research on the viability of flatfish culture." The objective was to identify species most suited to being cultivated in Galicia. After the relevant biological, commercial, and market factors were analyzed, the turbot was selected as the first marine species to be cultivated on an industrial scale (Iglesias, 2009).

Subsequently, in the period from 1984 to 1986, the first subsidy from the CAICIYT (Comisión Asesora de Investigación Científica y Técnica) for a turbot culture research project in Galicia was obtained. This project focused on two main types of activities. The first type involved obtaining fertilized eggs in captivity, maintaining (in IEO facilities) a stock of mature females, and using males from the Vigo fish market to obtain sperm. Here the incubation and larval culture processes were started by artificially fertilizing (in "dry" conditions) the mature eggs. In Galicia, the first turbot eggs fertilized in captivity were obtained in April 1984; these results were formally communicated to the *International Council for the Exploration of the Sea* in 1985 (Iglesias et al*.*, 1985).

The second type of activity addressed by this project was developed in the nursery Puerta Oviedo (Baiona), where 300 turbot juveniles were housed in order to determine the growth rate of this species in Galicia – that is, until reaching commercial size. The first results on turbot growth in Galicia obtained by an official research center were published in the journal *Marine Biology* (Iglesias et al*.*, 1987); these data were the essential reference source, on the

<sup>&</sup>lt;sup>1</sup> Advisory Commission for Scientific and Technical Research (1958–1987), a now defunct public extinct institution of the Spanish government.

cultivation of this species, used by later studies and initiatives of private companies carried out in Galicia.

In parallel with this project, two pioneers of the turbot industrial sector – Alfredo Fernández and Sergio Devesa – proposed in 1983 and 1984 that the IEO monitor the maintenance of the first turbot juveniles to be fattened on an industrial scale. These juveniles were initially conditioned in the Plan Marisquero de Galicia<sup>2</sup> facilities (Vilanova de Arousa) and were sampled monthly until being moved to Insuiña S.L. (O Grove), the original Galician turbot farming company.

The Vigo IEO centre proposed that the other turbot farm then installed in Galicia, Cultipec S.L. (also in O Grove), become the first company to handle the entire turbot production cycle – that is, including the hatchery and nursery phases. The plant was designed based on guidelines provided by IEO technicians, and the company's first biologists were also the beneficiaries of IEO scholarships.

Thereafter, the IEO coordinated successive projects related to turbot culture development. Examples include a study of the nutritional benefits of larvae (FAR-UE Project), a study of pathologies (with the University of Santiago de Compostela), the use of a dry feed in a study undertaken with the company Ewos (CDTI Project), the design of floating cages in Baiona Bay, and a genetics project for the production of sterile turbots and all-female populations (which have the highest growth rates).

In light of the surplus turbot juvenile production at the IEO plant in Vigo, a European project began in 1989 to establish the basis for future repopulation programs: "Evaluation of stock enhancement of marine flatfish" (Støttrup et al*.*, 1998). The project consisted, on the one hand, of learning about the distribution, survival rate, and feeding of cultivated turbot juveniles released in the Vigo estuary; this information could then be used to determine sustainable recapturing percentages. On the other hand, this project analyzed the minimum optimal age at which to release specimens and compared the mortality of cultivated specimens with that of wild individuals in the natural population. All these data, published in accesible scientific journals (Iglesias et al*.*, 1994; Iglesias et al*.*, 2003), served as a reference for the turbot repopulation plan of the Xunta de Galicia (Galician Local Government) Fisheries Department.

After the *Prestige* oil spill off the coast of Galicia (2002), the Xunta de Galicia initiated stocking programs for turbot (among other species) toward the end of restoring their populations. Stocking began in 2005, and the program lasted five years until 2009; releases took place at two Atlantic sites on the Galician coast (5,000 and 10,000 fish released per year) and came from a mix of broodstock of wild origin (25%) and from aquaculture companies  $(75%)$ . Most of these programs were carried out using juveniles  $(0+$  or  $1+$  year class), which were released in shallow coastal habitats. Released turbot exhibit a mortality rate similar to that of wild turbot. Although there are differences between wild and hatchery turbot with regard to prey and feeding behavior, released hatchery turbot can evidently adapt to a natural diet within a few weeks. Releases of hatchery turbot have been proposed to enhance fisheries recruitment when integrated with a resource management program of sustainable fisheries and habitat restoration. Of course, such releases should proceed with great care becasue both positive and negative ecosystem effects are anticipated at the species, community, and ecosystem level (AquaTrace, 2014).

#### **4.2. Vaccine Research**

In 2000, researchers at the University of Santiago de Compostela (USC) patented an anti– *Vibrio anguillarum* vaccine (GAVA-3) for the prevention of vibriosis in turbot and *Salmonidae* fish; they also patented the process for producing that vaccine. The GAVA-3 can be administered by short bath, prolonged bath, or injection, and it gives both turbot and salmon remarkable levels of protection against vibriosis.

In 2008, the first vaccine for turbot parasites was registered by USC researchers. The efficacy of a vaccine against the fish pathogen *Philasterides dicentrarchi* was evaluated in four groups of turbot by measuring the production of specific antibodies and the length of protection (Sanmartín et al*.*, 2008).

#### **4.3. Genetic Research**

In 2007, the turbot was genetically mapped by researchers of the Veterinary Faculty of Lugo (University of Santiago de Compostela). This study represented the first linkage map in the turbot, and it is suitable for the identification of productive traits in this species and for further evolutionary studies in fish and other vertebrate species (Bouza et al*.*, 2007). The 2007 genetic mapping was concluded in 2016.

The turbot is the first vertebrate genetically sequenced in Spain. The results of the turbot's complete genome sequencing – carried out by scientists from the Spanish National Research Council (CSIC), the University of Santiago de Compostela, and Spain's National Centre for Genome Analysis (Barcelona) – were published in the magazine *DNA Research* in March 2016 (Figueras et al., 2016). According to this study, the turbot has a much more refined visual system than other fish because it has evolved to adapt to the seabed's shortage of light. In addition, the fat in the cell membranes is double that of other species, which enables turbot to withstand the low water temperatures of their habitat. These results could be used in the future design of genetic selection programs or of vaccines. This work was funded by the Spanish Government and the Xunta de Galicia Local Government.

Researchers compared the turbot genome with model fish genomes to investigate teleost chromosome evolution. They identified gene family expansions and positive selection of genes associated with vision and metabolism of membrane lipids, which suggests adaptation to (respectively) a demersal lifestyle and cold temperatures. The data indicate a quick evolution and diversification of flatfish to adapt to benthic life, and they provide clues for understanding the origin of these species (which is a subject of controversy). Scientists have also investigated the genomic architecture of growth, gender determination, and disease resistance, which are key traits for understanding local adaptation and thereby boosting turbot production. The genomic architecture of these productive traits has allowed for the identification of candidate genes and has enriched pathways that could yield information useful for future, genetic marker–assisted selection of turbot.

The turbot, with both eyes on its left side, underwent a process of metamorphosis during its development, which is when it began to develop a body distribution atypical of flat fish. It lives on the seabed because of this circumstance, so it has been forced to adapt to an environment of very little light and chillier waters. Many of the genes involved with sight (mainly, those that carry pigment codes), and others involved in forming the eye crystalline, are repeated in this vertebrate – that is, more so than in other fish. The implication is that the turbot has evolved, refining its sense of sight as an adaptation to the low light levels in its environment. In order to tolerate the low temperatures, the turbot has a number of genes related to fatty acids in the repeated cellular membranes, which are found in lower numbers (or not at all) in organisms that live at higher temperatures. The lipid composition of these membranes is a key factor when it comes to withstanding cold.

Scientists have managed to identify the most important genes involved in growth, sexual differentiation, and disease resistance, including which specific parts of the genome affect these production traits. This information is essential to the development of more efficient genetic selection projects, which aim to identify the breeding fish with the best production traits. Another of the challenges facing this sector is how to shorten the time required for fish to reach a marketable size. This problem can be addressed by selecting for the genes involved in growth and sexual differentiation – given that females grow at a much faster rate than do males.

The study concludes that the genome sequence of turbot is among those with highest coverage within fish (and similar, in that regard, to that of the tongue sole) as well as one of the most compact sequences among vertebrates. These findings contribute immensely to our understanding of the organization and evolution of fish genomes. The integration of the turbot genetic and physical maps and their comparison with model fish genomes are powerful tools for future studies in turbot, fish, and vertebrates. This genome has shed light on the genetic basis of relevant productive traits, and it represents a milestone for boosting turbot production through more efficient, marker-assisted selection programs.

## **5. THE SPANISH TURBOT INDUSTRY**

The first industrial turbot farming company in Spain, Insuiña, was set up in 1983 by three entrepreneurs in O Grove (Galicia). The first production of turbot was sold in 1985 at a profitable €15 per kilogram (Fernández, 2013). Galicia was the only Spanish region producing turbot until 1986, when Cantabria and the Basque Country regions commenced their turbot production; Asturias also produced turbot during the period 2003–2007. The Basque Country ceased production in 2013, so Galicia and Cantabria are now the only two Spanish regions producing turbot. There are currently about 20 turbot-rearing farms and five nurseries in Galicia, but there is only one rearing farm in Cantabria (property of Rodecan, S.L.).

In 1988, Galician turbot producers joined to create AROGA (Asociación de Productores de Rodaballo de Galicia). This association now consists of seven companies whose most important production centers are located in Galicia: Acuidoro, S.L.; Aquacria Arousa, S.L.; Insuiña, S.L.; Luso Hispana de Acuicultura, S.L.; Piscicola del Morrazo, S.A.; Punta Moreiras, S.L.; and Stolt Sea Farm, S.A. The last-named company, Stolt Sea Farm, is the world's leading producer of farmed turbot. The company produces a million juveniles annually in two hatcheries in Galicia, which in turn supply five grow-out facilities in the region. Stolt Sea Farm is, moreover, the leader of a group including two other companies in France and Portugal. In was also during 1988 that moist feed was first used by Galician turbot farms.

In 1989, a crisis motivated creation of the Mar Novo Galician Turbot Cooperative, which centralized all marketing activities as well as the procurement of fry and other supplies. That year, the first vaccine for *Listonella anguillarum* (also known as *Vibrio anguillarum*) was used in Galicia. Production was limited by an unstable source of juveniles owing to high mortaly rates during the larval stages. Vibriosis has been  $-$  and still is  $-$  one of the major disease problems of the aquaculture industry. *Vibrio anguillarum*, *V. salmonicida*, *V. ordalii*, and *V. vulnificus* are among the pathogens responsible for the greatest losses in aquaculture worldwide (Sandlund et al*.*, 2010).

Spanish turbot aquaculture faced a crisis in 1992, before the sector's commercial structure had become firmly established. More than 1,000 t. of turbot were offered on the market that year  $-$  a 52% increase in production  $-$  but the industry then lacked a consolidated commercial marketing network. Fish farms were small and had high production costs. So whereas 1991 production costs were  $\epsilon$ 7.50/kg, the 1992 sales price peaked at  $\epsilon$ 5.42/kg. Company losses could not be averted, and a restructuring of the industry ensued. This crisis led to the closure of six farms. Reorganization of the sector commenced shortly thereafter, which ended up increasing not only the volume of production but also the number of countries in which turbot is farmed (Fernández, 2013).

In 1993 there emerged the first reports of zoonosis (human–vertebrate disease transmission) associated with Galician turbot production. The resulting greater mortality of juveniles reduced production volumes in 1996 and 1997 as compared with predictions based on the growth trends in previous years; see Table 1 and Figure 1 (in Section 6.1). Also in 1993, the use of additional oxygen in the commercial cultivation of turbot began (Fernández, 2013).

The Galician Aquaculture Cluster was born in 2000 from the association of eleven Galician companies dedicated to the growing of turbot. Its main objective is to consolidate the competitive position of the Galician aquaculture sector by generating and fostering its members' advantages through research and development. Other objectives include increased cooperation among association members and the promotion of a "business innovation" culture. The Aquaculture Cluster in Galicia has become an international repository of information about the farming of flatfish, turbot, and sole. Its members, which manage facilities throughout Europe, represent 85% of the European production of flatfish (turbot and sole). The Aquaculture Cluster's operating model has inspired the creation of other clusters and similar networks in Spain and Europe.

Under the Aquaculture Cluster's tutelage, the Galician Aquaculture Technological Centre (CETGA) was designed as a pilot aquaculture factory dedicated to experiments. The CETGA researches and develops critical, high-impact technology and scientific projects whose success is instrumental in the *sustainable* development of Galician aquaculture.

In 2002, the OPP 59 (Organización de Productores del Rodaballo) was created; also, the Asociación de Productores de Rodaballo was included – as a national-level fishery producers organization – in the General Register of Fishing Producers Organizations of the General Direction of Fisheries Management. However, that recognition was removed in December 2016 at the association's own request.

In 2008, the Plataforma Tecnológica Española de la Pesca y la Acuicultura (PTEPA) was established. This "Fisheries and Aquaculture Spanish Technology Platform" is a nonprofit association whose main purpose is promoting technological development and innovation – to include the processing and marketing of products – in the fisheries and aquaculture sector. In

general terms, the platform provides members with valuable information about innovation while facilitating their elevation to a more privileged position within the national aquaculture and fisheries sector. One aim of PTEPA is bring together all stakeholders in the fisheries and aquaculture sector for the purpose of coordinating actions and information about the various technologies being employed. Thus, a common national strategy for research, development, and innovation is proposed to secure a competitive position for national aquaculture and fisheries companies.

## **6. TURBOT PRODUCTION IN SPAIN**

#### **6.1. Production Volume**

The increase in Spanish turbot production – from 15 t. in 1983 to 7,100 t. in 2016 – was nearly continuous, interrupted only by health-related problems and fry shortages. Spain's greatest turbot production (8,320 t.) was reported in 2009; subsequent years have seen relatively stable production, with annual volumes averaging about 7,500 t. Galician turbot production now represents nearly 99% of the total national volume, while Cantabria accounts for the remaining 1%; in 2015, their respective production volumes were 7,706 t. and 109 t. (see Figure 1 and Table 1).

Source: APROMAR.

Figure 1. Turbot production (tonnes) in Spanish regions, 1983–2016: Galicia (blue), Basque Country (red), and Cantabria (yellow).

The substantial increase in turbot production during the early decades of this time span can be attributed mainly to improvements in the technology of fry production, which increased the quantity and quality of the fish. As a consequence, the supply of juveniles was no longer a limiting factor in the development of aquaculture (Rodríguez and Fernández-Casal, 2008). The five nurseries in Spain (all in Galicia) achieved their maximum production in 2014: a total of 22.3 million juveniles (see Table 2).

## **Table 1. Spanish turbot production (tonnes), 1983–2016**

*<sup>a</sup>* Preliminary data.

Sources: APROMAR, Fishstat Plus.

### **Table 2. Number of juveniles produced in Spain, 1998–2015**

Within the European Union, Spain is the main producer of farmed turbot; in 2015, its 67.6% of the EU total amounted to 7,815 t. Portugal, with 3,144 t. (27.2% of the EU total) produced, is the second-leading country. Note, however, that this rank reflects the 2009 opening – by the Galician company Pescanova – of a plant in Mira that is now the world's largest turbot farm. Substantially smaller production (altogether 5.2% of the EU total) occurs in France, the Netherlands, and Iceland (see Table 3).

Note: N/A = not available. Sources*:* APROMAR, Fishstat Plus.

In global terms, the farmed production of turbot was almost exclusively EU based until 2008; the only two exceptions were South Africa (since 2000) and Iceland (since 2001). In recent years, however, production has increased dramatically on other continents. Farming was developed in China with broodstock imported from Europe. Data compiled by the FAO (FAO, 2016) indicates that, since 2009, China has produced about 60,000 t. of farmed turbot annually. In addition, Chile is producing some 300 t. per year.

#### **6.2. Production Value**

The production value of Spanish farmed turbot was generally increasing (similarly to the production volume trend) until 2011, when a maximum of  $\epsilon$ 70.9 million was attained (86.6%) of the EU total production value; see Table 4). The value of production has been stable in recent years, averaging  $\epsilon$ 57 million for the period 2012–2015 (see Figure 2 and Table 5).

#### **Table 4. European Union turbot production volume, production value, and first-sale price, 1985–2015**

Note:  $N/A$  = not available. Sources: APROMAR, Fishstat Plus.

Notwithstanding some severe oscillation in earlier years, turbot's annual average first sale price has remained relatively stable over the last two decades even as production levels have increased. The average first-sale price for the period 1995–2015 was  $\epsilon$ 8.60/kg. Recent years have evidenced a slight decline in that price – to  $\epsilon$ 7.36/kg in 2015 (see Figure 3 and Table 5).

Sources: APROMAR, Fishstat Plus.

Figure 2. Value of Spanish turbot production ( $\epsilon$  thousands), 1985–2015.

Sources: APROMAR, Fishstat Plus.

Figure 3. Spanish turbot: annual average first-sale price (€/kg), 1985–2015.

In some years (2009, 2012) there have been significant price reductions – to below  $\epsilon$ 7/kg. One possible explanation is that most turbot is harvested at a weight of 1.5–2.0 kg per fish and that larger fish fetch a higher price *per kilogram* than do smaller fish. Some companies that experienced financial problems during the Great Recession were forced to sell product at lower-than-optimal weights simply to maintain cash flow. These developments also put downward pressure on the prices that other companies can charge (Bjørndal and Øiestad, 2011).

For large farms in Galicia, the cost of turbot production ranges from €5.00 to €5.50 per kilogram. Packaging and transport amount to an additional  $\epsilon$ 1.00/kg. Smaller farms do not benefit from economies of scale and so have higher production costs (Bjørndal and Øiestad, 2011).

#### **Table 5. Spanish turbot production volume, production value, and first-sale price, 1985–2015**

Sources: APROMAR, Fishstat Plus.

#### **6.3. Markets for Turbo Production**

Spain is one of the world's largest turbot markets. That national market is served almost entirely by farmed product, since landings of wild turbot are negligible (41 t. in 2014). According to Bjørndal and Øiestad's (2011) analysis of the Spanish national turbot market, in 2009 supermarkets represented the most important retail channel (39% of total sales), followed by hypermarkets (24%) and fishmongers (19%). The relative shares of supermarkets and hypermarkets have evidently increased over time while that of fishmongers has declined. Although turbot is a traditional species in Spain (mainly in the northern area), it is consumed less than other farmed species such as seabream or seabass. Over 2005–2007, fewer than one in five Spaniards (about 18%) consumed turbot; the maximum frequency was about once per

month. Consumers view turbot as fish of good quality that is safe to eat but somewhat expensive (Bjørndal and Øiestad, 2011).

Spain is also, by far, the largest exporter of farmed turbot in Europe. Most of the national production is exported to European markets, which include Italy, France, Germany, and the United Kingdom. In 2014, 69.6% of Spain's total production (5,431 t., valued at  $\epsilon$ 35.4 million) was exported. In 2014, turbot exports fell 2.82% in volume yet rose 3.46% in value: to 5,278 t. and €36.7 million, respectively (ANFACO-CECOPESCA, 2016).

## **7. FUTURE OUTLOOK AND CHALLENGES FOR SPANISH TURBOT FARMING**

Further development of the turbot industry and market depends on factors such as innovative processes and institutional support (Sturrock et al*.*, 2008). Supply will be affected by the following factors: site availability and cost, while considering both physical availability and government regulations; support for innovation, including government and business investment in research and development; and the support of governmental and financial institutions for commercial (technology-based) risk takers (Bjørndal and Øiestad, 2011). On the demand side, turbot is a popular but premium fish species and so prospects for steady growth remain within price-based limits (Bostock et al*.*, 2008).

In Spain, a key factor in the further expansion of turbot farming is the future Aquaculture Law of Galicia. Now in preparation, it will be the first aquaculture law in Europe. The sector is not currently subject to any specific regulations beyond those pertaining to all fish products. Site availability for plants along the coast – and their possible environmental effects – is key aspects to be regulated. The impending legislation seeks to identify suitable areas for aquaculture uses, to establish how plants should be integrated with the surrounding landscape, and even to address the potential consequences for climate change. So that companies will have greater legal certainty, the law intends to clarify the competencies that each administrative body will have for granting concessions to occupy the public domain and for granting aquaculture permissions.

Future challenges faced by the Spanish turbot farming include turbot diseases, turbot nutrition, turbot genetics, environmental management, and government support (Fernández, 2013). As for diseases, several pathogens (bacteria, viruses, parasites) affect the health status of farmed turbot. Although there are effective vaccines and treatments that target a variety of such pathogens, there is no easy solution to the problem of other diseases – especially those induced by viral agents. Neither vaccines nor therapeutic treatments are commercially available for most of the viral diseases affecting fish (Pereiro et al*.*, 2016). More research on fish meal substitutes is also needed if aquaculture is to be sustainable. Several experiments have suggested that turbot requires a high level of dietary protein (50%–60% of the diet). Hence there is interest in replacing some of the fish meal, which accounts for 50%–70% of their diet, with protein-rich plant ingredients (Burel et al*.*, 2000).

Progress in genetic improvement is also essential, and the genome sequencing of turbot is a significant step forward in that regard. It may be necessary to "improve" the genetics of turbot in order for large-scale aquaculture to succeed in a highly competitive world market. The control of inbreeding, avoiding the loss of genetic diversity, the identification of genderdetermining mechanisms for manipulating gender ratios, and the selection of broodstock for disease resistance and growth rate are stepping-stones to improved turbot production (Bouza et al*.*, 2007). Selection of fast-growing and late-maturing fish is another way to increase turbot growth (Person-Le Ruyet, 2002). As regards environmental management, it is crucial to undertake detailed studies of coastal water behavior so that environmental disasters can be prevented. The environmental effects of water recirculating systems for turbot farming – such as the eutrophication and acidification of coastal waters – have been studied (Aubin et al., 2006) but certainly merit further attention. Finally, government support remains vital where legislation, advertising, marketing, and finance are concerned. That support is needed to advance the agenda of an Aquaculture Law in particular and of an aquaculture program more generally, both of which are needed for Spain's turbot farmers to remain competitive industry players.

#### **ACKNOWLEDGMENTS**

The authors acknowledge financial support from FEDER and Xunta de Galicia (GRC2014/022 and AGRUP2015/08) and from the Ministry of Economy and Competitiveness (ECO2014-52412-R and ECO2013-44436-R).

## **ABSTRACT**

Throughout the later years, the interest in studying the features and behavior of fish schools and their relation with fisheries management has increased. Of the total of teleost fish species, 25% might own some type of grouping which has been categorized into three main terms: aggregation, shoal and school. The gregarious behavior, serves to provide benefits to fish in relation to obtaining food, reproduction, protect the group and reduce energy expenditure, however the avoidance of predators being by several authors as the most mentioned advantage, but this will not always be effective, as it is closely related to the predator's ability to increase the rate of consumption on a polarized group of fish. The factors that cause the formation of certain type of group depend on several causes such as species type, age, biotic and abiotic factors, among other and the possible combinations between these. Here are discussed the anatomical adaptations that allow this behavior, as well as the advantages and disadvantages that the natural environment represents for fish organization as a school. On the other hand, humans have used the knowledge of this behavior for the fisheries, taking advantage of the great diversity of fish species that form shoals or schools. When fishes are grouped, they become relatively easy to catch and their abundance makes their extraction economically profitable. The present chapter examines some examples of how the study of gregarious behavior in teleosts is a complex topic that has been necessary for the modernization of fisheries,

which will allow the modification of capturing methods as well as the fishing gear that is necessary according to the site, season and target species.

**Keywords**: small pelagic fish, school, shoal, fishing gears

## **INTRODUCTION**

Nowadays, teleost fish represent the vertebrates group with the most diversity of species, which exhibit a great variety of behaviors to ensure their survival. In a strict meaning and according to Collocot & Dobson (1974), behavior includes all the observable and measurable activities that a living animal presents as a response to its interaction with the environment, including contractions and expansions of tissue responsible for movement, color change, glandular secretions, etc.

A type of particular behavior in the teleosts, is the related to the interspecific and intraspecific interactions of the individuals and that can be referred as "gregarious behavior" which according to Shaw (1978), is present at some stage of at least 25% of the described fish's species.

According to Pavlov & Kasumyan (2000), a confusion persists in the applied terminology to refer to the fish groups types, caused by a vague distinction between different terms. This is because the internal organization and the relation patterns among the individuals are widely varied, due to they are subject to diverse factors like the type (or types) of specie, age, diverse biotic and abiotic factors, lifestyle and possible combinations between these.

In accordance with the amount of interaction between fish, three main concepts can be defined for this gregarious behavior:

In the first place, we have the term *"aggregation"* that involves a group of fish gathered time-space, attracted by different factors like diet, temperature and/or shelter (Pitcher, 2001; Helfman et al., 2009). On the basis of this concept, the group can be conformed by individuals of one or various species with a relatively random orientation between them (unpolarized), does not necessarily derive in a social attraction. From this point forward, it is necessary to mention the word "grouping" as referring to fish groups, in spite of any of the three levels of interaction that the group might present, with the purpose of avoiding a confusion with the word aggregation (Figure 1a).

The second concept is named *shoal,* which involves a group of three or more fish on the same ontogenetic phase or not, with well defined social characteristics and where each individual reacts to the movements of adjacent fish, adjusting speed and direction of their swim (polarized) without showing a high level of synchrony in response to external stimulus (Partridge, 1982; Pitcher, 2001). Shoals are usually conformed by individuals of a specific kind. Although there are other fish that can assimilate, these must have swimming aptitudes that are similar to most fish in the group as well as synchrony (Figure 1b).

Finally, *school*, which includes temporary fish groups on similar conditions to the ones of a shoal. In this organization a high relation of mutual attraction exists among the individuals that results on a high level of swimming coordination, which benefits all the individuals of the group (Radakov, 1973; Pitcher et al., 1983; Pitcher & Parrish, 1993; Pavlov & Kasumyan, 2000; Figure 1c). This high degree of coordination produces a discrimination effect among members, allowing fishes of a same species and cohort be part of the group, or individuals of other species with sizes, ontogenetic phase, and similar swimming and reaction capacities join the group.

Figure 1. The degree of socialization among members of different groupings determines if we have an aggregation (a), a shoal (b) or a school (c).

One of the advantages of this last term is that schools formed by "familiar" members probably entail the formation of hierarchy with more stable dominances and, therefore, a reduction of aggressive behavior among members of the school (Gómez-Laplaza, 2005), besides, forming schools with familiar individuals eases the evolution of altruistic behavior (Utne-Palm & Hart, 2000), which in turn increases the probability of survival. In addition, this characteristic of familiarity has demonstrated that anti-predator behavior is better than those who do not show this feature (Griffiths et al., 2004). For example, it has been shown that in the salmonid species levels of aggression are lower when these have a familiar relation (Brown & Brown, 1993). Likewise being away from the shoal must be avoided, for lonely fish will lose antipredatory advantages associated to the grouping's lifestyle (Bertram, 1978; Rubenstein, 1978). In the studies made by Tien et al., (2004), it is noted that the degree of cohesion is larger in the presence of a predator, in comparison to swimming activity or search for food (sensu the 'life-dinner' principle [Dawkins & Krebs, 1979]).

### **ADVANTAGES AND DISADVANTAGES OF GROUPING BEHAVIOR**

#### **Advantages**

Based on the concept of aggregation it is hard to observe advantages that benefit all the fish that form this type of grouping, given the reduced interaction of all members; however, fish who swim far from the attacking source can be attracted when receiving sensorial stimuli

from other fish making use of a resource and in this way benefit in the face of the detection for possible threats.

On another hand, amongst the main advantages that characterize the groupings as shoal or school we can emphasize: diet, reproduction, protection, vigilance and the reduction of energy expenditure in swimming (Radakov, 1973; Partridge, 1982; Fréon & Misund, 1999).

The most evident benefit of schools and shoals is protection, due to these groupings coexist on the same habitats as their predators, the first step to avoid being hunted is the early detection of possible sources of danger and at this point vigilance starts to become the first antipredatory advantage, which works in the following way: the presence of many detection organs (mainly visual and mechanoreceptor-related) acting in ensemble for the location of possible threats difficult the predator's attempts to come close the grouping without being detected (Figure 2a). This first defense mechanism requires for the visual conditions to be beneficial in most individuals and thus keep a suitable distance from the predator, which can allow an appropriate response for the attack (Cushing & Harden-Jones, 1968; Pavlov & Kasumyan, 2000). This can explain the alteration of the school structure in the face of a predatory threat (e. g. when a flattened school becomes more spherical to permit a better vigilance on different angles; Partridge, 1980; Figure 2a).

If the predator continues to get close the group, the defense will continue to employ mechanisms of confusion (Landeau & Terborgh, 1986; Pitcher & Parrish, 1993). Visual confusion in teleosts that present grey tonalities is very common, this fact difficult for the predator to focus their sight on a bright target of a moving mass that, besides, presents different contrasts of tonalities and light reflections. This is one of the reasons why the attacks on fish that form schools are often more successful at dawn or at dust, where the effectiveness of the glint of the fish scale towards the predator's sight is reduced (Moyle & Cech, 1988).

Regardless of coloring, there is another effect of confusion towards the predator's sight when trying to locate multiple potential targets. Some authors have even mentioned that the possibility of becoming a prey during a predatory attack, inversely declines in relation to the group size (Bertram, 1978; Foster & Treherne, 1981).

The confusion effect can also be aimed to the ear and the mechanoreceptor (octavolateralis system) of the predator. Vibrations of the surroundings, fish swimming, vocalizations and other mechanic disturbances generate gradients of pressure near the already stated source when generating diverse flows in the water. The fin movements of a lonely fish can act as an emission source of punctual-shaped waves, these signs can help the predator fish detect the prey with help of its internal ear and its lateral line. When finding lots of generator sources of densely grouped waves, as it is previously mentioned, they will cause an overlay of the hydrodinamic signs and the sensors of the internal ear of the predator will not be able to decipher the spatial details of the prey, avoiding its detection of the group (Larsson, 2012; Figure 2b).

If the predator gets closely enough to carry out attack tactics, breaking the minimal distance of approximation, the group can perform coordinated maneuvers of escape, for which imitation behavior is extremely important, mostly in the school's configuration, helping to keep the unity within the school during quick and complicated maneuvers when fish are scared (Pavlov & Kasumyan, 2000; Figure 2c).

Figure 2. Defense mechanisms start with vigilance (a), when finding a near predator, it will be perceived by a great amount of receptive organs that will alert the fish group (b), and if it breaks minimal distance the grouping could perform escaping tactics (c).

The main tactics of escape were described by Charnov & Krebs (1975), based on four main types of behavior: "Escaping and the minimum approach distance", is based on the distance that is supposed to be between the herd and the predator, as well as the direction of their swim opposite to the attack in order to improve the escape tactics and acceleration. A second tactic is the one called "Fountain effect," where the predator's velocity maximizes, when it is about to attack the school; nevertheless, the school reorganizes itself behind the predator. When the herd is too big, this tactic can even simulate an ameboid behavior of the school or shoal, where the predator gets sucked into a sort of vacuole.

These last two tactics require a high communication and cohesion among individuals, this is why they are only possible in school groupings. The "Trafalgar Effect" is another tactic where in the face of a great number of pounding stimuli, there can be a great number of maneuvers, product of the fast transference of information across the organisms that are part of the school. Finally, the "Bait ball" tactic, that schools of small pelagic fish use, which increases the degree of cohesion in the herd to be able to shelter in a strongly compressed spherical formation where the individuals located in the middle are less likely to be hunted. Hamilton (1971), proposes that this is a "selfish" tactic because all organisms seek to be positioned at the center of the herd, however, this configuration allows to detect approximations from all possible angles and react on time, benefiting all the members of the herd.

It is important to point out that the defensive advantage maintaining the group is not always effective, this will depend on the predator's abilities. If the measure of the predator's attacks increases in proportion to the school's size, the probability of becoming a victim will be the same as a lonely fish (Pitcher, 1986). It is important to observe that when this behavior appears, lots of ichthyophagous predators will be excluded of accessing to one of the

members of the herd, nevertheless the competition of defense and attack, only some species will be capable of avoiding these mechanisms and feed from fish that form schools.

This defense instinct is so important that it persists when the abundance of sardines, sardinellas or anchovies is low, which tend to form mixed schools among them, this due to it is priority being member of a school that has fish with size and shape alike (individuals that are similar targets in the face of potential predators), this distinctive feature called *school trap*, which indicates a strong meaning of survival to remain a member of a school and indirectly displays the strong reluctance of any individual to leave the school voluntarily (Bakun & Cury, 1999).

Another of the documented advantages, is the increase of resistance in a fish's swim, which increases two to six times when it is part of a school; this hydrodynamic difference is due to vortices generated by the flick of tails to find an even flow to save swimming energy expenditure. Under a diamond-shaped configuration, the most advantageous position is the one located behind the middle point between two fish that are at front, this without remaining too far from their vortices (Weihs, 1973).

This swimming advantage makes it easier for migrations with an active swim for hundreds of kilometers to function, maintaining high velocities during this period. It has been observed that in species like *Clupea harengus* the shifting as a school not only makes it easier for fish to find ideal migratory routes, but it also increases their precision (Pitcher & Parrish, 1993). It is likely that the level of motivation attached to the behavior of imitation works as a filter to group those individuals that are prepared to participate in a migration. This effect favors the formation of big schools of clupeoids and gadids when long migrations of spawning and diet begin to happen.

Another necessity for the survival of the species is reproduction and remaining in group turns out to be advantageous for this, not only in the search and shifts to spawning sites, but also with the encounter of couples too. There are coastal fish like the case of gulf corvina *Cynoscion othonopterus*, which makes a migratory circuit inside the delta of the river "Río Colorado" in Mexico (Chao & Musick, 1977) including a period of diet and growth, until they reach maturity. Once they are mature, the individuals penetrate the delta for spawning, which has a duration of approximately two months. Once this is over, the organisms return to the sea to start a state of non-reproductive activity for a year (Solana-Sansores et al., 2012). Within the same region the poorly-studied spawning behavior of the gulf grunion, *Leuresthes sardina,* can be found. It only has a five-day duration. During the spawning period (mainly related to tides), the fish of this species come together throughout the beach zone, the female buries the posterior region of its body, while the male surrounds the female for the spawning stimulation (Carmona et al., 2015), and like these cases, there are lots of teleosts species of commercial importance that present reproductive groupings.

In the pelagic environment where dimensions can be spatially larger, movements from one place to another are often in big distances, and because of this pelagic fish tend to remain short time in the spawning sites and when finding themselves grouped with potential couples the spawning events speed up (Fréon & Misund, 1999). In sardines the reproductive events are performed when they have the right physiological conditions in a great number of grouped fish, due to they have a promiscuous behavior of external fertilization, where the individuals spawn and fertilize gametes without any apparent coordination between both sexes, creating in this way Aneer et al. (1983) a "mass orgy."

Another of the advantages of remaining as a group is that the foraging ability can improve, due to the ability of transference of information over the distribution of food (Pitcher et al., 1982; Ranta & Juvonen, 1993). This can occur latitudinally like the big sardine and anchovy shifts along the coast exploring from bay to bay in search of food. Nevertheless, the same effect can occur with vertical shifts that the big shoals of mesopelagic fish generate, that in their search for food in superficial waters they transfer and redistribute energy and organic matter among the epipelagic and mesopelagic zones as a consequence of their daily migratory behavior (Beamish et al., 1999).

#### **Disadvantages**

Despite the great amount of advantages that the formations of fish groupings can have, there can also be a series of disadvantages in this type of behavior. The benefits are closely related to the costs and the survival of the organisms, well there is indeed a bigger competition for resources among the group, a bigger risk of directly catching parasites and diseases, among others. Some studies have shown that the decision making related to grouping will be based on the values of the aforesaid costs against the benefits (e.g., Ashley et al., 1993; Krause & Godin, 1994).

One of the main disadvantages is the cost that has to be paid for belonging to a grouping, like the increase of competition for resources, like food, which can damage the smallest individuals (Booth, 1995). The strongest fish choose their competition with the weakest fish with the purpose of maximizing their own intake of food (Gregson & Booth, 2005).

Another example is that lots of predators individually possess better systems of detection (visual, olfactory, sensorial or acoustic), that together with the attack tactics increase their rate of consumption over grouped fish, generating devastating effects for the survival of a big number of fish when they are in a school. This puts a restrain in the argument that says that the protection of an individual increases when being part of a school, in comparison to dispersed fish; only the average members of the group will be protected if the rate of consumption of the predator is lower when feeding off fish groups (Pitcher, 1986). In the particular case of aggregations, the cumulus of fish in a certain zone does not only attract fish competitors for the resource, also attracts potential predators that are attracted by the fish cumulus, because of the absence of a social behavior among all individuals the success of the predation will have a higher efficacy.

An example of the prior can be observed in ensemble attacks coming from air and in water, which generate a feeding frenzy of different types of predators over fish groupings. A great list of organisms can include: from all different flocks of birds like elegant terns, cormorants, pelicans, diving birds, among others, that generate disturbances in the surface to make fish organizations lose control. In addition to this, in the water, attacks from billfish, dolphins and sea lions create confusion in the fish formations through multiple fast attacks, just as sharks or cetacean that through aiming a direct flick of their tails to the schools they generate the same effect. The humpback whale takes advantage of this group characteristic in a special way, forming bubble clouds to gather a considerable amount of fish, in an area near the surface to at last devour whole schools of sardines.

Finally, another inconvenience that can appear when finding lots of gathered individuals is the possibility of a quick distribution of parasitic infections, which negatively alter the school's behavior and that can increase the susceptibility of the group in the presence of predators (Barber & Huntingford, 1996). Parasitism produces an energy expenditure in the host, whether because of the direct use of the host's resources for its own growth and development or because of the immune response that results from a high energy cost or when increasing the energetic costs of locomotion (Barber et al., 2000), in addition, other adverse conditions like weight and health loss, erratic energy and swimming, which makes them vulnerable to predators.

## **GROUPING'S STRUCTURE**

The choice of formation for a certain school or shoal does not happen randomly, this behavior is influenced by a whole diversity of factors like body size (Ranta et al., 1992; Krause & Godin, 1994), competitive capacities and abilities (Krause, 1993; Krause & Ruxton, 2002), group size (Krause & Ruxton, 2002), parasitic load (Ward et al., 2005), level of predation (Johannes, 1993; Brown & Warburton 1997) or coloring (McRobert & Bradner, 1998; Modarressie et al., 2006). Besides, the preferences of shoal formations is very linked to the preferences of certain habitats (Pitcher & Parrish, 1993; Brown & Warburton, 1997).

For the specific case of pelagic fish, gregarious behavior in wild conditions has been studied to a lesser extent compared to the attention it has received in laboratories (Pitcher, 1993). To know the size and shape of pelagic schools in the environment different methodologies have been put into practice all around the world. The aerial observations has been one of them, where through registers quick change in shape and structure of compaction and dispersion of sardine schools during feeding or avoid predators events (Hampton et al., 1979; Hara, 1985; Fréon & Misund, 1999).

The school organizations can be defined by size, density and three-dimensional position and location of the fish group in the column of water (Bahri & Fréon, 2000). The group dimensions can thoroughly change, fish of the same species can form very different schools that go from a few meters to hundreds of meters (Tikhonov, 1958).

The vision and octavolateralis system (SOL) development in the fish increase the grade of perception. In fish with size and shape similar, hydrodynamic signals generated have the same intensity, and that together with sensorial increase, can avoid be part of a school with bigger fish. It has been seen that small fish avoid being part of a school with big fish, although big fish do not avoid being part of a grouping of smaller fish (Lachlan et al., 1998). It is through the mechanoreceptor system that discrimination for schools' sizes can happen, generating a more homogeneous shoal or bank with an increase in the group synchrony capacity.

The positioning of an individual in the school can also influence survival (Larsson, 2012). Fish that leads the school can have a better access to food than other members; however, it has been observed that fish leaders are attacked on a higher frequency unlike fish in other positioning in the school (Krause et al., 1998). Some authors like López et al., (2012) suggest that forming schools is regulated by three behavioral basic rules, listed as following:

- The attraction rule, which allows group cohesion due to fish discrimination to produce groupings of individuals with similar physical and physiological conditions. Vision governs this rule (Pitcher & Parrish, 1993).
- The alignment rule, which allows a directed swim of the grouping adjusting direction and velocity of the fish's swimming and is governed both by vision and mechanoreceptor system.
- The repulsion rule, where individuals seek to keep a certain distance between them to avoid collisions. This rule is governed by the mechanoreceptor system (Pitcher  $\&$ Parrish, 1993).

If there are slight changes in distance among close fish members, they can generate a change in the number of fish by unit of volume, just as any change of polarization has an effect on the school's structure, which can be considered disorganized when fish lack uniform orientation and swim in opposite directions (Fréon & Misund, 1999; Domenici et al., 2010).

According to the theory of compactation and stretching of schools, when the stress is too big the distance among individuals diminishes and the vacuoles forms (spaces within the grouping) in the interior of the school quickly collapses. The generated evasion reaction is quickly transmitted but a great amount of repeated stimuli to compact a whole school is necessary.

In the spherical-shaped defensive method described for schools of pelagic species it is possible to observe a maximum compaction within a spherical structure of fish that takes the repulsion rule to its limits. In the same way the schools that are not in movement tend to be spherical to observe their surroundings in a defensive way (Radakov, 1973).

The group will decompress just as the individual exploratory behavior commences; every fish will chose what fish will stay by their side, with the purpose of maintaining that maximum distance between members, and the small vacuoles will start to appear (Fréon et al., 1992).

# **INFLUENCE OF THE BEHAVIOR OF GROUPING TYPE IN THE DEVELOPMENT OF FISHING ACTIVITY**

From the perspective of fishing, the behavior of fish can be observed from two contexts, as a grouping behavior and as an individual behavior (Howarth, 2016). During the last years, the interest in studying the grouping features and behavior in relation with the management of fisheries has increased. Behavioral ecology has taken advantage as a complimentary knowledge of fishing studies, since some of the aspects of fish behavior like distribution, growth, escaping, etc. are closely related with the implementation of fishing technology (Fréon & Misund, 1999). As it is previously mentioned, some predators have known how to take advantage of the cumuli of prey in a reduced space, to feed off a great number of individuals in each of their attacks; and humans have not ignored this behavior in their search to obtain larger fish captures, developing fishing gears and capturing methods that contemplate grouping behavior.

In species that are commercially exploited, remaining united does not appear to be very advantageous. If, in a conservative way, we defined species that form schools, such as

scombroid, carangid and clupeoid fish these would include up to 50% of annual captures with approximately 35-40 millions of metric tons of fish (Parrish, 1999). The vast majority of these species are important targets in fishing, not because of their individual value, but because when grouped they become relatively easy to capture and their global abundance makes their extraction economically profitable (Parrish, 1999). With the exception of some tunas, where only an individual can represent high commercial value, which will depend on its biomass and the conservation quality.

Humans have developed different fishing strategies and gears depending on the degree of grouping in which fish are. A exploitation of the aggregation can be exemplified with the empirical observation of the attraction of small species that tend to shelter themselves or stick their eggs (e. g. Exocoetidae o Hemiramphidae) on floating objects like trunks, trash, seaweed, among others, in the pelagic system; with which aggregations of different fish species are generated, that according to distance and the degree of dependence among them and the object, they can be classified as intranatant (a distance below 50 cm), extranatant (from 50 cm to 2 m) and circumnatant (further 2 m *sensu*; Parin & Fedoryako (1999)).

Gooding & Magnuson (1967) y Hunter & Mitchell (1967) began to explain causes that determinate aggregate behavior of fish under these floating objects. In that regard, there are various theories on their utilization on behalf of fish, among them the employment of the objects as refugee and food source; besides serving as a transport for dispersion as in the case of objects adrift, there are studies who consider that these are references to restructure schools along migratory routes. However, this behavior depends not only on the species, but also on the development phase and size of the individuals (Castro et al., 2002; Santana-Ortega, 2015).

In addition, it is known that according to peculiar characteristics of a floating object (physical or structural) it will be the type of fish that will be attracted to them (Workman et al., 1985; Bard et al., 1985; Hall et al., 1999).

The prior is used for artisanal, industrial or sport fishing of pelagic fish of major sizes like swordfish, candlefish, dolphin fish and tunas, that are circumnatant predators temporarily associated to the object and that can swim from a great distance of it (Castro et al., 2002).

In the case of fish of the Scombridaec family they move along the pelagic zone in a lonely way or in school in search of food, when locating a region where there are fish aggregations it has been observed that tunas temporarily stay in the area while they eat. This behavior was observed by fishers, who based on their empirical knowledge, started to design devices that would have the same attraction of species of commercial importance. It is here where fishers have taken advantage, reducing search time for shifting schools.

The design of these fish aggregating devices (FAD´s) generates the same effect as natural floating objects in an artificial way, indirectly aggregating individuals susceptible to fishing in a determined area definite by the fleet, saving time and money in the operation. The first devices were installed in Philippines with the purpose of attracting *Thunnus albacares* (yellowfin tuna) and its success has been such, that the tuna industry has employed this knowledge during the last four decades in its operations involving searching, location and capture of the resource (Castro et al., 2002).

Studies referred to the FAD's observed that this devices tend to concentrate a bigger amount of juvenile organisms belonging to a certain number of species. These young organisms can be responsible for the accumulation of species of a higher economical value, as is the case of tunas and dolphin fish. Besides, the studies mention that the annual season can be the main cause that regulates composition of the ichthyofauna as well as its abundance (Castro et al., 2002; Santana-Ortega, 2015).

These devices can be anchored or adrift (accessible through radio wave broadcasting devices), these being the most used in commercial fisheries, even the most modernized have echo sounder that transmit real time data of fish groupings, as it happens in the Spanish fleet where this data alert near boats when the concentrations of tuna are sufficiently elevated for a commercial capture (Ariz et al., 1992 in: Fréon & Misund, 1999).

Like this, some tuna boats use bait to aggregate schools beneath themselves and in this way, capture them in a more prolonged way, meaning that they act as FAD´s. This technique is known as "patch," which, once it is formed, can be moved to more shallow zones to make capture easier. The boat acts as an aggregating device, once its boat freezer are full of fish, it is replaced by another ship while the first one directs itself to the port to discharge (Santana-Ortega, 2015).

There are some controversies about the employment of the FAD's, on one side, some authors mention that the massive use of these devices could produce overfishing in various groups of fish, because they do not only group adult fish, but because the majority are juveniles, lots of species are also captured as a part of the by-catch, which are discarded afterwards due to its lack of economic value (Fonteneau et al., 2000; Filmalter et al., 2013). In contrast, there are those who considers that FAD's can be used as a sustainable fishing method while they are well regulated (Dagorn et al., 2013).

On another hand, among the methods that fishers recur most on to attract fish and concentrate them on action zones of fishing gear, we can find chemical attraction through odors, which mainly consists in place a site with specific bait (alive or dead) for the target species. The odor emanating from the bait moves in the water in the form of dissolved chemical substances, which makes fish perceive it and makes them feel attracted by them.

Attraction with artificial light is another fish aggregating technique that was very used until halfway through the twentieth century to capture tuna and other pelagic fish. This effect is possible due to lots of groupings of fish possess positive phototaxis, which means that in lighting stimulus these tend to move to the source that generates them. Long time ago fishers used torches to generate artificial light and attract fish and other marine species like squids; further, with the appearance of new illumination systems such as electric lanterns, kerosene and gas, the infrastructure of fishing also got modernized. Nowadays, electric lamps and chemical or bioluminescent devices that emit artificial light are still being used in an industrial way, which mimics with the light that the prey species would generate (Sokimi  $\&$ Beverly, 2010).

In the fishing of tuna or swordfish bait is usually formed by dead squid, that with submarine chemical or bioluminescent lanterns they attract the resource to the fishing hooks. Some commercial fishing boats employ powerful submerged lights or even from deck to attract small pelagic fish to the surface and be able to perform capturing maneuvers.

The degree of attraction to the light will vary in species depending on age, physiological and environmental conditions (Fréon & Misund, 1999). For example, small sardines of the S*ardinella* genus usually show higher positive phototaxis than big sardines (Ben-Yami, 1976). It has been set out that in the case of sardines artificial illumination allows necessary visual contact to generate the school's behavior near the surface and the advantages that this entails (Fréon & Misund, 1999).

In the same way, a temporary factor of great interest for fishers are the lunar cycles, due to lots of species aggregate more densely during nights with a full moon (Nikonorov, 1973). In Bangladesh, the most important fishing gear to capture *Sardinella spp.* traditionally are the beach seine nets, which are employed while they swim along the coast. Schools are captured in the majority of the year's months in coastal waters mainly during the night, obtaining a maximum capture in nights with a full moon and new moon in the months of November to December and February to April. It has been reported that there is a vertical differential distribution of the sardine species that inhabit fishing zones, both industrial and artisanal fisheries have an impact over the *Sardinella* species due to they are captured between 10 and 50 m deep, while the *Dussumieria* genus that usually distributes between 40 and 60 m deep can only be available for trawlers of the industrial fleet (midwater trawlers) that make fishing operations between 10 and 80 m deep (Jit et al., 2013).

In Japan, different nets have been used historically on a small scale to capture sardines, such as: gillnets, beach seines and traps, the intensity of the sun's light has influence on certain capturing methods; where when fishing during twilight moments of the day fishermen increase their catch, even until the 1980s the use of systems of gleaming flashlights is registered to attract the sardine schools to make their capture easier (Cifuentes et al., 1986; Parrish, 1999; Sonu, 2001).

Either by attraction, exploitation of aggregations, or a combination of both, when encountering organisms in a group the search to capture them diminishes, and their abundance makes their extraction economically profitable. Fish use their habitat differently depending on local conditions, for a predator or a fisher this translates into a different capturability for the target species when conditions change.

As it has been mentioned previously, among the most important groups subject to fishing exploitation and form shoals or schools, we have the small pelagic fish. This artificial group of marine fish of relatively small size (between 10 and 40 cm) is formed by different species depending on the region of the planet. The most distinctive species belong to the Order of the Clupeiforms where the sardines and the anchovies are, as well as some Perciforms of the Carangidae and Scombridae families. Nevertheless, diverse species of the Exocoetidae, Hemiramphidae, Caesionidae, Atherinidae families, among others, can be considered as small pelagic fish.

The worldwide captures of small pelagic make a total of 17 million tons that represented 22% of the total of global captures in 2012 (FAO, 2014). Without doubt, the fishing of these fish on a global scale has been one of the most important and profitable for the abundance that its represents, that is why there are diverse artisanal fishing gears for their extraction, as well as industrial.

Before the dominance of occidental technology, the survival of sardine and anchovy fisherman relied on the knowledge of the location of schools, the local material available to catch and when these were more accessible for fishing, as well as techniques to attract them and concentrate them (Parrish, 1999).

Despite that lots of local knowledge got lost in favor of technological advances with the expansion of the western world (Johannes, 1980 in: Parrish, 1999), on a global scale there are still a wide amount of techniques for capturing sardines and anchovies in artisanal fisheries.

Until before the 1900s the catch of *Sardinella brasiliensis* in Brazil were mainly carried out by traditional fishermen and used as food in coastal communities (Diegues, 1995). This traditional fishing still exists in lots of regions of the country, which is performed using cast
net and purse seine net at bays and estuaries, using knowledge about tide fluctuation to concentrate and catch fish that come in and out some coastal lagoons (Lieber, 1994; Van Marlen, 2003).

Temporary nature is very important for coastal fishing of small pelagic fish. In Ghana, *Sardinella maderensis* is exploited during most of the year, while *S. aurita* is essentially captured during the largest upwelling periods (July-September) extending itself to months with lower upwellings like January, February or March, in such way that the artisanal capture of the country depends on the quality of these seasonal events (Cury  $\&$  Roy, 1991).

There are regions like the Indian Ocean and the Western Indian Pacific where have the largest amount of clupeid, more than any tropical region, due to the abundance becomes larger in tropical regions in comparison with septentronial or meridional regions with a mild weather (Lavoué et al., 2005). Besides this, fishery in lots of countries of this zone is traditional, performed on a traditional way with beach seine, having in this way a low production (5% of worldwide capture) and only foreign fleets that operate in the area (mainly Korea, Japan, France, Taiwan and Spain) can access the resource farther from the coast (Al-Jufaili et al., 2006; Sherman et al., 2009). A similar case occurs in Western Africa, where even countries like Mauritania have given in to the exploitation of their exclusive economic zone to fleets of industrial countries like Germany or Russia (Cury & Roy, 1991).

## **INDUSTRIAL FISHERIES OF SHOALS AND SCHOOLS**

Inside the industrial fishing sector there are different types of fleets: tuna purse seine, shrimp trawl fleet, coastal purse seine fleet, among others. In Ecuador, the coastal purse seine fleet extracts schools of small pelagic to be used as raw material for the production of fish flour, preserved canned food, as well as fish oil. The main species that are captured are *Sardinops sagax, Scomber japonicus, Opisthonema spp., Cetengraulis mysticetus, Etrumeus teres, Trachurus murphyi* (Aguilar, 1998).

On another hand, we can mention the east coast of the United States as an example of the transition to the fishing modernization of small pelagic simultaneous with knowledge on aggregations. Since the decade of the 1880s there has been fishing of sardines in that region, in places like Monterey's bay, during fishing season from the middle August until halfway through February, fishers would use the first ships with lamps to attract schools during the nights (Shillinglaw & Burnett, 2011). However, towards 1919 the country's marine already used an aerial detection system to support the location of *Sardinops sagax* schools, which consisted in training pilots to locate and report groupings of fish on surface, once detected, any vessel of the marine would give a sign to the group of boats to move to the place and commence fishing maneuvers. The whole operation was performed during dark nights where the gleam of schools underwater were more visible to pilots (characterized by the green interior and the red exterior edges) (Ueber & MacCall, 1992).

Before, the vessels that were employed had a lower autonomy and were built with wooden hulls, with time they were modified until being completely made of steel. Today modern boats for the fishing of these species are self-sufficient, within their infrastructure they contain detection equipment in real time, better storage capacity and fishing gears that allows them to extract great volumes of the resource in only one operation (Itano, 2002).

These fishing gears can be of different types and they are usually classified in two: active and passive. The category is related to the gear's manueverability and the behavior of the target species. In the case of passive gears, a fish usually heads towards the gear (e. g. set nets), while the active gears involve a pursuit aimed to the target species (e. g. trawls, purse seine, etc.).

## **PELAGIC FISHERIES WITH PURSE SEINE NET**

Technified fishing has increased the captures four times larger between 1950 and 1990 (Platt et al., 1995). Nowadays industrial fishing of tuna, sardines and anchovies is dominated by the use of purse seine ships due to their efficacy to catch a great amount of fish, considering that the social configuration for this type of fishing gear are the schools or shoals of pelagic species. As it has been mentioned previously, in a school the individuals have a high mutual attraction among them which allows the cumulus of a great amount of fish in a small area and volume, this is used as advantage by the ships with purse seine nets saving, in this way, time and fishing effort.

Although fishing with purse seine net, was performed with canoes or sailboats while ago, the addition of "power block" to purse seine vessels during the decade of the 1950s was a key factor for the mechanization of capturing methods. This invention provided a lot to the effectiveness of the technique, making it the most efficient gear to captures fish species that grouping in schools or that are near the surface, which caused the substitution of traditional fishing methods in many places (FAO, 2016).

The ships with purse seine net, depend on the detection and location of the fish species that are gathered in schools (Misund, 1997). Before, the search for schools was exclusively done in a visual way, and lots of detection methods still prevail among fishers around the world (Au & Pitman, 1986). A sample of this is the fishing for small pelagic in Mexico, particularly in the Gulf of California where fishing is done essentially at night. The beginning of sardine fishing season is closely related to the behavior of schools in regards to the lunar phases, just like with the beginning of the shift of the first schools of *Sardinops sagax* along the coast of Sonora; it is in this way that fishing begins in October during a period of approximately 22 days, centered on each month's new moon (Sokolov, 1974; Cisneros-Mata et al., 1991; Nevárez-Martínez et al., 1996; Martínez-Zavala et al., 2010). In traditional embarkations of Mexico and other countries, the location of schools is done visually due to these produce a luminous effect that allows them to be seen at 15 or 20 meters far in this dark period, in addition to this, the fleet starts its voyage to fishing sites during sunset which allows them to observe biological activity on the sea's surface such as: flock of birds feeding, unusual movement on the surface of a calm sea, dolphins, among others (Cifuentes et al., 1986; Parrish, 1999; Tesco Real Food, 2016).

The detection in modern embarkations is performed in a complementary way with acoustic instruments. When schools swim bellow 60 m it is not possible to observe traces of them from the surface, which is why in most countries that keep an industrial fleet echo sounders are employed (Cifuentes et al., 1986; SAGARPA, 2006; KinoshitaFishingNet, 2009). At present fishing boats can detect schools any time of day, however, bigger success in their capture depend on the depth of schools distribution, this is why they usually prefer

working at night taking advantage of the behavior that small pelagic have of emerging to more shallow layers (Bahri & Fréon, 2000; KinoshitaFishingNet, 2009).

The fishing capacity depends on the boat's size, for example, there are embarkations with purse seine of until 200 m of keel that allow a potential access to deeper schools during daytime (SAGARPA, 2006), although these diurnal maneuvers will depend on a major degree of factors like the crew's expertise, hydrographic, geographic and meteorological conditions, as well as the season to have a successful catch.

The fishing maneuver can be carried out by one or two embarkations, once that the aggregation has been detected, the net opens around the fish school, forming a circle (whether it is with another embarkation or an auxiliary embarkation), when the net is in the water every sound generated by the boat must be avoided and all the lights go off except the navigation ones, this to avoid sudden movements of the school (Tesco Real Food, 2016; Figure 3b). The net is closed by pulling a seine that goes through loops that are in the inferior with the purpose of generating some type of bag to avoid fish from escaping by swimming under, afterwards the bag is moved closer in a slow way to one of the boat's sides (FAO, 2016; NMFS.NOAA, 2016). When the school is compressed inside the net it is possible to lift it to deck through suction pumps, nets of smaller size in the shape of a spoon or even by directly tying the product like it happens with tuna.

Figure 3. The mechanism of following a leader is a distinctive feature of fish that swim in shoals, schools and that is taken advantage of in set nets (a). The compaction of a great amount of fish in a school is an advantage in the purse seine fishing method (b). When fish are dispersed forming shoals the trawling fishing method can capture a portion of the fish group (c).

As it has been mentioned, in the oceanic system fishers have a distinguishing availability of small pelagic species throughout the day, which is linked to daily vertical migrations (Parrish, 1999).

Besides, it has been described that during nights, the small pelagic groups feed on the surface because in their adult phase they are planctonivore microphages and in this zone there are larger amounts of food. Some of them, like the sardine, are usually selective with their prey, after observing it has come to the conclusion that there is a high percentage of planctonivore organisms swallowed in their stomach, which were found in a low percentage in the water column (Culley & Kerkut, 1971). This selectivity of prey and habitat determines for most fleets for the majority of trawls to be profitable when fish are organized in shoals in superficial layers during the night (Fréon & Misund, 1999). Tied to this, the sardine shows a strong escaping during the day and less during the night, unless fish come in contact with the net (Parrish, 1999).

In New Zealand, there is a great commercial interest for the fishing of S*ardinops sagax*, although *Engraulis australis* (Australian anchovy) is also captured. Since 1993 most captures are performed in oceanic waters with embarkations that use purse seine, however, fishing net lights of similar appearance to the purse seine but smaller are also used, which combines the attraction for light and the enclosing maneuvers since it has lights in the central part. It does not have a rope in the bottom that allows to make a bag, whereas the bottom rope is much shorter than the rope that contain the floats forming a partial floor when the net is near the school, particularly in the central portion. Just like the purse seine, the fishing net light is placed around the school and the ends of the two wings are pulled together, the school shifts to the interior and it is held in the central portion until the net is taken near the boat so afterwards the fish can be taken with a submersible net (Paul et al., 2001).

## **PELAGIC FISHERIES WITH MIDWATER TRAWL NET**

Midwater trawls are one of the most employed gears to capture at open sea, the same with purse seine, the social configuration for this type of gear can be for schools, but are mainly shoals of pelagic species of shallow or profound waters, however, unlike the purse seine, this one does not necessarily require for fish to be gathered in a determined area (FAO, 2016; NMFS.NOAA, 2016).

The ships are equipped with radars and echo sounders that allow the detection of shoals and schools, a single trawl can capture a substantial fraction of a school (Parrish, 1999) (Figure 3c). The net is towed behind one or two vessels and depending on the target species and the net design, the trawl velocity varies from 2.0 to 5.0 km. The wings or doors that are in the cable of the net has generate horizontal opening, while vertical opening is caused by positive floatability that is given by buoys from the superior edge and the counterweight of the inferior edge.

The process in which fish enter and stay in the net involves a complex sequence in their behavior. In the previous zone to the trawl, reaction to sounds of low frequency of the embarkation, can generate an escaping behavior that shows with direction change (vertical movements of fish happen at the beginning of the trawl when the embarkation's noise abruptly increases) and with a change in their swimming's velocity (He, 2010). Both patterns seem to be adaptive from a point of view of predatory escape (Lima & Dill, 1990). In the zone between tables and the net's entrance it has been observed that fish tend to execute the "fountain effect" to keep the threat (in this case the net's entrance) on the verge of their visual range. Fish that swim to the exterior of the doors will escape, while those that swim inside will immediately enter the bag's trajectory (He, 2010).

Just like purse seine fishing, the capture with midwater trawls of pelagic fish is usually less complicated on nocturnal hours, suggesting that a visual detection on a vigilance schedule allows the precise location of the net and increases the coordinate escape reactions of the species (Fréon & Misund, 1999).

## **PELAGIC FISHERIES WITH SET NETS**

Other fishing gears to capture small pelagic on a big scale are set nets, which are big fixed structures spread out in coastal waters through which fish access and are guided to different spaces where they cannot find an exit, trapping themselves (He, 2010). The social configuration for which this type of gear is designed are shoals and schools of pelagic species, this due mainly to the imitation behavior that fish have, where a leader with a swimming direction can make other members of the school to follow him, in this case, to the fishing nets.

Due to these fishing nets stay fixed, they have a series of advantages: they can function 24 hours of the no-vigilance day; it is not necessary to detect and follow schools; fish usually stay alive until their extraction; it is possible to know the volume of the catch before collecting it, which allows to prepare the amount of ice and the transport to move it properly, without spending excessive energy; the effort to collect the fishing net is minimal, besides that a selective fishing and the liberation of other living organisms of other species is allowed.

Japan is the country that most uses stationary nets, obtaining around 25% of the total of their coastal waters catch in the 1980s. Likewise, another area where these traps are widely used is on the east coast of Canada, where traps receive the name of spillways and that with seine boats they are the most employed fishing methods for the capture of small pelagic like *Clupea spp.*, *Scomber spp.* and *Mallotus spp.*

In some places, traps consist of wooden posts buried in the bottom, laid out in a semicircular pattern which holds on to fishing nets in a way that it resembles a corral, once the sardines enter the area of the main container they are caught and can stay alive until their extraction is required, which can be through a suction pump on the embarkation with smaller nets (Brunswick, 2016).

These traps are passive fishing gears that must be installed on a strategic way all along the coast, on small coves visited regularly by schools. Lots of schools are captured because of the effect of following the leader, when studying this effect with different species it was observed that only a small number of schools entered the traps without their leader, in contrast with the number of schools (76%) that entered with their leader moving towards the interior. Leaders can have an influence of up to 60 m of distance over the school, however, this distance depends on the species and the visibility of the site (He, 2010).

The position and angle of the entrances are placed on a certain way to intercept groupings of fish along their migratory routes (Figure 3a). The previous knowledge of predictions in migration patterns in terms of route and season are extremely important for the success of trapping operations.

It is frequent to find regions where industrial fishing is performed employing more than one capturing method, like in the fishing of *Sprattus sprattus* and *Clupea harengus* (Atlantic herring) in the east of Northern America, from New Scotland (Canada) up to Gulf of Maine (United States) which employs fixed fishing nets to capture sufficient volume of the resource during migration season, the seine nets are usually used to fish in shallow waters or to fish shallow schools, while the other boats with trawls are more effective to fish schools in deeper waters (Brunswick, 2016). In contrast, fishing sectors can also have conflicts trying to capture schools in a same place, as it happens in the Western Indian Ocean, where foreigner fleets tend to destroy set nets from local communities besides reducing the available resources in the area (Sherman et al., 2009).

As it has been mentioned throughout this chapter, the aggregative behavior of fish has played a very important role in technological advance of fisheries, however, it is necessary to establish well backed-up norms which will allow to maintain ecological balance and sustainability.

## **ABSTRACT**

For years, marine resources have been an important part of human development due to the high nutritional contribution they possess. *Mussels* sp. are the most consumed species in the world. As a result of requirements and needs exceeding the natural global production, man developed aquaculture in order to regulate the imbalance between nutritional requirements and natural production.

Under natural conditions, there are several and wide ranging varieties of mussels, with multiple sea habitats: sandy, rocky and stratified bottoms in the water column in rocky strata. This allows them to assimilate a varied diet of micronutrients consisting mostly of phytoplankton. Although, depending on their habitat, mussels can filter waste

 $\overline{a}$

from other species such as feces, pseudofeces, microcellular debris or compounds from anthropogenic input.

From the many species of phytoplankton, about 80 of them are known for producing phycotoxins through blooms, *Dinophysis* sp. being the species of dinoflagellates associated with the production of toxins in the Austral Pacific fjords. These dinoflagellates are filtered and accumulated by hydrobiological organisms, such as mussels, that accumulate toxins in the digestive glands. Here they are subjected to numerous reactions of biotransformation mediated by enzymatic pathways, nonenzymatic pathways or by bacteria present in bivalves, which extends the toxic spectrum of the assimilated toxins, an event that is magnified by the interaction of vector organisms that expand the toxic forms through the trophic chain.

Lipophilic marine biotoxins (OA-, AZA-, PTX- and YTX-group), constitute the group of toxins that affect mussels from natural origin and aquaculture the most. These kind of toxins are accumulated in the tissues of mussels where they are retained according to their chemical affinity and/or modified into more toxic forms (AZA- $1 \rightarrow AZA-3$ ) and/or thermodynamically more stable forms (PTX-2-SA $\rightarrow$ 7-epi-PTX-2-SA), in some cases allowing accumulated toxins by mussels to become harmless (DTX- $1 \rightarrow DTX-3$ ; YTX $\rightarrow$ carboxy-YTX).

Since blooms associated with lipophilic marine biotoxins may occur simultaneously, different species of mussels and those species related to their habitat can accumulate and/or transform the wide spectrum of toxins. This generates a toxin profile and variable toxicity in their tissues, which lasts according to the exposure time to the bloom and the purification pathway of toxins from mussels.

In this chapter, the main events associated with lipophilic marine biotoxins (OA-, AZA-, PTX- and YTX-group), as well as their interaction in the habitat of *Mussels* sp. in the Austral Pacific fjords are presented.

#### **1.INTRODUCTION**

Mytilids, internationally known as "mussels", are bivalves. They are filter-feeding molluscs that belong to the family Mytilidae, bivalvia class, which pump seawater through their gills to filter out food items and other suspended particles. They release filtered water back into the environment. Materials retained by a mucous material on the gills—including tiny organisms, detritus, suspended sediment, and contaminants—are eaten and then assimilated into their tissues or passed through their bodies undigested. By filtering, they remove the phytoplankton and inorganic particles from the water column, thereby reducing turbidity. Therefore, turbidity reduction is directly proportional to the abundance of bivalves [Asmus & Asmus, 1991].

On the southern Pacific coast, mytilids are distributed from Perú to the Strait of Magellan and, on the Atlantic Coast, along the coast of Argentina to Brazil. From the 70 species of mytilids described in the South Pacific Region, three species are economically important resources in Chile: Blue mussels (*Mytilus chilensis*), Giant mussels (*Choromytilus chorus*) and Ribbed mussels (*Aulacomya ater*). There are closures during certain times of the year to control the extraction of these mussels from natural beds and to ensure their availability in the future [Avila et al., 1995].

Under natural conditions, there are diverse and wide ranging varieties of mussel species with multiple habitats at sea, such as sandy, rocky and stratified bottoms in the water column in rock strata together with species such as *Pyurapreaputiali*s, *Lessonia nigrescens* and *Perumytilus purpuratus*. This allows them to absorb a varied diet of micronutrients consisting mainly of phytoplankton, and depending on their habitat, waste from other mussel species such as pseudofeces, micro-cellular debris or compounds from anthropogenic inputs. These baseline nutritional intakes are added to the ascending variable produced by climate change that could be a predominant factor in the development of marine resources from natural beds or aquaculture development products.

For years, natural marine resources have been an important part in human development given the high nutritional content they have. Their contribution has been so significant that requirements and needs have exceeded natural contribution worldwide. Previously sustainable resources have become endangered or have been deemed under threat of extinction. In order to reduce the disparity between nutritional requirements and natural production, man developed aquaculture. Through aquaculture, it is possible to reduce naturally occurring damage caused to natural resources and to allow adequate separation between natural resources and those resources coming from farming centers, thus preventing the extinction of more mussel species of great commercial interest. About 85% of the global production comes from aquaculture activities. With the exception of a few countries where the extraction is strictly controlled, natural beds have been overexploited. The supply of this kind of global resource is based on the stability of the activity and the ability of farmers to increase their crops and to improve products [Cortez et al., 2012].

The phytoplankton biomass increase associated with the nutrient-enriched input is beneficial for filter feeder bivalves. Nevertheless, N and P inputs from anthropogenic sources alter the nutrient ratio  $(16:1)$  to very high levels  $(70:1)$  by nutrients from agriculture through rainwater. In nutrient-enriched systems with high levels of primary production, intra- and interspecific competition for food is minimal when the abundance of bivalves is at low or intermediate levels. However, in less productive systems with limited water circulation and/or high levels of bivalve biomass, intra- and interspecific competition may occur between stocks from natural bivalves and those produced by aquaculture [Cloern, 2001].

Additionally, organic imbalance (N:P) generated in some areas globally, produces a variability in marine phytoplankton communities. In many cases, this generates an exponential growth of these species, which, even though they are still a nutritional source for multiple species of mussels, generate high commercial and human impact, by being associated with the production of toxins capable of killing people [Newells, 2004].

To date, 5,000 phytoplankton species have been described, from which, under certain circumstances, 300 species have a high proliferation rate resulting in a high density of microalgae in the sea, a condition called a "bloom". The circumstances or factors triggering these "blooms" are still not completely determined, but what is certain is that specific changes of climatic and hydrobiological conditions play an important role in the conditions leading to a "bloom". These "blooms", in general, generate beneficial conditions for the development of aquaculture and marine biology. However, about 80 species, out of the 300 already mentioned found in phytoplankton, are dinoflagellates and diatoms that -under certain circumstancesproduce phycotoxins (marine toxins). The abundance of this kind of toxic phytoplankton range from a few hundred thousand up to several million per liter in the sea, reaching maximum levels called "Harmful Algal Blooms" (HABs) [James et al., 2010; Anderson et al., 2012].

HABs are produced by a group of cells (dinoflagellates, cyanobacteria and diatomae) that, due to different natural environmental or anthropogenic conditions, may alter the relative abundance of these species, allowing for them to prevail over other microplankton species. The above mentioned is associated with the production of powerful toxins that dramatically affect marine fauna, mammals and people. Authorities of inhabited zones where HABs are detected, react by closing large sea areas to fishing and halting harvesting activities in zones where farmed and wild molluscs and bivalves are found, triggering a chain reaction of economic damage at industrial, touristic and sanitary levels (Figure 1) [Hallegraeff, 2010; Picot et al., 2011].

Figure 1. Summary of environmental impacts of Harmful Algal Blooms (HABs) on carnivorous shellfish (mussels) and miticulture from the South Pacific Ocean.

Phycotoxins can be accumulated in several marine species, such as fishes, crabs and every kind of filtering bivalve [Oyaneder et al., 2017]. Mussels, because of their high rate of filtering, can accumulate great amounts of phycotoxins in their digestive glands, with no adverse effects. However, when highly contaminated mussels are eaten by animals or humans, they can produce severe intoxications. The worldwide number of phycotoxin induced intoxications per year is about 60,000 cases. Additionally, there is a strong impact on ecosystems, the environment and the economy, and as a consequence of the negative effect on tourism, recreation and miticulture and aquaculture industries [Gerssen et al., 2010; Kudela et al., 2015].

Visibly occurring in all seasons except summer, mussels coming from aquaculture facilities can alter the nutrients in the water column, where phytoplankton grow faster, not being able to control the phytoplankton biomass. Moreover, water flows increase the seston

flow through the crop sites, thus ensuring an adequate supply of food to bivalves [Nakamura & Kerciku, 2000].

In Europe, annual estimated losses in the tourism sector, as a consequence of HABs, are approximately  $\epsilon$  700 million and  $\epsilon$  116 million on miticulture [Morgan et al., 2009]. In order to prevent intoxications caused by eating phycotoxin contaminated shellfish and to mitigate their harmful effects, international agencies have produced regulations, legislation and monitoring programs [EU, 2011].

Health risk prevention, as well as the industry need for monitoring phycotoxin presence within several toxin carrying vectors, has made it necessary to develop a potentially toxic microalgae watch program. Several phycotoxin detection methods have been developed, many of which allow detection of phycotoxins within shellfish far below dangerous levels. These methods challenge many difficult issues, such as insertion of toxin within complex carrying matrix and the presence of mixtures of structurally related analogs [Fernandez et al., 1996].

The basic contribution of toxins provided from harmful phytoplankton is varied, depending on the involved species and the areas where the bloom is produced at a global level. It should also be considered that different species of toxin-producing microalgae may produce simultaneous blooms, thus, causing the same species of hydrobiological organisms, from both natural beds or aquaculture facilities, to possibly accumulate more than one variety of toxin resulting in a toxic profile and variety of toxicity which is increased as they get involved in the trophic chain. Nevertheless, mussels do not only accumulate these toxins inside their bodies, but also in their metabolic pathways and pathways mediated by enzymes; they make key modifications in order to decrease the toxicity towards them, which often cannot be extrapolated to humans, for whom these chemical modifications may become more toxic. This impact of natural origin not only affects natural resources, but also resources from the development of aquaculture by adding, economic and social development repercussions in local communities that make a living from this activity [García et al., 2005; García et al., 2016].

By affecting the development of aquaculture, HABs not only contribute to the basal level of toxins for mussels, but there is also a contribution of toxins derived from biotransformation processes caused by mussels and toxins produced by the different stages of the production development process (canned or frozen products). These products, when subjected to different physical-chemical variables, further expand the toxin's forms that mussels possess, transforming from innocuous to toxic forms [McCarron et al., 2008; Blanco et al., 2016; García et al., 2016].

Based on the chemical properties of the toxins found in phytoplankton and shellfish, they have been classified in two classes: hydrophilic and lipophilic toxins. Toxins associated with the Saxitoxin group (STX-group) are hydrophilic and share a common trait: they are of low molecular weight (about 500 Dalton). Toxins associated with lipophilic toxins, the Okadaic acid group (OA-group), the Azaspiracid group (AZA-group), the Pectenotoxins group (PTXgroup) and the Yessotoxins group (YTX-group) share two common traits: 1) their molecular weight is between 600 and more than 2000 Dalton; and 2) they have a lipophilic chemical nature [Gerssen et al., 2010].

## **2. LIPOPHILIC MARINE BIOTOXINS**

Lipophilic marine biotoxins are formed by a group of toxins of lipophilic nature corresponding to the Okadaic acid group (OA-group), the Azaspiracid group (AZA-group), the Pectenotoxins group (PTX-group) and the Yessotoxin group (YTX-group). Initially, PTX-, YTX- and the AZA-group had been classified within the OA-group, since a large proportion of this group of toxins was co-extracted along with other toxic groups, during the evaluation processes in mussels and phytoplankton. Thus, the symptoms detected in the bioassays, or those caused by intoxication of people, tended to be associated with the entire group of lipophilic toxins. Subsequently, it was determined that this group was composed of different types of toxins, very different from each other from a chemical point of view and with different toxicological properties. The PTX, YTX and AZA groups were then excluded from the DSP group and classified as independent groups [Paz et al., 2008; Dominguez et al., 2010; Gerssen et al., 2010].

The EU has established guidelines for maximum toxin levels in shellfish for human consumption of OA, DTX and PTX, whether combined or single value whose edible parts of seafood cannot exceed 160 μg OA equivalent/(shellfish kg), while maximum levels of YTX cannot exceed 3.75 mg YTX eq./(shellfish kg) and 160 μg AZA equivalent/(shellfish kg) for AZAs. As of July 2011, the Commission Regulation (EU)  $N^{\circ}$  15/2011, amended Regulation (EC) No. 2074/2005, which recognized testing methods for detecting marine biotoxins in live bivalve molluscs and established the EU-RL LC-MS/MS method was established as the reference method for detection of lipophilic toxins and used as a matter of routine, both for the purposes of official controls at any stage of the food chain and in house inspections by food business operators [EU, 2011; EU, 2013].

#### **2.1. Okadaic Acid Group**

The Okadaic acid group (OA-group) is a gastrointestinal disease caused by ingestion of shellfish with accumulated fat-soluble polyether toxins produced by dinoflagellates of the *Dinophysis* and *Prorocentrum* genera. The density of cells associated with a bloom of OAgroup corresponds to  $< 10^4$  cell L<sup>-1</sup>, with an abundance of  $< 10^3$  cell L<sup>-1</sup>. Intoxications associated with OA-group are a worldwide threat to public health and the shellfish industry [James et al., 2010; Glibert et al., 2012; Reguera et al., 2014]*.*

The first documented intoxications with OA-group were recorded in Holland (1961) [Kat, 1979]. To date, high levels of these toxins have been found repeatedly off the coast of Europe (U.K., Ireland, Denmark, Sweden, Norway, France, Spain, Italy, Portugal, Holland and Belgium); Canada; South America (Chile and Argentina); Japan; Australia and Africa (Morocco) [García et al., 2004; Elgarch et al., 2008; Gersenn et al., 2010]. In the South Pacific Ocean, blooms associated with OA-group usually occur in spring-summer periods (October-March) [García et al., 2012].

Okadaic acid (OA) and its isomers dinophysistoxin-1 (DTX-1) and dinophysistoxin -2 (DTX-2) are the main toxins produced by OA-group-producing dinoflagellates (Figure 2) [Yasumoto et al., 1978], which present specific toxicity equivalence factors (TEFs), OA= 1.0 (TEF); DTX-1 = 1.58 (TEF); DTX-2 = 0.48 (TEF) [EFSA, 2008a].

The minimum dose of OA and DTX-1 necessary to induce toxic symptoms in humans has been estimated at 40 and 36 µg, respectively [Hamano et al., 1986]. Death of intoxicated patients has not been reported, but okadaic acid (OA) and methyl-okadaic acid (DTX-1) have been shown to be potent tumor promoters in animals [Fujiki et al., 2013]. Therefore, they might increase the risk of cancer among regular consumers [Cordier et al., 2000; Maneiro et al., 2008].

Toxins associated with OA-group are powerful cytotoxins that inhibit various types of serine/threonine phosphoprotein phosphatases 2A (PP2A) [Huhn et al., 2009; Hayat et al., 2012]. These proteins are a group of enzymes that carry out dephosphorylation of numerous proteins, a very important function which is closely related to many essential metabolic processes of eukaryotic cells [Van den Heuvel, 2002]. OA and DTXs are more potent against PP2A than PP1 (OA-IC<sub>50</sub> 2.87 ng/ml and DTX-2-IC<sub>50</sub> 5.96 ng/ml) [Huhn et al., 2009; Hayat et al., 2012].

Depending on the species and natural depuration, OA-group toxins are modified inside the molluscs, where OA, DTX-2 or DTX-1 are esterified in the hydroxyl group of Carbon 7, palmitic acid being the most common fatty acid found in dinophysistoxin-3 (DTX-3) (Figure 2). Normally, palmitic acid amounts to 90% of the total fatty acids linked to the 7-*O*-acylderivative of dinophysistoxin-1 to produce DTX-3 in Chilean samples [García et al., 2005]. Although other forms of acyl derivatives, such as C14:0, C16:1, C16:0, C18:1 and C18:0 have also been detected in *M. galloprovincialis* and *D. trunculus* in samples collected along the Portuguese coast [Vale, 2006].

Figure 2. Chemical structures of okadaic acid-group and analogues. **R** indicates the substitution of the corresponding radical in the molecule.

Vectors play an important role in transmitting OA-group toxins through the food chain, causing unknown toxic effects to other organisms [Landsberg, 2002; Torgersen et al., 2008a; Torgersen et al., 2008b].

Periodic OA exposure in mussels results in changes in gene expression, either by specific interactions of OA-group with receptors or indirectly by inducing intracellular signaling cascades, producing a loss of stabilization of focal adhesion and cytoskeletal disorganization [Svensson & Förlin, 2004; Manfrin et al., 2010].

Since mussels are the main vector of OA-group toxins and its contamination causes great harm to mussels coming from natural beds and/or from farming facilities, multiple methods of detoxification have been developed. These methods are required to be quick, efficient, easy to apply and should not alter the organoleptic qualities of products. Among these processes, thermal shock, freezing, evisceration, supercritical  $CO<sub>2</sub>$  with acetic acid, ozonation and radiation are highlighted; these processes are characterized by destroying or reducing the toxicity of mussels [Reboreda et al., 2010; García et al., 2016].

From the above mentioned processes, the most widely used corresponds to radiation, because it is able to destroy pests and pathogens in large production processes of different kinds of foods [EFSA, 2008a; EU, 2009]. Thus, mussels containing toxins close to the regulatory limit of 0.16 µg OA equivalents  $g^{-1}$  mussel tissue, when subjected to  $\gamma$  - irradiation, show a marked decrease in their toxic content, resulting in products that are suitable for consumption and sale. However, it should also be considered that this procedure can lead to highly toxic or carcinogenic compounds (2-alkylcyclobutanones and radyolitic derivatives of triglycerides) [Raúl et al., 2002].

Another frequently used method corresponds to ozonation; when this method is applied to homogenized mussels, it generates a highly positive and favorable effect for the destruction of OA-group toxins, this is attributable to the penetration capacity of the gas (ozone) on the tissue of the mussel, thus, having the option of directly interacting with the molecules of OAgroup. However, when the toxic profiles of mussels are dominated by toxic varieties such as acyl-derivatives (acyl-OA or DTX-3), the ozonation process may cause a decrease in ester forms (DTX-3), producing an OA-group increase in nonacylated forms (OA or DTX-1). Therefore, ozonation may alter the toxin profile of OA-group toxins, with the final product (canned mussels) being dominated by a highly toxic profile of toxins. It must be taken into account that the toxicities of 7-O-acyl-esters forms may have toxicities similar to the OAgroup-toxins if the esters are hydrolyzed in the human digestive system [Jørgensen et al., 2005; García, 2015].

From a toxicological point of view, the toxicity of mussels highly depends on the variability of lipid content in the hepatopancreas ( $\approx$  10 - 20%), which favors the toxins' retention factor [Svensson et al., 2003; García et al., 2006; García et al., 2012]. This explains why these toxins mostly predominate in this tissue, in comparison with the whole body which has a lipid content of only 3%.

Despite the high levels of exposure to blooms associated with OA-group toxins, mussels do not show mortality effects of species from natural beds or culturing centers during their adulthood and this may be attributed to a protective effect of mussels against blooms. *In vitro* studies have established that PP1 and PP2A from mussels are inhibited by OA-group toxins like those from any organism. However, *in vivo* studies have demonstrated that the toxic effects of OA-group toxins on cytosolic enzyme (glycogen synthase) are lower, suggesting that mussels have a mechanism that prevents the accumulation of OA-group toxins in ambient cytosolic. This response against the intracellular effects of OA is mainly due to multixenobiotic resistance (MXR) in the blood cells of mussels, which by being exposed to OA are more resistant against the toxin's cytotoxic effects [Chambers et al., 1993]. This route of resistance is related to the over-expression of a plasma membrane phosphoglycoprotein (pgp) which is particularly in the gill, mantle tissue, digestive gland membrane vesicles and blood cells and which functions as an ATP-dependent drugs efflux pump [Cornwall et al., 1995; Kurelec, 1995].

Another protective mechanism associated with mussels exposed to OA-group toxins is related to the uptake and storage of OA/DTX-1 in the lysosomal system and whose organelles are known by concentrating foreign compounds, such as lipophilic xenobiotics. Thus, contaminants such as OA/DTX-1 would be captured and carried through vesicles to lysosomes, predominantly favoring it, because toxins filtered by mussels (OA/DTX-1) are associated with degraded algae fragments, so they are captured by endocytosis to intracellular digestion in lysosomal compartments. This would finally explain why there is no accumulation of OA-group toxins in the cytosol in mussels and, therefore, no effect on the activity of cytosolic enzyme regulated by PP1 and PP2A [Svensson et al., 2003].

Since OA-group is a serious problem for aquaculture worldwide, it has been established that its predominance in the aquatic environment further responds to the ability that toxins, of which they are composed, have to inhibit the growth of a variety of microalgae in a concentration-dependent manner, thereby suggesting an allelopathic role of toxins. In dinoflagellates, cells mainly produce toxic forms such as OA-diol-ester and dinophysistoxin-4 (DTX-4) which are rapidly hydrolyzed to produce OA or DTX-1 (Figure 3). In the early stages of the production of toxins, DTX-4 is the majority toxin and, therefore, the route of excretion of toxins from cells, which is rapidly hydrolyzed to OA-diol-ester and then to OA by enzymes, and it may even be effective against predators that break their cells during feeding. Through *in vitro* studies, it has been determined that DTX-4 is 50 times less effective than OA on PP2A inhibition, where the OA-diol- ester toxic form is relatively inactive [Hu et al., 1995a; Hu et al., 1995b]. mes, and it may even be effective against predator  $1 - 10$ 

**DTX – 5**

Figure 3. Toxins that compose the toxicity profile of OA-group producing dinoflagellates and that are part of the initial stage prior to being disposed of in the sea or filtered by bivalves. Dinophysistoxin-4 (DTX4); Dinophysistoxin-5 (DTX-5).

An important factor is related to the fact that since OA is a lipid-soluble polyether, its carboxylic group can be ionized at physiological pH, which would make diffusion difficult through the membrane. Thus, since pre-toxic forms such as OA -diol-ester have no ionizable groups, they can move through the membrane with relative ease, allowing it to mobilize into the cell and being inwardly hydrolyzed acquiring toxicity 1,000 times higher than its predecessor.

#### **2.2. Yessotoxins Group**

The Yessotoxin group (YTX-group) corresponds to a group composed of sulphated polyethers (Figure 4), which were isolated for the first time from the Japanese oyster *Patinopecten yessoensis*. Yessotoxin (YTX) is produced by the marine phytoplanktonic microalgae *Protoceratium reticulatum* (Gonyaulax grindley) [Satake et al., 1997], *Lingulodynium poliedrum* (Gonyaulax polyedra) [Tubaro et al., 1998; Paz et al., 2008] and *Gonyaulax spinifera* [Rhodes et al., 2006; Paz et al., 2008; Sosa et al., 2013]. At present, this group of toxins have been identified in different countries worldwide such as New Zealand, Italy, Spain, Norway, Russia, Canada, United Kingdom, Japan, Argentina and Chile [Paz et al., 2008; Alvarez et al., 2011; Paz et al., 2013; Akselman et al., 2015]. Blooms associated with YTX-producing dinoflagellates are characterized by a concentration of cells of  $10<sup>3</sup>$  cells L<sup>-1</sup>, where the production of YTX toxins in dinoflagellates corresponds to an average of 34 pg cell-1 , in which homo-YTX and YTX are the principal toxins that compose the profile in variable concentrations and depending on the area where they had been identified [Paz et al., 2008].

Historically, YTXs have been classified within the DSP-toxins group. However, these toxins do not induce diarrhea in mouse bioassays, nor do they produce protein phosphatase inhibition. This is reason enough to classify them in a separate group [Ogino et al., 1997; Tubaro et al., 2003]. The precise mode of action currently remains unknown, although YTX is known as a potent phosphodiesterase activator [Alfonso et al., 2003].

Symptoms caused by poisoning with YTX in humans are relatively unknown because no human intoxication case has been reported to date [Dominguez et al., 2010]. YTX toxic evaluation, in bioassays, has determined that after an intraperitoneal injection of approximate concentrations of 150 μg kg-1 , symptoms that begin 4 hours after the injection is given are: reduced motor coordination, dyspnea, tremors and cramps [Aune et al., 2002; Alfonso et al., 2003]. EFSA has established that toxic effects may not occur if the concentrations do not exceed the levels of 3.75 mg YTX-equivalent kg<sup>-1</sup> shellfish [EU, 2013].

Currently, 100 natural derivatives of YTX have been identified and characterized by NMR and detected by liquid chromatography coupled with mass spectrometry (LC-MS). Some YTXs are directly produced by dinoflagellates (norYTX, 41-keto-YTX and 41a-homo-YTX) while shellfish metabolize through different oxidation pathways, such as hydroxylations, carboxylations, desulfations, methylations and amidation to other YTX analogs [Ciminiello et al., 2003; Miles, 2006; Paz et al., 2008].

The main vector of YTXs corresponds to scallops and mussels, which can accumulate a large amount of toxins in their tissues due to the high filtration capacity they have. The hepatopancreas is the main tissue of accumulation and according to chemical modifications caused by mussels, they can spread to other tissues such as mantle, gill and adductor muscle

[Aasen et al., 2005]. Thus, YTX-toxins have been found in gastric glands of mussels, associated with several enzymatic metabolism derived toxic forms, of which new forms have been identified so far such as 45-hydroxyYTX, 1a-homoYTX, 45-hydroxy-YTX and 45 hydroxy-1-homoYTX (Figure 4) [Suzuki & Quilliam, 2011]. Each of them present a specific toxicity equivalence factor (TEF),  $YTX = 1.0$  (TEF); 1A-homo-YTX = 1.0 (TEF); 45- $OHYTX = 1.0$  (TEF) and 45-OH-1<sup>a</sup>-homo-YTX = 0.5 (TEF) [EFSA, 2008b].

Figure 4. Chemical Structure of the Yessotoxins-group and their chemical analogs identified in dinoflagellates and bivalves. **R** indicates the substitution of the corresponding radical in the molecule.

When mussels are exposed to this type of bloom composed of yessotoxin-producing dinoflagellates, they absorb algae and the YTX-toxic content is rapidly oxidized via enzymatic action- to 45-OHYTX to then be slowly transformed into carboxy-YTX, an isomer which is more typical in the depuration phase of mussels [Ciminiello et al., 1999; Ciminiello et al., 2000; Ciminiello et al., 2001].

#### **2.3. Pectenotoxins Group**

The Pectenotoxins group (PTXs group) are a family of polyether macrolide toxins (Figure 5) which are produced by the same species that produce the toxic forms of OA-group, namely: *Dinophysis fortii*, *Dinophysis acuta*, *Dinophysis acuminata*, *Dinophysis caudata* and *Dinophysis norvegica* and in heterotrophic dinoflagellates such as *Protoperodinium divergens*, *Protoperodinium depressum* and *Protoperodinium crassipes* [Miles et al., 2004; Li et al., 2010]. Their names come from the name of the shellfish were each of them was first found. For example, Pectenotoxin-2 (PTX-2) was isolated from the Japanese scallop *Patinopecten yessoensins* [Yasumoto et al., 1985]. To date, however, numerous PTX analogs have been found in algal cultures, shellfish and blooms associated with dinoflagellates that produce this kind of toxin.

Several new isomeric forms of PTX-2, such as PTX-4, PTX-6 and PTX-7, have been found in natural blooms (Figure 5). Also, when filtered by shellfish and metabolized in the hepatopancreas (digestive glands) they undergo biotransformation. PTXs have been reported in Ireland, Croatia, New Zealand, Portugal, Norway, Japan and Chile [Krock et al., 2009a; Dominguez et al., 2010; García et al., 2012]. To differentiate isomeric forms of PTX-2 found in dinoflagellates from those found in shellfish, the nomenclature coined the term PTX-seco acid (PTX-SA) [Dominguez et al., 2010]. Toxic isoforms such as Pectenotoxins-2 (PTX- 2), Pectenotoxins-2 seco acid (PTX2sa) and 7-epi-Pectenotoxins-2 seco acid (7-epi PTX2sa) are the predominant toxic forms found in Europe [Vale & Sampayo, 2002]. To date, 15 forms of toxic analogs of PTX have been described. The last identified isomers esterified forms of PTX-2A-SA (37-O-acyl-ester-PTX-2-SA, 11-O-acyl-ester-PTX-2-SA and 33-O-acyl-ester-PTX-2-SA) were found only in shellfish but not in PTX producing dinoflagellates [Miles, 2006; Aasen et al., 2006].

The coextractability of PTXs with diarrhetic toxins of okadaic acid group led PTXs to be included with okadaic acid analogues in the OA group toxins [Suzuki et al., 2005; Miles, 2007]. However, PTXs are now classified as a separate toxin group, on the basis of their toxicity, thus for example, PTX1 and PTX6 do not inhibit PP2A. Consequently, based on the association of symptoms and the toxic ability of mussels, it has been determined that the amount sufficient to cause toxic symptoms is 2.0  $\mu$ g PTX-2-SA/Kg for a 70 kg person [Burguess & Shaw, 2001].

Available information on PTXs is still insufficient with just a few biological results. These few results are from *in vitro* and *in vivo* experiments, aiming to provide information about the risks to human health that ingestion of these toxins may pose [Dominguez et al., 2010]. PTX toxicity after intraperitoneal (*i.p.*) administration and after oral ingestion is considered comparable. For example, hepatic damage in mice after *i.p.* administration and oral ingestion seem to be the same. However, diarrhea was never reported in those experiments [Miles et al., 2004]. In addition, PTX-2 has been found to be potentially citotoxic in lung, colon and kidney carcinogenic cell lines, an effect that cannot necessarily be extrapolated to its toxic forms, such as PTX-2-SA and 7-epi-PTX2-SA. This shows the importance of the initial structure of toxins that initiate citotoxic effects [Jung et al., 1995], where 7-epi-PTX-2-SA is the result of interconversion of PTX-2-SA to thermodynamically more stable forms and may be understood as a protective detoxification effect by mussels [Suzuki et al., 2001; Miles et al., 2004].

Name	R <sup>1</sup>	$\mathbb{R}^2$	$R^3$	$C-7$
Pectenotoxin-1 (PTX-1)	CH <sub>3</sub> OH	H	H	R

Figure 5. Chemical Structure of Pectenotoxins-group and their chemical analogs identified in dinoflagellates and bivalves. **R** indicates the substitution of the corresponding radical in the molecule.

To date, no case of intoxication by PTX-type toxins has been reported. However, biotransformation of PTX-2 has been found in some shellfish species and these toxic forms have been detected with increasing frequency [Miles et al., 2004].

Studies from various toxins have determined a difference in the profiles from producing dinoflagellates and in the bivalve profiles, establishing that the metabolic transformation occurs in mussels after ingestion of toxic algae [Suzuki & Quilliam, 2011]. Through standard incubation periods (24 h/ digestive gland), it is shown that the biotransformation of PTX-2 toxin has two stages:

- 1. Assimilation and biotransformation
- 2. Distribution of biotransformed toxins to the different tissues.

Based on the results obtained, it has been determined that this process occurs exclusively in the digestive gland at pH 7.5, which is related to the environmental conditions of its habitat (the south of Chile). In addition, it has been shown that the biotransformation kinetics of PTX2 is low (23.98%) and that, therefore, sandy bottom-dwelling species (*Venus antiqua*) do not represent a health risk, since the final product is only associated with non-visceral tissues (foot), in which no biotransformation of the PTX-2 toxin is produced and whose identification is only related to biotransformed toxins coming from the distribution from the digestive gland of the bivalve [Oyaneder et al., 2014].

#### **2.4. Azaspiracid Toxins Group**

The AZA-group corresponds to toxins produced by toxic dinoflagellates, *Protoperidinium crassipes*, *Azadinium spinosum* and the sponge, *Echinochlathria* sp. [James et al 2004; Tillman et al., 2009; Potvin et al., 2012; O'Driscoll et al., 2014], although direct evidence between the high level of cells that produce AZAs and the concentration of toxins in shellfish that filter them, has not been yet provided [Krock et al., 2009b]. The first intoxication cases related to this type of toxin happened in Holland in 1965, where the symptoms were initially linked to the presence of OA and DTXs.

To date, 24 different forms of Azaspiracids (AZAs) have been found, the most common forms being Azaspiracid-1 (AZA-1), Azaspiracid-2 (AZA-2) and Azaspiracid-3 (AZA-3) (Figure 6) [Rehmann et al., 2008]. All of them are characterized by having specific toxicity equivalence factors (TEFs)  $(AZA-1 = 1; AZA-2 = 1.82; AZA-3 = 1.43)$  [Botana et al., 2017].

Identification of AZAs in shellfish has been reported in Ireland, UK, Norway, France, Portugal, North Africa (Morocco), Chile and U.S.A. [Amzil et al., 2008; Twiner et al., 2008; Hess et al., 2015]. However, new forms of AZAs are detected every year by the monitoring programs in countries of the EU, which translates to variable toxic profiles, depending on the species that accumulate the toxins and the extent of their biotransformation in the hepatopancreas. These last isoforms of AZAs have only been observed with LC-MS/MS analysis, which has been implemented as an alternative technique in sanitary controls of shellfish [James et al., 2008; McCarron et al., 2011].

Action mechanisms of this type of toxin have not been clearly determined. However, preliminary *in vitro* studies in mammal cells show alterations in the cytoskeletal structure and in the E-cadherin system, responsible for cell to cell interaction [Twiner et al., 2005; Ronzitti et al., 2007]. These experimental results could somehow explain symptoms associated with the described intoxications; gastrointestinal disorders, abdominal pain and diarrhea [James et al., 2002]. Bioassays in mice with shellfish extracts with low concentrations of AZA do not induce diarrhea [Ito & Satake, 2002], however after a while animals show paralysis and respiratory disorders leading to death about 1.5 hours post injection of the extract [Satake et al., 1998]. Further studies have demonstrated that the lethal *i.p.* dose in mice depends on the toxic form present in the shellfish extracts. AZA-1 has a lethal dose of 200 μg kg<sup>-1</sup>, while isomers AZA-2 and AZA-3 are significantly more toxic with lethal doses of 110  $\mu$ g kg<sup>-1</sup> and 140 μg kg-1, respectively [Twiner et al., 2008].

Biotransformation may play a significant role in the number of toxic variations within shellfish. Toxic variations AZA-4 and AZA-5 were found in mussels that originally only had AZA-2 and AZA-3 (Figure 6) [O'Driscoll et al., 2011; Jauffrais et al., 2012]. These biotransformed variations, although less toxic, constitute a source of concern from a public health standpoint [Twiner et al., 2008; Furey et al., 2010].

On the other hand, oral toxicity of AZA-1 at high doses  $(900 \mu g kg^{-1})$  in mice, produce significant damage to the small intestine, while a 500  $\mu$ g kg<sup>-1</sup> dose will only produce hepatic damage, evidenced by a volume increase of the organ (38% post-ingestion) [Ito et al., 2000]. Parallel toxicological studies have established that the lowest observed effect level (LOEL) for AZA lies between 23 and 86 μg kg<sup>-1</sup> per person, even when levels of 80 μg AZA eq kg<sup>-1</sup> of shellfish could not produce AZA related intoxication symptoms. However, doses of 30 μg AZA eq kg-1 (shellfish kg) in 400 g of ingested shellfish have produced intoxication syndromes in humans. These apparently contradictory data may be explained when

considering the biotransformation produced towards AZA, which generates different toxic forms (analogues) during their assimilation in the mussel (*Mytilus chilensis*) [Hess et al., 2015].

Figure 6. Chemical Structure of Azaspiracids-group and their chemical analogs identified in dinoflagellates and bivalves. **R** indicates the substitution of the corresponding radical in the molecule.

Based on both the toxic information in humans and the biotransformations determined in mussels, EFSA has established that toxic effects in humans may not occur if the concentrations of AZAs do not exceed the levels of 30  $\mu$ g AZA-1-equivalent kg<sup>-1</sup> shellfish [EFSA, 2009].

Proteomic studies on the hepatopancreas of *Mytilus edulis* exposed to AZA, indicate that they show an increase in the protein levels associated with the defense mechanisms of mussels, thus establishing that the hepatopancreas plays an important role in the metabolism of toxins [Nzoughet et al., 2009]. The toxicity in mussels contaminated with AZA persists for an average period of five months, which, in some cases, is explained by the high distribution of toxins in the different tissues of the mussel in relation to the digestive gland [James et al., 2002]. Even when AZAs are usually concentrated in the hepatopancreas, these toxins may migrate to other tissues of the mussel (gonads and adductor muscle) given their chemical qualities of zwitter-ion [James et al., 2002; Magdalena et al., 2003].

Under production conditions, mussels contaminated with AZA which are subjected to thermal processes for a short time and in the absence of water, experience high levels of AZA-3, a situation that is repeated by subjecting mussels to low temperatures  $(4^{\circ}C)$  for a prolonged time. In both instances, the toxic precursors AZA-1 and AZA-2 have no considerable variations to the originally evaluated levels, even when the levels of AZA-3 correspond directly to those provided by AZA1/AZA-2. A plausible answer is that toxic contributions come from other sectors of the matrix of mussels or also by bioconversion from unidentified toxins such as AZA-17, which is decarboxyled when subjected to high temperatures, generating AZA-3. A similar situation occurs with decarboxylation of AZA-19, AZA-21 and AZA-23, which tend to form AZA-6 [McCarron et al., 2009]. These important factors are emphasized when considering that multiple production processes of mussels may damage the walls of their internal bodies in order to facilitate the distribution of toxins to other compartments.

## **3. COMPOSITION AND BIOTRANSFORMATION OF LIPOPHILIC MARINE BIOTOXINS IN MUSSELS**

Assessment and identification of lipophilic marine biotoxins (OA, YTX, PTX and AZA groups) and of their described and identified toxic forms resulting from metabolism processes (acyl-derivatives) in shellfish, whether these come from rocky strata or soft bottom habitats, demonstrate that the profiles are always characterized by the predominance of DTX-1 (65% average among species), followed by a toxic variability dependent on the involved species. Hence, the sequence of predominance of toxins in *Mytilus chilensis* is composed by DTX-1>OA>PTX-2>YTX>AZA-1, where each toxin is followed by the toxic forms which have resulted from the metabolic transformations occurred in the tissues of the mussels (Acyl-DTX-1>PTX-2SA>45-OHYTX>7-epi-PTX-2SA>homoYTX>AZA-2>Acyl-OA>AZA-3). For its part, Ribbed mussels (*Aulacomya ater*) are characterized as having a profile dominated by DTX-1>PTX-2>YTX>AZA-1>OA and their toxins resulting from biotransformation by PTX-2SA>Acyl-DTX-1>45-OHYTX>7-epi-PTX-2SA>Acyl-OA>homoYTX>AZA-2>AZA-3 (Figure 7). Meanwhile, the profile of dominance of toxins in bivalves in soft bottom species (sand), which are part of the infauna, are likewise different. The dominance criteria for *Venus antiqua* is DTX-1>YTX>PTX-2>OA>AZA-1, where Acyl-DTX-1>45-OHYTX>AZA-2>homoYTX>AZA-3>Acyl-OA>PTX-2SA >7-epi-PTX-2SA dominate in its biotransformed toxins (Figure 7).

The main toxic forms of the biotransformation of PTX-2 correspond to PTX-2-SA/7-epi-PTX-2-SA, which may dominate in the variety of PTX in mussels after one month. This dominance is related to the chemical stability of metabolic forms and to the high retention affinity in the mussels' tissues, where this transformation pathway is also related to the protective effects towards mussels. This toxic profile may present strong toxic stratification in mussels from farming facilities because the availability and assimilative capacity of food may vary as the depth increases or decreases.

The identification of AZA-1 in mussels was dominant and also directly related to their interaction with the other aquatic organisms in the related habitat. The presence of AZA-

2/AZA-3 isomers, known toxins structures that result from the bioconversion of AZA in mussels is also established (Figure 7).

The variability in the accumulation of lipophilic toxins in shellfish can be largely explained by the different degrees of hydrophobicity that toxins have in the different species. Their direct relationship in the lipid content must also be considered, where Blue mussels (*Mytilus chilensis*) and Ribbed mussels (*Aulacomya ater*) are dominant species, known for having high and varied concentrations of lipids [Freites et al., 2002; Pazos et al., 2003; Svensson & Förlin, 2004, García et al., 2006; Rossignoli & Blanco, 2010].

Figure 7. (Continued).

Figure 7. Comparison of lipophilic toxin profiles of bivalve species: A) Blue mussels (*Mytilus chilensis*); B) Ribbed mussels (*Aulacomya ater*); C) Razor clam (*Tagelus dombeii*) and D) the carnivorous gastropod Loco (*Concholepas concholepas*) from the South Pacific Ocean.

The detection of toxic forms resulting from biotransformation, evidences the conversion capability that mussels and habitat-associated species have to modify lipophilic toxins, where the transformation ratio is again associated with the degree of compartmentalization of toxins provided in the bloom and where each of them will be chemically modified according to the degree of exposure of the species to the bloom and also to the degree of retention or purification by the aquatic organism. Such factors may also vary according to the availability of food by filter-feeding organisms, where the diet may be also subjected to food from feces and pseudofeces more directly exposed to the water column, producing a contribution of toxins which were already subjected to metabolic or biotransformation processes by other species present in the water column (Figure 8A) [Suzuki & Mitsuya, 2001; Miles, 2006; Torgersen et al., 2008a].

The main assimilation tissue of lipophilic toxins in mussels is the digestive gland (hepatopancreas), in a ratio of 7:3 with respect to non-visceral tissues (gonads, gills, mantle and adductor muscle) (Figure 8B-E). This distribution is variable over time due to: a) the modification the profile in each tissue; b) the biotransformation processes; and c) the affinity variables of toxins in the tissues of mussels. The transformation of DTX-1 by mussels favors the accumulation of DTX-3 principally in mantles, which can reach an accumulation level of 90% depending on the period of evaluation after the bloom ( $\approx$  5 months).

Toxic profiles of carnivorous species such *Concholepas concholepas* were characterized as having profiles directly related to the typical diet (*Mytilus chilensis*) and by the high biotransformation capacity they have.

The precise mechanisms of purification of these kinds of toxins in the assessed species are unknown, although the literature suggests a relationship between quality and quantity of available food, together with additional elements such as salinity and temperature conditions, factors that could affect the purification levels of bivalves, and which periods may last as long as 44 days after the bloom occurs [Svensson & Förlin, 2004; Duinker et al., 2007]. However, parameters regarding the chemical configuration of some toxins and their purification levels in bivalve species, establish that esterified forms from OA, DTX-1 and DTX-2 toxic forms are purified faster than free forms (nonesterified forms), depending largely on the involved fatty acid, which directly influences the rate of purification of toxins ( $\approx$ 10-17 days) [Torgersen et al. 2008a].

From the point of view of the contribution of lipophilic marine biotoxins to different species, variability can be explained on the basis of the predominance in the bloom of dinoflagellates species that provide this type of toxin and the profile of toxins provided from cells to bivalves. For instance, the cell concentration of *Dinophysis* sp. in the water column may represent a small fraction of it, since according to the oceanographic conditions, this species is capable of experiencing vertical migration generating growth according to the nutritional needs [Maestrini, 1998; García et al., 2015]. The latter is an equally important point, considering that according to the abundance of food, in this case of toxic dinoflagellates, the filtration rate of the different species of bivalves may experience a decrease in their physiological needs for food on a regular basis [Sampayo et al., 1990].

Furthermore, the determination of the levels of lipophilic toxins has determined the different retention levels that bivalves and gastropods have. Similarly, some species have a higher retention capacity or a greater degree of insensitivity to these toxins, because if they are subjected to repeated blooms, early stages of development of some species could be affected due to the low effectiveness of their detoxification enzymatic processes, thus decreasing bivalves or gastropods populations.

It should be pointed out that these blooms may affect various larval stages of the different studied species (mussels) by affecting the oxygen uptake rate by larvae, which causes a reduction in their capacity for locomotion. This generates a negative effect since it directly affects the migration of different larval stages involved in vertical migration in the water column. This may cause the different larval stages to be exposed to considerable populations of predators (chaetognaths, fishes and/or hydrozoans) affecting the balance of the adult population in a zone of great impact on economically profitable resources and with some endemic cases in the country [García et al., 2013].

Figure 8. Schematic representation of the distribution, accumulation and biotransformation of lipophilic-toxins from phytoplankton to the mussels' tissues (modified and updated by Moroño et al., 2003). Anatomical distribution (B) OA-group toxins in visceral and non-visceral tissue in mussels; (C) PTX-group toxins in visceral and non-visceral tissue in mussels; (D) YTX-group toxins in visceral and non-visceral tissue in mussels; (E) AZA-group toxins in visceral and non-visceral tissue in mussels.

## **4.IMPACT OF LIPOPHILIC MARINE BIOTOXINS ON AQUACULTURE DEVELOPMENT IN THE SOUTH PACIFIC FJORDS**

The *Mytilus chilensis* samples collected in the area are exclusively destined for aquaculture development in the South Pacific Ocean (Chiloe Island and Austral fjords). Given the constant conditions of annual blooms, these tend to occur in summer periods (October – April), where mussels tend to present variable levels of lipophilic marine biotoxins, which may exceed international standards. The different amounts of each type of detected toxin are associated with the location of the sample in the water column, since each sample is collected at different depths of the shellfish aquaculture lantern and, therefore, exposed to different densities of toxic dinoflagellates. Mussels that are at the lowest depth (10 meters) and in the most superficial positions (1-3 meters from the surface) show the lowest amount of DSP toxins, 67.2 and 33.5 – 36.7 nanograms of DTX-1/gram of digestive gland, respectively. Similar results are obtained in STX-group toxin analysis [Zamorano et al., 2013].

These data show a clear stratification of the lipophilic marine biotoxins in the shellfish samples in the water column. This stratification measured in the mussel extracts obtained from mussels from aquaculture at different water column depths can only be explained by the stratification of the toxic dinoflagellates in the water column (Figure 9).

Another important factor to be considered is that the exploitation of these resources generates production batches that may come from different areas of the same culturing area and also from different depths. In the first instance, this may cause errors in the determination of the profile and toxicities of the exploited mussels, tending to qualify products as free from STX-group-toxins and/or lipophilic-group-toxins.

These data become relevant, considering that 90% of Blue mussels that Chile exports (from Austral fjords) are farmed mussels, whereas exported Ribbed mussels are harvested from wild banks. The notorious differences in toxin levels found are directly related to the filtration capacity of each species [García et al., 2016].

In recent years, the production of mussels has been subjected to the determination of previously unidentified lipophilic marine biotoxins (AZAs and YTX). This impact, that is more relevant during the spring–summer season in this region, may be attributed to the presence of algae, mainly due to the favorable luminescence and nutrient conditions during this time of the year. We must also consider the Chaitén Volcano eruption (Chiloe Island surroundings, 2008), the Aysén Volcano eruption (Austral fjords, 2010), the Calbuco Volcano eruption (Los Lagos region, 2015) and the earthquake–tidal wave in the year 2010. These phenomena could explain the population dynamic change in marine microalgae that would allow the development of dinoflagellates that produce different types of toxins (YTX, AZA and PTX) in areas of higher production of mussels from aquaculture [Zamorano et al., 2013].

In addition, the latitudinal distribution of phycotoxins along the coasts of Chile in the Austral fjords, in which some studies have clearly detailed the presence of isomers of YTX, OA and AZAs groups, has been defined [Trefault et al., 2011]. However, geographical definitions associated with the presence of lipophilic marine biotoxins are an off-shore assessment in certain points but they cannot be considered a representation of the behavior of HABs in Austral fjords, areas where farming centers of mussels are preferably set up. It has been determined that *Dinophysis* sp*.* may exhibit preferences for certain sea and habitat conditions, which could explain the regional toxic differences in the fjords of the same

species and that result in different initial toxic profiles prior to the consideration of a contribution of a toxins' biotransformation by bivalves [García et al., 2004; Elgarch et al., 2008; García et al., 2010]. Comprehensive assessments on the complex oceanography and geography of the Austral fjords show very different behavior in the presence of HABs, in which local zones (estuaries), that make up the fjord's geography, determine very different levels of *Dinophysis* sp. blooms' behavior in different points [Díaz et al., 2011]. Therefore, individual (oceanographic) characteristics of each fjord make the HABs' behavior very different and unique, or difficult to characterize, among others, by particular physio-chemical parameters in some cases.

Figure 9. Procedure for identifying harmful algal blooms (HABs). A) Plankton monitoring and B) Toxin monitoring.

The distribution of different *Dinophysis* species (*Dinophysis acuta* and *Dinophysis acuminata*) has been defined as variable and it is directly associated with oceanographic conditions, determining the simultaneous presence of species, with a variability associated with the water column. The characterization of a region composed by multiple fjords is delimited to the transitions from upwelling to downwelling in fjords at different times of the year (inland seas) [Escalera et al., 2012]. Therefore, defining a characteristic condition of a profile or predominance of *Dinophysis* sp. or a toxin in particular, responds directly to the methodological and sampling inadequacy in space-time with which HABs are related in this zone of Austral fjords.

Additionally, lipophilic marine biotoxins act as an exogenous source of oxidative stress, producing reactive oxygen species (ROS) that will damage different aquatic species through the lipid peroxidation (LPO) of biological membranes. Therefore, as they are produced inside the cells, ROS are able to react with all types of biomolecules, organelles (mitochondria) and enzymes (cytochrome P450) [Inoue et al., 2003]. Xenobiotics, such as lipophilic marine biotoxins, can not only cause ROS overproduction, but also alter the antioxidant levels which can lead to an oxidative stress condition [Amado et al., 2009]. Some studies indicate that

dinoflagellates, such as *Dinophysis* sp., cause alteration of antioxidant enzymes and promote the induction of oxidative stress in different tissues of different bivalve species as well as in some fish [Clemente et al., 2010]. Thus, lipophilic marine biotoxins can be bioaccumulated throughout the food chain by decreasing the activity of superoxide dismutase (SOD), GST, glutathione peroxidase (GPx) and causing oxidative stress in different biological structures such as proteins and DNA.

Bivalves tend to be excellent biomonitors and bioindicators of pollution given their special characteristic as sessile benthic filter feeders, so they can accumulate and tolerate high concentrations of chemical pollutants, allowing them to provide reliable measurements over time of the bioavailable portion of total contaminants [Glibert et al., 2014; Oyaneder et al., 2017].

On a physiological level, exposure to harmful algal blooms that generate accumulation of lipophilic mairne biotoxins and ROS toxins for bivalves implies a variability of the closure of shells, adductor muscle paralysis, retraction of the mantle, and production of mucus [Perovic et al., 2000; Hegaret et al., 2012]. Facing this event of algal exposure and lipophilic marine biotoxins, it has been possible to determine a positive correlation detected between SOD and GPxs, which indicates that GPxs are an important pathway of degradation of hydrogen peroxide and that the coordinated action of both enzymes acts against the oxidative damage induced by lipophilic-toxins.

#### **CONCLUSION**

Mussels and bivalves exposed to HAB accumulate filtered microalgae in their digestive glands (hepatopancreas) where 70% of the total amount of the detected toxins is present in this organ. From these glands, toxins are subjected to biotransformation mechanisms by three types of pathways:

- (a) By bacteria such as *Pseudomonas* sp. and *Vibrio* sp. which are an important part of their environment.
- (b) By aquatic organisms which are characteristic of diverse habitats.
- (c) By enzymes identified in bivalves which play an important role in esterifying and metabolizing toxins into chemically more stable, easy to purify isomers by mussels.

The mechanisms of biotransformation (hydrolysis and acylation) of toxins present in bivalves lead to the formation of new pseudo-toxic forms. They are directly associated with the stage of excretion of toxins by bivalves where these new pseudo-toxic forms are often not detected by conventional detection methods (bioassays). Their intraperitoneal and oral toxicities are not related, which generates naturally contaminated products as toxin free products, often causing these nontoxic forms to again be transformed into toxic forms during production processes of processed seafood or by enzymatic action in the digestive processes of the human body.

This lipophilic marine biotoxin biotransformation process is relevant because it cannot be detected by conventional monitoring methods (such as mouse bioassay), which then may classify the tested individuals as toxin free bivalves or could lead to an erroneous definition of the bloom effect depuration processes.

The need to determine the profile of toxins in contaminated bivalves and their biotransformation levels during or after an exposure to a HAB has become extremely necessary in order to define the levels of toxic and chemical modifications of toxins in bivalves subjected to industrial manufacturing processes due to two essential factors:

- 1. the high variability and transformation probability to which toxins are subjected to enzymatic processes in bivalves which impedes the collection of adequate information about the evolution of toxic events and/or purification processes in bivalves.
- 2. the difficulty in identifying new conjugated or biotransformed forms by conventional methods such as bioassays, since there is no reference material available in most cases which impedes the identification and quantification of new toxic forms.

Knowledge of the interactions among contaminated shellfish and the evolution of the transformation of toxins in this study may allow for an a efficient risk management of resources to be performed. This will reduce adverse effects from an economic standpoint, as shellfish extraction is more efficient and extended closures as a result of toxic blooms can be avoided.

## **ABSTRACT**

*Nannochloropsis* genus includes marine unicellular organisms with spherical shape, a parietal chloroplast, and a characteristic pigment composition (with only chlorophyll and high amount of violaxanthin). This genus is used in aquaculture as live feed for fish larvae, rotifers, bivalves, and other organisms, because of its nutritional quality. Recently, some researchers have proposed that this genus can produce triacylglycerols, which can be used to obtain biodiesel based on the fact that under stress conditions, the lipid content in the dry biomass of *Nannochloropsis* can reach 50% and because fresh water is not required for its culture. *Nannochloropsis* usually obtains nitrogen from nitrate, nitrite, ammonium, or urea. The provision of nitrogen from different sources is a strategy used to modify the biomass composition. In this chapter, the effects of the modification of nitrogen source and addition of CO<sup>2</sup> on the growth and lipid content of *Nannochloropsis* sp. are analyzed. Nitrate is the preferred nitrogen source and gives the highest biomass concentration and specific growth rate when compared with urea and ammonium. This effect is higher when the cultures are bubbled with  $CO<sub>2</sub>$ -enriched air because

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: rcanizar@cinvestav.mx.

*Nannochloropsis* does not have an external carbonic anhydrase and depends on the flux of bicarbonate, which is very low when only air is insufflated. Both  $CO<sub>2</sub>$  enrichment and nitrogen source modification cause slight modifications in the specific lipid content. The lipid productivity strongly depends on the biomass concentration and the growth rate of the culture. If the objective is the mass culture of *Nannochloropsis*, nitrate is the best nitrogen source. However, it is important to highlight the ability of *Nannochloropsis* sp. to use ammonium, because this permits it to obtain nutrients from wastewater, while delivering high value products (like biomass and lipids).

## **1.INTRODUCTION**

Microalgae are photosynthetic, eukaryotic or prokaryotic, microorganisms that are distributed in diverse environments, such as oceans, lagoons, rivers, and estuaries [1]. The microorganisms in this group grow faster than plants, and do not require fertile lands and potable water for their cultivation. Thus, they can be potentially used for the production of high value compounds, such as carbohydrates, proteins, pigments, and polysaccharides [2]. Their use is favored by the higher biomass production vis-à-vis the plants, with some reports indicating biomass close to an order of magnitude higher than those of crops, like corn and rape, etc. This could cause a huge reduction in the land and infrastructure required for the production of same quantities of biomass [3–5]. The tendency for the production of lipids (oils) is also similar, with higher production compared to that obtained from oleaginous seeds [6–8].

*Nannochloropsis* is a genus of preferably marine oleaginous microorganisms that have been investigated in the last few years, with lipid contents around 30%; under stressful conditions the content of non-polar compounds (bio-oils) can reach upto 60% [9].

### **1.1. Microalgae**

The term "microalgae" is commonly used to refer to a huge group of microorganisms with the capability of carrying out oxygenic photosynthesis; these organisms do not have a common origin, and are, therefore, considered as a polyphyletic group. They are very similar to plants in terms of their metabolism and accumulate the same compounds as carbon reservoirs. The autotrophic microalgae obtain their energy by the process involving absorption of light, reduction of CO2, and oxidation of water molecules [1]. Despite the metabolic similarity with plants, microalgae are more efficient in the conversion of solar energy because they have a simple cellular structure. The fact that they are suspended in liquid permits an efficient nutrient supply (mainly of nitrogen, phosphorus, and  $CO<sub>2</sub>$ ) [1, 10].

The size of microalgae varies from 0.2–2.0 µm, and they can grow either submerged or partially exposed to the atmosphere. The aquatic microalgae are distributed in waters that are fresh or salty, and are tolerant to wide fluctuations in  $pH$ , temperature, turbidity, and  $O<sub>2</sub>$  and CO<sup>2</sup> concentrations [1].

### **1.2. Eustigmatophyceae**

The Class Eustigmatophyceae was appeared upon careful study of the microorganisms that were previously included in the Class Xanthophyceae; differences were observed in the metabolism and pigment composition of some members of Xanthophyceae, based on which researchers decided to include them in a new Class, which was named as Eustigmatophyceae [11–14].

Some members of Eustigmatophyceae have been isolated from samples collected from salty and marine ecosystems as well as from soil samples (Hibberd 1990). At microscopic level, the members of Eustigmatophyceae are coccoid, yellowish-green in color, and almost all the genera have spherical shape with diameters ranging from 2 to 8  $\mu$ m [12–14]. Their small size and similarity with other genera makes it difficult to classify them only on the basis of microscopic observations, and identification using genetic tools is, therefore, preferred [15].

### **1.3.** *Nannochloropsis*

As of date, six species are included in the genus *Nannochloropsis*. This genus includes isolated elliptical cells  $(3-4 \mu m)$ , with parietal chloroplast and a pyrenoid visible under the optical microscope. The vegetative cells have a small red-colored body that increases its size in aged cultures. The organisms included in this genus have a particular pigment composition: chlorophyll a, which is characterized by a high content of violaxanthin, and a low vaucheraxanthine: violaxanthine ratio (compared to that in the members of the Class Xanthophyceae); few species also contain  $\alpha$ –carotene [8, 11–14, 16].

The majority of the members of *Nannochloropsis* grow in salty or marine environments. For this reason, the artificial media used for their culture have salinities ranging from 28 to 44‰. These microorganisms use nitrate, nitrite, ammonia, or urea as nitrogen source; normally, the growth is similar when nitrate and ammonia are used and it is usually lower when urea is used. Inorganic phosphate (sodium or potassium) is used as the source of phosphorus [16, 17]. The growth of *Nannochloropsis* remains unchanged in the pH range from 7.0 to 8.5 [18–20].

The carbon absorption in the members of *Nannochloropsis* is carried out by active transporters because there is no extracellular carbonic anhydrase and the absorption of carbon is in the form of  $HCO<sub>3</sub><sup>-</sup>$ . This process is dependent on light and can be maintained by brief period afterlight exposure (for some minutes) [21]. This system of bicarbonate transport increases the concentration of inorganic carbon inside the cells and the intracellular carbonic anhydrase maintains the equilibrium between  $CO_2$  and  $HCO_3^-$  [22, 23].

The microorganisms of the genus *Nannochloropsis* are used in aquaculture, especially in the production of fish larvae, rotifers, and bivalves, as live-feed because of their small-size and nutritional qualities. In the last three decades, the benefits of using these microorganisms as live-feed have been demonstrated, and their use is recommended over microorganisms of other genera, as *Scenedesmus* and *Chlorella* [18, 24]. Some of the most important characteristics that make these microorganisms useful as live-feed are high protein content (which could be higher than 30% of the dry biomass in some strains), presence of all the essential amino acids, high lipid content, and the fact that almost 50% of the fatty acids are polyunsaturated, with eicosapentaenoic acid (EPA) (20:5  $\omega$ -3) being the predominant polyunsaturated fatty acid [25].

Few years ago, microorganisms of the genus *Nannochloropsis* were proposed to be feasible sources of bio-oil for the production of biodiesel owing to their high lipid content and because the majority of their lipids could be esterified [26, 27]. However, the accumulation of lipids is a specific aspect and can vary among different strains. Moreover, the accumulation of carbon sources (lipids or carbohydrates) only occurs when the specific growth rate diminishes, that is, during the stationary phase [15, 28–30].

The members of *Nannochloropsis* preferably accumulate non-polar compounds (lipids) during the stationary phase [6]. The term lipid includes the fraction extracted from the biomass using non-polar solvents, such as hexane and chloroform. The amount of lipid extracted depends of both the solvent employed and the pretreatment (lyophilization, grinding, etc.) that the biomass is subjected to [31]. The lipids of *Nannochloropsis* include mono, di, and triacylglycerols, as well as phospho and glucolipids [6]. Under stressful conditions, the lipid content can reach almost 60% of the dry biomass [15, 28–30]. This chapter describes the analysis of the effect of  $CO<sub>2</sub>$  addition and modification of nitrogen source on the growth, lipid content, and productivity of *Nannochloropsis* sp.

## **2. EFFECT OF NITROGEN-SOURCE MODIFICATION AND CO<sup>2</sup> ADDITION ON** *NANNOCHLOROPSIS* **SP.**

#### **2.1. Effect of CO<sup>2</sup> Addition on** *Nannochloropsis* **Cultures**

Normally, the biomass production of *Nannochloropsis* is carried out in airlift photobioreactors (PBR), with either tubular or flat panel configurations. In these kinds of PBRs, the mixing is caused by bubbling air and this permits accumulation of biomass to concentrations ranging from 1 to 2 g  $L^{-1}$  [18, 19, 29, 32–34]. In these PBR configurations, the cells are exposed to low shear stress and the cultures are mixed well [35]. However, the  $CO<sub>2</sub>$ concentration in air is very low and its supply is not enough to maintain exponential growth for several days for achieving high biomass concentrations. Thus, addition of  $CO<sub>2</sub>$  to the gaseous stream favors higher biomass concentrations. Several researchers recommend the enrichment of the gaseous stream with at less 1% CO<sub>2</sub>; there have been reports where pure  $CO<sub>2</sub>$  was used [29, 36, 37]. For mass culture, the strategy that is most frequently employed is to link the  $CO_2$ -supply with the pH value; usually, the introduction of  $CO_2$  initiates when pH reaches 8–8.5 and is interrupted when it is 6.5–7 [30, 32]. This strategy helps in diminishing the loss of  $CO<sub>2</sub>$  to the atmosphere.

Under some culture conditions, the effect of  $CO<sub>2</sub>$  addition is immediate and very strong. The effect of enrichment of the air bubbled through a culture of *Nannochloropsis* sp. with 3%  $CO<sub>2</sub>$  is shown in Figure 1. The enrichment with  $CO<sub>2</sub>$  caused an increase in the biomass by approximately 20% in the first 2 days of culture; however, the increase in the biomass was much higher (being 200–400% of the biomass obtained from the culture in which only air was bubbled) from the third day to the end of the experiment. This effect was because of the mechanism used by *Nannochloropsis* for CO<sub>2</sub> absorption. As stated earlier, this microorganism lacks extracellular carbonic anhydrase and the supply of inorganic carbon depends on the concentration of bicarbonate, which has to be added continuously [22, 38]. The effect is more important considering the fact that the uptake of bicarbonate is activated by light [21]. Several researchers have reported increases in both biomass production and productivity by the addition of CO<sub>2</sub> to *Nannochloropsis* cultures (Table 1).

Figure 1. Effect of CO<sup>2</sup> addition in the insufflated stream on *Nannochloropsis* sp. cultures. Closed circles indicate the cultures bubbled with  $CO_2$ -enriched air (3% v/v) [76].

As mentioned above, in mass cultures of *Nannochloropsis*, the most commonly used strategy for  $CO<sub>2</sub>$  supply is to link  $CO<sub>2</sub>$  addition with pH because the concentrations of bicarbonate, carbonate, and  $CO<sub>2</sub>$  are directly related to the pH of the culture medium. This is because of the fact that  $CO<sub>2</sub>$  dissolves in water to produce carbonate and bicarbonate ions and carbonic acid, all of which remain in dynamic equilibrium; the proportion of these moieties depends on the pH. In the case of *Nannochloropsis*, the optimum pH is 8.5 because at this pH bicarbonate is the predominant ion, which provides the inorganic carbon inside the cell in this microorganism; this guarantees both higher growth rate and productivity [20, 32, 39, 40].

### **2.2. Effect of the Nitrogen Source on** *Nannochloropsis* **Cultures**

The supply of  $CO<sub>2</sub>$  is very important to ensure high biomass concentration in *Nannochloropsis* cultures. Nitrogen source is another parameter that modifies the biomass concentration, growth rate, productivity, and the biomass composition. The *Nannochloropsis* species are capable of using different nitrogen sources, most common of which is nitrate; however, the use of ammonia, urea, as well as commercial fertilizers has also been reported [17, 41–49]. In all the cases, the biomass concentration and productivity are related with the strain and the culture conditions that are employed.

Normally, the highest biomass concentration is obtained when nitrate is used as a nitrogen source (Figure 2). However, the effect of nitrate is almost negligible when air is used as a carbon source; the effect is more evident when the insufflated air is enriched with  $CO<sub>2</sub>$ . This is because the cultures supplied with nitrate and ammonia grow faster and make the differences higher. As shown in Figure 2, the cultures supplied with nitrate and ammonia insufflated with  $CO_2$ -enriched air  $(3\%)$  reached 100 and 200% higher biomass concentrations than the cultures that were insufflated with air. In the comparison between cultures that were supplied with different nitrogen sources (along with enriched air), the culture in nitrate containing medium reached a biomass concentration that was  $\sim$ 80 and  $\sim$ 200% higher than the concentrations obtained in the cultures supplemented with ammonia and urea, respectively. Several studies have shown the capability of *Nannochloropsis* to use different nitrogen sources present in the culture medium. The values for the production/productivity of biomass in the presence of different nitrogen sources are listed in Table 2.

Figure 2. Effect of modification of nitrogen source on *Nannochloropsis* sp. cultures. (●)Nitrate,  $(\triangle)$  Ammonia,  $(\triangle)$  Urea. The closed symbols denote results for cultures supplied with CO<sub>2</sub>-enriched air (3% v/v) [76].

Usually, *Nannochloropsis* strains are cultivated in media with nitrate as the nitrogen source [15, 29, 32, 44, 50, 51]. However, recent studies have proposed the use of residuals as the source of nutrients [52–54]. These residuals have diverse composition and in some cases may contain very high levels of ammonia, which can have negative effects on the growth of the microalga. When wastewater is used as nitrogen sources, it is important to highlight the toxicity of ammonia to the photosynthetic organisms. Tolerance to ammonia toxicity depends on the strain used as well as on the culture conditions [55, 56]. The toxicity of the ammonia is due to the fact that it decouples the electron transport chain in the chloroplast [57].

**Table 2. Biomass production/productivity using different nitrogen sources in** *Nannochloropsis* **cultures**

Sometimes, the bioprocesses of microalgal biomass production are evaluated with regard to the final biomass concentration. However, ideally the evaluation must be carried out by comparing the values of biomass productivity, because this parameter considers not only the biomass produced but also the time used in the process [29]. Usually, the biomass productivity values achieved in *Nannochloropsis* cultures range from 100 to 300 mg L<sup>-1</sup> d<sup>-1</sup> (Table 1).

It is important to highlight the fact that biomass productivity is not linear or constant; the maximum biomass productivity is attained in the middle of the exponential growth phase (Figure 3); thereafter, it diminishes with the beginning of the deceleration phase. The biomass productivity depends on the specific growth rate (which is maximum in the exponential phase) that decreases when nutrients (carbon, nitrogen, phosphorus, etc.) and light become limiting [29, 58, 59].

Figure 3. Effect of nitrogen source modification on the biomass productivity in *Nannochloropsis* sp. cultures. ( $\bullet$ )Nitrate, ( $\blacktriangle$ ) Ammonia, ( $\blacklozenge$ ) Urea. The closed symbols denote results for cultures supplied with  $CO_2$ -enriched air (3% v/v) [76].

## **2.3. Effect of Nitrogen-Source Modification and CO<sup>2</sup> Addition on the Content and Profile of Lipids**

Several studies have demonstrated that the specific content of lipids (accumulation) is directly related to the growth rate [29] and that the nitrogen source can modify the biomass composition, because the incorporation rate of nitrogen is different for each source [60]. Under standard culture conditions, *Nannochloropsis* has specific lipid content close to 25%; but some stress conditions can cause an increasing in the amount of lipids and the specific content can reach around 55% of the dry biomass (Figure 4 and Table 3). Irrespective of the nitrogen source used, the content of lipids does not change significantly. Only under nitrogen starvation conditions, a significant effect in the percentage of lipids was observed (Figure 4). The starvation phase can be eliminated by the providing stress conditions and the percentage of lipids can be increased. The specific contents of lipid achieved by employing different induction methods in previous studies are shown in Table 3.

Figure 4. Effect of nitrogen source modification on the specific content of lipids in *Nannochloropsis* sp. cultures. Closed bars indicate the results for cultures bubbled with  $CO_2$ -enriched air (3% v/v) [76].

## **Table 3. Effect of stress conditions on the specific lipid content in**  *Nannochloropsis* **cultures**

Different stress conditions, such as increase in the salt concentration of the medium, temperature, and quality of the light supplied, favor an increase in the lipid content (Table 3). However, such conditions are not useful in the development of a large-scale process because the lipid productivity values reached are very low [15, 29, 61]. Several researchers have reported lipid productivities ranging from 4 to 450 mg lipids  $L^{-1}$  d<sup>-1</sup> depending on the strain employed [15, 20, 29, 61–64]. Nevertheless, the processes with highest lipid content had lower lipid productivity because under stress conditions, the cellular division and the production of new biomass is very low [15, 29]. This is the result of an inverse relationship between lipid accumulation and growth rate [29]. Because of this, recently, some researchers

have proposed intensive lipid production in two stages: the first stage involves the production of biomass under optimal conditions (even in a continuous culture) and in the second stage, the accumulation of lipids is induced by imposing a stress for a short duration. This strategy favors an acceptable biomass and lipid productivities in the process [29, 65–69].

### *2.3.1. Fatty Acid Profile*

Usually, fresh water microalgae (mostly green) have a lipid profile that is rich in saturated and monounsaturated fatty acids but the marine microalgae, such as *Nannochloropsis* species, typically have high amounts of polyunsaturated fatty acids [3, 70]. The lipid profile can be modified by changing the operation conditions of the process. However, in *Nannochoropsis*, modification of the conditions is not much important and the amount of unsaturated fatty acids remains almost constant. The typical fatty acid profiles of different *Nannochloropsis* strains as reported in some studies are shown in Table 4. It is important to highlight the fact that the fraction of saturated fatty acids in all the strains ranges from 19 to 39% whereas the proportion of unsaturated fatty acids is close to 55%.

**Table 4. Fatty acid profile reported in different** *Nannochloropsis* **strains**

Owing to the presence of high amounts of neutral lipids, recently *Nannochloropsis* strains were proposed to be potential sources of fatty acids for the production of biodiesel [71]. Biodiesel can provide sustainable energy supply, which is needed urgently. It is possible to obtain biofuels, such as hydrogen, bioethanol, and biodiesel from microalgae [72, 73]. In particular, biodiesel can be obtained through esterification of the triacylglycerols present in the biomass [6, 7]. The production of biodiesel from *Nannochloropsis* is not easy because the

fatty acid profile of the strains is not appropriate for its production. *Nannochloropsis* contains large amounts of polyunsaturated fatty acids, mainly EPA, which can reach 20–25% of the total lipid content under some conditions. The biodiesel produced from oil containing high amounts of polyunsaturated fatty acids does not fulfill the quality parameters required by the international organizations [70].

For the production of biodiesel from oil, it is necessary to perform transesterification of fatty acids, irrespective of the source of oil (wasted oil, vegetal oil, or lipids obtained from microalgae). The fatty acids methyl esters (FAMEs), typically methyl, ethyl, and propyl esters, formally constitute the biodiesel, the quality of which can be modified by changing the characteristics of the oil used for its production [6]. Some of its characteristics can be altered by changing the proportion of the polyunsaturated fatty acids; the most important characteristic is the oxidation stability because the double bonds are reactive sites susceptible to be attacked by free radicals. The higher is the number of unsaturated bonds, the easier it is to degrade the biodiesel [70]. The standard EN 14214 of the European Committee for Standardization refers to the maximum proportion of unsaturated fatty acids (measured as linolenic acid methyl ester, 18:3) being lower than 7.5%. All the reports included in Table 4 show that the amount of unsaturated fatty acids in *Nannochloropsis* is higher than 18%, because of which the biodiesel produced from the lipids of *Nannochloropsis* does not reach the European normativity.

It is important to highlight the fact that the lipids of *Nannochloropsis* can be used for biodiesel production if a hydrogenation process is included before the transesterification reaction [72]. Although the lipids of *Nannochloropsis* are not ideal for biodiesel production, this microalgae has continuously been proposed as an option because it grows in salty and marine water and could be an endless source compared to the microalgae that flourish in fresh water [6, 7, 72]. The oil obtained from *Nannochloropsis* can also be used as a source of EPA in animal feedstock as well as for human nutrition [74]. The potential of *Nannochloropsis* as a source of fatty acids is very important but the production of biomass must be performed in a biorefinery with the objective of obtaining the highest benefits (in terms of the production of carbohydrates and pigments, polysaccharides, etc.) from the biomass, favoring economic feasibility of the entire process [75].

## **CONCLUSION**

*Nannochloropsis* is a genus of microalgae, capable of growing in marine water, and has high amounts of lipids when cultured under standard conditions. For the mass culture of these organisms, a sufficient amount of  $CO<sub>2</sub>$  is necessary because the entry of inorganic carbon inside the cells is not efficient. For large culture volumes, the most useful strategy for  $CO<sub>2</sub>$ supply is to link pH to the operation of the  $CO<sub>2</sub>$ -valve. The pH must be from 7 to 8.5 to ensure an optimal condition and a sufficient quantity of carbon in the medium.

This genus can achieve specific lipid content, higher than 50% of the dry biomass, under stress conditions imposed on the culture. However, under such conditions, the productivity (biomass or lipids) of the process is very low. For the development of a large scale process, it must be performed in two stages. The first stage should be for biomass production under optimal conditions and sufficient supply of nutrients (even in continuous cultures), which

should be followed by the induction stage, employing a stress condition, over a short period of time, that could cause an increase in the lipid content. According to some recent reports, this stress condition could be an increase in salinity achieved by the evaporation of the water if open systems are employed for the cultivation of *Nannochloropsis*.

The oil obtained from the biomass of *Nannochloropsis* can preferably be used in animal feedstock because it contains almost 25% EPA. However, when the objective is the production of biodiesel, the lipids must be hydrogenated before their transesterification for attaining the international standard and for increasing the oxidation stability, consequently prolonging the useful life of the biodiesel.

**ABSTRACT**

Microalgae are an important source of beta glucans (βG). Its content varies from 0.96 to 411.9 pg·cell-1. It has been proposed to microalgae, for example *Nannochloropsis*, as potential candidates for the production of these compounds at industrial levels for the following: the molecular structure of their βG are similar to so called biological response modifiers, industrial scale microalgae biomass can be obtained through photobioreactors and it can modify the composition of microalgae via increasing carbohydrates fraction. Therefore, in the present work the βG content was evaluated in three strains of *Nannochloropsis* (Ochrophyta, Eustigmatales) and a commercial

 $\overline{a}$

microalgae concentrate of *N. oculata* (Nanno 3600®, Reed Mariculture Inc). Cultures of the three strains (Keys: NN-X-1, CIB76 and NpUNAM) were performed in batch systems (n=9) and cell division rates  $(\mu)$  were registered to identify the stationary phase (Σμ) of growth curves (NN-X-1: 14d, CIB76: 18d & NpUNAM: 22d) which was the reference for obtaining lyophilized biomass that was used to determine the concentration of βG through the enzymatic method (Megazyme®; K-YBGL 12/16). *Nannochloropsis*  strains had 23-31% dry weight as carbohydrates, of which 14-21% were βG. The individual content of  $\beta G$  is ~1 pg·cell-1, with a maximum volumetric productivity of 81.55 mg·l-1. However, although the presence of βG in *Nannochloropsis* cells has been demonstrated, molecular characterization is not yet available. Thus, common methods for characterization of βG from diatom and non-diatoms microalgae that can be applied for this purpose are described. In conclusion, *Nannochloropsis* (particularly NpUNAM) has great potential for the industrialized production of βG and because of its probable molecular characteristics, it can be estimated that there are potential applications as an immunostimulant. Future research is necessary to characterize βG isolated to *Nannochloropsis*, optimize its production and assess its capacity as an immunostimulant.

**Keywords:** microalgae, carbohydrates, beta glucans, immunostimulants

## **1.INTRODUCTION**

Microalgae are highly diverse photosynthetic microorganisms that play an important role as primary producers in aquatic food chains. These organisms convert inorganic substances into organic matter rich in lipids, proteins, carbohydrates and other molecules, so they are potential sources of natural components with biotechnological and therapeutic applications  $[1-3]$ .

An important group of microalgae are the *Nannochloropsis* spp. (*Nannochloropsis*) species. This genus belongs to the Eukaryota empire, Chromista kingdom, Ochrophyta division, Eustigmatophyceae class, Eustigamatales order and family Monodopsidaceae. At present, there are 12 nominal species, of which only 5 are recognized as valid species: *Nannochloropsis australis*, *Nannochloropsis granulata*, *Nannochloropsis limnetica*, *Nannochloropsis oceanica* and *Nannochloropsis oculata*. These non-motile unicellular microalgae are components of marine and freshwater picoplankton. Its cells are spherical, slightly oval (2-4  $\mu$ m in diameter) or ciliary (3-4 x 1.5  $\mu$ m), with chloroplast of green-yellow color [4]. Chlorophyll a is the only chlorophyll present in this genus, and its main accessory pigment is violaxanthin [5].

Two important characteristics in *Nannochloropsis*, its growth in wide salinity ranges [6] and its high nutritional value due to its high content of proteins and polyunsaturated fatty acids, especially eicosapentaenoic acid [7, 8]. It is for these qualities that *Nannochloropsis* are widely used by industry [3, 9]. For example, in aquaculture they have been widely used as food for molluscs, zooplankton and for early stages life of crustaceans and fish [10].

However, although the nutritional utilization of carbohydrates from biomass *Nannochoropsis* (and is generally applied to microalgae) have not been as essential, they have been considered as the preferred substrate for significant biofuel production (such as bioethanol, biobutanol, Biohydrogen, etc.) through biotechnological conversion technologies [11]. But the greatest potential of microalgal carbohydrates lies in their application as

immunostimulants [9, 12], since they are mostly presented as β-1,3 glucans that can be found both in the cell wall [13] and in cytoplasmic vacuoles [14]. Similar beta glucans (βG) are considered to act as reserves in several classes of microalgae. For example, species of eustigmatophyte class belong to *Nannochloropsis* [13].

The ΒG are polysaccharides constituted per heterogeneous groups of glucose polymers that have different molecular weights and branching degrees [15]. The name of βG comes from its structure. The suffix "*an*" describes a molecular structure consisting of a single carbohydrate (Glucose), while the prefix "*Gluc*" means polyglucose. Thus, a polyglucose (polyglucopyranose) is called a "glucan." Moreover, β-1,3 glucans, is the most common term for homopolysaccharides link β-1,3 in backbone, but may also possess β-D-glucosidic bonds in position 6 and 4 [15, 16]. These polysaccharides can also be found in a variety of plants, fungi, yeasts and algae [17].

Otherwise, the immunostimulation capacity is due to the fact that molecular structures of βG are characteristic of microbial communities and are therefore called "Pathogen-associated molecular patterns," PAMPs [15, 18]. PAMPs play a role as alarm molecules that activate the immune system, because they are identified through specific pattern recognition receptors (PRRs), such as Dectin-1, TLR2, C3 and Scavengers, present in macrophages, neutrophils and natural killer cells [19]. ΒG can activate the inflammatory response through binding to their receptors, which activate signaling pathways that culminate in the transduction of intracellular signals and transcription factors [20]. This effect is decisive in the transcription of genes, synthesis and release of preinflammatory cytokines, as well as for activation of different immunological responses associated with the presence of pathogens [15].

### **1.1. Carbohydrate Metabolism in Microalgae**

In microalgae, carbohydrates act as structural components of cell walls and as storage components within cells. Carbohydrates, as storage compounds, provide the energy required for metabolic processes and allow, if required, temporary survival in adverse conditions [21].

Microalgae transform solar energy into chemical energy through photosynthesis [22]. There are two main types of photosynthetic reactions, light and dark. In clear reactions, solar energy is absorbed through pigments of photosynthetic antennas and is used to divide water into protons, electrons and oxygen [11]. Electrons and protons are used to generate energy carriers (NADPH and ATP), which support the metabolic needs of the cell. In dark reactions, carbon dioxide is reduced to carbohydrates via Calvin Cycle inside the chloroplast, using energy derived from NADPH and ATP [23]. In Calvin Cycle, the first step is assimilation of carbon dioxide, which is catalyzed per ribulose-1,5-bisphosphate carboxylase oxygenase (Rubisco). Carbon dioxide is used for carboxylation of five-carbon compounds (ribulose-1,5 bisphosphate) in two three-carbon compounds (3-phosphoglycerate), one of which is used as a substrate for formation of carbohydrates, while the other is used to achieve the next Calvin Cycle [11].

The carbohydrate profiles of microalgae can vary greatly, but their main monosaccharides are glucose, galactose, mannose and ribose, with others in varying proportions [24]. Although, *Nannochloropsis* profile monosaccharide are predominant glucose and mannose, in addition to galactose, ramosa, ribose and fucosa in smaller proportions [25]. Brown et al., [7] reported that *N. oculata* polysaccharides represented

approximately 88% of total carbohydrate, of which 68.2% is glucose and about 4 to 8% is ramosa, mannose, ribose, xylose, fucose and galactose. Recently, Jia et al., [26] demonstrated the presence of eight monosaccharides in *N. oceanica*: glucose, galactose, mannitol, fucose, rhamnose, mannose, ribose and glucosamine, although the first three are more abundant.

As the polymerization process of any biopolymer polysaccharide generation involves three stages; initiation, elongation and termination of the chain. The principal microalgae polysaccharides are β-1,3-glucans, while the most studied are Chrysolaminarin (branched, β-1,3/1,6 glucans) and Paramylon (linear, β-1,3 glucans) [27]. In marine diatoms (*Skeletonema costatum*), carbohydrates produced through the Calvin Cycle are rapidly converted to glucose-1-phosphate and polymerized into glucan per UDP-glucose pyrophosphorylase and glycosyltransferase [28]. It should be mentioned that *Nannochloropsis* species do not synthesize starch [5]. Moreover, the activity of exo-1,3-β-glucanase (exo-Glu) was detected in several diatoms and upregulation of this activity coincided with βG degradation in *S. costatum* [29]. It has been proposed that exo-Glu and endo-1,3-β-glucanase (endo-Glu), and β-glucosidase (BGL) are the main enzymes involved in βG degradation, as shown in figure 1; in *Eustigamotos* cf. *Polyphem,* single-cell soil [30].

Figure 1. Chrysolaminarin biosynthesis and degradation pathway reconstructed based on the *de novo* assembly and annotation of *E.* cf. *polyphem* transcriptome. Identified enzymes are shown in boxes and include: UGPase, UDP glucose pyrophosphorylase; UDPG, chrysolaminarin synthase; exo-Glu, exo-1,3-b-glucanase; endo Glu, endo-1,3-bglucanase and BGL, b-glucosidases. G-1-P, glucose-1-phosphate; PPi, pyrophosphate (taken from Wan et al., 2012). http://journals.plos.org/ plosone/article?id=10.1371/journal.pone.0035142.

### **1.2. Factors and Strategies to Improve βG Production from** *Nannochloropsis*

Culture medium and environmental conditions significantly affect microalgal biomass composition [31]. Therefore, control of some cultivation or environmental conditions seems to be a feasible route for the manipulation of microalgal biomass composition, in order to increase or maximize carbohydrates accumulation [32]. The most frequently reported factors influencing carbohydrate content in microalgal biomass are starvation and/or limitation of nutrients, saline stress, light intensity, temperature and metabolic types [11]. The effects of these factors and reported strategies are described below:

### *Metabolis Type*

There are three main strategies for cultivating microalgae; photoautotrophic, heterotrophic and mixotrophic cultures [33]. Generally, microalgae are cultured through fixation of dissolved inorganic carbon and absorption of light energy; this is a fotoautotrófico culture. In heterotrophic culture, microalgae use organic components as sources of carbon and energy for their growth, without need for light energy. Only some species have this type of metabolism [34]. Moreover, mixotrophic cultures rely on microalgal growth using simultaneously inorganic and organic carbon sources in the presence of light [35]). That is, photoautotrophic and heterotrophic metabolism occur simultaneously.

Perez-Garcia & Bashan [36] indicate that supplementing organic carbon sources to microalgae heterotrophic culture causes an increase in biomass production and lipid/carbohydrate content in cells. Generally, energy storage molecules, such as lipids and carbohydrates accumulate under heterotrophic and mixotrophic conditions. Therefore, the biomass content of these compounds is greater than under photoautotrophic conditions [37]. However, studies on the effect of mixotrophic or heterotrophic cultures on the reserve carbohydrate content in microalgae, particularly βG, are scarce.

Studies with *Nannochloropsis* have demonstrated that it is able to maintain a mixotrophic metabolism in the presence of organic carbon sources such as glucose, glycerol and lactic acid [38–40]. Some of these organic carbon sources are industrial byproducts of biofuel production [41] and fish silage [42]. In mixotrophic cultures with glycerol as a source of organic carbon, *Nannochloropsis* reaches a higher biomass density and lipid production than in photoautotrophic cultures [43].

### *Temperature*

The effect of temperature on microalgae chemical composition is contradictory. Renaud et al*.*, [44] did not observe significant differences in the biochemical composition of tropical microalgae under stress due to temperature variations. However, other research indicates that the effect of temperature is potentially capable of changing the microalgae biochemical composition. For example, in cultures of *Spirulina* sp, an increase in temperature from 25 to 40°C resulted in a carbohydrate increase of 14 to 21% [45]. It is considered that this response is generated per decrease in protein content, while synthesis of carbohydrates is shown to be stimulated [46]. In diatom *Chaetoceros* cf. *wighamii*, carbohydrates were higher when exposed to lower temperatures [47]. Therefore, the effect of temperature on microalgae carbohydrates accumulation seems to be highly dependent on the strains of microalgae used [48]. However, to date there are no studies of this type in *Nannochloropsis*.

#### *Osmotic Stress*

Tolerance to salinity variations differs between microalgae. According to this, microalgae can be grouped into; halophiles (require specific salinity for optimal growth) and halotolerant (with response mechanisms to survive in a highly saline environment) [49]. Variations in salinity influence growth and proximal composition of marine microalgae. These respond to osmotic stress accumulating carbohydrates of low molecular weight, which act as osmolytes, therefore an increase in carbohydrate content is a mechanism of protection against damage caused by osmotic stress [50, 51].

Thus, salinity decline is proposed as a unique way to change the biochemical composition of marine microalgae [52], but the role of salinity in carbohydrate metabolism is variable and dependent on the specific nature of the species and of the cultivation conditions.

Yao et al. [52], reported that *Tetraselmis subcordiformis* in nitrogen limitation and a decrease in salinity (20% normal salinity) strengthened biomass and carbohydrate accumulation, regardless of irradiance. The highest carbohydrate content was 58.2% dry weight. Authors argue that reduced salinity combined with nitrogen limitation generate moderate stress that causes an accumulation of carbohydrates. Therefore they propose that the manipulation of salinity can be applied effectively for an improved production of carbohydrates in marine microalgae, for example *Nannochloropsis*.

### *Lighting Type and Intensity*

High light intensity increases polysaccharides production in microalgae cells [53]. In diatoms, βG are synthesized during day and degraded overnight [29, 54]. Moreover, Tredici et al*.*, [55] demonstrated that carbohydrate content in *Spiulina platensis* grown in interperie, was significantly higher on sunny days than on cloudy days. Friedman et al., [56] reported a 0.6 to 3-fold increase in polysaccharides obtained from *Porphyridium* sp. and *Porphyridium aerugineum* cultures, when light intensity increased from 75 to 300 μmol m<sup>-2</sup> s<sup>-1</sup>. Similar results were obtained with *Odontella aurita*, where light intensity of 300  $\mu$ mol m<sup>-2</sup> s<sup>-1</sup> produced close to a 2-fold content of Chrysolaminarin compared to 100  $\mu$ mol m<sup>-2</sup> s<sup>-1</sup> [57].

Conversely, a dominant wavelength of light spectrum (blue and red) decreased the content of carbohydrate in *Isochrysis* and *Chaetoceros* [58, 59]. However, *Nannochloropsis* exposure to a monochromatic blue light source resulted in higher biomass productivity than exposure to green or red light, as well as white [43]. We need to know the effect of monochromatic light on βG production in *Nannochloropsis.*

### *Nutrient Limitation*

The nutrient limiting strategy [32] is considered a feasible approach for microalgae production rich in carbohydrate. This technique is practically accessible because it is relatively easy to control the nutrients in the culture medium. According to Markou et al. [11], most studies discuss nutrient limitation as an effective strategy to modify the composition of microalgae, but omit nutrients of interest from the start of microalgal cultures. So, the results of nutrients' omission are decreased growth rates and low biomass production. Therefore, optimization of nutrient concentration is very important [60]. Limited nutrient optimization has a dual scope: support adequate biomass production and act as limiting factor to control biomass composition [11].

Although several nutrients are in the culture medium, the most studied for their effect as limiting are nitrogen and phosphorus. In diatoms, nitrogen depletion results in a significant increase in Chrysolaminarin accumulation, reaching  $\sim 80\%$  of the total organic carbon of cells [54]. Conversely, when nitrogen is abundant, the Chrysolaminarin is degraded to support protein synthesis [61].

Furthermore, Jia et al., [26] reported total carbohydrate in *N. oceanica* increased from 5.8 to 17.9% of dry biomass during the first 4 days after abrupt nitrogen depletion, and then increased to 19.1% on day 14. In this same work, it was evidenced that 1,3-β-glucans content, increased from 1.63 to 7.87% on day 8, after stress through nitrogen depletion, to finally decay to 6.28% on day 14. The authors concluded that in abundant nitrogen conditions, βG may be the main carbon storage in these cells, which serves as temporary storage of the same and probably competes for carbon sources with triacylglycerol. Conversely, in depleted nitrogen conditions, positive regulation of β-1,3-glucan metabolic pathways together with pyruvate dehydrogenase-mediated acetyl-CoA synthesis and membrane lipid turnover/ degradation contributed to increased triacylglycerol synthesis.

Similarly, the effect of phosphorus starvation on microalgae biomass composition results in simultaneous accumulation of carbohydrates and lipids, in addition to a decrease in protein synthesis [62, 63]. Carbohydrates are significantly promoted in the starvation of phosphorus and their accumulation is more than lipids [64]. However, in some studies, phosphorus starvation was observed to cause only lipid accumulation. For example, in *Nannochloropsis* F&M-M24 cultures, lipids were increased to 50% [65] and *Scenedesmus* LX1 cultures up to 53% [66].

### *Supply Inorganic Carbon*

Inorganic carbon is added to a microalgae culture either in the form of bicarbonate (NaHCO<sub>3</sub>) or carbon dioxide gas (CO<sub>2</sub>). It has been observed that the addition of these compounds promotes both, production of biomass as well as that of lipids and carbohydrates, in addition to improving nitrogen assimilation [67, 68].

Hsueh et al., [69] observed in *N. oculata* an accumulation of total carbohydrates of 29% of dry biomass per supplying  $5\%$  CO<sub>2</sub> in aeration, while using  $8\%$  CO<sub>2</sub>,  $37\%$  of total carbohydrates. This suggests that carbohydrate content, as well as the lipid content, is proportional to  $CO<sub>2</sub>$  supply.

### *Production of βG in Two-Stage Process*

Some authors suggest that the best option to obtain high-carbohydrate microalgae biomass is the two-stage process; the first stage of the process results in biomass production under optimum conditions of cultivation and in the second stage, microalgae harvests are exposed to stress conditions in order to alter biochemical composition [11]. Therefore, photobioreactors should be efficient systems for this strategy, since biomass can be obtained massively [70] and are suitable for factors control [71, 72] that may be stressful for *Nannochloropsis* as described above, thus causing the production of biomass rich in βG.

## **1.3. Molecular Structure and Capacity as Immunostimulants of βG**

βG have different molecular structures that generally depend on their origin, for example; βG of oats and barley have linear structures with short stretches of β-1,3 and β-1,4 bonds [73], whereas structures of yeasts (*Saccharomyces cerevisiae*) and basidiomycetes (*Schizophyllum commune*), which apparently correspond to the most active form of βG [18, 74, 75], are composed of β-1,3 glucan bonds with β-1,6 branching, which in yeasts are long and short in fungi (β-1,3/1,6 glucans) [76]. Moreover, bacterian βG present a varied group of structures such as β-1,3 glucans, cyclic β-1,3 glucans, β-1,3/1,6 cyclic glucans and β-1,3/1,2 glucans [77].

The βG microalgal reported structures are β-1,3 glucans, β-1,3/1,6 glucans and β-1,6/1,3, see Table 1. β-1,3/1,6 glucans of marine diatoms are known as Chryolaminarin [78–80] and β-1,3 glucans of freshwater *Euglena gracilis* are named Paramylon [81]. It is recognized as important, knowledge about the quantification and characterization of βG in microalgae species. For example: *Chaetoceros debilis* βG present molecular structure β-1,3/1,6 glucans with molecular weight of 4.9 kDa and 30 polymerization degree [80]. *Chaetoceros mulleri*, the molecule has been found and characterized  $\beta$ -1,3/1,6 glucan configuration structure with 19 polymerization degree and 0.005 branching [78]. Moreover,  $β-1,3/1,6$  glucans with molecular weight of 7.75 kDa were reported from *Odontella aurita* [57]. Additionally, also reported was the isolation and characterization of βG from *Isochrysis galvana* with inverse bonds to diatoms molecular structure; β-1,6 /1,3 [82].

However, molecular characterization has not yet been performed for βG from Eustigmatophyta lineage, and no studies are known regarding storage location of its reserve carbohydrates, even though this group includes important microalgae for industrial applications such as *Nannochloropsis* [84].

A variety of βG have the ability to stimulate the immune system. Therefore, pharmacologically they are classified as biological response modifiers [85]. Also, βG are considered nutraceutical compounds, because their consumption has been related to the prevention and/or treatment of diseases [86]; or as additives for management of aquatic animal health [87].

Figure 2. Molecular configuration of β-1,3/1,6 glucans (modified from [83]). https://www.ncbi.nlm.nih. gov/pmc/articles/PMC2704234/.
The immunostimulating effect of βG is dependent on several factors related to molecular structure [88]. The most effective molecular weight of clinically useful βG ranges from 100 to 200 kDa, with branching degree between 0.2 and 0.5 [85]. Moreover, in aquaculture, βG with reported immunostimulatory effects are mainly yeast, fungal or microalgae isolates, and have lower molecular weights ranging from 5 kDa of seaweed *Laminaria digitata* [89, 90] to 200 kDa of yeast *Saccharomyces cerevisiae* [91]. The molecular weight interval of principal βG microalgal, Chrysolaminarin, is 4-40 kDa, Table 1.

Microalgae	<b>Structure</b>	MW (kDa)	<b>PD</b>	<b>BD</b>	Reference
Diatom					
Chaetoceros debilis	$\beta - 1, 3/1, 6$	4.9	30	$\overline{\phantom{a}}$	[80]

Therefore, due to important infectious disease scenarios in aquaculture [98], an alternative called immunostimulation has made an application of compounds to increase or activate immune system of organisms in cultures. Such a strategy has the purpose of boosting the immune system and increasing resistance of the host against infectious diseases [74, 75, 99, 100]. The central axis of these strategies are immunostimulating agents, defined as those natural compounds that modulate the immune system through increasing the resistance of the host to diseases that in a majority of circumstances are caused by pathogens [75]. The result is a change in the number and/or function of cells involved in immune responses. The most proven effect of immunostimulants is to increase functions of phagocytic cells and increase their bactericidal and fungicidal activities [101].

The most promising immunostimulants are  $\beta$ -1,3/1,6 glucans, as they have been extensively studied in different vertebrate and invertebrate species [18]. They have a welldefined chemical structure and their mode of action generates beneficial effects to organisms [15, 102, 103]. Aditionally, their degree of safety has been recognized as generally safe (GRAS) by the US Food and Drug Administration [86].

β-1,3/1,6 glucans, are commonly known as Zymosan when isolated from *S. cerevisiae* and are composed of βG and mannose, and to a lesser extent lipids and proteins [104]. These yeast βG can be found commercially as MacroGard® [105]. But the warning that exists about the problems generated through the impurities of Zymosan should be considered when attempting to describe the molecular mechanisms of immunological responses. When Zymosan is given in animals, it induces a wide range of responses [18, 102, 103], and it is very difficult to identify which component or structure of this compound is inducing what effect [88]. There are other βG from different sources that present the same structure as Lentinan, Schizophyllan and Chrysolaminaran, and may not present the same problem.

Nevertheless, due to its structure, it has been noted that Zymosan can simultaneously induce two of the major types of PRRs during induction to inflammatory response; C-type lectin receptors (Dectin-1) and Toll-like receptors (TLR2) [106]. It also demonstrated preferential binding of β-1,3/1,6 glucans of fungal origin to same receptors [107] generating responses to mediators of inflammation [108]. Based on the above, it would be possible to obtain similar immunological responses with β-1,3/1,6 microalgal glucans.

Activation of Dectin-1 per its binding to βG increases activation of NF-κB, through synergistic effect of TLR2, and these receptors act together increasing production of cytokines such as IL-12 and TNF- $\alpha$  [108]. Dectin-1 has been reported to be expressed at higher levels in macrophages and neutrophils, but to a lesser extent in dendritic cells and in subpopulation of T cells [109]. Also, it was shown that Dectin-1 in conjunction with Zymosan, triggers production of reactive oxygen species (ROS). For their cooperation with TLRs, βG can promote responses associated with Th1 immunity (cell-mediated immunity: macrophage activation and B-cells to produce opsonizing antibodies) including production of IL-12 [106]. Such responses are critical for defense against many pathogens [75].

Although investigations on the immunostimulatory effect of microalgal βG are scarce, they are considered as potential immunostimulatory agents. For example,  $\beta$ -1,3/1,6 glucan from *C. mulleri* was evaluated as an immunostimulant of atlantic cod larvae (*Gadus morhua*), obtaining an increase in survival and growth of larvae fed with rotifers enriched with these microalgal βG during first feeding, in comparison to larvae fed with rotifers with and without Zymosan. According to the authors, results are due to the low molecular weight and high branching degree of microalgal βG that generate better immune response [12]. Furthermore, in experiments, the biological activity of  $\beta$ -1,6/1,3 from *I. galvana* directly inhibits proliferation of human lymphoma cells of leukemic U937 monocytes, and therefore is predicted to have high potential anti-tumor activity [82]. Moreover, Russo et al., [110] in vitro results indicate that linear βG from *E. gracilis*, obtained per sonication and alkaline treatment can act as safe and effective coadjutant of innate immune system response, regulating proinflammatory factors (NO, TNF- $α$ , IL-6 and COX-2) in lymphomonocytes.

Sletmoen & Stokke [88] suggest that primary structure, solution conformation and/or polymer degree may play a determining role in the ability of  $βG$  to bind receptor(s) and modulate immunological functions. To date, most reports related to βG effect on fish have proposed these polysaccharides as potent, valuable and promising immunostimulants, however their effects on growth and modulation of the immune system are dependent on the structure, dose, mode, duration or time of administration, ambient temperature, and species under study [18, 111].

### **1.4. Characterization of Microalgal βG**

The first step to achieve the characterization of microalgae βG is proper extraction of a total carbohydrate extract. This first step is relevant so that the choice of the most appropriate extraction method depends on the source and molecular structure of βG expected to be produced [112]. This is because the nature of the extraction procedure has a significant effect on structure and molecular weight of generated  $\beta G$  [113]. For example, differences in

molecular weight estimates of βG may come not only from its source such as *Nannochloropsis*, but also from influence of methods used for extraction and purification. Commonly, the phenomena of aggregation and depolymerization occur during the extraction stage [16]. Therefore, to determine the structural characteristics of molecular βG isolates, extraction procedures need to ensure the integrity of parent molecules, and optimize yield and purity of βG [114]. Currently, sulfuric acid extraction for diatoms and hot water-ethanol for non-diatoms are the most used method to extract microalgal carbohydrates (Table 2). Other methods reported for different sources are alkaline extraction [115], ultrasound assisted extraction [116], microwave assisted extraction [117], enzymes as a trigger for extraction [118] and acid extraction [119]. However, there are some drawbacks with the extraction methods which have to do with demand for long periods of time per process, high costs and little environmental sustainability [112]. Some of the new extraction methods, such as accelerated extraction of solvents [116] and superheated water extraction [120], are useful to mediate with current problems of extraction, along with higher yields.

Hence, post-extraction and before performing rigorous structural analyzes of  $\beta G$ , it is necessary to estimate its purity. That is, to know the proportion of polysaccharide components and presence of impurities. Total and/or reductive carbohydrate assays, as well as assays for other compounds are commonly used to solve this task. The term "total carbohydrates" covers all mono-, oligo- and polysaccharides as compared to non-carbohydrates (proteins, lipids, aromatic compounds, mineral compounds, etc.) which may be present in carbohydrate extracts. In a pure polysaccharide, concentration of reducing sugars (those having a free carbonyl group at reducing ends) represent amount of terminal reducing groups, depending on polymerization and branching degrees. The next analytical task is estimation of bonds and structures, which are typical for non-target polysaccharides, including some glucans [17].

Subsequently, more rigorous structural analyses of purified polysaccharides are required to clarify their structure. For this purpose, a set of spectroscopic, chemical and separation methods is used. Among them, nuclear magnetic resonance (NMR) spectroscopy is recognized as a powerful tool for the structural analysis of glucans in both solution and solid state. Together with chemilolytic methods (methylation analysis, periodate oxidation, partial chemical or enzymatic hydrolysis, etc.), correlation NMR experiments are able to determine the exact structure of polysaccharides tested. Moreover, spectroscopic methods of infrared vibration are sensitive to the anomeric structure of glucans and can be used for purity control. Molecular weight distribution, homogeneity and branching of glucans can be estimated through size exclusion chromatography, laser light scattering and viscometry [17]. Table 2 shows experiments and NMR analysis reported for the characterization of βG of microalgae.

Finally, βG from *Nannocloropsis*, which is an important species for industry and widely used in aquaculture, has not been quantified or characterized. Therefore it is considered of great importance to evaluate the effect of βG from *Nannocloropsis* on immune response modulation of vertebrates and invertebrates. Hence, this chapter's aim is to quantify the concentration of βG in biomass harvests of three *Nannochloropsis* strains, and describe the qualities and possibilities that project to species of this genus as potential for the production of βG.

# **Table 2. Methods used for extraction, purification and characterization of βG microalgae**

\* Molecular weight cut-off (MWCO).

# **2. MATERIALS AND METHODS**

#### **2.1. Microalgae Strain and Cultures**

The present study was carried out in Laboratory Microalgae of Center Research in Food and Development, A.C. Unit Mazatlan. Three *Nannochloropsis* strains were used and are conserved with the keys: NN-X-1, CIB76 and NpUNAM. NN-X-1 strain was obtained from the microalgae collection of Center Scientific Research and Higher Education (CICESE), Ensenada, Baja California Norte, Mexico. CIB76 is characterized as *Nannochloropsis oculata* and belongs to the microalgae collection of Center Biological Research of the Northwest (CIBNOR), Baja California Sur, Mexico. NpUNAM belongs to the microalgae collection of Marine Biotoxins Laboratory, Institute Marine Science and Limnology (ICMyL-UNAM), Mazatlán, Sinaloa, Mexico.

Batch cultures were done in triplicate  $(n = 9)$  in 16 liter polycarbonate bottles. The culture medium f/2 [122], prepared with sea water (34 ups), filtered (1  $\mu$ ) and chlorinated was used. Culture conditions were:  $19.2 \pm 1.8$  °C,  $8.6 \pm 0.5$  pH and continuous flourescent lighting and aeration [123]. Cell concentration was determined daily with hematocytometer (0.1 mm depth, with improved Neubauer reglilla, Brighline Optik Labor) and composite microscope (Leica model CME) according to Guillard & Sieracki [124]. The cell density was plotted and the logistic model was applied using theCurveExpert Basic 1.4 software (Pindyck & Rubinfeld, 1981) [125]. The cell division rate  $(\mu)$  of each strain was calculated according to Nieves et al., [126]. The cultures were sampled in stationary phase of growth curve determined per maximum value of  $\Sigma \mu$ ; Considering this cultures phase as a condition of nutrient depletion, mainly nitrogen and phosphorus, and consequently carbohydrates accumulation in cells.

$$
\mu = \frac{\ln(C_{t+1}/C_t)}{\ln 2} \tag{1}
$$

Where:

 $C_{t+1}$ = Cellular concentration at time t+1  $C_1$ = Cellular concentration at time t

#### **2.2. Determination of Dry Weight and Organic and Inorganic Content**

Samples of microalgae were collected in triplicate  $(n = 27)$  in the stationary stage to determine dry weight, and organic and inorganic content of strains through the method of incineration proposed by Sorokin [127].

### **2.3. Total Carbohydrates Determination**

Total carbohydrates were determined through phenol-sulfuric colorimetric method by Dubois et al. [128], samples from stationary phase in triplicate of each replicate were analysed ( $n = 27$ ).

### **2.4. Enzymatic Quantification of Beta Glucans**

A Megazyme<sup>®</sup> enzyme kit developed for adequate measurement of  $\beta$ -1,3/1,6 glucans and  $\alpha$ -glucan in fungi and yeast products (CAT # K-YBGL, 12/16; Lot: 161124-3) was utililized. The existence of a unique method for microalgae is unknown. Triplicate samples of lyophilized biomass (pool of replicates) from stationary phase cultures were analyzed. Additionally, quantification in lyophilized biomass of commercial concentrate of non-viable *Nannochloropsis oculata* (strain CCMP 525; Nanno3600®, Lot: 16267; Reed Mariculture Inc.) was performed and as control, yeast beta glucans were quantified with 49% of purity supplied by the kit (Lot: 130905b). Total glucans were determined using controlled acid hydrolysis (H2SO4), and released glucose was determined using glucose oxidase/peroxidase reagent (GOPOD). α-glucans were measured after hydrolysis of starch/glycogen to glucose, and from glucoamylase and sucrose to glucose more fructose with invertase. Glucose was

measured with GOPOD reagent. βG were determined through the difference between total glucans and  $\alpha$ -glucans [129].

# **2.5. Volumetric Productivity of Beta Glucans**

A literature review per data  $\beta G$  cell concentration (pg·cel<sup>-1</sup>) and volumetric productivity of βG (mg·l-1 ) of various microalgae species were obtained. The same variable for *Nannochloropsis* strains were calculated using following equations:

$$
Cellular\ concentration\ \beta G = \frac{\% \beta G \cdot DW}{CD} \tag{2}
$$

$$
Volumetric Productivity \beta G = \% \beta G \cdot DW \cdot CD \cdot V \tag{3}
$$

Where,

% βG= βG percentage through enzymatic determination DW= Dry weight CD= Cellular density  $V=$  Volume

### **2.6. Statistical Analysis**

In order to compare total carbohydrates obtained in *Nannochloropsis* strains, percentages were transformed using the arcsine function of the square root [130]. Subsequently, the normality and homogeneity of variance for all variables was tested by techniques Levines and Kolmogorov-Smirnov, respectively. Since data was homoscedastic, tests of variance analysis and Tukey's multiple comparisons were performed [131]. Statistical analyses and growth functions were performed with SigamPlot v11 program.

# **3. RESULTS**

# **3.1. Growth Curve**

The highest cell density and cell division rate were registered on different culture days (d) for strains. CIB76 showed the highest cell density  $(64.5 \times 10^6 \text{ cells} \cdot \text{ml}^{-1} \text{ d15})$ , followed by NN-X-1 (63.3 x 10<sup>6</sup> cells·ml<sup>-1</sup>, d13) and NpUNAM (63.2 x 10<sup>6</sup> cells·ml<sup>-1</sup>, d22). Values of cell division rate  $(\mu)$  were 1.05, 1.0 and 0.98 for CIB76, NN-X-1 and NpUNAM, respectively. Therefore, the beginning of the stationary phase, and consequently sampling day, also were registered in different culture days: NN-X-1, d17; CIB76, d19 and NpUNAM, d25 (Figure 3).

Figure 3. Population growth of *Nannochloropsis* strains. Circles represent the mean values (± SD) of cell density  $(n = 3)$ , while the line is the approximation determined with a logistic model:  $a =$  Maximum value in the curve,  $b =$  Maximum load capacity and  $c =$  Slope of the curve. The arrow indicates when the culture reached the stationary phase.

### **3.2. Volumetric Production of Biomass and Carbohydrates Accumulation**

Biomass production in total dry weight did not show significant differences ( $P < 0.05$ ) among strains. The highest yield was  $0.40 \text{ g} \cdot l^{-1}$  obtained with NN-X-1. Cellular organic composition, in terms of individual dry weight, organic and inorganic dry weight and total carbohydrates did not present significant differences  $(P < 0.05)$  between strains. Percentage of total carbohydrates of NpUNAM 30.9  $\pm$  3.0 was higher than CIB76, 23.5  $\pm$  7.1% and NN-X-1 22.7  $\pm$  4.3%. However, there were no significant differences ( $P < 0.05$ ) (Table 3).

**Table 3. Biomass production in cultures of three strains** *Nannochloropsis***, no significant differences**  $(P < 0.05)$  (Mean  $\pm$  s.d., n = 3)

<b>Strains</b>	Total dry weight	Dry weight	Organic dry weight	Inorganic dry weight	Total carbohydrates	Total carbohydrates
	$(g \cdot l^{-1} \pm s.d.)$	$(pg\text{-}cell^{-1} \pm s.d.)$	$(% \pm s.d.)$			
$NN-X-1$	$0.40 \pm 0.04$	$6.6 \pm 1.1$	$5.7 \pm 0.8$	$0.9 + 0.4$	$1.3 \pm 0.2$	$22.7 \pm 4.3$
CIB76	$0.39 \pm 0.03$	$6.7 \pm 0.9$	$5.7 \pm 0.9$	$0.9 \pm 0.5$	$1.3 \pm 0.4$	$23.5 + 7.1$
<b>NpUNAM</b>	$0.38 \pm 0.04$	$6.0 \pm 0.3$	$5.5 \pm 0.3$	$0.5 \pm 0.2$	$1.8 \pm 0.2$	$30.9 \pm 3.0$

# **3.3. Cellular and Volumetric Productivity of Beta Glucans**

NpUNAM presented the highest percentage of total glucans,  $23.4 \pm 0.7$ , while similar percentages of NN-X-1 and CIB76 were  $15.8 \pm 0.9$  and  $16.8 \pm 0.5$ , respectively. Besides,  $\alpha$ glucans in all sources account interval 1.1-1.7%. The lowest percentages of βG were registered in Nanno3600<sup>®</sup> (6.2 ± 0.1%). With respect to the strains, NpUNAM presented βG a higher percentage (21.7  $\pm$  0.7%) than CIB 76 (15.4  $\pm$  0.5%) and NN-X-1 (14.3  $\pm$  0.9%) strains. Yeast  $\beta G$  control presented total glucan approximate values (48.8  $\pm$  1.4%), specified by the kit  $($   $\sim$  49%), Figure 4.

Figure 4. Cellular content of beta glucans in *Nannochloropsis* strains through enzymatic determination (Mean  $\pm$  s.d., n=3).

Table 4 shows the high content of βG (Chrysolaminarin) in diatom cells reported in literature, up to 411.9 pg·cell<sup>-1</sup> in *Thalassiosira weissflogii* [79]. Comparatively, *Nannochlopsis* strains presented low concentrations, 1.1, 1.0 and 0.9 pg·cell<sup>-1</sup> βG in CIB76, NpUNAM and NN-X-1, respectively. NpUNAM and NN-X-1 were significantly different (*P*  $> 0.05$ ) in concentrations of βG cellular (pg·cell<sup>-1</sup>), and other comparisons were not significant.

However, volumetric productivity also depends on harvested cell density. Therefore, the diatom with the highest productivity in batch culture is *Chaetoceros mulleri*, with 71.57 mg·l-<sup>1</sup>[79]. In contrast, *Nannochlopsis* strains showed similar volumetric productivity, NN-X-1: 57.63 mg·l<sup>-1</sup> and CIB76: 60.50 mg·l<sup>-1</sup>. However, it should be noted that NpUNAM has a volumetric productivity of  $81.55$  mg·l<sup>-1</sup>, which is higher than diatoms reported in batch cultures. Although the volumetric production registered with  $306 \text{ mg} \cdot l^{-1} \cdot d^{-1}$  was reported in the photobioreactor system with the marine diatome *Odontella aurita* [92]. Regarding volumetric productivity, NpUNAM was significantly different  $(P > 0.05)$  than other strains, and volumetric productivity of NN-X-1 and CIB76 were not different ( $P < 0.05$ ).

\*Photobioreactor production, mg $\cdot 1^{-1} \cdot d^{-1}$ .

Statistical analysis only for evaluated strains, different letters mean significant differences ( $P > 0.05$ ).

# **4. DISCUSSION**

Total carbohydrate content depends on the *Nannochloropsis* strain. NpUNAM presented the highest content of total carbohydrates from stationary phase, 30.9%. Some microalgae may naturally contain more than 50% of their weight as carbohydrates [48]. In particular cases such as non-photosynthetic mutant of *E. gracilis*, Paramylon accumulates up to 90% of dry cell weight with glucose as a carbon source, therefore total carbohydrates are a higher percentage [133]. With respect to *I. galbana*, carbohydrates account for about 13% of dry weight [82].

Regarding *Nannochloropsis*, in some cases it has been reported as one of the species with the lowest percentage of carbohydrates presented, Templeton et al. [25] reported a value less than 10%. Nevertheless, Hsueh et al*.* [69], observed in *N. oculata* an accumulation of total carbohydrates of 29% of dry biomass, per supplying  $5\%$  CO<sub>2</sub> in aeration, while using 8% of CO<sup>2</sup> obtained 37% of total carbohydrates. Moreover, Jia et al. [26] reported that total carbohydrate content in *N. oceanica* increased from 5.8% to 17.9% of its dry biomass during the first 4 days due to abrupt nitrogen depletion in culture medium and then increased to 19.1% on day 14. This indicates that total carbohydrates *Nannochloropsis* biomass can vary from 10% to 40% of its dry weight, depending on growing conditions and time of harvest, but it can still be up to 60% when NN-X-1 grown under conditions of nutrient limitation (Piña-Valdez PhD, unpublished data). Obviously, *Nannochloropsis* has high potential as a carbohydrate source for a wide industrial use.

The βG represented 21.7, 15.4, 14.3 and 6.2% dry biomass of NpUNAM, CIB76, NN-X-1 and Nanno 3600®, respectively. In diatoms, it has been reported that Chrysolaminarin has a representation of up to 64.86% of dry weight [57]. It should be noted that with Nanno  $3600^{\circ}$ 6.2% of βG was registered and CIB76 presented 15.4% of βG even though both sources are considered to be *Nannochloropsis oculata.* This may indicate that other monosaccharides, not glucose, are represented in concentration commercial biomass. This is evidenced in the percentage of total carbohydrates for each source; Nanno 3600®, 62.5%; NN-X-1, 69.5%; CIB76, 71.5% and NpUNAM, 75.8%. Moreover, Mohammady et al. [132], reported 3.6 pg·cell-1 Βg in *N. salina* under conditions of stress per diesel fuel pollution. However, the determination was of total carbohydrates and referred to them as βG, but even so, total carbohydrates per cell were higher than those reported in present study.

This is the first study on enzymatic determination of  $\beta G$  content in microalgae cells, especially *Nannochloropsis* (K-YBGL 12/16; Megazyme®). This method is relatively easy to use and its principle allows for reliable beta glucans quantification in sources not yet studied.

However, the most important variable for determining the potential of microalgae as a source of  $βG$  is volumetric productivity. The registered 306 mg·l<sup>-1</sup>·d<sup>-1</sup> was obtained with *O*. *aurita* in a photobioreactor system under nitrogen limitation which registered production of 6.36 g·l<sup>-1</sup> of biomass [57]. Another important production of βG was achieved with *Chaetoceros mulleri* for batch culture, 71.57 mg·l-1 [79]. In the present study, *Nannochlopsis* strains showed similar volumetric productivity, NN-X-1: 57.63 mg·l<sup>-1</sup> and CIB76: 60.50 mg·l <sup>1</sup>. But it should be noted that NpUNAM has a volumetric productivity of 81.55 mg·l<sup>-1</sup>, which is higher than diatoms reported in batch cultures. However, considering that production of *Nannochloropsis* dry biomass (strain 211/78) in flat plate photobioreactor systems has been reported from 4.7 g·l<sup>-1</sup> [134], then it is possible to speculate a high yield of βG from production massive biomass of *Nannochloropsis* strains, for example NpUNAM, in photobioreactor systems.

Moreover, the molecular weight of microalgae βG could be directly relateds to the cell size of microalgae. For example, diatom *O. aurita* has the highest MW of 7.75 kDa [57] and a greater cell size of 10-95 microns (μm). Conversely, *C. debilis* with lower MW 4.9 kDa was registered [80] and less cell size of 10-40 μm. Likewise, from *I. galbana* MW of βG was reported 1.2-5.2 kDa [82] and cell size of 4-8 μm. Therefore, it could be expected that for cellular size of *Nannochloropsis* (1-2 μm), the molecular weight of its βG is smaller than diatoms and *I. galvana* (Cell size from [4]). This may be determinant in its molecular characteristics such as low polymerization degree and high branching degree.

In summary, the advantages of *Nannochloropsis* as a potential source of βG are as follows: I) Fresh water is not required to culture most of its species [135]. II) Biomass can be obtained on industrial scale from photobioreactors [134]. III) It is possible to modify the

biochemical composition of biomass to increasing fraction of carbohydrates [32]. IV) High volumetric productivity of  $\beta G$  in batch cultures (81.55 mg·l<sup>-1</sup>). V) Microalgal  $\beta G$  can be obtained for simple extraction techniques [79] because they are not bound for covalent bonds to other structural components of cells, facilitating purification of these polysaccharides from biomass [135]. VI) Possibly present molecular structure similar to their homologues of levaduduras and diatoms [13, 80].

### **CONCLUSION**

*Nannochloropsis* strains (NN-X-1, CIB76 & NpUNAM) present 23% to 31% dry weight in the form of carbohydrates, of which  $14\%$  to  $21\%$  are  $\beta G$ , from stationary phase in batch cultures. Individual content of  $\beta G$  is  $\sim 1$  pg·cell<sup>-1</sup>, with a maximum volumetric productivity of 81.55 mg·l-1 . *Nannochloropsis* (particularly NpUNAM), has great potential for βG industrialized production and due to its possible molecular characteristics, it is estimated that there are potential applications as immunostimulants. Future research is necessary to characterize βG isolated to *Nannochloropsis*, optimize its production and assess its capacity as an immunostimulant.

#### **ACKNOWLEDGMENTS**

The authors would like to thank Miguel Angel Sánchez Rodríguez of CIAD-Mazatlán for his valuable technical support for enzymatic determination beta glucan and to PhD Pablo Piña Valdez of FACIMAR-UAS for his valuable advice.

# **PULSED ELECTRIC FIELD (PEF) ASSISTED PROTEIN EXTRACTION FROM** *NANNOCHLOROPSIS*

# *Mathilde Coustets and Justin Teissié\**

Institut de Pharmacologie et de Biologie Structurale, Université de Toulouse, CNRS, UPS, France

# **ABSTRACT**

Extraction of cytoplasmic soluble proteins is one of the challenges for successful development of microalgae biotechnological potential. The consequence of the delivery of properly selected Pulsed Electric Fields is the release of cytoplasmic soluble proteins.

**Keywords:** electroporation, nannochloropsis, batch, flow process, pulsed electric field

# **1.INTRODUCTION**

*Nannochloropsis* is a robust industrial alga, which can extensively grow in outdoor ponds and photo bioreactors for aquaculture (Sukenik A et al., 2009). Photosynthetic performance of outdoor *Nannochloropsis* mass cultures has been evaluated under a wide range of environmental conditions. *Nannochloropsis* is a rich source of high-quality protein (Volkman JK et al., 1993).

Extraction of cytoplasmic soluble proteins is one of the challenges for successful development of microalgae biotechnological potential. Several approaches are under investigation. Among those PEF (Pulsed electric field) is proposed as one of the most promising (Günerken E et al., 2015; Vanthoor-Koopmans M et al., 2013). Pulsed electric fields (PEFs), that are routinely used to perturb the cell membrane of microorganisms (electropermeabilization), are directly applied on an aqueous cell suspension. This process triggers a permeabilization of the cell membrane and a perturbation of the cell envelope,

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: Justin.teissie@ipbs.fr.

which are associated with an enhanced transport of natively non-permeant molecules. Previous studies showed that PEFs were effective for the plasma membrane electropermeabilization of walled eukaryotes but the cell wall prevented the transport of macromolecules (Azencott et al., 2008; Ganeva et al., 1995; Ganeva et al., 2014). Nevertheless, after optimization of the treatment, PEF is a routine method for gene transfer valid for bacteria, plant cell and yeasts. More recently, gene electrotransfer was performed on microalgae, including *Nannochloropsis* (Kilian O, et al., 2011; Li et al., 2014), allowing gene editing (Wang et al., 2016).

The consequence of the delivery of properly selected PEF can be the release of cytoplasmic content including proteins. This was validated on yeast, with a flow process system, for its development at the industrial level (Ganeva et al 2003). The technology was then developed to be efficient on *Nannochloropsis*.

Different protocols are available where a train of successive electric pulses is delivered on the microalgae aqueous suspension. Pulses can be low field long duration (ms) (LFLD) (Coustets et al, 2013), high field short duration  $(\mu s)$  (HFSD) or high voltage electrical discharge (HVED) (Grimi et al, 2014). Those protocols will apply different physical and chemical stresses on the cell envelope. The cell suspension buffer (during PEF) is water, which is poorly conductive in order to limit the Joule heating effect. Pulses can be applied on the microalgae suspension either on a batch or on a flow process system.

# **2. BASIC TECHNOLOGICAL DESCRIPTION OF ELECTROPULSATION**

Pulsed electric fields (PEF) are obtained by delivering a controlled voltage between a set of two electrodes during a short duration of time.

As the electrodes are flat and parallel in the electroextraction process, the field is

$$
E = V/d \tag{1}
$$

where d is the gap between the electrodes.

The voltage is either constant during the pulse duration (T) (square wave used in the LFLP approach) or exponentially decaying (capacitor discharge system used in the HFSP process). The decay is characterized by a time constant  $\tau_c$  that depends on the charge storage capacitor (C) (where the high voltage is stored) and on the load R (the electrical resistance due to the cell suspension between the electrodes).

$$
\tau_{\rm C} = \rm{RC} \tag{2}
$$

As the cell suspension electrical characteristics would change during the voltage delivery (i.e., R is not constant due to the leakage of cytoplasmic ionic content), there is a need to monitor the voltage profile during the pulse delivery with a digitized oscilloscope (Figure 2).

In all applications, a train of repetitive pulses is delivered on the suspension. Each single pulse in the train can be similar and the delay between each of them (or the frequency) controls the effect. The pulse in a train can be either monopolar or bipolar. In the latter, two delays should be described as the train may be the application of successive pairs of bipolar pulses (with a short delay) with a longer delay between each pair.

The energy consumption W that is delivered to the sample during the train of N pulses is

i) for square wave pulses  $W = VINT$  (3) ii) and for capacitive discharge systems

$$
W = CV^2N/2
$$
 (4)

where  $C$  (=200 nF) is the capacitance of the capacitor for the HFSP and HVED models.

This electrical energy is mostly converted in heat. Indeed the power supply associated to the pulse generator has to be suited for such an energy storage. Interestingly, the Joule heating effect depends on the conductivity of the microalgae suspension only in the case of square wave pulses, as the energy is related to the current I, i.e., a function of the conductivity through the Ohm's law. This explains the need to work with low conductivity buffers (0.2 mS/cm).

# **3. A BIOPHYSICAL DESCRIPTION**

# **3.1. An Electric Field Has Physical Effects**

Physicochemical effects of electrical pulses are complex as contributions are of physical and electrochemical nature (Rems and Miklavcic, 2016).

#### *3.1.1. Electrochemistry at the Electrodes (pH, Corrosion)*

Delivering a voltage between two electrodes on a conductive liquid is associated to many electrochemical reactions at the metal-solution interface. Large currents are delivered across the electrode-liquid interface in a PEF treatment chamber. These currents would result in large-scale electrochemical reactions along the electrode surface (Morren et al., 2003).

Electrode reactions induce changes to the chemical structure of the liquids and produce toxic chemicals release such as reactive oxygen species (ROS). Electropulsed solutions where chlorine is present are toxic even a long period after pulse delivery. PEF associated electrochemistry in the solution is complex. A cascade of reactions is induced with short term and long term biological consequences. Changes of pH are observed in the bulk suspension (Turjanski et al., 2011). In non-buffered conditions (as used for microalgae electroextraction), pH-shifts of more than 4 units are predicted and observed as a result of a treatment time shorter than ms at electric field strength of 10 kV/cm, used for HFSP approaches. Interestingly, the use of bipolar pulses with a short inter-pulse delay prevents the interfacial electrochemical reactions and the potentially damaging pH shifts. Bipolar pulses were used in the LFLP process.

#### *3.1.2. Electrophoresis in the Suspension*

Microorganisms have a surface negative charge resulting in electrophoretic drift when submitted to an electric field. The microalgae are pushed toward one of the electrode surfaces. The formation of a film adjacent to the treatment electrode (fouling) causes local electric field distortion and can result in arcing. The bipolar approach prevents fouling.

#### *3.1.3. Electrophoresis in the Cell Membrane*

Membrane components, which are not linked covalently to the cytoskeleton or the extracellular matrix, are freely mobile in the cell membrane (glycolipids, proteins). As their polar groups in the external solution are highly charged, which is the case of glycosylated byproducts, a force is present when the external field is applied. This results in an electrophoretically driven lateral movement. An accumulation of the affected molecules towards one pole of the cell is observed (Poo 1981). Charged domains are formed as a result and non-covalently bounded components of the cell wall are affected.

#### *3.1.4. Stretching of the Cell*

In the presence of electric fields, vesicles are deformed, because of an electric stress brought by the external electric field on the membrane (considered as a dielectric flexible sheet such as a lipid bilayer), that is given by the Maxwell stress tensor. The deformation results from a gradient of electrical conductivities between the external buffer and the internal content of the vesicle. This gradient is high under PEF conditions, where a buffer of low conductivity reduces the Joule heating effect and energy costs. Stretching of the pulsed cells under electric Maxwell stress results in vesicle elongation. The cell membrane is connected to the cytoskeleton and/or to the cell wall. Its mechanical properties are such that deformations under a mechanical stress (as induced by the electric field) are dependent on the rate of the stress and of course on its duration (Evans et al., 2003). Irreversible deformations may appear. When a small stress is present for a sufficiently long duration, irreversible strains become large and a dramatic elongation affects the cell assembly.

### *3.1.5. Induction of Acoustic Shock Waves*

PEF mediates non-electrical factors, such as pressure transients, that bring external mechanical stress on the cell membrane. Pressure transients can result in inertial cavitation shock waves as observed optically (Roth et al., 2015). Such disruptive effects are present under the LFLP conditions as observed by the fragmentation of lipid vesicles (Wasungu et al., 2014). Pressure transients affected the wall organization in ultrasound treatment of microalgae.

# **3.2. The External Field Induces Membrane Potential Difference Modulation**

An external electric field modulates the transmembrane potential (TMP) of a cell that can be considered as a spherical capacitor [Rems and Miklavcic 2016]. The TMP induced by the electric field after a (capacitive) charging time,  $\Delta \Psi_i$  is a complex function  $g(\lambda)$  of specific conductivities of the membrane  $(\lambda_m)$ , pulsing buffer  $(\lambda_o)$ , cytoplasm  $(\lambda_i)$ , of membrane thickness, cell size (r) and packing. Thus, when assuming that a cell is a sphere,

$$
\Delta \Psi_{i} = f g(\lambda) r E \cos(\theta) (1 - \exp(-t/\tau_{m}))
$$
\n(5)

in which  $\theta$  designates the angle between the direction of the normal to the membrane at a considered point on the cell surface and the field direction, E the field intensity, r the radius of the cell and f, a shape factor (a cell being a spheroid, 1.5 for a sphere).  $\Delta\Psi_i$  is a linear function of the cell size. Higher fields must be applied on small cells to get the same  $\Delta \Psi_i$  as induced on the large cells Induced TMP is the highest at the positions of the cell facing the electrodes. The last term in Eq. 5 is telling that the TMP steady value is obtained only after a charging period  $\tau_m$ .  $\tau_m$  depends on the cell size r and on the external buffer conductivity. The associated loading time strongly depends on the external conductivity  $\lambda_o$ .

$$
\tau_{\rm m} = rC_{\rm membr} \left(\lambda_{\rm i} + 2\lambda_{\rm o}\right) \left(2\lambda_{\rm i}\lambda_{\rm o}\right) \tag{6}
$$

Charging is fast with small microorganisms such as Nannochloropsis. A decrease in the charging time of TMP occurs with an increase of the external solution conductivity. This charging time was calculated to be long (50 μs) in a very low conductivity buffer (3 μS/cm) and affected the steady value of  $\Delta \Psi_i$  with short pulses. With more classical buffers (0.2) mS/cm and 1 mS/cm),  $\tau_m$  were as short as 1 µs, meaning that the steady state TMP should be reached only during LFLP pulse (Blanckaert et al., 2015).

#### **3.3. Electropermeabilization**

When the resulting transmembrane potential difference  $\Delta \Psi$  (i.e., the total between the resting value of cell membrane  $\Delta \Psi_0$  and the electro induced value  $\Delta \Psi_i$ ) reaches locally more than 250 mV ( $\Delta\Psi$ <sub>iperm</sub>), that part of the membrane becomes permeable for small charged molecules.

The field strength controls permeabilization. Field intensities larger than a critical value  $(E_{p,r})$  must be applied to the cell suspension.  $E_{p,r}$  is such that:

$$
\Delta \Psi_{\text{iperm}} = f g(\lambda) r E_{\text{p,r}} \tag{7}
$$

Permeabilization is therefore a local process on the cell surface. The permeabilized surface on a spherical cell, A<sub>perm</sub>, is given by:

$$
A_{perm} = A_{tot} (1 - E_{p,r}/E) \tag{8}
$$

where  $A_{\text{tot}}$  is the cell surface and E is the applied field intensity. Increasing the field strength will increase the part of the cell surface, where an electropermeabilized state is present.

Post pulse leakage results from a concentration driven diffusion transport described by using the Fick equation on the cell electropermeabilized part. A permeability coefficient for the molecule s, Ps, across the electropermeabilized part is induced. The permeabilized part of the cell surface is a linear function of the reciprocal of the field intensity.

Under low-conductivity conditions, the electric stretching force contributes significantly to the increase in "electroleaks" across the plasma membrane, i.e., in Ps [Sukhorukov et al., 1998).

Experimental results, obtained either by monitoring conductance changes or by observation of the leakage of metabolites, show that the pulse duration strongly controls the density of the local alterations. Delivery of a train of successive pulses leads to an increase in the leakage with an increase of their number.

# **4. MATERIALS**

The marine microalgae *N. salina* used under the LFLP conditions was grown in an onsite closed photo bioreactor system using 3-W white LEDs. Growth was checked by measuring the density of algae under an inverted microscope with a Malassez slide. A 100 mL volume of *N. salina* suspension in water was centrifuged at  $1400 \times g$  during 10 min at room temperature. Supernatant was removed and the cells were resuspended in 100 mL of distilled water. The final conductivity was adjusted to limit the Joule heating effect (final conductivity =  $100 \mu S/cm$ ). The cells had approximately a spherical shape, and the mean diameter was found to be about  $2 \mu m$  (Figure 6).

The suspensions of *Nannochloropsis sp*. microalgae used for the HFSP and HVED trials were produced in two steps. In a first step, a large biomass was produced under non-stressful conditions and, to maximize the accumulation of lipids, the culture was then processed under conditions of nitrogen starvation. *Nannochloropsis sp.* was obtained as a frozen algae paste (12–15% solid content). The biomass was thawed at ambient temperature and then harvested by centrifugation and washed 3 times with deionized water to obtain a 1% (w/w) untreated (U) suspension with an initial electrical low conductivity of  $0.020 \pm 0.002$  mS/cm.

It was determined that the microalgae suspension contained 20% of proteins (w/w dry weight biomass).

#### **4.1. Analytical Methods**

#### *4.1.1. Analysis of Ionic Components*

The ionic components extraction is estimated by the measurements of the electrical conductivity  $\sigma$  of the supernatant before and after the electrical treatment of the sample.

#### *4.1.2. Analysis of Proteins*

Cells were pulsed and, after an overnight incubation at room temperature, centrifuged to form a pellet. The concentration of proteins,  $C_p$  (mg of bovine serum albumin equivalent/g of dry matter), in the supernatant was determined by a Bradford assay (Bradford 1976).

With the LFLP method, results are given in protein amount, while with the two other methods, the degree of extraction of proteins  $Z_p$  is estimated as:

$$
Z_p = (P - P_i)/(P_{\text{max}} - P_i)
$$
\n(9)

where P is the protein content after treatment,  $P_i$  is the initial value of P before treatment, and Pmax corresponds to the protein content in samples containing the largest amount of disintegrated cells.

# **4.2. Physical Techniques of Cell Disruption**

# *4.2.1. LFLP (Low Field Long Pulse)*

The PEF delivery system was on a flow system suited for the treatment of large volumes (Figure 1). Pulse generators (DEEX-Bio, Betatech, France) and flow through applicators (CNRS) were designed to apply trains of bipolar pulses on the flow. In the pulsing chamber, the distance between the parallel plate electrodes was 3 mm.

Figure 1. Scheme and picture (b) of the electroextraction system. (a) Scheme representing the electrical device, in which two Betatech S20 pulse generators are successively delivering similar pulses to the flow applicator with a controlled delay in between. A relay reverses the polarity of the second pulse in order to obtain bipolar symmetric pulses within the flow applicator. The bipolar pulse train is delivered at a frequency higher than 16 Hz (from *J Membr Biol*. 2013 Oct; 246(10):751-60 by courtesy of Springer).

Figure 2. Current profile. A current probe monitored on line the delivery of the electric pulse train. Symmetrical square waved profiles were observed (from *J Membr Biol*. 2013 Oct;246(10):751-60 by courtesy of Springer).

Washed suspensions of microalgae were flow processed through the pulsing chamber, according to the parameters ( $E = 6$  kV/cm, duration of pulses = 2 ms, bipolar pulses delayed by 16 ms, flow rate = 150  $\mu$ l/s) (Figure 2). Those were selected by taking into account the size of the microalgae, which was close to the one of the *E. coli* bacteria (Figure 4 and 5a). This electric treatment was effective for protein extraction (Coustets *et al.,* 2013).

The number of bipolar pulses delivered on average to each cell was 15 (30 pulses as a total). After the electric treatment, the pulsed suspension was collected and diluted five times in water or in a phosphate buffer (PB/DTT = PB 105 mM, 0.3 M glycerol, 1 mM DTT, pH 7). DTT (dithiothreitol) was shown to enhance the extraction from yeasts when present in the post PEF incubation medium (Ganeva et al., 2003). Samples were incubated overnight at room temperature. Supernatants were collected after centrifuging for 5 min at 2500×g.

#### *4.2.2. HFSP (High Field Short Pulse)*

HFSP PEF treatment was carried out in a cylindrical batch chamber between two parallel plate electrodes (Figure 3a). The distance between the electrodes was fixed at 2 cm and the corresponding electric field strength E was 20 kV/cm. PEF treatment comprised application of N successive pulses ( $N = 1$  to 400). The voltage between the electrodes decayed along the discharge,  $V(t) = V_0 \exp(t/t_0)$  with an effective decay time  $(t_0)$  of  $10.0 \pm 0.1$  µs. A delay of 2 s was present between each pulse. This system resulted in the delivery of pulses according to the following parameters:  $20 \text{ kV/cm}$ , pulse application duration  $1-4 \text{ ms}$ ,  $13.3-53.1 \text{ kJ/kg}$ .

#### *4.2.3. HVED (High Voltage Electrical Discharge)*

HVED treatment was done in the laboratory batch chamber with needle-plate geometry of electrodes (Figure 3b). The distance between the tip of the central stainless steel needle ( $\Phi$ 10 mm) and the grounded dish plate ( $\Phi$  25 mm) electrodes was 10 mm. HVED treatment consists in the application of repetitive pulses ( $N = 1$  to 400) with an initial voltage peak amplitude of  $V_0 = 40$  kV, delivered at a frequency of 0.5 Hz, giving a treatment time ranging between 2 and 800 s. The temporal profile of each single pulse was complex with damped oscillations, at a period of  $0.5 \pm 0.1$  us superimposed on the exponential decay of voltage V exp (t/t<sub>p</sub>) with an effective decay time (t<sub>p</sub>) of  $10.0 \pm 0.1$  µs. The parameters of the pulses were 40 kV/cm, pulse application duration  $1-4$  ms (N= 100 to 400), 13.3–53.1 kJ/kg. A polarity inversion of the field was repetitively present in HVED, due to the damped oscillations. A pulsed streamer discharge in water is associated to the HVED ( $V_0 = 40$  kV, 1–4 ms, 13.3– 53.1 kJ/kg, duration 200-800 s). It is usually accompanied with localized high electric fields (heterogeneous spatial distribution), production of short ultraviolet light, strong shockwaves, cavitations, liquid turbulences, ozone, hydroxide radicals (ROS) production, etc. These secondary phenomena to the electric field effect induce cell structure damages and facilitate externalization of intracellular compounds, but may also induce protein inactivation.

Figure 3. The schemes of the experimental pulsing chambers used for HVED treatment (a), PEF treatment (b) (Redrawn from *Food Bioprocess Technol* (2013) 6:576).

# **5. RESULTS**

# **5.1. LFLP**

#### *5.1.1. Microalgae Electropermeabilization*

The current delivered by the pulse generator at a given applied voltage was a direct assay of the conductivity of the solution present in the pulsing chamber (Figure 2). This current was much higher than the value measured before the pulse delivery, just after washing the cultures (100 μS/cm). This high value was further checked by measuring the conductivity of the recovered pulsed samples. A 2.5 to 3 times increase was observed for a pulsed suspension of  $5x10<sup>7</sup>$  cells /mL. This conductivity increase was larger when the microorganism density was brought from  $5\times10^7$  to  $10^8$  cells/ml. This observation was indicative of the release of the ions present in the cytoplasm due to the plasma membrane electropermeabilization. A 3 kV/cm applied field did not trigger such ionic leakages.

This ion leakage resulted in a sharp temperature increase due to the Joule heating effect. Temperatures up to 50°C were transiently observed but cooling was also observed in the downstream tubing. The temperature in the collector was close to the room temperature.

Figure 4. Phase-contrast microscopic observation of the effect of the electric pulse train. *Nannochloropsis* was observed before and after the electro treatment (from *J Membr Biol*. 2013 Oct; 246(10):751-60 by courtesy of Springer).

Phase-contrast microscopic observations of the samples, before and after electric treatment, showed a loss of contrast after pulse delivery and a swelling of the cells (Figure 4). Both results indicated that the cytoplasmic content of the pulsed sample was strongly affected, compared to the control, due to the membrane electropermeabilization.

#### *5.1.2. Protein Extraction from N. salina*

A spontaneous and rather low protein leakage was observed, after the overnight incubation, from the negative control incubated in water without any treatment applied to the suspension. This export of cytoplasmic soluble proteins overnight was also observed in yeast experiments (unpublished results). This phenomenon may be the result of an endogenous secretion of eukaryotic cells and/or passive diffusion through the plasma membrane and the cell wall of cytosolic proteins during the incubation period. The electroextraction method, with water as a post-pulse incubation medium, improved the recovery of soluble proteins by 400% after overnight incubation compared to the negative control (Figure 5b). No increase, above the low leakage observed on the negative control, was obtained when cells were treated with a field of 3 kV/cm.

Those results confirmed that the train of electric pulses permeabilized the plasma membranes of *N. salina* (as shown already by the conductance assay), but as demonstrated on yeasts previously, it induced a structural reorganization of the wall. Cytoplasmic proteins

could leak out indicating that the wall was permeable. These proteins were easily recovered, as no debris were present in the supernatant.

Figure 5. Total protein assay of *Nannochloropsis* electroextraction. (a) Size histogram of the population. (b) The concentration of microalgae suspension in those assays was  $1.10<sup>8</sup>$  cells/ml. Unpulsed suspensions of microalgae, respectively incubated in water or methanol and vortexed, provide negative and positive controls. The remaining suspension in water was processed by a 6kV/cm electroextraction and then incubated in water. The incubation period of all samples and controls was 18 h at room temperature in the dark. Concentrations of total proteins were determined by a classical Bradford assay, using BSA as a standard  $(n = 6)$ . (c) Same as in (b), but those assays were conducted at a concentration of  $5.10^7$  cells/ml (n = 2). Statistical analyses for b and c were made by Prism software using standard error means and a t test (from *J Membr Biol*. 2013 Oct;246(10):751-60 by courtesy of Springer).

The possibility for treatment of more concentrated suspensions (from 5.10<sup>7</sup> up to 10<sup>8</sup>) cells/ml) was checked. Levels of extraction were two times higher with the higher density suspension in comparison to the lower density (Figure 5c). However, the conductivity of the pulsed suspension increased with the higher microorganism load. A higher current was delivered, resulting in an increase in the Joule heating effect. A deformation of the electrical pulse associated voltage and current was observed as the conductivity is temperature dependent.

Figure 6. Electrophoretic analysis of proteins in cell extract and supernatant of control, electrically treated and mechanically extracted cells. Protein samples in SDS-PAGE sample buffer containing 2-mercaptoethanol were boiled for 3 min at 90°C prior to electrophoresis on 12% acrylamide gel. Gels were stained for protein by silver nitrate (from *J Membr Biol*. 2013 Oct;246(10):751-60 by courtesy of Springer ).

The proteins from supernatants of control, electrically treated and mechanically extracted cells were analyzed by SDS-PAGE under reducing conditions (Figure 6). Bands were detected between 35 and 170 kDa. The bands present in negative controls appeared on pulsed samples with a higher intensity. Several new proteins appeared after electroextraction in comparison to the negative controls. Most of the proteins recovered by the glass bead extraction, where the cell wall was completely disrupted, were also present after electroextraction.

### **5.2. HFSP and HVED Treatments**

### *5.2.1. Microalgae Electropermeabilization*

Disrupted algae suspension characteristics were measured between successive applications of the HVED or PEF pulses.

Application of HFSP PEF brought only an insignificant increase of buffer low conductivity up to 0.07 mS/cm. The application of the HVED technique resulted in a more powerful cell disintegration and in a larger increase of conductivity, up to 0.3 mS/cm. This release of cytoplasmic ionic compounds was the direct effect of the cell membrane electropermeabilization.

Figure 7. Microalgae permeabilization. It was assayed by the Ratio of electrical conductivities of the supernatant after and before treatment  $\sigma/\sigma_i$  versus the specific power consumption W expressed in kJ/kg. Results are shown in black after PEF treatment and in grey after the HVED treatment (adapted from Bioresource Technology 153 (2014) 254–259).

This increase in conductivity, along the field discharge, resulted in a Joule heating effect. The initial temperature before HFSP PEF or HVED treatments was 22°C and the temperature elevation after electrical treatment never exceeded 30°C.

#### *5.2.2. Microscopic Observations*

Under the microscope, the cells were observed to be free and almost not aggregated in untreated (U) and HFSP PEF treated suspensions. This was not the case with the HVED treatment, where the microalgae treated suspensions were noticeably agglomerated and formed large clusters. Those results indicated that large damages were induced by the treatment, changing the hydrophobicity of the wall. The HVED-produced shockwaves, cavitations and liquid turbulences can facilitate aggregation and provide micronization, a set of physical stresses destructive for the cell wall. The treatment affected sedimentation of microalgae because of cell debris formation. Thus, sedimentation was acting on large aggregates and small cell debris.

#### *5.2.3. Protein Extraction*

The treatment was done sequentially, meaning that the protein content in the supernatant was first checked with control cells (U), then after a HFSP treatment (PEF) and eventually after addition of a HVED treatment (HVED). Analysis of the supernatant was operated just after the electrical treatment with no further incubation.

The total quantity of extracted water-soluble proteins in the control was  $Z_p = 0.7\%$  (w/w DW biomass) while the microalgae proteins content was  $20.0% \pm 0.8%$  (w/w DW biomass). The effect of HFSP treatment was associated with  $Z_p = 5.2\%$  and should be considered as rather significant when compared with the low supplementary contributions of HVED (1.15%) (Figure 8).

Figure 8. Degree of extraction of water-soluble proteins  $Z_p$  (%) (Eq. (9)) for 1% microalgae suspensions: untreated (U), -treated by PEF  $(20 \text{ kV/cm}, 4 \text{ ms})$ , and HVED  $(40 \text{ kV/cm}, 4 \text{ ms})$ , redrawn from *Bioresource Technology* 153 (2014) 254–259.

Figure 9. Concentration of proteins (mg/g), after basic aqueous extraction coupled to PEF treatment. The data (light grey) are presented for extracts obtained using  $PEF_n$  (neutral pH),  $PEF_b$  (basic pH), and  $E<sub>b</sub>$  extraction procedures. The effects of post PEF aqueous extraction are shown in dark grey. The pulse time duration was t<sub>PEF</sub> = 4 ms (N=400), and t<sub>Eb</sub> = 10,800 s for PEF and E<sub>b</sub> extraction procedures, respectively (Adapted from *Algal Research* 8 (2015) 128–134).

A direct aqueous extraction of algae proteins from *Nannochloropsis* biomass was obtained at pH 11 and a temperature of 333 °K (Gerde et al., 2013). The relevance of this pH dependent spontaneous extraction was investigated on the PEF induced extraction.

HFSP PEF were delivered  $(N=400)$  on a suspension either at a close to neutral pH (8.5) (PEF<sub>n</sub>) or under basic conditions (pH 11) (PEF<sub>b</sub>). The neutral condition was more effective
for protein extraction (Figure 9). A supplementary basic extraction  $(+E_b)$  was done under the optimized conditions described for the reported basic extraction  $(E_b)$  method (pH=11, T=323°K, incubation during 10,800 s). This additive treatment brought an improvement to the protein extraction, regardless of the PEF treatment pH, but with a slightly larger effect after PEFn. The most important conclusion was that the PEF pretreatment improved the yield of protein extraction. The concentration of proteins in the supernatant was increased 3 times when the pH 11 extraction was operated on a suspension, which was already pretreated by PEF at pH 8.5 (Figure 9).

Those observations clearly showed the improvement in protein extraction brought by a PEF pretreatment application in a normal medium ( $pH = 8.5$ ) followed by a basic medium supplementary extraction ( $pH = 11$ ) (Figure 9). The potential of PEF pre-treatment was established as a preliminary step of pH-assisted aqueous extraction of algae components from *Nannochloropsis* suspensions.

#### **CONCLUSION**

The electrical methods provide soluble protein extraction from microalgae. The results were very interesting with the LFLP approach in which the PAGE results provided the evidence of the lack of damage on the extracted proteins. Previous results on yeasts showed that the protein activity was preserved (Ganeva et al., 2003).

The use of low conductivities buffers is problematic, when using short  $(\mu s)$  pulses, as the associated capacitive loading times are long. This means that the induced TMP does not reach its steady state value. Only a limited effect is present to induce permeabilization. This may be one reason why the extraction is more effective with the LFLP than with the HFSP processes. The cumulated time of PEF application is much longer with the LFLP (60 ms) than with the two other methods (less than 4 ms). The effect on the wall is associated with the plasma membrane permeabilization that may affect the covalent interactions between the two assemblies. However, a mechanical effect is associated with the LFLP procedure. Stretching of the cells brings an electromechanical stress on the wall and can induce rupture of molecular interactions. The DTT reduction of the disulfide bonds during the post pulse overnight incubation further increased the level of extraction. Another difference is that the LFLP technology is delivered on fresh cultures, in which the membrane organization was not pre-affected.

What is still missing to appreciate the advantages of the methodology is basic investigations of the biophysical processes that are responsible for membrane and wall alterations of the treated microorganisms. Cells are more than a vesicle with a dielectric shell. One should consider the different effects associated with the train of electric pulses and their control by the electric parameters (field strength, pulse duration, delay between pulses). Another level of complexity is the organization of the cell envelope and its complex response, not only to the physical (electromechanical) constraints, but also to metabolic stresses, which are associated with high-level membrane electropermeabilization.

#### **ACKNOWLEDGMENTS**

This work was supported by the European FP7 (Electroextraction, [FP7-SME-2007-1], Grant agreement n°222220) Projects. Research was conducted in the scope of the EBAM European Associated Laboratory (LEA) and resulted from the networking efforts of the COST Action TD1104 (http://www.electroporation.net).

## **ABSTRACT**

*Nannochloropsis* is a genus of marine microalgae including six known species (*N. gaditana, N. granulata, N. limnetica, N. oceanica, N. oculata, N. salina*), which are considered as promising microalgal cell factories for lipids production and bioactive compounds. Currently, *Nannochloropsis* is commercially cultured to produce biomass for various industrial applications. Due to its high nutrition profile, the marine microalgal is mainly used as an energy-rich food source for aquaculture such as fish larvae and rotifers. Nevertheless, it has become more widely recognized as potential lipids source for biodiesel production, while generating biomass residuals that have been utilized for  $\text{bioH}_2$ and lactic acid production. Ingredients (mainly polysaccharides, vitamin B12, Vitamin C) extracted from *N. oculata* biomass were also used for cosmetics formulation. Moreover, *N. oculata* biomass was recently explored as a high-value organic slow-release fertilizer to enhance carotenoid and sugars content in tomatoes. More recently*,* lipid-extracted *N.*

*salina* residual and whole biomass of *Nannochloropsis* sp. were utilized as fillers for biocomposites fabrication with polymers. Industrial large-scale cultivation of *Nannochloropsis* is expanding, meanwhile biorefinery is evolving to valorize all biomass constituents (e.g., proteins, lipids, carbohydrates, pigments) for products development in relevant industries. This chapter presents recent advances in the utilization of *Nannochloropsis* biomass for commodity chemicals, feeds, high value products, biofuels, cosmetics, fertilizers, and materials production. Challenges and future perspectives in application of *Nannochloropsis* biomass for biorefinery development in microalgae-based industry are also highlighted.

**Keywords**: *Nannochloropsis*, high value products, commodity chemicals, feeds, biofuels, cosmetics, biofertilizers, materials, biorefinery

#### **1.INTRODUCTION**

The greatest challenges that society faces this century are climate, energy, and food security. BioEnergy with Carbon Capture and Storage (BECCS) has been proposed as a primary measure for mitigation of  $CO<sub>2</sub>$  emission while simultaneously producing renewable energy on global scale [1]. However, since BECCS based on utilization of terrestrial biomass, the method has many negative environmental impacts for land, nutrient, and water use as well as biodiversity and food production. Contrastingly, industrial-scale cultivation of marine microalgae for algal biomass production could provide a more environmental favorable approach for satisfying the climate goals that were agreed and singed at the 2015 Paris Climate Conference. Marine microalgae is an attractive alternative to traditional crops-based biomass and have been considered as the third generation feedstock for bioenergy production [2]. They offer substantial advantages over terrestrial plants, due to higher photoconversion efficiency, possibility to be grown in brackish, saline or wastewater and cultivated on nonarable land, with low seasonal variation of production mode and biomass productivity [3]. Furthermore, microalgae accumulate a broad range of potential compositions, mainly polysaccharides, proteins, and fatty acids (lipids), which are much more suitable for processing in a biorefinery [4]. Particularly, microalgae biomass also contains many minor components including antioxidants, vitamins, and pigments such as astaxanthin, lutein, etc, that can be extracted and purified as high value ingredients for pharmaceutical [5, 6] and cosmeceutical industries [7].

*Nannochloropsis* is a typical marine microalgal strain that is potential for industrial cultivation. Many studies have been carried out to investigate pilot culture of *Nannochloropsis* in outdoor open race way pond [8], flat panel photobioreactors [9], photobioreactors [10], and annular reactor [11]. *Nannochloropsis* was also used for pilot-test to grow in anaerobic digestion of municipal wastewater (as nutrient source) with dilution rate of 15-30% in seawater in both tubular and raceway reactors [12]. The marine microalgal has high productivity, high protein content and lipid composition, making it a promising source of nutrition [13]. Due to its high accumulation of polyunsaturated fatty acids (PUFAs) [14], it has recognized as a potential candidate for nutraceuticals (e.g., EPA) and raised growing interest for the investigation of biodiesel production [15-17]. It is also known that *Nannochloropsis* could accumulate variety of pigments including chlorophyll *a*, zeaxanthin, canthaxanthin and astaxanthin, thus it is considered as a source of valuable pigments [18].

Biomass production is a preliminary step for commercialization of algae-based industrial products. Most commercial facilities of *Nannochloropsis* focus on one single product such as whole biomass for aquaculture or animal feed, or EPA for nutraceutical industry. However, since *Nannochloropsis* biomass simultaneously contains lipids, carbohydrates, proteins, pigments, therefore utilization of all these components to develop specific products will maximize exploitation of the biomass and allocate all constituents in different markets. In order to implement the task, biorefinery research is prerequisite. Biorefinery of microalgal biomass is the next step for the commercialization of products from algae. The biorefinery process strategy depends on the product portfolio, and may result in different market scenarios for biofuels, chemicals, food/feed, food additives, and cosmetics/healthcare. The present chapter provides updated research activities on the utilization of *Nannochloropsis* biomass for the development and production of commodity chemicals, feeds, high value products, biofuels, cosmetics, fertilizers, and materials. Different biorefinery scenarios based on four primary products production from *Nannochloropsis* are also highlighted.

# **2. COMMODITY CHEMICALS PRODUCTION FROM** *NANNOCHLOROPSIS*

#### **2.1. Lipids Production via Solvent Extraction**

Lipids extraction from algal biomass is a crucial step before subsequent conversion to biofuels or lipids-based bioproducts. Because lipids body is embedded in internal compartment of microalgal cells and protected by highly rigid cell walls. Therefore, cell disruption is necessary to make lipids droplets to be accessible to extracting solvents. Moreover, extraction of lipids from wet algal biomass is considered as more costly effective than that from dry biomass because dewatering step can be omitted. The use of solvents to recover crude lipids from disrupted algal biomass is necessary. Searching for an efficient solvent is also important. Solvent used to extract lipids should provide a reasonable partition coefficient, forcing the solute to migrate to the solvent phase [19]. Lipids should have high partition coefficient in the selected solvent. Principally, hydrophobic lipids (e.g., neutral lipids such as TAG) is preferably partition into the nonpolar solvent phase (chloroform, hexane), whereas polar lipids are not so easy to dissolve in nonpolar solvents due to their bindings with biomass matrices. Therefore, co-solvents are traditionally applied to break the linkages between the polar lipids and biomass, leading to increase the solubility of the polar lipids. Recent study conducted by Angles et al. [20] pointed out that the cell disruption appeared to be the main controlling step if low water soluble solvents were used for *Nannochloropsis* sp. Furthermore, it was found that extraction of lipids from suspension of disrupted microalgae was more efficient than extraction from dried biomass (same solvent, same energy, and time) and water liberated with the disrupted biomass improved selectively for saturated fatty acids (SFA) recovery. Lipids extraction yield achieved 50% when disruption rate of 84% by high pressure disruption cell was obtained in 10 min, while the SFA content was enriched up to 72% of the total extracted lipids. Two solvents including methyl tert-butyl ether (MTBE) and cyclo pentyl methyl ether (CPME) were screened out from 11 experimental solvents (cyclohexane, heptane, chloroform, toluene, methyl isobutyl ketone, ethyl acetate, dimethyl carbonate, R-limonene, 2-methyltetrahydrofuran, methyl ter-butyl ether, and cyclo pentyl

methyl ether) showed to have the highest lipids recovery, while ease to be recyclable and safety. Chloroform (CHCl<sub>3</sub>) is the most encountered in lipid extraction from dry algal biomass for standard analytical methods. However, it was rarely found to apply for microalgae oil recovery from wet form. In a study carried out by Chatsungnoen and Chisti [21], implementing optimization of oil extraction from *N. salina* biomass paste (72% water) using chloroform, methanol and water as co-solvent. The optimal volumetric ratio of chloroform/methanol/water was 5.7:3:1, which was then applied for single-step extraction experiments to optimize the extraction time, temperature and the volume of the solvent mixture required for oil recovery from 1 g dry biomass (equivalent to the wet paste). The optimal extraction conditions were  $25^{\circ}$ C, 2 h using 33 mL of solvent mixture. The developed protocol resulted in saving by 48% of solvent and 78% of extraction time when compared to the conventional Bligh & Dyer process [21].

#### **2.2. Biocrude Production via Thermal Process**

Algal biocrude from *Nannochloropsis* biomass can be produced via two typical thermal processes which are pyrolysis and hydrothermal liquefaction (HTL). Adamczyk and Sajdak performed pyrolytic experiments using *N. gaditana* biomass at 400-600 °C under  $N_2$  (50 mL/h) in a 1 kg fixed bed reactor [22]. Char, bio-oil, and gas were main products (of the pyrolysis process), which were characterized by a gas chromatography (GC) with mass detection. The bio-oil produced under  $600^{\circ}$ C achieved 38-40% efficiency with the highest heating value of 12.6 MJ/kg, while the highest composition of bio-oil including alkanes and alkenes were determined under  $500^{\circ}$ C. In the gas phase, methane content was the largest composition with greater 50%. Biochar contained up to 70% ash that can be used as a fertilizer. When catalyst (HZM-5) was used at 1/1 loading over dry weight of algal biomass, the pyrolysis process of *Nannochloropsis* sp. resulted in a 20.7% bio-oil at 400°C, which was significantly lower than 31.1% that obtained from pyrolysis without catalyst [23]. Bio-oil products produced via pyrolysis are a complex consisting of numerous chemical compounds having various functional groups and a wide range of molecular weights that may cause unwanted characteristics. Therefore, the pyrolytic bio-oil needs to undergo further upgrading or treatment in order to enhance its properties for the targeted use. Nam et al. [24] employed atmospheric fraction distillation and vacuum distillation for physical upgrading *N. ocutala*derived bio-oil (pyrolyzed at  $500^{\circ}$ C in a batch reactor in 30 min [25]) for alternative transport fuels. Properties of each distillates were analyzed for energy and mass yields, elemental, and chemical composition, total acid number (TAN) to compare with characteristics of petroleumbased fuels. It was noted that the similar tendency of physical and chemical characteristics of each fraction from both distillation methods was observed. The middle fraction had heating value of 41.2 MJ/kg and water content of less than 1.25%, but the TAN as high as 17-25 mg KOH/g (higher than 0.12 mg KOH/g measured for the light fraction). The lowest viscosity of 0.61 cSt was obtained for the light fraction from fractional distillation to be equivalent to that of gasoline fuel, while the largest chemical compositions in the light fraction were olefins (26-31%), aromatics (14-17%), and paraffins (43-49%) and alcohols (4-5%) were predominant in the middles fraction. Nitriles were evaluated to account for 25-42% in the heavy fraction. To meet the petroleum transportation fuel substitute, the physically upgraded pyrolytic bio-oil was chemically upgraded using Pd/C catalyst [26]. The light, middle fraction and raw bio-oil was catalytically treated under temperature of  $130-250^{\circ}$ C and pressure of 4.1-8.3 MPa using response surface methodology (RSM). Results revealed that the physical distillation prior to catalytic upgrading led to a better quality of upgraded bio-oil when compared to the direct bio-oil upgrades. Moreover, both the oxygen and hydrogen contents of light and middle fraction upgrades were enhanced, while the upgraded raw bio-oil showed a limited improvement. The higher heating value (HHV) and TAN for the middle fraction was respectively improved to 42.9 MJ/kg and 1.09 mg/KOH due to most of the ketones in upgrades were removed under severe conditions. Paraffin and aromatic chemical groups were remarkably generated via hydrogenation and hydrodeoxygenation of olefin groups. These results indicated that sequentially physical distillation followed by catalytic upgrading effectively enhanced the quality of biofuel that can be petroleum fuels substitutes or additives.

Hydrothermal liquefaction (HTL) can be alternatively applied to convert algal biomass paste to biocrude, but not necessary under absent of oxygen. Recent HTL for *Nannochloropsis* sp. was systematically investigated by Vanldez et al. [27] at a range of temperatures of 250-400°C, times of 10-90 min, water densities of 0.3-0.5  $g/mL$ , and biomass loading of 5-35%. Biocrude of HTL for algal biomass commonly includes light and heavy fractions that are associated with gaseous, aqueous, and solid by-product fractions. It was reported that the yields of light and heavy biocrude depend on reaction time and temperature, while the total yield depends on temperature only. Among biocrude-related products, carbon proportion in aqueous phase and the light biocrude accounted for 51 and 75 wt%, respectively, regardless of reaction time and temperature. Moreover, approximate 67% of N in the raw algal biomass was distributed to the aqueous phase with 84% partition here, whereas up to 85% of the P was distributed to the aqueous phase in the form of free phosphate. This interesting data provides a fundamental evidence to recover N and P from aqueous phase for nutrient recycling. Based on these quantitative results, a reaction network for *Nannochloropsis* sp. liquefaction was developed, that comprises the pathways for consumption and formation of each product fraction [28]. Based upon the reaction network, quantitative kinetic model for HTL of *Nannochloropsis* sp. was also developed [29] to describe influence of time and temperature on the gravimetric yield of gas, solid, biocrude, and aqueous-phase products from isothermal HTL of 15 wt% slurry.

#### **2.3. Sugars Production via Enzymatic and Acidic Hydrolysis**

Microalgae can produce carbohydrates as major products via photosynthesis and the carbon fixation metabolism. The carbohydrates are accumulated as starch in plastids or cellulose in algal cell wall with total content up to 16.4-70% dry cell weight (DCW) depended on cultivation conditions [30, 31]. The reducing saccharides generated from algal carbohydrates mainly consists of glucose, xylose, mannose, galactose, rhamnose, which can be utilized by bacteria or yeast for liquids (i.e., ethanol, butanol, etc.) or gas fuels (i.e., hydrogen, etc.) production via fermentation [31]. Microgalgal sugars can be produced via enzymatic hydrolysis [32, 33] or chemical pretreatment. Due to high cost of enzyme, thermochemical treatment of algal biomass for sugars production are currently implemented with the aid of chemical acid catalysts (i.e.,  $H_2SO_4$ , etc.) [34, 35]. The primary research has focused on development of algal lipids-based biofuels (i.e., biodiesel, jet-fuels), while the leftover was used for biogas, electricity, animal feed, fertilizer, or materials production. But the biomass residual after lipid extraction is approximately estimated as a haft of total algal biomass weight, which generally contains carbohydrates that can be derived for further producing other liquid fuels such as ethanol. Therefore, Mirsiaghi and Reardon [36] made an effort to develop enzymatic hydrolysis and acid-aided degradation process of lipid-extracted algal biomass of *N. salina* (LEAB) for sugar recovery. For enzymatic hydrolysis, an optimal enzyme mixture of Accellerase 1500, 0.05–0.25 mL/g biomass; Accellerase XC, 0.0125– 0.125 mL/g biomass; Accellerase XY, 0.005–0.05 mL/g biomass; and pectinase, 0.04–0.153 mL/g biomass was made to use for biodegradation of the LEAB under  $50^{\circ}$ C for 5 h with  $5\%$ (w/v) biomass loading, giving the yield of sugar release and maximum sugar release rate of 77.9 mg sugars/g LEAB and 87.0 mg sugar/g LEAB/h, respectively. For the acid hydrolysis, the highest yield of released sugar (243.2 mg/g LEAB) was achieved via one-step sulfuric acid process with 10% acid concentration (w/w) at  $90^{\circ}$ C for 5 h (biomass loading of 5%,  $w/v$ ), while using 10% HCl catalyst gave maximum sugars release yield of 164.6 mg sugars/g biomass under the same conditions applied for  $H_2SO_4$ . It was also reported that yeast can be grown on the sugars-rich hydrolysate after enzymatic and acid degradation without addition of other nutrients. The study demonstrated that development of value-added chemicals (i.e., sugars, ethanol, etc.) from LEAB via development of biorefinery can improve economic feasibility of microalgae-based biofuels production [36].

#### **2.4. Lactic Acid Production via Fermentation**

Dry biomass of *N. salina* contains a total lipid and carbohydrate content of 39.8% and 18.2%, respectively, was subjected to pretreatment with sulfuric acid  $(5\%, w/v)$  at  $120^{\circ}$ C for 1 h to disrupt the algal cells and degrade polysaccharides to monosugars. The hydrolysate was employed for lipid extraction with hexane (40 °C and 200 rpm) to obtain lipids, while recovering lipids-free hydrolyzed mixture containing reducing sugars (3-25 g/L, mainly glucose and xylose) [37]. The resulted mixture was neutralized to remove acid and used as a carbon source for anaerobic fermentation with *L. pentosus* at 30°C under shaking rate of 150 rpm for 48 h, giving lactic acid (LA) concentration of 10.1 g/L and LA yield of of 92.8%. The sugar and lipid yields after the acid hydrolysis of the algal biomass were measured as 64.3% and 85.6%, respectively, presenting a high potential for simultaneous lipids extraction and sequential sugar recovery and microbial LA production from algal biomass via acid pretreatment [37]. However, the hydrolysate has to be deionized for maintaining LA yield of over 90% at a sugar concentration of over 11.2  $g/L$ . Moreover, it was estimated that, the volumetric productivity of LA of 0.45 g/L/h is low and needs to be improved for cost effective production of LA at the industrial scale [37].

#### **2.5. Protein Isolation from Defatted** *Nannochloropsis* **sp. Biomass**

Generally, after lipid extraction, algal residue contains a countable amount of proteins that can be isolated as a co-product for specific uses. This can improve the economic feasibility and sustainability of the feedstock. Temperature and pH were optimized for maximizing protein recovery from *Nannochloropsis* biomass [38]. Maximum quantity of protein was solubilized at  $60^{\circ}$ C and pH 11 and recovered at pH 3.2. The isolated protein

fractions contained 56.9% and 40.5% protein when using isopropanol defatted and nondefatted biomass as starting materials, obtaining protein yields of 16 and 30%, respectively. This indicated that protein extraction yield was decreased when isopropanol pretreatment was applied. Although the isolation process produced a protein-rich product that may have unique functional properties due to the high degree of glycosylation, the overall recovery of the protein is relatively low, thus it should be further improved [38].

# **3. AQUACULTURE AND ANIMAL FEEDS PRODUCTION FROM** *NANNOCHLOROPSIS*

#### **3.1. Aquaculture Feed Production from** *Nannochloropsis*

The global market for aquaculture products such as carp, molluscs, crustaceans, salmon, trout and other fish was estimated at 156.27 billion US\$ in 2015 ( $\sim$  71,190  $\times$ 10<sup>3</sup> tons) and is expected to reach 209.42 billion US\$ in 2021, growing rate at a CAGR of 5.0% between 2016 and 2021 [39]. Several microalgal species such as *Chlorella, Tetraselmis, Isochrysis, Pavlova, Phaeodactylum, Chaetoceros, Nannochloropsis, Skeletonema, Thalassiosira* [40] and *Schizochytrium* sp. [41] are considered as outstanding sources of proteins, carbohydrates, lipids, and vitamins and have been utilized widely as food and/or feed additives for aquaculture larvae for over 40 years [42, 43]. Moreover, microalgal cultures are "greenwater" maker for larvae tanks. Thus, microalgae are importantly functioned in aquaculture hatchery in terms of the nutritional values from natural food chain as well as maintenance of water quality in the hatchery environment [44]. *Nannochloropsis* is well known as a cell factory to produce pigments such as chlorophyll *a*, zeaxanthin, canthaxathin, and astaxanthin [18], vitamins [45], protein [46] and polyunsaturated fatty acids, mainly EPA (C20:5n3) [47- 50]. It is commonly grew in fish hatcheries as a primary food for zooplankton production, such as rotifers and copeponds, which is then feed for rearing larvae of diverse species of mollusk, crustaceans, and fish [51]. Particularly, the broadly nutritional profile of *Nannochloropsis* is comprehensively summarized in Table 1 to 4, representing a potential live and formulated feed source for aquaculture.

#### **Table 4. Fatty acids composition of lipids from** *Nannochloropsis* **(expressed as weight percentage of total fatty acids)**

<sup>a</sup>Data obtained for *Nannochloropsis* sp. grew under irradiance level of 35 and 290 μmol E/m<sup>2</sup>/s, respectively.

<sup>b</sup>Data obtained for *Nannochloropsis* sp. grew at dilution rate of 0.2-0.92 (1/day)

<sup>c</sup>Data obtained in semi-continuous cultures maintained with daily renewable rate of 40% of the volume of the cultures ND: Not detected.

For the live feed, *Nannochloropsis* sp. was cultured in 1200 L plant made of ten 50 cm annular reactors with combined illumination to produce 270 g dry biomass annually. The concentrated algal suspension  $(50 \text{ g/L})$  was successfully used by fish hatcheries as a live feed for rotifers and rearing seabream larvae with the green-water techniques [11]. Biomass of *Nannochloropsis* sp. rich in EPA was produced in a flat plate (10 cm light-path), vertical reactor made of 10 mm glass plates glues together to form 500 to 1000 L reaching the optimal cell density of  $6\times10^8$  cells/mL (12 g DCW/m<sup>2</sup>/day and 650 mg EPA/m<sup>2</sup>/day) for aquaculture [52]. To produce sufficient the algal biomass for production of rotifer quantity required by seabream hatchery producing 8×10<sup>6</sup> fingerlings annually, production of *Nannochloropsis* sp. was scaled up in 2000 L reactor to harvest 175 kg dry biomass per year [52]. Semicontinuous cultivation of *N. gaditana* for live feed production for the rotifer *Brachionus plicatilis* enrichment was investigated [53]. It was figured out that selection of the appropriate culture conditions is crucial for the production of microalgae having high biomass and nutritive profile for rotifer enrichment, because only microalgal cultures subjected to high growth rates and nutrient availability are suitable to improve the biochemical composition of rotifers, as indicated by very high positive correlations between the contents of EPA and  $\omega$ -3 fatty acids in *N. gaditana* and *B. plicatilis* in the short time of exposure periods 24 h [53]. Marine *Nannochloropsis* is commonly cultured due to their high growth rate and proportion of polysaturated fatty acids (particularly EPA). However, freshwater species such as *N. limnetica* also owns a potential for rotifer nutrition. Recent study described that *N. limnetica* grew well in the range of  $15{\text -}27^{\circ}\text{C}$  and reached maximum biomass productivity of 0.64  $g/L/d$ ay at  $22^{\circ}$ C, while its fatty acid profiles was found to be similar to that of well-known marine species *N. gaditana* [54]. Interestingly, growth and egg-ratio of the rotifer *B. plicatilis* cultured with *N. limnetica* in laboratorial scale experiments were two-fold higher than that when cultured with the same concentrations of *N. gaditana*, while fatty acids profile in the algae-rotifers mixture was similarly maintained [54]. Moreover, hatchery-scale experiments within five days indicated that *B. plicatilis* fed with baker's yeast supplemented with either on-site produced fresh microalgal cultures or with concentrated algae achieved similar growth rate with both *N. limnetica* and *N. gaditana*, but obtained higher dry weight and slightly better

egg ratio with the freshwater species [54]. This implies that *N. limnetica* can be a potential substitute of the freshwater *Chlorella* and marine *N. gaditana* in live feed production. Another study used *N. limnetica* for fatty acids production carried out by Krienitz et al. [47] pointed out that with a high content of phosphate  $(40 \text{ mg/L K}_2)$  in the culture medium under non-aerated suspension culture, *N. limnetica* can accumulate 22.19 mg/g DCW linoleic acid, 10.52 mg/g DCW arachidonic acid (ARA), and 55.56 mg/g DCW eicosapentaenoic acid (EPA), which were ten-fold higher than in the other picoplankton *Choricystis minor* and *Pseudodictyosphaerium jurisii*, and higher than in the nanoplanktonic green algae *Chlorella vulgaris*, *Monoraphidium neglectum* and *Scenedesmus obtusiusculus* indicating a high-quality food resource in fresh food chains [47]. Culturing large volumes of single microalgal for rotifer cultivation is heavy burden on hatcheries. Therefore, effect of the combination feeding of both high density of *N. oculata* (N) and condensed freshwater *Chlorella* (FC) on the fatty acid composition of L-type rotifer *B. plicatilis* (R) in a continuous culture system was performed [55]. It was pointed out that, the combination N+FC-feeding positively affected rotifer density when the culture was conducted at  $24^{\circ}$ C and  $25-27$  psu (salinity) in a 2000 mL bottle with 50% of water exchanged daily. Moreover, the fatty acid profile (e.g.,  $\Sigma$ n-6/ $\Sigma$ n-3 ratio, EPA and DPA content, and polar/non-polar lipids ratio) of the N+FC-R and FC-R grew in a continuous culture system was affected by both N and FC [55]. The artificial detritus (detritus) originated from macroalgae *Ulva pertusa*, *Undaria pinnatifida*, and *Chondrus ocellatus* were used as individual substitute diets or combination with *Nannochloropsis* for investigation of population growth and nutritional content (amino acid and fatty acid compositions) of *B. plicatilis* [56]. In terms of population growth, maximum population density, and population growth rate, macroalgal detritus are not as good as *Nannochloropsis,*  as they contain lower nutritional profile than *Nannochloropsis.* Interestingly, when the macroalgae-based detritus mixed with *Nannochloropsis*, the *B. plicatilis*'s populations maintained high levels and achieved higher maximum population densities as well as population growth rates [56]. Regarding to nutritional value of *B. plicatilis* fed with *U. pertusa* and *Nannochloropsis*, particularly, the amino acids, polyunsaturated fatty acids (PUFA), and docosahehaenoic acid (DHA), were recorded to be higher than those of other diets. Notably, DHA/EPA ratio in rotifers feed with *U. pertusa* and *Nannochloropsis* was reached 6.9 times higher than that fed with *Nannochloropsis* only. This indicates that *U. pertusa* can be partly substituted in the feed for enrichment of *B. plicatilis*, potentially reducing requirement of large volume of microalgae culture (e.g., *Nannochloropsis*, *Chlorella*, etc.) [56]. Concentrated algal paste of *Nannochloropsis* used for the production of *B. plicatilis* was studied by Pfeiffer and Ludwig [57]. Experimentally, rotifers were cultured in four translucent and low-density polyethylene tanks with a culture volume of 45 L of artificial seawater. The feed solution was a mixture of commercially available *Nannochloropsis* algal paste and artificial seawater. During a 21 days culture period, the rotifer population in each of four tanks was maintained between 500 and 1,500 rotifers/mL. A volume of 15 L was harvested when the rotifer count was 1,500 rotifers/mL or more. The results indicated that the simple and inexpensive use of a concentrated algal paste as a food source is suitable for the production of rotifers [57]. Very recently, fish growth hormone (GH) production in *N. ocutata* was studied by Chen et al. [58]. In the study, plasmid phr-YPGHs containing fish GH cDNA driven by a heat shock protein 79A promoter and a RUBISCO SSU 2 promoter was introduced into the protoplast of *N. ocutata* by electroporation. It was reported that four transgenic clones were screened and treated with heat shock for GH

production, which was determined as  $0.27$ -0.42  $\mu$ g/mL from 50 mL culture medium. The transgenic *N. oculata* was incubated with artemia for 6 h and fed to redtilapia larvae. Result revealed that the growth rate of larvae fed with artemia incubated with transgenic microalgae was greater than that of larvae feed with artemia inculated with nontransgenic microalgae with respective to weight gain (316% vs 104%) and body length (217% vs 146%). Moreover, the transgenic microalgae were existed stably at least until the  $50<sup>th</sup>$  generation. Therefore, engineering *N. oculata* can enable production of functional GHs for aquaculture [58].

For the form of solid feed, commercial aquaculture products produced from *Nannochloropsis* are presently available in the forms of chilled, frozen, condensed or freeze dried, which have been shown to support good rotifer growth [59-61].

As early mentioned, aquaculture industry is rapidly growing, therefore it needs stable supply of feed source of both quantity and quality for its future growth, particularly the DHA and EPA-rich feeds which have been long originated from fish oils. According to a recent report, approximate 70% fish oil is still utilized for current aquafeeds production [62]. However, the global supply of fish oils is limited, while other emerging  $\omega$ -3 markets are growing and competing with the traditional resource. DHA and EPA from microalgae are considered as a promising alternative which possess a highly potential to fulfill the global demand. However, current microalgae production technology is not yet to be economically feasible. A recent techno-economic analysis (TEA) of microalgae production implemented based on biological and technical parameters published in the literature under various scenarios indicated that, biological productivity, geographical locations and production technology are important factors which must need to be optimized to lower production cost [62]. Specifically, cost of EPA and DHA production was estimated to be the lowest for flat panel photobioreactors in locations with near sky conditions. Moreover, sensitivity analysis revealed that optimizing photosynthetic efficiency and doubling of the EPA and DHA yield could reduce the cost to 11.9 USD/kg total (EPA and DHA), which is a great potential for aquaculture feed formulation [62]. This is the targeting goals of coming researches on microalgae-based aquaculture feed production.

#### **3.2. Animal Feed Production from** *Nannochloropsis*

Microalgae have received much attention as a source of biomolecules and whole biomass for feed formulation. The application of microalgae biomass in poultry nutrition [70] and livestock [71] has been comprehensively reviewed. They are not only formulated into poultry diets as a DHA/EPA-rich source, but they can also be used as a source of protein, microelements, vitamin and antioxidants, and pigmentation agents for skin and egg yolks. The incorporation of microalgae biomass into poultry feed can have beneficial effects on meat and egg quality, i.e., increasing  $\omega$ -3 fatty acids and carotenoids, as well as enhancing performance indices and immune function of the poultry [70]. The use of whole algal biomass in animal feeds has been studied for over 50 years [72]. Initially, algae were cultured in ponds followed by sequential harvesting, drying and formulating/using as a protein source for animal diets. Recently, lipid-extracted microalgae biomass generated from biofuels production has been utilized to study as feed supplement for various animal diets, mainly originated from *Spirulina*, *Chlorella* [70], but also other lipids-rich strains such as diatom *Staurosira* sp. [73], *Schizochytrium* [74], and astaxanthin-rich algal meal *Haematococcus pluvalis* [75].

The early study on utilization of *Nannochloropsis* as a supplement feed for rats was dated back to 1992, when chemical composition, nutritional and toxilogical evaluation of *Nannochloropsis* sp. was determined [76]. Data revealed that, the algal biomass produced in an outdoor photobioreactor (diameter  $= 4$  cm, volume  $= 64$  L) enriched with seawater medium, consisted of 40 wt% protein, 25.5 wt% lipids, 5 wt% crude fiber, 11.5% nonnitrogen extract, and 10% ash. The main fatty acids found in total lipids of the algal biomass were palmitic (23 wt%), palmitoleic (24.5 wt%), and eicosapentaenoic (23 wt%), while the minerals content presented an absence of bioconcentration of toxic elements. The whole nutritive value (fiber, protein, lipids, minerals and energy composition) of *N. oculata* has been examined to evaluate its potential as a source of animal feed like steam-flaked maize and soybean oil meal [77]. Results after evaluating the feeds and *N. oculata* showed variations in the protein content as well as amino acid contents, however such variations can be adjusted during formulation of feeds for animal. This study confirmed the promising potential of *N. oculata* as an ingredient in animal feeds [77]. Moreover, safely assessment of *N. oculata* carried out on male and female Sprague-Dawley rats administered a 0 or 10 mL *N. oculata*/kg rat  $(10^8 \text{ viable cells/mL})$  suspension by oral gavage once daily for 14 consecutive days indicated no mortalities occurred and no signs of toxicity were observed during the study, confirming that the algal strain used in the production of omega-3 oil is not pathogenic when administered orally to rats [78].

Bruneel et al. [79] reported an increased content of DHA in egg yolks of hens fed a diet containing *N. gaditana* and suggested that this algae may be used as an alternative to current sources of ω-3 for the production of DHA-enriched eggs. Lemahieu et al. [80] compared the efficacy of four different algae species (*Phaeodactylum tricornutum*, *Nannochloropsis oculata*, *Isochrysis galbana* and *Chlorella fusca*) on the enrichment of egg yolks in ω-3. They reported that the highest enrichment with ω-3 as well as increased yolk color was achieved with supplementation using *Phaeodactylum* or *Isochrysis*, and these two microalgae could be used as an alternative to current sources for the enrichment of eggs. A study carried out to evaluate three microalgae (*Nannochloropsis oceanica*, *Phaeodactylum tricornutum* and *Isochrysis galbana*) as potential nutrient sources in diets for monogastric animals by Skrede et al. [81] reported that there was a significant linear reduction in crude protein (CP) digestibility with increasing dietary inclusion of all algae products at 60, 120 and 240 g/kg as is, replacing fish meal (*N. oceanica* and *P. tricornutum* had similar crude protein (CP) content (47.7 and 49.0% of DM, respectively), amino acid composition and lipid content (8.4 and 7.4%, respectively), whereas *I. galbana* contained 20.1% CP and 16.2% lipids). The apparent CP digestibility determined by linear regression for *N. oceanica, P. tricornutum* and *I. galbana* was 35.5, 79.9 and 18.8%, respectively. The individual amino acid digestibility showed acceptable values for *P. tricornutum*, but low and highly variable values for *N. oceanica* and *I. galbana*. Although the algae contributed a minor proportion of dietary lipids, lipid digestibility declined with increasing inclusion of all algae and especially with the highest level of *N. oceanica*. It was concluded from the mink study that among the investigated algae, *P. tricornutum* was the preferable source of digestible nutrients [81].

# **4. HIGH VALUE PRODUCTS PRODUCTION FROM** *NANNOCHLOROPSIS*

#### **4.1. Production of Eicosapentaenoic Acid (EPA) from** *Nannochloropsis*

*Nannochloropsis* sp. is well known to accumulate high content of eicosapentaenoic acid (EPA) (around 2-5% DCW) [82, 83], therefore large scale autotrophic outdoor cultivation of *Nannochloropsis* sp. in tubular photobioreactors [84-86] and flat panel photobioreactors [87] for EPA production has been widely investigated. Several techniques have been developed and applied for extraction of EPA including ultrasound-assisted extraction [88], hydrothermal-acid treatment [89], solvent extraction [90], and pressurized fluid extraction [91].

The using of ultrasound is to disrupt cell wall of the microalgal to make lipids body and fatty acids to be readily accessible to extracting solvent. It was reported that recovery of EPA was significantly influenced by extraction temperature and time, whereas hexane to biomass ratio (v/w) was not statistically important variable for EPA yield [88]. The optimal conditions established for extraction temperature, reaction time and solvent to biomass ratio were  $27.6$ °C, 34 min, and  $21:3$  (mL/mg), respectively, at which the EPA yield and content in total fatty acids reached 62.8% and 16.25%, respectively [88]. Supercritical carbon dioxide (SC-CO2) is regarded as safer and more environmental friendly than hexane-based extraction because the process uses  $CO<sub>2</sub>$  as a solvent, short extraction time and low temperature, and giving high quality final product. Andrich et al.  $[92]$  applied SC-CO<sub>2</sub> for bioactive lipids extraction from *Nannochloropsis* sp. at temperature and pressure of 40-55 °C and 10-77 MPa, respectively, resulted in 39.3-44% DCW total lipids containing 29.4-33 wt% EPA in 6 h extraction and  $CO<sub>2</sub>$  flow rate of 10 kg/h. Pressurized fluid extraction (PFE, trades as "Accelerated Solvent Extraction," ASE®) was considered as an efficient solvent extraction methodology because it employs elevated temperatures and high pressure to accelerate penetration of solvent into biological matrix, while dissolving interested compounds. This is particularly beneficial when microalgae having highly-rigid cell walls are utilized as extraction substrates. ASE is a promising alternative to supercritical  $CO<sub>2</sub>$  extraction (SC-CO2). Pieber et al. [91] used ASE for EPA extraction from N. oculata using alternative solvents including hexane, hexane/propan-2-ol  $(2:1, v/v)$  and ethanol (96 vol.%). Results revealed that the highest extraction yield of total lipids, total fatty acids, and EPA obtained from ASE with ethanolic solvent were 36%, 16.7%, and 3.7%, respectively. This indicated that EPA production from N. oculata and extraction with ethanol via ASE is economically beneficial because ethanol is generally recognized as safe (GRAS) solvent, which can be completely removed without toxic effect on EPA nutrition ingredient. Furthermore, ethanol liberated with residual biomass after the extraction can be also completely removed without effect on protein quality of the leftover, which can be utilized for other applications (animal feed, aquaculture) with respect to biorefinery [91]. Recently, hydrothermal acid pretreatment of microalgae biomass for lipids extraction was intensively studied. Acids such as sulfuric acid, hydrochloric acid, and nitric acid are highly active and efficient in disruption of microalgal cells and hydrolysis of algal cells wall containing cellulose and make lipids and fatty acids in algal biomass to be accessible to extracting solvents. The optimal conditions for hydrothermal acid treatment of wet *N. salina* and EPA extraction were identified using statistical technique (response surface methodology, RSM) [89]. It was reported that maximum EPA yield of  $43.93$  mg/g DCW was obtained with 1.27% of sulfuric acid, 113.34 $\degree$ C of temperature and 36.71 min of reaction time, when using hexane (96 vol.%) for 1 h extraction. The study pointed out that the acid treatment can be indeed a noteworthy alternative for EPA extraction [89].

#### **4.2. Production of Pigments from** *Nannochloropsis*

Pigment composition was reported to vary among six strains of *Nannochloropsis*. Ketocarotenoids astaxanthin and canthaxanthin was accumulated in higher concentration in *N. salina* and *N. gaditana* than in other strains [18]. Zeaxanthin content in *N. gaditana* could increase up to 100% when culture salinity experimented in the range of 15-100 practical units. In culture with cell density of 109 cells/mL, pigment production reached: 350 mg/L for chlorophyll *a*, 50 mg/L for violaxanthin, 5 mg/L for canthanxanthin, and 3 mg/L for astaxanthin. Total canthaxanthin and astaxanthin in *N. gaditana* can reach 0.7% dry cell weight [18]. Moreover, the highest accumulation of beta-carotene was observed in *N. salina* among six microalgae including *Phaeodactylum* sp. (Bacillariophyceae), *Nannochloropsis* sp. (Eustigmatophyceae), *Chlorella* sp., *Dunaniella* sp., and *Desmodesmus* sp. (Chlorophyta) when they were grown on municipal wastewater [93]. The availability of diverse pigments including chlorophyll *a*, zeaxanthin, canthaxanthin and astaxanthin, each with high production levels indicating that *Nannochloropsis* is a source of valuable pigments.

# **5. BIOFUELS PRODUCTION FROM** *NANNOCHLOROPSIS*

#### **5.1. Biodiesel Production from** *Nannochloropsis*

Since *Nannochloropsis* contains high lipids content, the biomass has been widely used as an interested feedstock for biodiesel production study [94, 95]. Conventionally, lipids of *Nannochloropsis* can be primarily extracted before subsequent conversion to biodiesel with alcohols using chemical homogeneous and heterogeneous catalysts, biocatalyst, and supercritical conditions. However, due to its high cost, direct conversion of oil-rich *Nannochloropsis* biomass with alcohols to biodiesel were investigated extensively. A recent application of *Nannochloropsis* biomass for biodiesel production is summarized in Table 5.

#### **5.2. Biodiesel Production from** *Nannochloropsis* **via Chemical Heterogeneous Catalysis**

Typically, Umdu et al. [96] described fatty acid methyl esters (FAME, biodiesel) synthesis from *N. oculata*-extracted lipid over solid base catalysts  $(CaO/AI<sub>2</sub>O<sub>3</sub>$  and  $MgO/Al_2O_3$ ) at 50°C. It was found that single CaO and MgO metal oxide powder did not show any activity, while  $CaO/Al<sub>2</sub>O<sub>3</sub>$  binary synthesized powder (80 wt% CaO loading) was the highest active catalyst, which resulted in 97.5% biodiesel yield when methanol to oil molar ratio applied of 30:1 combined with catalyst loading of 2 wt% (based on oil weight),

# **Table 5. Conversion of oil-rich** *Nannochloropsis* **biomass to biodiesel**

MeOH, Methanol; EtOH, Ethanol; FFA, Free fatty acids; Temp., Temperature; SL, Saponifiable lipids; Ref., Reference.

stirring rate of 1100 rpm and reaction time of 4 h (Table 5). Lipids extracted from *N. gaditana* with methanol and stirring under reflux was employed for biodiesel production using synthesized hierarchical zeolites (ZSM-5, h-ZSM-5, Beta, and h-Beta) as heterogeneous catalysts [97]. It was reported that hierarchical h-Beta zeolite catalyst showed the highest activity in the transesterification of *N. gaditana*'s oil with methanol, which gave biodiesel as high as 25% under the reaction conditions of methanol to oil molar ratio of 100:1, catalyst loading of 2 wt% (oil + methanol), temperature of 115 $\degree$ C, stirring rate of 1100 rpm, and reaction time of 4 h (Table 5). Lipids extracted from *N. salina* refined with  $1\%$  (v/v) phosphoric acid (chlorophyll removal), followed by refluxed with KOH 1M and acidified with sulfuric acid to obtain free fatty acids (FFA), which was then utilized as a substrate for selective esterification with methanol over heterogeneous HZSM-5 catalyst for simultaneous biodiesel production and polyunsaturated fatty acids (PUFA) enrichment [98]. Results indicated that the zeolite catalyst preferentially converted shorter-chain fatty acids (SCFA) into fatty acid methyl esters (FAME) achieving 65% conversion and enriched high-value PUFA 78% in the unreacted free fatty acids (FFA) stream ([98], Table 5).

Microwave and ultrasound are alternatively physical means to assist cell rapture during direct biodiesel conversion from *Nannochloropsis* biomass [99]. It was reported that microwave oven method appeared to be the most simple and efficient technique among two applied processes for single-stage direct transesterification of *Nannochloropsis* with chloroform/methanol  $(2/1, v/v)$  catalyzed by base SrO solid catalyst (30 wt% DCW) at 50- $60^{\circ}$ C. Biodiesel yield obtained by microwave oven and ultrasound reached 40 wt% and 20 wt% based on dry biomass, respectively [99].

# **5.3. Biodiesel Production from** *Nannochloropsis* **via Chemical Homogeneous Catalysis**

Saponifiable lipids (SLs) (with SL purity of 71% and low polyunsaturated fatty acids of 16.9 wt%) were derived from *N. gaditana* biomass (86% water) using homogenization at 1700 bar and low temperature of  $20-22$ <sup>o</sup>C [100]. The crude SLs was then used for biodiesel conversion via H<sub>2</sub>SO<sub>4</sub>-catalyzed transesterification with methanol at  $60\text{-}80\text{-}C$  during 2-4 h reaction. Data indicated that FAME conversion reached 95-97% using methanol/SL ratio of 12-20 mL/g and H2SO4/SL ratio of 0.22 g/g ([100], Table 5). Wet paste of *Nannochloropsis* sp. (75% water) was employed for lipids extraction using high pressure extractor under extractive conditions of 1.5 MPa,  $120^{\circ}$ C, and 50 min to obtain crude oils containing acid value of 6.5 mg KOH/g [101]. The crude oil was used for biodiesel production via two-step sequential catalytic process, which consisted of H<sub>2</sub>SO<sub>4</sub>-catalyzed-preesterification followed by KOH-catalyzed transesterification with methanol. The optimal conditions for biodiesel yield of 70.4% at the same reaction temperate of 65 $^{\circ}$ C were 30% methanol, 1% H<sub>2</sub>SO<sub>4</sub>, and 2 h reaction (for pre-esterification) and methanol to oil molar ratio of 12:1, KOH loading of 2%, and reaction time of 30 min (for the transesterification) ([101], Table 5). Recently, Hita Peña et al. [102] developed a five-steps process producing biodiesel from saponifiable lipids (SLs) extracted from wet *Nannochloropsis gaditana* biomass. Firstly, wet biomass containing fatty acids was transformed to potassium fatty acid salts using KOH/ethanol (96%) at  $60^{\circ}$ C for 1 h. Secondly, water was supplied to the fatty acid salt to make a solution with  $30\%$  (w/w) water, which was then mixed with hexane (1:1, v/v) at  $20^{\circ}$ C for extraction of unsaponifiable

lipids (hexane phase). Thirdly, ethanol phase containing fatty acids was acidified to  $pH = 5$ with HCl 37 wt% and subsequently supplied with hexane at volume ratio of 1:1  $(v/v)$ (hexane/ethanol-water) for fatty acid extraction (hexane phase). Fourthly, the extracted fatty acids were converted to fatty acid methyl esters (FAME) via methylated esterification catalyzed by 1.8 wt%  $H_2SO_4$  (based on FA weight) at 60 $^{\circ}$ C, 200 rpm, 2 h with molar ratio of methanol to FA of 10:1, resulted in biodiesel yield and purity of 82 wt% and 74.8 wt%, respectively. The crude biodiesel was further purified with bentonite (bentonite/crude biodiesel ratio 2:1 w/w) at 40 $\degree$ C for 24 h to achieve FAME purity of 96.5% [102].

Direct conversion of algal biomass to biodiesel is a promising process as it can lower total cost of biodiesel production. Kim et al.  $[103]$  used  $H_2SO_4$  as homogeneous catalyst for simultaneous disruption of *Nannochloropsis salina* cell (wet paste) and catalysis of transesterification of the algal lipids with alcohols (methanol and ethanol) to fatty acid methyl (and ethyl) esters [103]. It was described that biodiesel yield reached over 90% at  $105^{\circ}$ C with 2.5-5%  $H_2SO_4$  (v/v in alcohol) in 30 min reaction for 200 mg biomass used. Moreover, the pre-determined reaction conditions were found to work well with biomass scale up to 100 g, which resulted in over 100% conversion of biodiesel presenting highly potential for large scale application ([103], Table 5). To maximize value of biodiesel production, Im et al. [104] recently developed and reported a protocol for concurrent production of biodiesel and chemicals (ethyl levulinate (EL), ethyl formate (EF), diethyl ether (DEE)) via wet in *situ* transesterification of *N. gaditana* with ethanol in chloroform and catalyzed by H2SO4. It was evaluated that EL, EF, and DEE were significantly generated up to 23.1%, 10.3%, and 52.1%, respectively, of the fatty acid ethyl esters (FAEE) with the FAEE yield reached over 90% at  $125^{\circ}$ C [104]. The formation of EL, EF, and DEE is attributed to the hydrolysis of algal cell wall (contains cellulose) by acid, leading to generation of reducing sugars and lactic acid (LA) and formic acid (FA) in presence of ethanol. In turn, LA and FA become precursors for esterification reaction to generate EL and EF in excess ethanol [104]. This is a promising ideal for newly establishment of biorefinery of microalgae biomass for biofuels and chemical production. Using homogeneous acid catalysts (e.g., H2SO4, HCl, etc.) in conversion of lipids-rich algal biomass with alcohols can directly produce fatty acid alkyl esters via simultaneous transesterification and esterification. In contrast, catalysis of algal lipids with alcohols by alkaline (e.g., KOH, NaOH, etc.) generates soap because algal lipids contain certain amount of free fatty acids. Therefore, in order to obtain biodiesel, the soap should be precipitated by a common inorganic salt to form a precipitation which is then can be separated by filtration for further reaction to produce biodiesel when acid catalysts are employed. A recent study carried out by Binnal and Babu [105] reported that, direct saponification of wet paste of *N. oculata* (80 wt % moisture) harvested at the end of the exponential phase was subjected to direct saponification in a low-cost microwave reactor using ethanolic KOH as a alkaline catalyst to convert the algal lipids to soap. The soap floated as an upper layer was precipitated and separated from other unsaponifiable matters by saturated KCl and subjected to simultaneous acidulation and esterification with methanol catalyzed by  $H_2SO_4$  to form biodiesel of high purity (97.04% FAME in final biodiesel). Optimum parameters of esterification of fatty acids in microwave reactor were: microwave power of 450 W, molar ratio of methanol to fatty acids of 80:1, concentration of sulphuric acid of 2.5 wt %, reaction time of 11 min and reaction temperature of 60°C, under which the final biodiesel yield of 97.11% and reaction rate constant of esterification of 0.452 min−<sup>1</sup>

were achieved. Moreover, Cetane number and oxidation stability index of biodiesel were evaluated as 59.349 and 3.298 h, respectively [105].

#### **5.4. Biodiesel Production from** *Nannochloropsis* **via Enzymatic Catalysis**

Biocatalyst (enzyme) owns a promising capability to catalyze esterification and transesterification of algal lipids (containing free fatty acids) with alcohols to biodiesel because of its high activity, low reaction temperature, and greener than chemical catalysts. The main disadvantage of the biocatalysis is costly due to high cost of biocatalyst production. However, application of biocatalyst for biodiesel production from microalgae lipids have been widely documented in the literature. Navarro Lopez et al. [106] recently used wet paste of *N. gaditana* for saponifiable lipids (SLs) extraction and subsequently conversion to biodiesel by lipase-catalyzed transesterification using a commercial enzyme Novozym 435. Results revealed that lipids extracted by ethanol (96%)-hexane had 31% SLs, which was then increased up to 95% after degumming with cold acetone at  $4^{\circ}$ C. The transesterification of the SLs were performed at  $40^{\circ}$ C using 0.225 g biocatalyst/g SL in 10 mL *t*-butanol/g SLs as solvent, and 11:1 methanol to SL molar ratio as acyl acceptor for three step addition of alcohol, to result in 94.7% biodiesel yield (Table 5). This best conversion was reported to decrease to 9.8% after three cycles of reusability of the biocatalyst [106]. On the other hand, the optimal transesterification conditions for the SLs conversion to biodiesel with the highest yield of 83% when using *Rhizopus oryzae* intracellular lipase as biocatalyst were methanol to SLs molar ratio of 11:1, biocatalyst loading of 70 wt% SLs, 10 mL *t*-butanol/g SLs, temperature of 35°C, and reaction time of 72 hr [107]. Although biodiesel yield achieved by *Rhizopus oryzae* lipase was lower than that with Novozym 435, the FAME conversion was remained as high as 71% of initial conversion after three cycles of reusability, indicating that *Rhizopus oryzae* lipase had higher durability than Novozym 435 [106].

#### **5.5. Biodiesel Production from** *Nannochloropsis* **via Supercritical CO<sup>2</sup>**

Supercritical CO<sup>2</sup> was employed to catalyze transesterification of lipids-rich *N. oculata* biomass with methanol and extract FAME at low temperature (37 and  $55^{\circ}$ C) and pressure (5.9 and 7.6 MPa) [108]. The presence of FAME peaks in methanolic extracts indicated that extraction and transesterification is achievable in a single step process with  $SCCO<sub>2</sub>$  using methanol as acyl acceptor. In term of energy consumption, it seems that, this data was superior to results of previous study that was reported by Patil et al. [109] conducting reactions at the harsh conditions (high temperature  $(255^{\circ}C)$  and pressure (1200 psi)) on a wet *Nannochloropsis* sp. paste (90% water), however, further investigation should be carried out (e.g., measuring biodiesel yield, biodiesel productivity and biodiesel purity) in order to fully evaluate the efficiency of two conversion processes. Although FAME can be simultaneously converted and extracted to a certain level under low supercritical conditions, the quality FAME product may not be satisfy. This is because FAME utilized for purification to reach fuel grade biodiesel requires purity of over 95 wt% which is usually obtained under a high temperature and pressure supercritical technology to achieve a high FAME yield.

#### **5.6. BioH<sup>2</sup> Production from** *Nannochloropsis*

Hydrogen is a green fuel (zero-emission fuel) because combustion of  $H_2$  generates  $H_2O$ only and releases energy, which is completely unharmful for the environment. Production of hydrogen via fermentation of sugars derived from biomass (i.e., lignocelluloses, algae, etc.) is considered as an alternative route over the conventional hydrogen-producing processes such as water electrolysis and steam reforming because of its high sustainability [110]. Microalgae biomass is a promising feedstock for  $\text{bioH}_2$  production due to fast growing, high carbohydrate content, and diverse distribution [31]. The main biochemical compositions of *Nannochloropsis* species used for biological fermentation are carbohydrates (20-38%) and proteins (10-43%), in which carbohydrates are assimilated as carbon sources, while proteins are utilized as nutrition for anaerobic bacteria [111, 112]. However, high molecular weight polymers such as carbohydrates and proteins are not ready to be utilized by the hydrogenproducing bacteria. It requires a pretreatment step to degrade these polymers to reducing saccharides and amino acids, which are easily metabolized by the bacteria for hydrogen production. In a recent study, Xia et al. [113] reported a microwave-assisted pretreatment of acidic *N. oceanica* biomass for sugars and amino acids generation before utilization for bioH<sup>2</sup> production via three-stage process of dark fermentation (at  $30^{\circ}$ C), photofermentation (at 30<sup>o</sup>C), and methanogenesis (at 35<sup>o</sup>C) with *Clostridium butyricum*, *Rhodopseudomonas palustris*, and *Methanosarcina* and *Methanothrix*, respectively. The optimal conditions of the microwave-assisted pretreatment obtained for sugars production were temperature of  $140^{\circ}$ C, reaction time of 15 min, 1% (v/v)  $H_2SO_4$  of catalyst loading, and 50 g/L biomass loading, which achieved a sugars and amino acids concentration of 4.8  $g/L$  and 0.87  $g/L$ , respectively, that was much higher than that in raw algal biomass [113]. The thermodynamic analysis for dark fermentation between amino acids and reducing sugars from *N. oceanica* hydrolysate revealed that the total utilization efficiencies of amino acids and reducing sugars were equivalent to 95%. However, the consumption time of the reducing sugars is two times faster than that of amino acids. In three-stage process on utilization of sugars- and amino acids-rich *N. oceanica* hydrolysate, the maximum hydrogen and methane yields were estimated as 183.9 ml/g-total volatile solids (TVS) and 161.3 ml/g-TVS, respectively. Furthermore, the total energy yield of hydrogen and methane produced from *N. oceanica* via the developed method (three-stage) was respectively 1.7 and 1.3 times higher than those via two-stage (dark fermentation and methanogenesis) and single-stage (methanogenesis) methods [113]. More recently, biomass of *Nannochloropsis* sp. strain was firstly used for lipids and pigments extraction via supercritical  $CO<sub>2</sub>$ , subsequently followed by the utilization of the leftover as carbohydrates-rich feedstock for bio $H_2$  production via dark fermentation [114]. It was reported that under the supercritical conditions of 40 $\degree$ C, 300 bar, and CO<sub>2</sub> flow rate of 0.62 g/min, 33 g lipids can be recovered from 100 g dry biomass. Moreover, supplement of 20 wt% ethanol with  $CO<sub>2</sub>$  as co-solvent resulted in lipids recovery of 45 g/100 g dry biomass and recovered 70% pigments. The residual biomass obtained after the supercritical extraction was employed for dark fermentation with *Enterobacter aerogenes* resulting in a hydrogen production yield of 60.6 mL/g dry biomass [114]. This experiment was used as a biorefinery template for energy and  $CO<sub>2</sub>$  emission and economic analysis toward evaluation of the potential of microalgae as energy sources for biofuel production. The energy consumption, economic assessment, as well as  $CO<sub>2</sub>$  emission from whole refining process including *Nannochloropsis* sp. cultivation, harvesting, dewatering, milling (pretreatment), extraction

(using soxhlet extraction (SE) and supercritical fluid extraction (SFE)), and fermentation of residual for bioH<sup>2</sup> production were simultaneously evaluated. It was reported that the oil production pathway by SE showed the lowest value of energy consumption and  $CO<sub>2</sub>$ emissions, which were estimated as  $177-245$  MJ/MJ(prod) and  $13-15$  kg  $CO<sub>2</sub>/MJ(prod)$ , respectively. Although the SFE consumed and emitted c.a. 20% more than the SE pathway, production of oil via SFE proved to be more economically viable, with a cost of 365  $\epsilon$ /kg oil produced, while simultaneously recovering of high-value pigments. The bio $H_2$  as co-product may be advantageous in terms of product yield or profit [115].

# **6. COSMECEUTICALS PRODUCTION FROM** *NANNOCHLOROPSIS*

Cosmeceutical originated from cosmetics and pharmaceutical is the term that was coined by the dermatologist Albert Kligman since 1980 [116, 117]. Cosmeceuticals are cosmetics products having biologically active ingredients, which own medical or drug-like benefits by treating and preventing imperfections of the skin. Microalgae are a source of natural products including proteins, vitamins, polysaccharides, and minerals, which are potential applications for cosmeceuticals [118]. Metabolites produced from cyanobacterium under extreme conditions in hyper-arid habitats was reported to have high water retention capacity and potentially to be used in cosmetic products as moisturizers [119]. The cyanobacterium also produce UV screening compounds such as mycosporine-like amino acids and scytonemin, which are good candidates as alternatives to current synthetic UV filters [119]. Benefits of microalgae in skin care are: (i) microalgae are a good source of  $\omega$ -3 fatty acids, which help reduce the appearance of fine lines and wrinkles, prevent dryness and fight skin problems like eczema and acne, (ii) algae regulate the production of sebum that is necessary for the skin to be moisturized and thereby prevent dehydration of the skin, (iii) algae offer antioxidant properties that avoid free radical damage which causes of skin aging. Moreover, algae help to fight free radicals and also help aid in the production of collagen and elastin, which are essential to having firmer skin, (iv) algae are loaded with essential minerals and vitamins that offer regenerative, protective and intense rejuvenating properties to prevent the aging process while also repairing skin damage.

*Spirulina* and *Chlorella* are the main species that are well established in skin care industry [120]. Recently, it was reported that tyrosinase activities were inhibited by the extract of several microalgae [121]. For the development of *Nannochloropsis*-based cosmetics, antityrosinase zeaxanthin from *N. oculata* has been recently examined [122-124]. In commercial market, many *N. oculata*-based skin care products have been launched. Typically, new products made from ingredients (polysaccharides, amino acids and vitamins, particularly vitamin C (an effective antioxidant) and vitamin B12) of *N. oculata* with excellent skin-tightening properties (short and long-term effects) (Pepha®-Tight) has been marketed by Pentapharm (Basel, Swizerland). NuFountain LLC (Colorado, USA) recently developed and launched C20 Vitamin C Serum for skin care which used purified *N. oculata* extract containing Vitamin C and B<sup>12</sup> as main ingredients. Algoid Technologies (Florida, USA) also developed and marketed a "Morning Rose Facial Elixir" for skin care made from 100% naturally-derived ingredients of live *N. oculata*, *I. galbana* (T-iso) and *T. chuii* plankton. AlgaeEnergy (Madrid, Spain) has developed diverse research and developments programs for

*Spirulina*, *C. vulgaris*, *T. suecica*, *I. galbana*, and *N. gaditana* strains in order to increase the value of cosmetic formulae. Their products will be launched in coming years. Solazyme (San Francisco, USA), an algae-based fuel startup company recently unveiled Algenist, a luxurious anti-aging cream skincare line that used compounds-originated microalgae as a main ingredient. The products are marketed to help visibly restore the skin resiliency and elasticity, delivering a firmer, tighter, more toned appearance. It also visibly strengthens the most fragile skin texture and softens facial contours, minimizing the appearance of fine lines and deep wrinkles to unveil skin's youthful radiance.

# **7. SOLID BIOFERTILIZERS PRODUCTION FROM** *NANNOCHLOROPSIS*

The use of chemical fertilizers is well known to have adverse effect on soil, plant, and the environment. To mitigate this issue, the interesting in organic farming has attracted considerable attention recently. Microalgae can accumulate high content of proteins, lipids, vitamins, and minerals under favorable conditions. Particularly, microalgae can be used as a biological agents to utilize nitrogen, phosphorous, and organic carbon source in wastewater for wastewater bioremediation purpose via photosynthesis using solar energy, while simultaneously producing biomass and generating oxygen, which is beneficial for the environment. Microalgae biomass can be directly introduced into soil inoculation to increase crop productivity, offering an alternative to vicious cycle of chemical fertilizers, soil deterioration, and dependency on imports. Moreover, algae fertilizers can also boost the profitability of wastewater treatment industry by generating additional income from fertilizer's sale. Although numerous studies have reported positive responses on using algal fertilizers for crop plants [125-129], the current development of algal fertilizers has not been well-established. The first study using blue-green microalgal *Tolypothrix tenuis* was observed to increase in rice yield in Japan [130]. Later, the increase in germination of rice seeds compared to control samples was also recorded when the rice seeds pretreated with cyanobacteria *Phormidium foveolrum* [131], which were silimar to observation of Tripathi et al. [132] and Saadatnia and Riahi [133]. The combination of *Aulosira fertilissima* (2.25 g) + *Spirulina platensis*  $(2.25 \text{ g})$  + diamonium phosphate (DAP)  $(0.5 \text{ g})$  was found to increase number of tomato fruits and productivity up to 522% and 977%, respectively [134]. Extract, culture medium, and whole biomass of microalgal strain *Acutodesmus dimorphus* was recorded to notably increase germination rate of seeds and improve growth and productivity of of Roma tomato [127]. More recently, *Spirulina plantensis* was used to treat aquacutlure wastewater containing nitrogen (mainly amonia and nitrate) and produce biomass, which was utilized as a organic fertilizer for study of seed germination and growth of several crop plants including *Arugula* (*Eruca sativa*), *Bayman Red Bayam Red* (*Ameranthus gangeticus*) và *Pak Choy* (*Brassica rapa* ssp*. Chinensis*) [128]. Data revealed that the pretreatment with the algal suspenstion culture remarkably increased germination rate of seeds of Chinese Cabbage (*B. rapa* ssp. *Chinensis*) and Kai Lan (*Brassica oleracea alboglabra*). Furthermore, the supplement of solid biomass with standard soild improved growth rate of Arugula (*Eruca sativa*), Bayman Red Bayam Red (*Ameranthus gangeticus*) and Pak Choy (*Brassica rapa* ssp. *Chinensis*). Interestingly, a recent study reported that extract and culture medium of several microalgae contain phytohormones (e.g., gibberellins, auxin, and cytokinin), which play an

important roles in plant developement [135]. Algal turf scrubbers (ATS) biomass produced via growing in N- and P-rich anaerobically digested dairy manure has been successfully employed as an organic slow-release fertilizer [136, 137]. The dried biomass was amended with potting mix as N- and P-slow release fertilizers to grow cucumber and corn deedlings, which presented equivalent growth rate (seedling dry weight and nutrient content) with comparable levels of chemical fertilizer-supplemented potting mixes. This suggested that dried ATS grew in wastewater can be a substitute for commericial fertilizers as a potting substrate for crop production [137]. The using of *Nannochloropsis* for wastewater treatment and  $CO<sub>2</sub>$  sequestration from flue gas to produce biomass for biofertilizers application was recently carried out by Coppens et al. [125]. Microalgal bacterial flocs (MaB-flocs) grew in a raceway pond treating aquaculture wastewater and *N. ocutala* phototrophically cultivated on a landfill site using  $CO<sub>2</sub>$  from flue gas were harvested and used to study their slow-release fertilizer potential for tomato cultivation in comparison with conventional inorganic and organic horticulture fertilizer systems [125]. It was reported that there was no significant difference in growth rate of the tomato inoculated in microalga and commercial organic fertilizers. Interestingly, although lower tomato yield was achieved, the microalgal fertilizer enhanced the fruit quality as it increased sugar and carotenoid content of the tomato fruit. However, further study is needed to determine the optimal fertilizer mixture that produce high quality of fruits with satisfactory yields. In term of economic point of view, optimization of the amendment ratio of conventional fertilizers with algal biomass produced from N- and Prich and cheap medium (wastewaters) could make microalgae-based fertilizers to be economically feasible [125].

# **8. MATERIALS PRODUCTION FROM** *NANNOCHLOROPSIS*

*Nannochloropsis* is a potential candidate for simultaneous CO<sub>2</sub> sequestration and lipid production [138, 139]. Therefore, it is tremendously promising to use *Nannochloropsis* to convert  $CO<sub>2</sub>$  from industrial flue gas as a cheap feedstock for biomaterial production, while mitigating  $CO<sub>2</sub>$  release, which is mainly responsible for the global warming cause [140]. However, one  $CO<sub>2</sub>$  is captured and transformed to macromolecules (lipids, carbohydrates, proteins) in the microalgal biomass, the sustainable utilization of the biomass should be taken into account. This is because, algae biomass can be degraded and re-transformed to  $CO<sub>2</sub>$  and CH4, which are then released back to the atmosphere, if it is not captured permanently [141]. Conversion of algae into useful polymeric materials can be easily accomplished by a simply extrusion technology. A determined proportion of algae biomass i.e., 20% can be formulated with matrices originated from non-biodegradable polymers such as polyolefin, which is highly resistant to abiotic or biotic degradation [142]. Interestingly, one algae biomass is incorporated into polymeric matrices, it is long stored in a form of material and will not be fastly decomposed to release CO2. Shi et al. [142] recently blended *Nannochloropsis* biomass with starch to form a formulated filler for composite fabrication with commercial polypropylene (Polypropylene Pro-fax® SV954 (PP)), glycerin, mono-di-glycerin as matrix, plasticizer, and surfactant, respectively. Although polymeric material fabricated by 80% PP and 20% algal/starch (70/30, w/w) exhibited lower mechanical strength than the neat PP

([142] and Table 6), these properties are acceptable for a number of industrial applications such as packaging, personal care products, agriculture film, container, building materials, etc.

*Nannochloropsis* offers excellent nutrient composition with a substantial amount of PUFAs, a broad spectrum of vitamins (especially  $B_{12}$  and E), and contains all essential amino acids and polysaccharides, hence, using whole *Nannochloropsis* for composite production, which is considered as a low value material, may not be applicable. However, lipids-rich *Nannochloropsis* can be converted to biodiesel via in situ transesterification, while generating residual microalgae biomass (RMB) as a byproduct of biodiesel production for biocomposites formulation instead of whole biomass [143]. Torres et al. [143] reported that RMB of *Nannochloropsis* can be formulated with biodegradable polymer poly(butylene adipate-coterephthalate) (PBAT) at proportion of 10, 20, and 30% with supplement of glycerol and urea as plasticizers. The best extruded formulation was a compound of 70% RMB, 30% of glycerol, 10 phr of water, and 7.5 phr of urea before employed for biocomposite fabrication with 80% PBAT, which resulted in improvement of mechanical properties of PBAT/RMB (80/20) (Table 6). The synthesized composite can be used for mulching film in agricultural industry without threatening the environment because it is biodegradable. The study provides an alternative way to produce biodiesel from *Nannochloropsis*, while simultaneously generating co-product (biocomposite). More recently, we developed a solution casting protocol for fabrication of biocomposite from lipid-extracted *Nannochloropsis salina* biomass (LEA) with poly(vinyl alcohol) (PVA) as a matrix [144]. Our result revealed that incorporation of LEA into PVA resulted in enhancement of thermal properties, but reduction in mechanical properties of PVA/LEA when compared to the neat PVA. Interestingly, addition of poly(diallyldimethylammonium chloride) (PD) as a plasticizer significantly improved mechanical properties of PVA/LEA/PD compared to PVA/LEA composites [144]. PVA was compounded with 20% LEA and 12% PD to synthesize the PVA68LEA20PD12 biocomposite (Table 6). In contrast to neat PVA, this biocomposite recorded the similar mechanical property but the enhanced thermal property. This type of biocomposite film can be applied in commercial industries as specialty materials, for instance, 3D printing material. This helps to improve the economic feasibility of microalgae-based biofuel production. Practically, the residual biomass after lipid extraction still contains high element content of carbon (41.82%), hydrogen (6.25%), nitrogen (5.63%), sulfur (3.94%) [144] which can be gasified to produce syngas for liquid fuels or methanol synthesis [145]. The leftover after gasification process is mineral ash which is rich in inorganic compounds such as  $SiO<sub>2</sub>$ ,  $SO<sub>3</sub>$ ,  $P_2O_5$ , CaO, etc. [146]. The ash is a potential filler for composite fabrication with PVA [146]. P**rior to** using it as a filler for composite fabrication with poly(vinyl alcohol), raw ash (RASH) was activated with NaOH and surface modified with (3-aminopropyl)triethoxysilane**.** Surface modification of activated ash (PASH) significantly improved interfacial interaction between surface-modified ash (GASH) and polymer matrix (Table 6). Higher ultimate tensile strength of PVA/GASH composites was recorded, compared with PVA/RASH and PVA/PASH. Young's modulus of biocomposites appeared to increase proportionally to loading of the fillers. Our preliminary results revealed that microalgae-derived ash can be potentially integrated to downstream processing of microalgal biorefinery, while reducing the total operating cost of microalgal-based facility via production of value-added byproduct ashes.

into biocomposite materials).

# **9. CHALLENGES AND FUTURE PERSPECTIVES OF** *NANNOCHLOROPSIS* **FOR BIOREFINERY**

*Nannochloropsis* presents a unique potential with respect to the biorefinery. The strain comprises of cellular compounds which can promisingly be valorized into multiple products, positioning small or large end markets. In order to valorize all constituents of the *Nannochloropsis* biomass, it is necessary to develop economically feasible production process. Since the composition and amount of residual biomass can vary significantly depending on cell stoichiometry and cultivation techniques, therefore, it requires appropriate biorefinery side-process strategies to be adapted to production of the primary product. Based upon biochemical processes which were presented in the above sections, production scenarios for biorefinery from *Nannochloropsis* can be developed based on four differently typical products which have different market volumes, including high- and medium- value products (e.g., pigments, EPA, neutraceuticals), whole biomass (e.g., aquaculture and animal feeds) and biofuels (e.g., biodiesel, bio-jet fuels). The biorefinery of *Nannochloropsis* can be principally presented in Table 7.

Scenario 1: Simultaneous production of high-value products and utilization of residual biomass (RB). The main ideal of this scenario is to use RB from production of high-value products. One high-value products (pigments such as astaxanthin with commercial price of over 1000 US\$/kg) are extracted from *Nannochloropsis* biomass, the RB containing carbohydrates and protein can be used to produce ethanol or biogas (via fermentation), aquaculture and animal feeds, fertilizers, biocomposite materials, and biocrudes (via hydrothermal process). Integrating production of products from RB will increase additionally economic benefits for the high-value products-based biorefinery that may facilitate to reduce the price of the high value products. Nitrogen and phosphorous released into liquid phase via extraction and hydrothermal treatment can be recycled as nutrients for *Nannochloropsis* cultivation.

Scenario 2: Combined utilization of medium-value bulk products from *Nannochloropsis*. This biorefinery focuses on production of commodity chemicals with large market volume and price ranging from few US\$/kg to 100 US\$/kg that are important segment of entire products portfolio of microalgae-based industry. Bulk chemicals produced from *Nannochloropsis* could be based on three main components including lipids, carbohydrates, and proteins. This biorefinery (e.g., lipids extraction) usually generates large amount of RB, therefore study on utilization of RB (fertilizers, materials, etc.) is very important for economic optimization of the process. Nitrogen and phosphorous released into liquid phase via extraction, hydrothermal treatment can be recycled as nutrients for *Nannochloropsis* cultivation.

Scenario 3: Utilization of whole cell for food and feed: Raw *Nannochloropsis* biomass (live culture or wet paste) having high nutritional value is directly utilized as an energy-rich food source for aquaculture. The raw biomass can also be further dewatered via a spray drying method to obtain algal powder, which is then directly used or formulated into tablets as a food additive for human and animals without releasing RB.

Scenario 4: Production of lipids-based biofuels (biodiesel, jet-fuels) coupling with utilization of RB: This biorefinery mainly converts *Nannochloropsis*-based lipids to biodiesel (fatty acid alkyl esters) or bio-jet fuels (hydrocarbons), while generating large amount of RB

that contain carbohydrates and protein. The RB can be further processed to produce ethanol, bioH2, lactic acid (via biochemical processes), materials, syngas and biocrudes (via thermal chemical process such as pyrolysis). Nitrogen and phosphorous released into liquid phase via extraction and hydrothermal treatment can be recycled as nutrients for *Nannochloropsis* cultivation.

#### **Table 7. Production of commodity chemicals, feeds, high value products, biofuels, cosmetics, fertilizers, and materials from** *Nannochloropsis* **via different biorefinery scenarios**

RB, Residual biomass.

Despite the promising feedstock for industrial application, the total quantity of microalgal biomass in general and *Nannochloropsis* in particular produced in current industrial process is relatively low and production processes are usually not economically viable [147]. Furthermore, although many chemical/biochemical processes have been developed to convert *Nannochloropsis* biomass to specific products, no *Nannochloropsis*-based biorefinery has not been established. We are still facing immature technologies for production and technologies not specifically designed for algae biorefinery [148]. Accordingly, this field is continuously evolving and reductions in costs can be expected in the coming years. The advancement in strain improvement (via genetic engineering) and cultivation is extremely important since enhancements in productivity, quality, and composition of the biomass are tightly relevant to both up- and down-stream processing, and finally affecting market price. Furthermore, the development of efficient and novel biochemical, chemical and thermal chemical processes to valorize all constituents of *Nannochloropsis* biomass to different products having different markets will facilitate complete commercialization of *Nannochloropsis-*based biorefinery.

# **GENETIC IMPROVEMENT OF MICROALGAE** *NANNOCHLOROPSIS* **SPECIES**

*Chen-Han Shih<sup>1</sup> and Huai-Jen Tsai<sup>2</sup>***,***\* , PhD*

<sup>1</sup>Agricultural and Biosystems Engineering Department, The University of Arizona, Tucson, Arizona, US <sup>2</sup>Institute of Biomedical Sciences, Mackay Medical College, New Taipei City, Taiwan

# **ABSTRACT**

Microaglae of the *Nannochloropsis* genus are essential phytoplankton able to survive in both fresh- and seawater. Using a low-cost prokaryotic microbial culture system can yield high biomass of these microalgae that contain high polyunsaturated fatty acid and high antioxidant pigments. These advantages endow *Nannochloropsis* species with high commercial potential as photoautotrophic green cell factories for application in aquaculture, biofuel and nutraceutical industries. Recently, nuclear genome sequencing of *N. oceanica* and *N. gaditana*, as well as mitochondrial and plastid genomes' sequencing of *N. gaditana*, were performed. The results lay the groundwork for analyzing metabolic pathways and cellular processes in addition to performing genetic manipulation. Meanwhile, many genetic improvement approaches have come to the forefront, including genetic transformation platforms, non-antibiotic selection markers, targeted gene silencing, insertion and mutagenesis methods. With such biotechnological advancements, transgenic *Nannochloropsis* varieties can be generated with the phenotypic traits required to serve as biofuel producers, protein and unsaturated fatty acid bioreactors, and food supplements. As a result of their asexual reproduction, *Nannochloropsis* species have little gene flow, being considered as environmental safety. Therefore, we suggest that transgenic *Nannochloropsis* microalgae possess a broad spectrum of applications in marine and plant biotechnology and that they represent a source of raw material for a wide range of industries, as detailed in this review. We also present a perspective outlining the future uses of this genus in the context of genetic improvement for new biotechnological applications.

## **INTRODUCTION**

Belonging to the Eustigmatophyceae class, *Nannochloropsis* species are photoautotrophic eukaryotic unicellular nonflagellate microalgae that include *N. gaditana*, *N. granulata*, *N. limnetica*, *N. oceanica*, *N. oculata* and *N. salina*. All of these species are spherical or ovoid in shape with diameter ranging from 2 to 4 μm and almost no difference in morphological characteristics. *N. gaditana*, *N. granulata*, *N. oceanica*, *N. oculata*, and *N. salina* are distributed primarily in the marine environment, but it has been reported that *N. limnetica* was found in freshwater and brackish habitats (Krienitz et al. 2000; Fawley and Fawley 2007).

*Nannochloropsis* spp. are emerging models of oil-producing photoautotrophic microalgae owing to high biomass and tolerance of extreme environmental conditions (Wei et al. 2013). This genus is capable of synthesizing large quantities of lipids, mainly in the form of triacylglycerols (TAGs) and marine derived n-3 long-chain polyunsaturated fatty acids (LCPUFA) (e.g., eicosapentaenoic acid (EPA) (20:5 n-3) and docosahexaenoic acid (DHA) (Ma et al. 2016). They produce and accumulate lipid contents up to 28.7% (Ash-Free Dry Weight (AFDW)), or even exceed 50% under nitrogen deprivation (Gouveia and Oliveira 2009). With their high TAGs and EPA contents, *Nannochloropsis* spp. are considered ideal organisms for use in aquaculture as natural feed for the cultivation of fish, Mollusca, and shrimp. They may also be applied industrially for biofuel production. These species can also produce a high concentration of pigments with antioxidant properties, such as astaxanthin, zeaxanthin and canthaxanthin. For example, *N. gaditana* can synthesize canthaxanthin and astaxanthin in 0.7% dry weight and zeaxanthin in 0.6% dry weight (Lubian et al. 2000). Thus, *Nannochloropsis* spp. can serve as an excellent source of high-value nutraceutical products.

As green factories, *Nannochloropsis* spp. can produce valuable lipids, pigments and even heterologous proteins for biotechnological applications. Important to this study, genetic manipulation of *Nannochloropsis* spp. can produce varieties with phenotypic traits useful in the biosciences. More specifically, the nuclear genome sequencing of six *Nannochloropsis* strains have been investigated and annotated partially (Pan et al. 2011; Liang et al. 2012; Radakovits et al. 2012; Vieler et al. 2012; Corteggiani Carpinelli et al. 2014; Wei et al. 2013) as well as chloroplast genome sequencing of *Nannochloropsis* spp. were performed (Radakovits et al. 2012; Wei et al. 2013; Starkenburg et al. 2014; Corteggiani Carpinelli et al. 2014) Moreover, transcriptome, proteome and lipidome analyses of *Nannochloropsis* spp. have also been reported [\(Vieler et al. 2012;](http://www.plantcell.org/content/26/4/1645.full#ref-89) Corteggiani Carpinelli et al. 2014; [Zheng et al.](http://www.plantcell.org/content/26/4/1645.full#ref-104)  [2014;](http://www.plantcell.org/content/26/4/1645.full#ref-104) Dong et al. 2013; Hu et al. 2014; Li et al. 2014). The results lay the groundwork for analyzing metabolic pathways and cellular processes, as well as gene expression, in addition to performing genetic manipulation. Mutagenesis of *Nannochloropsis* spp. has been performed with the aim of manipulating endogenous genes beneficial for developing lipid biosynthesis pathways and improving productivity of pigments, biomass and lipids (Schneider et al. 1995; Chaturvedi et al. 2004; Anandarajah et al. 2012; Ma et al. 2013; Perin et al. 2015; Beacham et al. 2015; Wang et al. 2016). Moreover, we can employ genetic engineering to express exogenous and endogenous functional proteins for lab research and

industrial applications. Genetic modification approaches for nuclear transformation of *Nannochloropsis* spp. include electroporation, particle bombardment and *Agrobacterium*mediated gene transfer, allowing the introduction of exogenous DNA into host nuclear genome to display any desirable genetic traits (Chen et al. 2008; Kilian et al. 2011; Kang et al. 2015a, 2015b; Cha et al. 2011). These genetically modified (GM) *Nannochloropsis* species show faithful expression of foreign proteins and enhancement of biomass and lipid productivity (Kaye et al. 2015; Iwai et al. 2015; Kang et al. 2015b; Li et al. 2016; Beacham and Ali 2016).

Similarly, with the development of a workable reporter gene applied to species of this genus, researchers could realize cellular localization and quantify the expression level of target genes in cells. Screening putative transformants after gene transfer on *Nannochloropsis* spp. is tedious, but the choice of proper reporter gene, or selective markers, would be a key factor in improving the screening efficiency and future application of transgenic cells. In fact, a new direction in GM *Nannochloropsis* transgenic strains has emerged and is compliant with all applicable rules and regulations (Li and Tsai 2009; Cha et al. 2011; Kang et al. 2015a; Moog et al. 2015; Shih et al. 2015). For example, the environmentally friendly, nonantibiotic-based selection maker purple chromoprotein (CP) has been isolated from the sea anemone *Stichodacyla haddoni* (sh) (Chiang et al. 2014). With a favorable food safety profile, shCP and its derivatives represent a consumable protein of marine food chain origin (Shih et al. 2015). More recently, gene knockdown, knockout and knockin techniques have been achieved for *Nannochloropsis* species. This has implications for the development of new approaches to functional gene analysis (Kilian et al. 2011; Wang et al. 2016; Wei et al. 2017). In this article, we will introduce current genetic engineering and manipulation techniques, including many genetic improvement approaches, such as genetic transformation platforms, non-antibiotic selection markers, targeted gene silencing and mutagenesis methods, all forging a path toward the genetic improvement of *Nannochloropsis* species.

# **GENETIC MODIFICATION APPROACHES IN** *NANNOCHLOROPSIS* **SPECIES**

Thus far, we highlighted four approaches that have been overwhelmingly used to generate GM *Nannochloropsis* varieties, including particle bombardment, electroporation, *Agrobacterium tumefaciens*-mediated genetic transformation and mutagenesis (Table 1). The first two approaches physically deliver the foreign DNA into the host genome, while *Agrobacterium* is known for its ability to transfer the exogenous gene between itself and the host genome after infection, and mutagenesis utilizes methods such as UV induction and mutagen manipulation. Originally designed to generate higher plants, these genetic modification platforms have been gradually modified for use in transgenic microalgae.

Transgenic method		Method	Host	Reference
Particle <b>bombardment</b>	Low pressure delivery with microcarrier gold particle		N. salina CCMP1776	Kang et al. 2015a

<sup>a</sup> protoplast: protoplast-based electroporation; <sup>b</sup> direct: direct electroporation.

#### **Particle Bombardment**

Particle bombardment, commonly known as the "gene gun", is said to be an effective and highly reproducible transformation method for establishing GM algae strains (Qin et al. 2012). This method mainly uses heavy metal coated with plasmid DNA which is then shot by air pressure, allowing DNA fragments to penetrate the target cell wall and integrate into nuclear chromosome, or organelles like chloroplasts, to generate transgenic microalgal varieties.

However, the "gene gun" strategy requires costly specialized equipment and has a relatively low rate of transformant recovery. Still, it can deliver multiple copies of exogenous DNA into the host genome, thereby increasing transformation efficiency (Potvin and Zhang 2010), suggesting that it is an effective way to establish nuclear or chloroplast transformation in a variety of microalgal species. For example, the sfCherry fluorescent protein was introduced in *N. salina* CCMP 1776, allowing the fluorescent signal to be microscopically detected within cells (Kang et al. 2015a) and, hence, serving as a new genetic manipulation platform for selecting transformant cells. Kang and coworkers (2015b) also showed that overexpression of a basic helix-loop-helix (bHLH) transcription factor (NsbHLH2) could increase biomass productivity and production of fatty acid methyl esters (FAME).

#### **Electroporation**

Electroporation is simple and effective, and it is commonly used for nuclear transformation in *Nannochloropsis*. An intense electrical field is applied to ensure that the cell wall and lipid bilayers are disrupted so that exogenous DNA fragments can penetrate the genome of transformants. However, its efficiency is dependent on field strength, pulse length, medium composition, temperature, membrane characteristics and DNA concentration (Potvin and Zhang 2010). This strategy involves either removal of the cell wall to allow protoplast to ingest foreign materials (Chen et al. 2008) or genetic transformation of intact call walls by direct electroporation, as in *Nannochloropsis* cells (Kilian et al. 2011).

Electroporation for nuclear transformation was first reported by Chen et al. (2008), who were successful in transferring exogenous DNA fragments containing fish growth hormone cDNA into the protoplast of *N. oculata* cells. They demonstrated that the growth of fish larvae fed with the transformed *N. oculata* could be enhanced. Two subsequently published articles reported the establishment of transgenic *N. oculata* strains by following this protoplast-based electroporation approach (Li and Tsai 2009; Shih et al. 2015). As noted above, Kilian et al. (2011) used genetic transformation of intact call walls to establish a transgenic *Nannochloropsis* species W2J3B. The transformants were generated by direct electroporation with a DNA construct which knocked out two genes involved in nitrogen metabolism by homologous recombination. This electroporation protocol is now commonly used for genetic transformation of *Nannochloropsis*.

#### *Agrobacterium tumefaciens***-Mediated Genetic Transformation**

*A. tumefaciens* is a Gram-negative soil bacterium. It is a widely used genetic modification tool for establishing transformed plants. *A. tumefaciens* harbors a Ti (tumor-inducing) plasmid which contains a DNA fragment, namely T-DNA, which can be transferred and randomly integrated into the chromosomal genome of host plant cells. Hence, the T-DNA region can be exchanged with exogenous DNA and transformed into the target cells to generate GM plants. Recently, this transformation approach has been successfully applied in microalgae, such as *Porphyra yezoensis* (Cheney et al. 2001), *Chlamydomonas reinhardtii* (Kumar et al. 2004), *Haematococcus pluvialis* (Kathiresan et al. 2009) and *Dunaliella bardawil* (Anila et al. 2011). Investigators claimed that stable transgenic *C. reinhardtii* and *H. pluvialis* strains could be obtained and that the transferred gene could be stably maintained for 18 months and 2.5 years, respectively.

The first successful case of applying *Agrobacterium*-mediated gene transfer for nuclear transformation in *Nannochloropsis* spp. was reported by Cha et al. (2011), who applied GUS assay to evaluate the transformation efficiency among acetosyringone, cinnamic acid, vanillin and coumarin, suggesting that, instead of acetosyringone, the other three phenolic compounds could become potential alternatives to *Agrobacterium vir* gene induction to achieve high *Agrobacterium*- mediated transformation efficiency for *Nannochloropsis* species UMT-M3. Interestingly, *A. tumefaciens*-mediated transformation was applied to transfer the *Saccharomyces cerevisiae* type 2 diacylglycerol acyltransferase *DGA1* gene into *N. salina* CCAP 849/3 (Beacham and Ali 2016). They found improved lipid content because an additional copy of the exogenous *DGA1* gene was introduced into *N. salina*. On the other

hand, they observed that transformants displayed transient expression because of gene silencing.

#### **Mutagenesis**

Genetic transformation can also be achieved through mutagenesis, as demonstrated by manipulating and altering the metabolite productivity and composition or increasing the photosynthesis efficiency and biomass productivity in the genus *Nannochloropsis*. The strategy can be implemented though either classical physical or chemical means. For example, ultraviolet (UV) radiation is a simple and commonly used physical method to acquire mutant *Nannochloropsis* strains (Sharma and Schenk 2015; Beacham et al. 2015). Gamma ray and heavy ion radiation were also applied to generate a mutant *Nannochloropsis* strain owing to its wide mutation spectrum and higher mutation frequency compared with the UV method (Schneider et al. 1995; Ma et al. 2013). Three alkylating mutagens have also been used to develop *Nannochloropsis* mutant strains, including ethyl methane sulfonate (EMS), N-methyl-N-nitrosourea (MNU) and 1-methyl-3-nitro-1-nitrosoguanidine (NTG). These mutagens are alkylating agents capable of causing a high nucleotide substitution or transition frequency. Therefore, they are commonly used to induce mutation in the genus *Nannochloropsis*.

Mutants of *N. salina* CCAP849/3 and other *Nannochloropsis* species were reported to display distinct phenotypes, such as improvement of total cellular lipid contents, EPA, PUFA and FAMEs, using UV-induced mutagenesis (Sharma and Schenk 2015; Beacham et al. 2015). In addition, mutation for the change of lipid composition induced by gamma ray in *Nannochloropsis* species was reported by Schneider et al. (1995). Meanwhile, Ma et al. (2013) reported that the mutant of *N. oceanica* IMET1 obtained from heavy ion irradiation mutagenesis had higher biomass accumulation, growth rate and lipid productivity compared with wild type. EMS is a commonly used mutagen to induce overproduction of metabolites, such as xanthophyll, TAGs and EPA in the genus *Nannochloropsis* (Perin et al. 2014). In contrast, only Chaturvedi et al. (2004) and Wang et al. (2016) have reported that the mutagens MNU and NTG can be used to establish mutant *Nannochloropsis* strains to enhance lipid productivity.

## **SELECTION MARKERS APPLIED TO THE TRANSFORMATION**

Recent studies have confirmed the use of antibiotic- and herbicide- resistant genes, or viral proteins, as selective markers for screening putative clones with the aim of generating transgenic *Nannochloropsis* strains. Reporter protein systems were also established for *in vivo* protein localization studies (Moog et al. 2015) and served as a substitute for normal antibiotics and herbicide selective markers (Shih et al. 2015). Several studies have also reported genetic modifications for either endogenous or exogenous gene overexpression, resulting in the improvement of lipid and protein production. Meanwhile, different *Nannochloropsis* mutants displayed distinctive biological traits or enhanced metabolites compared with wild type.

#### **Selective Marker of Antibiotic-Resistant and Reporter Genes**

The development of GM strains requires a proper and suitable selective marker system for identifying and isolating the putative transformed cells, and two major systems have been developed to select transformed *Nannochloropsis* cells (Table 2). One involves antibiotic- and herbicide- resistant genes, such as *sh ble* (Kilian et al. 2011), *HygR* (Kilian et al. 2011), *Bsr* (Kilian et al. 2011) and *aph7* (Vieler et al. 2012). These markers allow direct selection of transformed cells by conferring genes resistant to Zeocin or Hygromycin B. Another involves reporter genes, such as the red fluorescent protein gene (DsRed) (Li and Tsai 2009), sfCherry fluorescent protein gene (Kang et al. 2015a) and shCP gene (Shih et al. 2015). These markers do not exert direct selective pressure on transformed cells. Instead, they display distinctive coloration or fluorescent signal that can be identified by visual detection or fluorescent microscopy observation.

Antibiotic and herbicide selective markers are commonly used to isolate transformed microalgal cells. For example, Kilian et al. (2011) applied *sh ble*, *Bsr* and *HygR* antibiotic selective markers for nuclear transformation of *Nannochloropsis* species W2J3B after direct electroporation following with homologous recombination, conferring resistance to Zeocin or Hygromycin B. The transformation efficiency was  $2.5 \times 10^{-6}$  per μg of plasmid DNA (Umaima et al. 2016). The *aph7* selective marker gene was also introduced into *N. oceanica* CCMP1779 by direct electroporation, allowing the transformed cells to resist Hygromycin B and resulting in a transformation efficiency of 1.25 x  $10^{-6} \pm 0.6$  x  $10^{-6}$  per µg of plasmid DNA (Vieler et al. 2012). However, GMOs that originate from antibiotic gene selection raise public concerns over environmental and food safety. Therefore, the search for safe alternative selection markers is necessary. Attempts have been made to develop various environmentally safe reporter genes as selective markers. Although these reporters do not exert direct selective pressure on transformed cells, they do allow the selection of putative transformants based on the distinctive characteristic of phenotypes they present. More importantly, since these selective genes encode naturally consumable proteins, they may be considered environmentally safe for the selection of transformed cells. For example, DsRed originated from coral was the first fluorescent reporter to be employed as a selective marker for screening transgenic *N. oculata* strains using protoplast-based electroporation (Li and Tsai 2009). The red fluorescent signal could be detectable in transformants under fluorescence microscopy. After culturing colonies on agar plates, it does take some two months for the red fluorescence to appear, but when it does, it is easy to distinguish between transformants and non-transformants. However, the endogenous fluorescent signals from chlorophyll and pigments in the host microalga *N. oculata* could occasionally interfere with the identification of red fluorescent signal (Shih et al. 2015). To address this problem, Kang et al. (2015a) introduced the sfCherry reporter into *N. salina* CCMP1776 using particle bombardment. They demonstrated that the sfCherry reporter, which was derived from mCherry through directed mutagenesis with better folding and higher intensity of fluorescence signal (Shaner et al. 2004; Nguyen et al. 2013), could be an effective alternative to DsRed by the absence of interference between endogenous host fluorescent signals and those of the reporter. Still, reporters like sfCherry require expensive fluorescent instrumentation for screening of transformed cells that express fluorescent signals. To overcome this drawback, Shih et al. (2015) developed to use novel selection marker, CP. This marker is easily detected by the naked eye, and, more importantly, it meets food and environmental safety standards as well.

Gene coding for CP was cloned from the sea anemone *S. haddoni* (sh) in Tsai's lab. When the shCP marker was introduced into *N. oculata* NIES-2146 by protoplast-based electroporation, the transformed cells displayed a distinctive dark brown coloration, making it easy to distinguish transformants from non-transformants by direct visual detection without employing complicated fluorescence equipment. Since shCP is not a toxic protein, we noticed that no selective pressure was present on the agar plate, allowing both transformed and nontransformed microalgae to grow. Thus, screening positive transformants from among the many hundreds of cells grown on agar is, indeed, time-consuming. However, despite this disadvantage, shCP is a protein originated from sea anemone, which belongs one of member in marine food chain, and considered as an edible natural resources. Therefore, it complies with both environmental and food safety requirements, making this reporter protein simple and ecologically safe for selecting transgenic *Nannochloropsis* cells.

#### **GUS and GFP Reporter Genes Applied to** *Nannochloropsis* **Species**

The protein produced by reporter genes is easy to observe, detect and quantify. Hence, reporter genes are commonly used to evaluate the promoter activity of target gene in microalgal cells. Meanwhile, the GUS gene encoding β-glucuronidase and *gfp* cDNA encoding green fluorescent protein (GFP) are widely used as a reporter gene to assess transformation efficiency, monitor gene expression, search for protein localization, and trace the dynamic change of target gene within *Nannochloropsis* cells (Table 2).

GUS reporter gene has been applied in several different microalgae strains, such as dinoflagellates, including *Amphidinium* species, *Symbiodinium microadriaticum* (Michael and Miller 1998); the diatom *Thalassiosira weissflogii* (Falciatore et al. 1999) and *Chlorella* species (Wang et al. 2007). Cha et al. (2011) first reported the use of a GUS reporter gene to assess the influence of transformation efficiency of four phenolic compounds on *A. tumefaciens*-mediated genetic transformation in *Nannochloropsis* species UMT-M3. They demonstrated that cinnamic acid, vanillin and coumarin could produce a higher percentage of GUS-positive cells than those of acetosyringone. Subsequently, GUS assay was also used to evaluate the transformation efficiency between PCR fragment based-transformation and plasmid based-transformation systems among six *Nannochloropsis* species. As a result, they suggest that the transformation efficiency of PCR fragment based-method is higher than that of plasmid based-method (Li et al. 2014). Apart from GUS, GFP has also been used to trace target protein in *Nannochloropsis* and monitor gene expression, as well as trace protein localization, in microalgae, e.g., the diatoms *Phaeodactylum tricornutum* (Zaslavskaia et al. 2000) and *C. reinhardtii* (Kumar et al. 2004) and the red alga *Cyanidioschyzon merolae* (Watanabe et al. 2011). Moog et al. (2015) was the first the use the GFP reporter to perform an *in vivo* localization study in *N. oceanica* CCMP1779 after direct electroporation. They demonstrated that the terminal sequences could drive the location of proteins within the cellular compartments, such as plastid transport through endoplasmic reticulum and mitochondria of transformed cells.

Table 2. Current selective markers and reporters used in the transgenesis of Nannochloropsis species **Table 2. Current selective markers and reporters used in the transgenesis of** *Nannochloropsis* **species**

# **EXPRESSION OF FOREIGN PROTEINS APPLIED FOR AQUACULTURE AND LIPID BIOSYNTHESIS**

Since *Nannochloropsis* species have high biomass productivity and high commercial potential for producing valuable lipids, pigments and proteins, they are commonly used in industrial fields, such as aquaculture, as well as biofuel, bioreactor and nutraceutical industries. GM approaches to *Nannochloropsis* spp. are effective and well developed (Table 3), but the production of functional and valuable recombinant proteins obtained from different distinctive phenotypes can be improved.

From this perspective, *N. oculata* is frequently used as live feed for larvae of fish and shellfish in the aquaculture industry (Duerr et al. 1998). Chen et al. (2008) generated a transgenic line of *N. oculata* to produce functional yellowfin porgy growth hormone (YPGH) from marine fish *Acanthopagrus latus*. This transgenic *N. oculata*, which harbors a YPGH cDNA using protoplast-based electroporation, was first fed *Artemia*, a zooplankton. Then, these microalgae-containing *Artemia* was fed to red tilapia larvae. As a result, the growth of red tilapia larvae was greatly increased. Interestingly, Li and Tsai (2008) also demonstrated that the transgenic *N. oculata* harbors an antimicrobial peptide, bovine lactoferricin (LFB), using protoplast-based electroporation. After challenge by the pathogen *Vibrio parahaemolyticus*, the average survival rate of fish larvae orally fed with transgenic microalgae was increased to  $85 \pm 7.1\%$  compared with  $5 \pm 7.1\%$  of control group orally fed with non-transgenic microalgae, demonstrating the enhanced bacterial resistance of fish larvae fed with LFB-containing transgenic microalgae.

Moreover, several studies reported the overexpression of specific genes to increase lipid or biomass productivity. Genome, proteome and lipidome analyses of *Nannochloropsis* species are well established and, hence, the relevant knowledge of metabolic pathways in *Nannochloropsis* spp. For example, the overexpression of endogenous *N. oceanica* microsomal-likeΔ12 desaturase (*NoD12*), which is capable of regulating the primary step of LC-PUFA biosynthesis by transforming oleic acid (18:1 n-9) into linoleic acid (18:2 n-6) in *N. oceanica* CCMP1779, was achieved using direct electroporation (Kaye et al. 2015). In addition, the overexpression of homologous *NoD12* resulted in altering total lipid composition, which not only enhanced ratio of phosphatidylcholine by 18:2 in the triacylglycerol (TAG) under nitrogen starvation conditions but also converted part of linoleic acid (18:2 n-6) to arachidonic acid (20:4 n-6) without showing negative effect on the growth of cells. Furthermore, Iwai et al. (2015) isolated type-2 diacylglycerol acyl-CoA acyltransferase (CrDGTT4) from *C. reinhardtii* which is driven by sulfoquinovosyldiacylglycerol synthase 2 (SQD2) promoter. CrDGTT4 is able to induce the accumulation of TAGs under phosphorus starvation condition. They introduced *CrDGTT4* gene into *Nannochloropsis* species NIES-2145, resulting in the improvement of TAG accumulation and oleic acid content (18:1 n-9) and altering the lipid composition of the host to become more similar to *C. reinhardtii* under phosphorus starvation condition. Meanwhile, Li et al. (2016) reported the overexpression of type 2 diacylglycerol acyltransferase (DGAT2), which serves as a rate-limiting enzyme in TAG biosynthesis, in *N. oceanica* CCAP 849/10. The results showed that overexpression of *DAGT2* gene increased saturated fatty acids and PUFA, but Table 3. Exogenous and endogenous genes expressed in transgenic Nannochloropsis species **Table 3. Exogenous and endogenous genes expressed in transgenic** *Nannochloropsis* **species**

decreased the content of monounsaturated fatty acids. Additionally, neutral lipid content was increased by 69%, and TAG biosynthesis was also accelerated. *N. salina* can accumulate a high amount of palmitic acid (C16:0) and oleic acid (C18:1 n-9), according to Van Wagenen et al. (2012). Consequently, this microalgal strain has become a suitable recipient for transforming the *S. cerevisiae DGA1* gene to utilize acetyl-CoA substrate, such as palityl-CoA (C16:0) and oleoyl-CoA (C18:1). The transgenic *N. salina* CCAP 849/3 harboring the *DGA1* gene was generated through the *A. tumefaciens*-mediated genetic transformation approach (Beacham and Ali 2016). As a result, this transformed variety showed improved Fatty Acid Methyl Ester (FAME) content by 38%, although it caused the silencing of the transgenic gene. Recently, a basic helix-loop-helix (bHLH) transcription factor (TF), which functions as a regulator of growth, development and stress response, was overexpressed in *N. salina* CCMP1776 using particle bombardment (Kang et al. 2015b). When two bHLH TFs, named as *NsbHLH1* and *NsbHLH2*, were individually isolated and overexpressed in *N. salina*, *NsbHLH2-* overexpressing transformants displayed enhanced biomass productivity by 36% under normal condition and FAME productivity by 33% under nitrogen starvation.

# **REVERSE GENETIC APPROACHES OF SILENCING, KNOCKOUT AND KNOCKDOWN IN** *NANNOCHLOROPSIS* **SPECIES**

Reverse genetic approaches, or gene editing tools, such as homologous recombination (Sodeinde and Kindle 1993), RNA-mediated silencing (Rohr et al. 2004) and CRISPR/Cas9 (Shin et al. 2016) have been established and applied in a few species of microalgae (Wei et al. 2017). Unlike forward genetic engineering, reverse genetic approaches are commonly applied in studying specific gene functions or modifying the gene of interest to develop a desirable phenotype through knockout or silencing of target gene in the study organisms (Hlavova et al. 2015). Since *Nannochloropsis* species are emerging as an excellent microalgal model organism, these reverse genetic tools are now available for extensive genetic investigation and profiling. Three major studies have reported on the application of reverse genetics to *Nannochloropsis* spp. (Kilian et al. 2011; Wang et al. 2016; Wei et al. 2017) (Table 4).

Tool	Transgenic method	Target gene	Host	Reference
Homologous recombination	Direct electroporation	nitrate or nitrite reductase	Nannochloropsis species W2J3B	Kilian et al. 2011
CRISPR/Cas9 system	Direct electroporation	nitrate reductase	N. oceanica IMET1	Wang et al. 2016
RNA interference	Direct electroporation	carbonic anhydrase and bicarbonate transporter	N. oceanica IMET1 and <b>CCMP1779</b>	Wei et al. 2017

**Table 4. Reverse genetic tools used for** *Nannochloropsis* **species**

#### **Homologous Recombination**

*Nannochloropsis* spp. are potential feedstock candidates for biofuel and biochemical production, but our knowledge of the genes and enzymes involved in biosynthesis is lacking (Weeks 2011). To remedy this, homologous recombination is a common tool used to perform site-specific target gene knockout and replacement, enabling the integration of exogenous DNA into a specific region of the target genome and expression of the gene of interest. Kilian et al. (2011) demonstrated gene replacement of *Nannochloropsis* species W2J3B by homologous recombination after direct electroporation. The target endogenous nitrate or nitrite reductase gene was knocked out, and the desired transgene was inserted, resulting in a transgenic strain unable to rescue on nitrate- and nitrate/nitrite-containing medium. This work successfully opened the door for the functional analysis of genes, thus improving the outlook for future studies of genes involved in metabolic processes.

#### **CRISPR/Cas9 System**

Clustered, Regularly Interspaced, Short Palindromic Repeats-associated Endonuclease 9 (CRISPR/Cas9) has been used as a reverse genetic tool for functional analysis study in microalgae, such as *C. reinhardtii*, *Thalassiosira pseudonana* and *P. tricornutum* (Baek et al. 2016; Shin et al. 2016; Hopes et al. 2016; Nymark et al. 2016). The CRISPR/Cas9 system contains a specific guide RNA (gRNA) and a nonspecific CRISPR-associated endonuclease protein (Cas9), allowing sequence-specific cleavage of DNA double-strand breaks (DSB) in the target DNA loci region through base pairing of corresponding gRNA. As the result, it generates a knockout or replacement of the target gene in recipient cells or organisms (Brasila et al. 2017). More recently, heterologous genome editing to knock out the target gene through the CRISPR/Cas9 system was successfully achieved in *N. oceanica* IMET1 via direct electroporation (Wang et al. 2016). Five base-pairs were precisely knocked out, causing a frameshift of endogenous nitrate reductase by CRISPR/Cas9. As a result, transgenic *N. oceanica* failed to grow on nitrate-containing medium. This work demonstrated that the CRISPR/Cas9 system could potentially serve as an efficient strategy for genomic sequence editing in *Nannochloropsis* genomics and metabolomics.

## **RNA Interference (RNAi)-Mediated Gene Silencing**

Application of RNAi-mediated gene silencing has been reported in a wide range of microalgae, e.g., *C. reinhardtii*, *T. pseudonana*, *Dunaliella salina*, *P. yezoensis*, *P. tricornutum* and *Penium margaritaceum* (Rohr et al. 2004; Armbrust et al. 2004; Jia et al. 2009; De Riso et al. 2009; Liang et al. 2010; Sorensen et al. 2014). RNAi-mediated gene silencing is also a commonly used reverse genetic tool to silence target genes in different microalgae. However, some species of algae with small nuclear genomes have lost the RNAi machinery (Cerutti et al. 2011). Generally, RNAi is a post-transcriptional process which is triggered by double-stranded RNA (dsRNA) for targeted gene silencing, resulting in the degradation of specific target transcripts. Most recently, RNAi-mediated gene silencing was used to knock down carbonic anhydrase (CA) and bicarbonate transporter (BCT) in strains of

*N. oceanica* IMET1 and CCMP 1779 (Wei et al. 2017). CA and BCT play a key role in the inorganic carbon concentration mechanism (CCM) which represents biological adaptation to low carbon dioxide concentrations in the environment [\(Moroney and Ynalvez, 2007\)](http://www.sciencedirect.com/science/article/pii/S0960852410017037). Wei et al. (2017) reported that the transcription level of CA in the RNAi-knockdown strain was inhibited by 62-83% and that the photosynthetic oxygen evolution (POE) rate was increased by 68-100% under pH 6.0 but decrease by 39-45% under pH 9.0 compared with wild-type (WT), revealing the crucial correlation between CA and CCM. This work demonstrated that RNAi-mediated gene silencing is a potentially effective tool for knocking down target genes in *Nannochloropsis* for functional gene studies.

# **BIOSYNTHESIS MUTATION IN** *NANNOCHLOROPSIS*

Random mutagenesis is still another genetic manipulation tool commonly used to alter the biosynthesis pathway in *Nannochloropsis* species since this genus is recognized as a potential feedstock of lipid and nutrients. A variety of desirable mutant *Nannochloropsis* strains were obtained through random mutagenesis, resulting in the enhancement of its metabolite productivity, biomass productivity and photosynthetic efficiency. The development of a selective marker for mutant strains was also reported (Table 5).

Method	Approach	Host	Phenotype	Reference
Physical	Heavy-ion N. oceanica IMET1		Improved lipid productivity and photosynthesis efficiency	Ma et al., 2013
	UV	Nannochloropsis species BR2	Two-fold increase in EPA content	Sharma and Schenk 2015
Chemical	<b>EMS</b>	N. oculata ST-6	Obtained antibiotics resistance mutants with improved EPA and some long-chain fatty acid	Chaturvedi and Fujita 2006
		Nannochloropsis species	Four-fold increase of total fatty acid content and palmitoleic acid and decrease in EPA	Doan and Obbard 2012
		N. oculata	Improved two-fold violaxanthin, three-fold zeaxanthin and 1.8-fold xanthophyll content and decrease in lutein content	Lee et al., 2006
		N. gaditana <b>CCAP 849/5</b>	Increased in biomass productivity and decreased chlorophyll	Perin et al. 2015
		Nannochloropsis species	Improved biomass productivity, chlorophyll and lipid content	Anandarajah et al. 2012
	<b>MNU</b>	N. oculata	Improved total fatty acid, TAG, PUFA and <b>EPA</b>	Chaturvedi et al. 2004
	<b>NTG</b>	N. oceanica	Improved lipid productivity and decrease in PUAF and TAG	Wang et al. 2016
Physical and Chemical	Gamma ray and EMS	Nannochloropsis species	Devoid EPA, reduction in TAG and slower growth rate	Schneider et al. 1995
	UV and <b>EMS</b>	N. salina CCAP 849/3	Three-fold increase in lipid accumulation and decrease in growth rate and overall lipid productivity	Beacham et al. 2015

**Table 5. Current mutagenesis applied on** *Nannochloropsis* **species**

#### **Mutation to Enhance Lipid Productivity and Change Lipid Content**

*Nannochloropsis* species are widely known for their distinctive characteristics of rapid growth and high lipid productivity. Several studies have reported on improving lipid metabolism through mutagenesis, successfully establishing a variety of mutant *Nannochloropsis* strains with different enhancement in specific lipid contents, lipid accumulation and change in lipid composition. Several studies successfully used chemical mutagens, such as EMS, MNU and NTG, to trigger mutation for changing lipid profiles in *Nannochloropsis*. The enhancement of eicosapentaenoic acid (EPA) content in *N. oculata* ST-6 using EMS demonstrated that cerulenin- and erythromycin-resistant mutated strains increased EPA content by 29 and 12%, respectively (Chaturvedi and Fujita, 2006). Meanwhile, increase in the content of fatty acids (C14:0), (C16:0), (C16:1), (C18:0) and (C20:4 n-6) was also obtained. Moreover, Doan and Obbard (2012) reported a mutant of *Nannochloropsis* species obtained from EMS treatment that increased by four-fold the total fatty acid content with a 30% increase in palmitoleic acid (16:1) and a 45% decrease of EPA compared to wild-type strain, suggesting that it is possible to obtain mutants with enhanced fatty acid. In addition, Beacham et al. (2015) demonstrated a double-mutated *N. salina* CCAP849/3. This strain was first treated with EMS and displayed a change in PUFA content, which improved total FAME up to 156% compared with wild type. Then, the EMS-mutant strains were further subjected to UV radiation, obtaining double mutant strains with a threefold higher lipid accumulation than wild type. However, the growth rate of these mutants was reduced, which, in turn, caused an overall decrease in lipid productivity. Meanwhile, two mutants of *N. oculata* obtained from MNU treatment can resist quizalofop, an inhibitor of acetyl-CoA carboxylase (ACCase). Thus, they were able to change the fatty acid metabolism. As a result, total fatty acid content, PUFA, TAG, linoleic acid (18:2), arachidonic acid (20:4 n-6) and EPA (20:5 n-3) were improved (Chaturvedi et al. 2004). Recently, Wang et al. (2016) reported three mutants of *N. oceanica* through EMS and NTG mutagenesis, resulting in the improvement of lipid productivity. As a result, three mutants displayed increases of 33.54, 30.93 and 21.44% in lipid productivity, and lipid content was increased by 17.4, 23.7 and 29.4%, respectively. One of mutants was able to accumulate lipid as high as 31.34% of dry biomass and increased in (C16) to (C18) lipid content by 12.56%, while it was absent in some proportions of TAG composition, resulting in the decrease of PUFA content than that of wild type. This study also reported that NTG showed more mutation efficiency for establishing strains with high lipid content.

Physical mutagenesis was used to develop mutants of *Nannochloropsis* as well. Schneider et al. (1995) applied EMS and gamma irradiation to obtain a mutant of *Nannochloropsis* species which was completely devoid of EPA (20:5 n-3) but increased in the relative lipid content of (20:4 n-6) and TAG. Alternation of several lipid composition and membrane lipid levels in mutants was also observed. For example, mutants displayed the reduction in the percentage of  $(20:4 \text{ n-}6)$  in monogalactosyldiacylglycerol, digalactosyldiacylglycerol and phosphatidylglycerol following by the improvement of the percentage of (20:4 n-6) in phosphatidylcholine, phosphatidylethanolamine and phosphatidylinositol, compared with wild type level of (20:5 n-3). The negative influence on mutant was slower growth rate, fewer thylakoid stacks per chloroplast and a four-folddecrease of membrane lipid level. Heavy-ion irradiation mutagenesis was applied to improve lipid productivity and TAG content in *N. oceanica* IMET1 (Ma et al. 2013). The biomass

accumulation, lipid productivity and growth rate in this mutant were increased by 19, 6 and 28%, respectively. Meanwhile, the analysis of lipid composition has revealed that TAG was increased by 14% and polar lipid content was decreased by 15% compared with those of wild type. However, the improvement in photosynthetic efficiency in this mutant was also revealed. Enhanced lipid content in mutant *Nannochloropsis* species BR2 could also be obtained by UV radiation, which displayed a two-fold-increase of EPA content within 24 h that accounted to be approximately 30% of total fatty acids and constituted up to 12% of total dry weight at higher dose of UV treatment (1000 mJ/cm<sup>2</sup>) (Sharma and Schenk 2015).

#### **Mutation to Improve Pigment Productivity**

Antenna pigments are another valuable commercial product which can be extracted from *Nannochloropsis* species. Accordingly, the improvement of pigment production in the mutant of *N. oculata* strain was achieved through EMS treatment (Lee et al. 2006). Two mutants exhibited abnormal xanthophyll biosynthesis, and thus increased violaxanthin content by twofold, zeaxanthin content by two to three-fold and xanthophyll pool size by 1.8-fold under low light conditions, followed by a decrease in lutein content under low light conditions, while comparing with wild type with no negative influence on growth and cellular chemical composition. Although the investigators claimed high light condition may cause negative influence on the reduction of violaxanthin, a potential method for producing zeaxanthin can be applied in microalgal industries.

#### **Mutation to Increase Photosynthesis Efficiency and Biomass Productivity**

Since photosynthesis efficiency is highly associated with lipid and biomass productivity, improving photosynthesis should help microalgae to convert light energy to biomass and lipids. Therefore, mutation of the photosynthesis apparatus in *Nannochloropsis* strains was attempted based on this concept. Perin et al. (2015) did obtain improved photosynthetic activity in the mutant *N. gaditana* CCAP 849/5 using EMS. Although several mutants displayed reduction in cellular chlorophyll contents, some mutants exhibited improved photosynthesis productivity, and thus increased biomass productivity. In addition to improvement in biomass, two *Nannochloropsis* mutants produced chlorophyll a and lipids, resulting in increased biomass productivity by 25% under high light and by 21.3% under low light in one mutant strain. Chlorophyll a content in this mutant was also improved by 16.9% under high light. Meanwhile, lipid productivity was increased by 11.9 and 21.7% in both mutants, respectively. Yet, no significant change was observed in lipid composition (Anandarajah et al. 2012).

# **FUTURE PERSPECTIVES**

The genus *Nannochloropsis* is an important feedstock which provides a variety of natural compounds for biofuels, aquaculture and healthy foodstuffs. In response to technological

advances over the last decade, genomic sequencing, transcriptomics, lipidomics, proteomics, metabolomics, and forward and reverse genetic approaches have all been developed. Knowledge of this genus has increased, and a platform for its biological and genetic enhancement is well established. Although molecular biotechnological techniques have been applied to develop GM strains for generating commercial products, establishment of an effective and feasible platform for genetic manipulation in *Nannochloropsis* is still needed, especially with respect to transformation efficiency, expression of desired products, and exhibition of stable phenotypes.

#### **The Expression Level of Foreign Protein in Chloroplast**

Foreign genes expressed in cellular organelles within microalgae have been demonstrated, but the expression level has varied. Nuclear transformation is a commonly used method to obtain transformed microalgal strains. However, this technique has some limitations. One key disadvantage of nuclear transformation involves the expression level of foreign gene in transgenic microalgae, which is relatively low owing to positional effect, RNA silencing, compact chromatin structure, and unconventional epigenetic effects (Potvin and Zhang 2010).

In contrast, the level of foreign protein expression in chloroplast transformation is high as a result of viable protein folding, limited proteolytic pathways, and protection from degradation of foreign protein in chloroplast envelope (Potvin and Zhang 2010). The number of chloroplasts in a cell is abundant compared to one nucleus. In addition, chloroplasts are important components in algal cells by their involvement in several metabolite pathways, allowing alternative genetic manipulation options for analyzing or improving their endogenous gene functions (Umaima et al. 2016). The genomics of *Nannochloropsis* chloroplasts has been investigated, thus allowing a better understanding of gene expression in the chloroplast machinery. Consequently, chloroplast genetic engineering should be considered as a potential microalgal cell factory for producing highly valuable compounds or studying its metabolite pathways.

#### **Promoter Used in Gene Construct for Transformation**

Promoters control and drive the expression of foreign protein. As such, they can regulate the yield of desirable products. Selection of an effective promoter for expressing foreign gene at high level depends on the target organisms, cellular compartments and protein types which enable the correct recognition of elements associated with transcriptional machinery in the expression system. Thus, several exogenous and endogenous sources of promoters have been applied to the transformation of *Nannochloropsis*, resulting in variable expression efficiency and stability of foreign proteins.

Three types of promoters are available. First, the CaMV 35S promoter from Cauliflower mosaic virus (CaMV) is a widely used promoter, even though lacking the genetic information of endogenous promoter in microalgae strains (Qin et al. 2012). Cha et al. (2011) demonstrated the application of CaMV 35S promoter in *Nannochloropsis* species UMT-M3 and successfully drove the expression of GUS gene. Second, heat shock protein 70A

(HSP70A), a chimeric promoter, was combined with small subunit of RUBISCO (RbcS2) inducible promoter isolated from the model microalgal organism *C. reinhardtii*. Foreign proteins, such as yellowfin porgy growth hormone, antimicrobial peptide bovine lactoferricin and sea anemone (*Stichodacyla haddoni*) purple chromoprotein, were driven to conditionally express in *N. oculata* by this hybrid promoter (Chen et al. 2008; Li and Tsai 2009; Shih et al. 2015). In addition, SQD2-stress-inducible promoter from *C. reinhardtii* was also used to drive type-2 diacylglycerol acyl-CoA acyltransferase under phosphorus starvation in *Nannochloropsis* species NIES-2145. Third, *Nannochloropsis* is a source of native promoters, such as violaxanthin/chlorophyll *a*-binding protein (VCP) 2, lipid droplet surface protein (LDSP), β-tubulin (TUB), HSP70A and ubiquitin extension protein (UEP). Unlinked VCP2 bidirectional promoters coupled with VCP1 3' untranslated region from each gene were established to drive antibiotic *sh ble* (Zeocin- resistant) gene in *Nannochloropsis* species W2J3B (Kilian et al. 2011). This bidirectional promoter was also used to drive the gfp gene in *N. oceanica* CCMP1779. In addition, Radakovits et al. (2012) selected TUB, HSP70A and UEP native promoters to drive *sh ble* gene in *N. gaditana* CCMP526. The UEP promoter was also used to drive the bHLH transcription factor and sfCherry in *N. salina* CCMP1776. Additionally, Vieler et al. (2012) developed LDSP endogenous promoter from *N. oceanica* CCMP1779 to drive the *aphVII* gene (Hygromycin resistance).

#### **Codon Usage**

Although several studies reported the expression of foreign proteins in transgenic *Nannochloropsis* strains, the expression efficiency of exogenous genes from other organisms was hindered by the variation of codon usage pattern in the transformed cells, resulting in poor translation rate or incorrect expression of certain amino acids within the coding region, thus either losing functionality of target protein products or reducing overall protein productivity. These phenomena were observed while developing several transgenic microalgae strains (Qin et al. 2012). Hence, the optimization of codon usage of transferred genes can improve the expression level of foreign protein and reduce the gene silencing of nuclear or chloroplast transformation in host cells. In particular, because the codon preference in chloroplast genome is unique, the exogenous gene derived from animals should be optimized. Recently, *Nannochloropsis* genome research has provided data for codon optimization which is a relatively effective way to increase protein stability and expression efficiency and avoid undesirable gene silencing. In addition, several software programs have been developed to estimate Codon Adaptation Index (CAI), which serves as a quantitative tool to predict foreign gene expression based on codon usage within different organisms (Shih et al. 2015), thereby allowing feasible optimization of codon usage of nuclear genes and chloroplast in *Nannochloropsis* strains.

#### **Further Improvement of Selective Marker System**

Two types of selective marker systems have been successfully applied in developing transgenic *Nannochloropsis* strains. Antibiotics-related selective markers can confer selective pressure directly on transformed cells, which is considered a simple, but effective, method for isolating the desired transgenic clones. However, the application of such marker genes in generating GMO has raised public concern over environmental and food safety issues. Consequently, these markers with antibiotics-resistant genes have become an obstacle for transgenic strains developed for foodstuffs. As a result, reporters, such as sfCherry, endow the host cells with fluorescent signal and thus serve as a selective marker, even while not exerting selective pressure or requiring fluorescent microscopy to screen transgenic *Nannochloropsis* strains (Kang et al. 2015a). The shCP isolated from marine invertebrate and its derivatives can circumvent this disadvantage, enabling the transformed cells to display dark brown coloration which can be easily observed and screened by the naked eye, although transformation efficiency is low (Umaima et al. 2016) owing to the absence of selection pressure.

Nevertheless, it is possible to solve some problems associated with the disadvantages noted above. For example, marker excision methods, such as direct-repeat-mediated excision via homologous recombination (Fischer et al. 1996), co-transformation (Rochaix 1997) and site-specific recombination (Landy 1989; Dale and Ow 1991; Onouchi et al. 1995), have all been reported to produce marker-free transgenic algae and other plants. This strategy provides a feasible way to eliminate antibiotics markers within the host genome, allowing the development of transgenic strains via antibiotic selective markers without violating any laws and regulations. However, no study has reported on the application of marker excision methods for transgenic *Nannochloropsis* strains.

Nonetheless, several methods are available to improve the transformation efficiency of shCP for establishing transgenic *Nannochloropsis* strains. For instance, transformation protocol, promoter and coding gene sequence can be further optimized, thereby increasing transformation efficiency and paving a way for yet another selective marker option for generating transgenic *Nannochloropsis* strains.

# *BIOGRAPHICAL SKETCHES*

### *Chen-Han Shih*

**Affiliation:** Agricultural and Biosystems Engineering Department, The University of Arizona, Tucson, AZ, USA

#### **Education:**

Bachelor of Science, Life science, Fu Jen Catholic U., Graduation Date: June 2011

Master of Science, Molecular and Cellular Biology, National Taiwan U., Graduation Date: January 2014 Professional Science Master, Applied Biosciences, U. Arizona, Enrollment Date: August 2016

PhD student, Agricultural & Biosystems Engineering, U. Arizona, Enrollment Date: January 2017

### **Business Address:**

Shantz Bldg., #38, Room 427, 1177E. Fourth Street, Tucson, AZ 85721-0038

### **Research and Professional Experience:**

- Optimizing the productivity of photobioreactor for different microalgae species.
- Invented novel idea to compliance laws and regulation for developing GMOs.
- Developed transgenic algae to reduce risk of cardiovascular disease and symptom of erectile dysfunction for health food application.
- Created transgenic algae capable of increasing survival rate of fish larva for aquaculture application
- Isolated new strains of bioenergy producing microalgae and cyanobacteria.

### **Professional Appointments:**

- Researcher of photobioreactor application research project (September 2016-Present) Prof. Cuello Agricultural & Biosystem Engineering Lab, UA
- Group leader of microalgae application research project (September 2011-Feburary 2014) Prof. Tsai Molecular and Cellular Biotechnology Lab, NTU
- Project leader of research project for National Science Council (August 2014-present)

#### **Honors:**

Outstanding student scholarship, Fu Jen Catholic University, 2007-2010.

## **Publications from the Last Three Years:**

CH Shih, HY Chen, HC Lee, HJ Tsai. Purple Chromoprotein Gene Serves as a New Selection Marker for Transgenesis of the Microalga *Nannochloropsis oculata*. *PLoS One*, 2015; 10. doi: 10.1371/journal.pone.0120780

## *Huai-Jen Tsai*

**Affiliation:** Institute of Biomedical Science, Mackay Medical College, Taiwan

## **Education:**

PhD in Microbiology, Oregon State University, USA

Master of Science in Marine Biology and Fisheries Science (IFS), National Taiwan University (NTU)

Bachelor of Science in Biology, Fu-Jen Catholic University, Taiwan

#### **Business Address:**

No. 46, Sec. 3, Zhongzheng Rd., Sanzhi Dist., New Taipei City 252, Taiwan

### **Research and Professional Experience:**

Molecular Biology, Marine Biotechnology, Developmental Biology, Gene Transgenesis on Aquatic Materials

### **Professional Appointments:**

- 2/2015-now, Visiting Professor, Institute of Biomedical Science, Mackay Medical College; Adjunct Professor, Institute of Molecular and Cellular Biology (IMCB), NTU 2/2004-1/2015, Professor, IMCB, NTU 2/2004-7/2010, Professor and Director, IMCB, NTU 8/1996-7/2001, Professor and Director, IFS, NTU 8/1994-1/2004, Professor, IFS, NTU
- 9/1988- 7/1994, Associate Professor, IFS, NTU
- 1/1988-9/1988, Postdoctor, Department of Biology, The Johns Hopkins U.

### **Honors:**

- 2015 Outstanding Research Award, Ministry of Science & Technology, Taiwan
- 2007 Excellent Teaching Award, NTU
- 2006 Distinguished Professor, NTU
- 2006 Y. Z. Hsu Technology Invention Award (Biotechnology Category) for invention patent titled "Novel Gene Fragment for Use in Golden Zebrafish"
- 2003 Outstanding Research Award, National Science Council, Taiwan
- 1999 Outstanding Research Award, National Science Council, Taiwan
- 1997 Who's Who in Science and Engineering, 4th edition, Marquis Who's Who, USA.
- 1977 Who' Who in Medicine and Healthcare, 2nd edition, Marquis Who's Who, USA.
- 1996-1997 Who's Who in the World, 14th & 15th edition, Marquis Who's Who, USA.
- 1985 Tarter Research Fellowship, Corvallis, Oregon, USA.
- 1984 The Bowerman Scholarship, Eugene, Oregon, USA.
- 1973 The Distinguished Student Award, NTU, Taiwan.
- 1971 The Distinguished Student Award, Fu-Jen Catholic University, Taiwan.

## **ABSTRACT**

The challenges in addressing sustainability goals include minimizing the environmental impact, energy consumption and wastes, and maximizing socio-economic benefits especially for the poor segments of the society, apart from the industrial players. Biorefining is a sustainable conversion of whole crop, green or lignocellulosic feedstocks via acid/enzymatic, chemical, gasification or pyrolysis processes into useful products for energy, fuels, pharmaceuticals or chemicals. Oil palm (*Elaeis guineensis Jacq*), a monoecious plant, is an eminent source of oil for food and biodiesel, and its agro-wastes are equally important for biomaterials. The palm oil industry has contributed significantly in meeting the demand and supply of the oil and fat production in the world market, and serving the agro-industry communities. In the oil palm biorefinery set-up, microalgae can be a unique component, not only as the source of biochemicals and bioproducts, but also as a part of integrated scheme of waste treatment and bioenergy co-generation, with the extraction of important commodities such as bio-oil, celluloses, lignins or biomaterials. In this review, the general characteristics, its potential and the cultivation of *Nannochloropsis oculata* are described using an integrated biorefinery approach based on palm oil milling as a model system. Issues addressed include the bioengineering aspects for the conversion of light into biomass, co-location strategy to take advantages of the industrial wastes, energy, water and nutrients, productivities of the different reactor systems and configuration, utilization of palm oil mill effluent (POME) as an alternative source of nutrients, biomaterials co-utilization, bioenergy co-generation and downstream processing aspects for extraction, purification and conversion into value-added products for pharmaceuticals and functional foods.

## **1.INTRODUCTION**

The major thrust for the production of fuels and chemicals from renewable sources stems mainly from environmental considerations, and the concerns with regards to the depletion of fuel reserves and the instability of fossil fuel supplies and prices (du Preez, 2016). Physical, biochemical or chemical routes to the conversion of any raw materials to the end products may be more economical when implemented within the context of an integrated biorefinery set-up. In bioprocesses, enzymes, microorganisms, mammalian or plant cells, wild or recombinant, may convert the feedstocks into antibiotics, biofuels, protein, and sugar hydrolysates, enzymes, vaccines, biopesticides, beverage, organic acids, and others. The bioprocess may be at its simplest and advantageous when put next to the routes involving chemical synthesis for bioproducts (Damaso et al. 2014). Industrial biorefineries producing multiple products can take advantage of the differences in biomass components and intermediates and maximizing the value derived from the biomass feedstock. A biorefinery therefore may produce one or several low volume, but high-value chemical products and a low-value, but high-volume liquid transportation fuel, whilst generating electricity and process heat for its own use or for sale. These 'green and clean' biorefineries are the basis of bio-molecular transformations that contribute to the production of biochemicals, biofuels and biomaterials (Doelle & DaSilva 2009; Abdullah et al. 2015a, b, 2016a, b, c).

Microalgae, consisting of small eukaryotic algae and prokaryotic cyanobacteria, have the advantages of converting the solar energy and CO<sup>2</sup> into bioproducts. Algae perform oxygenic photosynthesis, and like higher plants with a large variety of species, live in a wide range of environmental conditions. Capable of capturing carbon from many sources, some species actually hold higher potential as the oil-producer than oil seed crops, and may be processed into a wide range of products including biodiesel, green diesel, gasoline replacements, bioethanol, methane, fertilizer, bio-oil, animal feed, or biopharmaceuticals (Christenson & Sims 2011; Abdullah et al. 2016a; 2017). Algae can be cultured in open ponds, in photobioreactors (PBRs) or in hybrid modes. Heterotrophic algal culture may give high oil productivities but is prone to contamination especially in open ponds, and the cost of organic carbon source can be astronomical. Phototrophic cultivation is attractive for large scale investment, but the operation costs for mixotrophic and photoheterotrophic are high because of the need for a special PBR to avoid contamination risk and satisfy the light requirements (Chen et al. 2011). Furthermore, all stages involved in the microalgal biodiesel production chain may require high energy which adds up to the high production costs as compared to the conventional fuels.

Despite the algal technology for biofuels production being greatly advanced over the past decade, the commercial endeavour suffers from the constraints of yield, productivity and price (du Preez, 2016). The cost of algae-based bio-crude has been reduced from \$240 to \$7.50 per gallon, but to meet the long term goal of \$3/gasoline gallon equivalent, a combination of improvements in all key technologies together with productivity, conversion, and processing, must be made (Picardo et al. 2013; Yang et al. 2016). In this regard, the

integrated biorefinery concept within the palm oil milling set-up is an ideal solution as the organic residues from the oil palm industries can be used as the carbon source and for the value-added conversion of biomaterials, and the co-cultivation with microalgal biomass is attractive for renewable generation of biofuels and bioproducts whilst remediating the environment. This represent a new route to the production of high-value biocompounds with much lower impact on the environment and less interference in the food supply than the conventional oil seed crops. The whole processes from upstream to downstream, and the production of high value, low volume and high volume, low value products can be optimized (González-Delgado & Kafarov 2011; Abdullah et al. 2016a; 2017). Starch rich microalgae are extensively studied (Choi et al. 2010), and species such as *Nannochloropsis*, *Chlorella*, *Dunaliella*, *Chlamydomonas*, *Scenedesmus* and *Spirulina* are some of the most abundant organisms on earth, existing in salt or fresh water (Ruiz et al. 2013). *Nannochloropsis* sp. is one of the few species accepted as fuel and food and is therefore of broad interest as a highly productive commodity for biorefinery application.

This chapter covers the analysis of the productivities of the most recent culture systems, co-location of the algae biomass production process to core industry, the use of POME as alternative sources of nutrients, and the challenges in the development of a biorefinery system based on *N. oculata*. The sustainability of the process while minimizing the energy consumption, the socio-economic benefits and the importance of large-scale integrated microalgae-based biorefinery for the production of biofuel and bioproducts including biofertilizers and aquafeed, using marine water and nutrients from POME, are also highlighted.

## **2. FACTORS AFFECTING** *NANNOCHLOROPSIS OCULATA* **CULTIVATION**

### **2.1. Effects of pH, Salinity and Light Intensity**

*N. oculata* are marine eustigmatophyceae, possesing a high biomass productivity which may reach up to 3  $gL^{-1}day^{-1}$  and up to 30–70% lipid by dry weight, which is suitable for biodiesel production (Rodolfi et al., 2009; Chen et al., 2011). Factors such as pH, salinity, light intensity and duration, availability of macro and micronutrients and reactor configuration and mode of operation could all influence the biomass and lipid productivity. Different geographical strains have different preferences towards salinity and optimal salinity may be a function of immediate conditions from which the strain is initially isolated. Species isolated at higher salinities will grow better at higher salinities and may not be as good at lower salinities (Cucchiari et al. 2008). Light is the main source of photosynthesis and light intensity influences cell photo-acclimatization for microalgal growth and lipid synthesis, where strong illumination may induce their accumulation (Takagi & Yoshida, 2006). The quantity of photon energy absorbed by each cell is further affected by factors such as cell density, photoperiod, length of optical path, thickness of layers, photon flux density and rate of agitation. The responses of microalgal strains to different light intensities are indication of the light antenna accessibility on cell surface and cell responds by modulating the composition of its photosynthetic apparatus, a response called acclimation (Simionato et al. 2011). Larger quantity of light energy may induce more metabolic flux channelled into lipid accumulation on a unit biomass basis. The high lipid content at high light exposure is measured as a total global radiation (TGR) where light and photoperiod may actually influence the cultivation temperature. Light and temperature therefore play a synergistic role in algal lipid synthesis and accumulation (Weldy & Huesemann, 2007).

In comparing the performance of two green microalgae (*N. oculata* and *Tetraselmis suecica*) with two brown microalgae (*Isochrysis galbana* and *Pavlova lutheri*) in Conway media in 250ml flask cultivation over two weeks period, all isolated from marine environment that thrive at high salinity, *N. oculata* shows superior performance in terms of biomass and lipid productivity. Only *P. lutheri* shows high lipid level comparable to *N. oculata*. The highest cell density of 75.5  $\times$  10<sup>6</sup> cells mL<sup>-1</sup> (maximum biomass of 0.80 gL<sup>-1</sup>) achieved at 35-40 ppt salinity by *N. oculata*, is almost 1.5-5 fold higher than the other 3 strains. Generally, the shortest doubling time is observed in pH 7–9 media, while the longest at pH 5-6 and 10. *N. oculata* and *P. lutheri* attain the highest lipid contents of 31.3-36.5% at pH 8 and 35 ppt salinity, while the lipid contents for *T. suecica* and *I. galbana* are lower, around 23.4-26.3% (Shah, 2014). The transition from low to high photoperiod and light conditions enhance both cell growth and lipid accumulation by 2-fold (Shah, 2014). This is in agreement with a study on *N. salina* which has the lipid enhanced from 10 to 70% when the light intensity is increased from 150  $\mu$ E m<sup>-2</sup> s<sup>-1</sup> to 350  $\mu$ E m<sup>-2</sup> s<sup>-1</sup> (Sforza, et al. 2012), and *Ochromonas danica* where the cell growth and lipid content increase with increasing light intensity (Verma et al. 2010). Increased microalgal lipid productions to  $26-36%$  at temperatures  $25-30^{\circ}$ C for several microalgal species have been reported. However, reduced lipid level to 15-20% at extremes of low (15<sup>o</sup>C) and high temperature (30<sup>o</sup>C) has been observed in *I. galbana and Nanochloropsis* species (Sayegh & Montagnes, 2011). Low temperatures reduce enzyme activity in glycolysis and the Krebs cycle and consequently the metabolism of carbon sources.

#### **2.2. Effects of Macro and Micronutrients**

The effects of nitrate, phosphate and iron investigated at  $120-150$  gL<sup>-1</sup> KNO<sub>3</sub>,  $12-15$  g L<sup>-</sup> <sup>1</sup> Na<sub>2</sub>HPO<sub>4</sub> and 4–5 g L<sup>-1</sup> FeCl<sub>3</sub> show that *N. oculata* maintain the highest cell density (72.3  $\times$ 10<sup>6</sup> cells mL<sup>-1</sup>) and maximum biomass (0.81 g L<sup>-1</sup>), followed by *T. suecica* with 46.5  $\times$  10<sup>6</sup> cells mL<sup>-1</sup> density and 0.70 g L<sup>-1</sup> biomass. The maximum specific growth rates,  $\mu_{max}$ , are 0.16–18 d-1 , with the doubling time, *td*, of 3.78–4.62 days. Both *I. galbana* and *P. lutheri* only achieve  $17 \times 10^6$  cells mL<sup>-1</sup> though almost comparable dry weight at 0.7 g L<sup>-1</sup>. Although cell growth appears to require excesses of nitrate, phosphate and iron, lipid production is only induced under conditions of nutrients limitation with the highest lipid content achieved by *P. lutheri* at 34.2-37.1% (in 40 g L<sup>-1</sup> KNO<sub>3</sub>, 2 g L<sup>-1</sup> FeCl<sub>3</sub> and 4 g L<sup>-1</sup> Na<sub>2</sub>HPO<sub>4</sub>) and *N. oculata* at 33.1-35.3% (in 10 g L-1 KNO3, 4 g L-1 Na2HPO4 and 2 g L-1 FeCl3). *I. galbana* and *T. suecica*  only attain around 23.8-26.8% lipid. Lipid production is therefore highly affected by nitrate and phosphate concentration where excesses could inhibit lipid production while iron shows little effect (Shah, 2014). The total lipid contents of 35.9, 29.8, and 32.1% respectively, have been reported for *N. oculata* SHOU-S14, *T. subcordiformis* SHOU-S05, and *P. viridis* SHOU-S16 cultured in different amounts of nitrogen level (Bondioli et al. 2012). The increase of lipid contents in *N. oculata* from 7.9% to 15.31% and *C. vulgaris* from 5.9% to 16.41% are achieved at reduced nitrogen as low as 75% (Harwood & Guschina, 2009).
**Table 1. Establishment of kinetics between 5 L PBR and 300 L open tank cultures at optimized conditions as predicted**  Table 1. Establishment of kinetics between 5 L PBR and 300 L open tank cultures at optimized conditions as predicted by Response Surface Methodology (Shah, 2014) **by Response Surface Methodology (Shah, 2014)**

c *I. galbana* : pH 9, Salinity (39.2 ppt), photoperiod (20.5 hrs), light intensity (188.7 μmol photons m−2 s −1 ), KNO3 (75.4gL −1 ), Na<sub>2</sub>HPO<sub>4</sub> (8.9gL −1 ) and  $FeCl<sub>3</sub>$  (2.8gL −1 ) d *P. lutheri* : pH 7.9, Salinity (35.5 ppt), photoperiod (24 hrs), light intensity (198 μmol photons m−2 s −1 ), KNO3 (62.5gL −1 ), Na<sub>2</sub>HPO<sub>4</sub> (3.92gL −1 ) and FeCl $_3$  (2.63gL −1 ) Note: For 300 L open tank photoperiod was 12 hrs and light intensity was 165-250 µmol photons m<sup>−2</sup> s −1 (shaded from direct sunlight). Table 2. Fatty acid profile at optimized pH and salinity (Shah, 2014) **Table 2. Fatty acid profile at optimized pH and salinity (Shah, 2014)**

Nitrogen stress on *N. oculata* (75  $gL^{-1}$ , 37.5  $gL^{-1}$  and 150  $gL^{-1}$ ) and *C. vulgaris* (75  $gL^{-1}$ , 150  $g L<sup>-1</sup>$  and 300 g  $L<sup>-1</sup>$ ) with nitrate in the form of NaNO<sub>3</sub> have been reported under light intensity of 70  $\mu$ E m<sup>-2</sup> s<sup>-1</sup> at 20°C. Low nitrogen in the growth medium increases the lipid production, as the higher nitrogen level could extend the growth cycle thus lowering the lipid productivity (Harwood & Guschina, 2009).

## **2.3. Effects of Reactor Configuration**

Reactor configuration may exert different hydrodynamics conditions that could affect algal productivity (Shah et al. 2014a; Abdullah et al. 2015b; 2016a; 2017). Comparing between cultivation in 250mL flask with 1L, 5L and 30L tanks, *N. oculata* and *P.* lutheri show the highest cell densities of 64.6 x  $10^6$  and 14.5 x  $10^6$  cells mL<sup>-1</sup>, respectively, in 250 mL flask, but the densities are lower at 52.6 x  $10^6$  and  $10.7$  x  $10^6$  cells mL<sup>-1</sup>, respectively, in 30 L tank. Only *N. oculata* and *P. lutheri* show higher lipid content at 32-37%, while the highest  $\mu_{max}$  of 0.15 d<sup>-1</sup>,  $t_d$  of 4.62 days and lipid content of 36.8 are achieved by *N. oculata* in 250 ml shake-flask (Shah, 2014; Shah et al. 2014a; Abdullah et al. 2015b). Comparing between cultivation in 5L PBR and 300L open tanks (Table 1), the highest cell density and biomass are achieved by *N. oculata* at  $78.8 \times 10^6$  in 5 L PBR and  $55.5 \times 10^6$  cells mL<sup>-1</sup> in 300 L tank with 0.93 and 0.65 gL<sup>-1</sup> biomass, respectively. All strains show the highest  $\mu_{max}$  of 0.21-0.24 d-1 (*t<sup>d</sup>* of 2.92-3.30 days) in 5 L PBR as compared to *μmax* of 0.19-0.23 d-1 (*t<sup>d</sup>* of 2.98- 3.61 days) in 300 L open tank. The lipid content remains higher in 5 L PBR at 42.2 and 41.2% as compared to 300 L open tank at 36.2 and 38.5% for *N. oculata* and *P. lutheri*, respectively (Shah, 2014). Table 2 shows that pentadecanoic acid C15:0 (6.1%, 14.7%); palmitic acid C16:0 (38.2%, 25.2%); palmitoleic acid C16:1 (11.0%, 5.2%); oleic acid C18:1  $(6.1\%, 7.9\%)$ ; and eicosanoic acid C20:0  $(6.0\%, 3.7\%)$  are the major components of the oil derived from *N. oculata* cultivated in PBR and open tank, respectively. The total saturated fatty acids (TSFA) (63.8%, 55.03%); monounsaturated fatty acids (MUFA) (17.1%, 13.1%); and (polyunsaturated fatty acids) (PUFA) (15.7%, 9.4%) are obtained for *N. oculata*, respectively. The major components of *P. lutheri* are palmitic acid C16:0 (32.3%, 28.4%); palmitoleic acid C16:1 (22.4%, 19.4%); oleic acid C18:1 (12.1%, 8.3%); and docosahexaenoic acid (DHA) C22:6 (5.7%, 4.8%) with the TSFA (46.9%, 38.1%); MUFA (34.5%, 27.6%); and PUFA (14.5%, 11.4%) respectively, for cultivation in PBR and open tank (Shah, 2014; Shah et al. 2014a; Abdullah et al. 2015b).

## **3. DIFFERENT TYPES OF BIOREFINERY**

Algae are like microscopic factories producing all sorts of useful compounds. They are composed of different lipids (7-23%), carbohydrates (5-23%) and proteins (6-52%) (Zhu, 2015). A way to improve the productivity is to obtain a full valorization of each microalgae components with products of the highest possible value (Vanthoor-Koopmans et al. 2013). Integrated biorefinery converts biomass into multiple end products to produce energy in the form of heat or by producing biofuels, molecules for fine chemistry, cosmetics or medical applications, materials such as polymers or plastics and sources of human food and animal

feed. Figure 1 illustrates the generalized outline of a biorefinery (González-Delgado & Kafarov 2011) which is derived from petroleum refineries, producing not only fuels, but also fine chemicals for the chemical industry (Markou & Nerantzis 2013). It combines in a single facility the production of various products by multiple steps, arranged into a cascade chain that use all the raw material components and prevent losses. But care must be taken at each step to not damage one or more of the products (Vanthoor-Koopmans et al. 2013). Moreover, several steps of any type of biorefinery need improvements to lower the global cost of the process. The different types of biorefinery are discussed below.

Figure 1. General outline of the biorefinery concept (adapted from González-Delgado & Kafarov 2011).

#### **3.1. Oil Recovery Biorefinery**

Current production methods for liquid biofuel production from microalgae produce approximately 60–70% residual biomass that is currently a byproduct. The oil recovery biorefinery uses transesterification process in the treatment of oil and fat, and domestic cooking oils originating from soybean, corn, palm, and canola, to yield fatty acid methyl esters commonly known as biodiesel. The conversion of triacylglycerides (TAGs) extracted from algae biomass to fatty acid methyl esters (FAMEs) is called transesterification reaction, which displaces an alcohol group from an ester by another alcohol (Demirbas 2008). Direct transesterification brings wet microalgae directly into transesterification process, before methanol recovery and biodiesel produced. The indirect method, in contrast, involves cell disruption, solvent extraction, and solvent recovery before transesterification, methanol and biodiesel recovery (Park et al. 2015).

Transesterification can be performed using different heating systems via catalytic or noncatalytic reaction systems. The technology is mature and used as a standard in the conversion of vegetable oils into biodiesel (Hossain et al. 2008) with ethanol and sodium ethanolate serving as the catalyst (Zhou and Boocock 2006). The products are separated by adding ether and salt water to the solution and mixed well. Biodiesel is separated from the ether by a vaporizer under a high vacuum. Base-catalysed transesterification is faster, but would leave free fatty acids behind and un-transesterified. This saponification can also result in significant losses due to the water solubility of the fatty acid soaps (Laurens et al. 2012). Another route in biodiesel production from algae is acid-catalyzed transesterification (Wahlen et al. 2008). The replacement of soluble bases by liquid-acid catalysts such as  $H_2SO_4$ , HCl, or  $H_2PO_4$ , is attractive as the acidic catalysts are less sensitive to the presence of water and free acids, which mitigate saponification and emulsification, to enhance product recovery (Ataya et al. 2007). However, these are more applicable to the transesterification of different lipid types and also have lower activity than the conventional alkaline catalysts.

The development of immobilized heterogeneous or homogeneous catalysts or enzymes that are efficient and inexpensive is needed (McNeff et al. 2008) and may hold a key role for economical method of biocatalytic transesterification (Gerken et al. 2013). Acid and base catalysts could be classified as Bronsted or Lewis catalysts. Lewis acid catalysts such as  $AlCl<sub>3</sub>$  or  $ZnCl<sub>2</sub>$ , have been proven as a viable means of converting TAGs into fatty acid methyl esters while the presence of a co-solvent such as tehtrahydrofuran, may be vital to achieve high conversion efficiencies of up to 98% (Soriano et al. 2009). Hetero-polyacids catalyzed transesterification of vegetable oil achieves higher reaction rates than conventional mineral acids due to their higher acid strength (Xu et al. 2008). Microwave heating can improve the kinetics of transesterification and the presence of catalysts further enhance the impact of microwave irradiation (Yuan et al. 2008). In the ultrasonic reactor, ultrasonic waves cause the reaction mixture to produce and collapse bubbles constantly and simultaneously, providing the mixing and heating for transesterification process (Armenta et al. 2007) with reduced reaction time, temperatures, and energy input (Kalva et al. 2008).

Chemical processes through high conversion of TAGs, resulting in their corresponding esters, are energy-intensive, and require the removal of glycerol and alkaline catalysts and the treatment of alkaline wastewater. Biocatalysts such as lipases offer more environmentally attractive option (Svensson and Adlercreutz 2008), but have not been scaled up due to the relatively high price of lipase and the short operational life caused by excessive methanol and co-product glycerol. Solvents are sometimes necessary to enhance the solubility of the TAGs during the extraction process that the enzymes used must be solvent and temperature tolerant to enable cost-effective biofuel production (Fang et al. 2006). Novel enzymes with desired characteristics may be produced by bioprospecting for the enzymes in extreme environments (Guncheva et al. 2008). Another route for a more powerful extraction than the traditional solvent-separation method is the supercritical processing of algal oil or extracts. The supercritical fluids are selective, providing high purity and product concentrations with no organic solvent residues in the extract or spent biomass (Demirbas 2009). They can be used on the whole algae without dewatering or coupled to transesterification reaction scheme to enable a "one-pot" approach to biofuel production (Anitescu et al. 2008). The extraction is efficient at modest operating temperature of less than 50°C, ensuring product stability and quality. Supercritical methanol or ethanol can be both the oil-extraction medium and the reagent for transesterification (Warabi et al. 2004; Hawash et al. 2009). The catalyst-free, supercritical ethanol transesterification, is capable of tolerating water, with conversion yield similar to anhydrous process for the conversion of vegetable oils. Water in the reaction medium however affects process efficiency but the decomposition of fatty acids is the main factor that limits the attainable ester content (Vieitez et al. 2009).

#### **3.2. Biogas Biorefinery**

The refinery uses natural consortia of microorganisms in anaerobic digesters, producing methane from decomposing organic material, organic wastes and manures. Combining and integrating alternative energy technologies with algal production, will foster synergistic development, supporting a self-sustaining community system (Shen, 2014, Abdullah & Ahmad, 2016). Three pathways have been defined for the implementation of anaerobic digestion into algal production processes:- Pathway 1 for the direct anaerobic digestion after the harvesting of biomass, or utilized in a wastewater process where the cell wall is degraded by bacterial activity within the digester; Pathway 2 for the anaerobic digestion of biomass after cell wall disruption prior to conversion; and Pathway 3 for the traditional biodiesel practice where lipid is extracted and residual algal biomass is converted to biogas by anaerobic digestion and methane fermentation (Ward et al., 2014). The system using anaerobically digested agricultural waste materials to feed algal cultures exhibits  $CO<sub>2</sub>$ abatement and reclamation and the use of other waste streams such as water and heat (e.g., from the digester and co-generation) supports optimum sustainable algal growth (Figure 2) (Shen, 2014). Anaerobic digestion is cost-effective as it eliminates processes such as drying, extraction and fuel conversion which incur high costs of algal biofuels. Although the cost of growing algae is high, methane production is a low value product. It can be utilized to generate *on site* electrical power or thermal heat to offset biomass processing and extraction processes, and allows nutrient recovery (such as nitrogen and phosphorous) from lipid extracted biomass. The methane produced readily separates from water without energy or chemical input, and can be converted to poly-hydroxybutyrate (bioplastics) blends to increase the value of biogas (Myung et al. 2015).

Figure 2. Schematics of an integrated algal culture system for bioremediation and biofuel production (adapted from Shen, 2014).

Scaling up to industrially relevant scales and optimizing the species-specific effects on methane production are two key challenges. Other issues include the low concentrations of digestible, algal biodegradable substrate, recalcitrant-substrate constituents, algal cell wall degradability, algal low carbon to nitrogen ratio, ammonia toxicity, and effects from salinity and associated metal ions (Ward et al. 2014). Co-digestion of other feedstocks with algal biomass may raise the carbon to nitrogen ratio, or proteins may be pre-extracted to use as coproducts prior to digestion. A two stage anaerobic digestion with different strains of algae could produce 180.4 mlg<sup>-1</sup>d<sup>-1</sup> of biogas with 65% methane concentration (Vergara-Fernández et al. 2008). Fugitive methane emissions must be managed via engineering or process flow as the emissions could be large (Frank et al. 2012). When processes are integrated and operated simultaneously, the benefits to microalgae biofuel production and wastewater treatment derived energy production are enhanced (Ward et al., 2014).

#### **3.3. Sugar Feedstock Biorefinery**

High-carbohydrate content from holocellulose-based cell walls and starch-based cytoplasm make algal biomass a suitable feedstock for bioethanol production. During microbial hydrolysis, carbohydrate polymers are broken into simple sugars, followed by fermentation to yield bioethanol (Kumar et al. 2013). Bioethanol production from algal biomass takes place by either the sugar or syngas pathway. Algae are directly fermented to produce bioethanol by the sugar pathway, while via the syngas pathway, hydrocarbons of algal biomass are converted to syngas through gasification followed by fermentation of syngas to produce bioethanol. Similar to cellulosic ethanol, algal bioethanol production requires four major unit operations:- pretreatment, hydrolysis, fermentation, and distillation. Different pretreatment methods have been evaluated to help separate cellulose, hemicellulose, and lignin so that the complex carbohydrate molecules in the algae cell can be broken down by enzyme-catalyzed hydrolysis into simple sugars. The fermentable sugars can be fermented into ethanol by ethanol-producing microorganisms before finally recovered and purified to meet the fuel specifications. Some separated solids can be recovered and utilized as a fuel to provide process heat and electricity at the production facility (Li et al. 2014 a).

Another promising fuel, butanol, has several advantages over bioethanol as it has higher energy content than ethanol and more similar to diesel fuels, in terms of energy content (Tigunova et al., 2013) and it could be blended with gasoline at any percentages. Butanol also has lower vapor pressure, absorbs less moisture and less corrosive as transported fuel. Butanol (C4H9OH) is a colorless liquid among the four carbon alcohols, and can be produced by chemical and biological methods. The economy of butanol production by chemical methods is highly dependant on the oil price while in biological methods, the cost of the raw material used is the determining factor. Due to the unstable price of crude oil, biological process is a promising route (Amiri et al., 2015), for a more economical and energy-efficient butanol production from biomass than ethanol, as some bacteria digest not only starch and sugars, but also cellulose (Huesemann et al. 2010). Different processes including batch, fedbatch, and continuous fermentation with and without *in situ* product removal using native and modified strains in the free and immobilized mode, have been reported (Chen et al., 2014; Rathore et al., 2015).

Overproduction of butanol can be achieved by mutagenesis, evolutionary engineering, and genomic studies and transcriptional analysis (Cooksley et al., 2012). For example, *Clostridium* produce acetone, butanol and ethanol (ABE) by anaerobic fermentation of both hexoses (C6) and pentoses (C5) (Van der Wal et al. 2013), but butanol is inhibitory to the fermentation which limits the yield and productivity. The fermentation of *Ulva lactuca* by *Clostridium* strains have produced butanol with a yield of 0.16 g butanol  $g^{-1}$  C5 and C6 sugars, but the yield of butanol is lower than that of ethanol produced under comparable conditions (Nikolaison et al. 2012). Using evolutionary dynamics and natural selection, referred to as artificial simulation of bio-evolution which is a repetitive evolutionary training, *C. acetobutylicum* could tolerate upto 4% butanol (Liu et al., 2013). Naturally occurring macroalgae (*Ulva*) has been found as a suitable feedstock for butanol (Potts et al. 2012). *Ulva lactuca* solubilised by hot water treatment, followed by hydrolysis using commercial cellulases to produce sugars, is used as a feedstock for fermentation by *Clostridium* for the production of ABE with a yield of 0.35 g ABE  $g^{-1}$  sugar (Van der Wal et al. 2013). However, ABE produced is proposed for the subsequent production of 1, 2 propanediol (propylene glycol) in a seaweed biorefinery to replace fossil fuel derived product rather than as a source of butanol. Macroalgae (e.g., seaweed) has also been examined for bioethanol fermentation due to the presence of sugars such as mannitol and laminarin (Ruiz et al. 2013). However, brown algae (*Saccharina*), produce low yields at 0.12 g g−1 extracted soluble solids (Huesemann et al. 2012) where the main fermentation substrates are mannitol and glucose derived from laminarin, and abundant. Brown algae, such as *Laminaria hyperobea*, is composed of organic fraction in the form of alginate and abundant alginates are recalcitrant and do not undergo fermentation (Horn et al. 2000).

## **3.4. Thermo-Chemical Biorefinery**

Hydrothermal liquefaction (HTL) processing technology is a representation of the natural geological processes in the formation of petroleum based fossil fuels. HTL of biomass converts wet algal slurry to a range of liquid fuels in a hot (523 K–647 K) and pressurized (4– 22 MPa) water environment at 3–5 mins residence times to disassemble cells into liquid components (Elliott 2016). At lower temperatures  $\left(\langle 275^{\circ} \text{C} \right)$  and pressure  $\left(\langle 2 \text{ MPa} \right)$ , hydrochar is produced, and at higher temperatures ( $>374^{\circ}$ C) and pressures ( $>22.1$  MPa), syngas is produced. The main product of liquefaction biocrude, which can be upgraded to the entire distillate range of petroleum derived fuels, typically accounts for 45% wt. of the feedstock on ash free dry weight basis for fast growing, low total lipid algae. The yields are much higher for high total lipid algae such as *Nannochloropsis* sp. cultivated to varying composition to achieve HTL biocrude yield of 33–68 wt% (Leow et al. 2015). The HTL processing of algae requires dewatering, usually accomplished by mechanical means to a slurry of typically 10–20% dry solids. Continuous-flow HTL reactor of microalgae yields between 38–64% (ash free dry weight basis) with an energy recovery of 60–78% (Jazrawi et al. 2013). Algal lipid, protein, and carbohydrate composition influences HTL-conversion efficiency, where higher total-lipid content and lower protein yield higher energy recovery (Li et al. 2014 b). High-protein content may result in higher nitrogen (N) concentration in the biocrude requiring significant denitrification during upgrading to limit nitrogen-oxide emissions (Sudasinghe et al. 2014). Potential production strains of algae have higher N

contents  $(4-10%)$  as compared to the lignocellulosic feedstocks  $(< 1%)$  (Vardon et al. 2012). HTL application to algae has the potential of nutrient recycling through the precipitation of solids, allowing phosphorous recovery and the transformation of N into ammonium that can be fed back into the algae pond (Elliott et al. 2015). Two step sequential HTL (SEQHTL) has been developed to isolate polysaccharides or other high-value products (Chakraborty et al. 2012) to produce biocrude with low N content (Prapaiwatcharapan et al. 2015), or to collect aqueous phase rich in organic carbon and nutrients to enhance biomass productivity (Selvaratnam et al. 2015). With SEQHT, there may be a trade-off between N removal and overall biocrude yield (Jazrawi et al. 2015) but higher biocrude yield is achieved as compared to HTL (Prapaiwatcharapan et al. 2015). The algal HTL processing to fuels is currently scaled up to pilot plant operations and several small algae processing companies are developing HTL of whole algae (Elliott 2016).

The thermochemical treatment of algae, or other biomass can result in a wide range of products, depending on the reaction parameters. Liquid product yield tends to favor short residence time, fast heating rates, and moderate temperatures (Huber et al. 2006). Pyrolysis is another common chemical decomposition method for a condensed substance by heating in the absence of O2. Pyrolysis is extremely fast, in comparison to other conversion methods, with reaction times of the order of seconds to minutes. Higher efficiency can be achieved by flash pyrolysis or fast pyrolysis technology, where finely ground feedstock is quickly heated to  $350-500$ °C for less than 2 seconds. For flash pyrolysis, typical biomass feedstocks must be ground into fine particles and dried to <10% moisture. Several commercial plants for fast pyrolysis of biomass have been built in Finland, Canada, and Netherlands to produce fuel oil for heating. Fast pyrolysis bio-oil is also marketed by Ensyn as food flavorings and fuel oil (López Barreiro 2013). The pyrolysis of algae takes place at 400–600°C (López Barreiro 2013). Algae have major advantages over other biomass sources because it exists fundamentally in small units with no fiber tissue and more homogeneous than most biomass or coal. However the major barrier to pyrolysis of algae is moisture content. The cost of algal drying has resulted in the overall process to be energy negative (Jena et al. 2011). Comparison of bio-oil from pyrolysis of algae and biocrude from HTL of algae shows that bio-oil from pyrolysis has lower energy content and also less stable (Jena et al. 2011). Elemental analysis of pyrolitic bio-oil production from the wastewater treatment pond of algal biomass indicates that the bio-oil contain >65 wt.% carbon, 6-9 wt.% N, 8–10.2 wt.% hydrogen and an energy content of 34.4-37 kJ/g, all with higher values at higher temperature (400°C–500°C) except for nitrogen (Mehrabadi et al. 2016). Biocrude produced from HTL and slow pyrolysis of *Spirulina* and *Scenedesmus* are similar in energy density, but the net energy yield of HTL is more favorable (Vardon et al. 2012). Pyrolysis may not be costcompetitive over the short-term unless an inexpensive dewatering or extraction process is developed with the bio-oil demonstrating superior properties to oil produced from other conversion processes.

## **4. PALM OIL MILL BIOREFINERY**

Palm oil industry in Malaysia has generated large amount of biomass and effluent in the form of empty fruit bunches (EFB), palm kernel shells, fibers, fronds, trunks and POME. The

palm oil mill biorefinery involves the utilization of oil palm biomass for the production of biofuels, the conversion of biomass residues into value-added products and the microalgal cocultivation developed within palm oil milling processes for environmental remediation and subsequent recovery of bio-products (Abdullah et al. 2016a, b, c; Abdullah & Ahmad, 2016). The refined crude palm oil (CPO) methyl ester can be used directly or blended with petroleum diesel as biodiesel but the use of CPO raises the issue of food versus fuel that need to be addressed. EFB contains cellulose, hemicelluloses, lignin, and extractives that can be converted into bio-oil; or into bioethanol. The solid residues such as shells and fibres can be used for steam and electricity generation in the mill, the EFBs re-used as fertilizer and the palm kernel cake composted. POME is considered one of the most polluting agro-industrial effluent due to its high values of COD and BOD concentrations ranging from 50,000 to 90,000 mg  $L^{-1}$  (Damayanti et al. 2010). Without effective treatment, considerable environmental problems could occur such as the percolation of POME into the waterways and ecosystems, land and water pollution and destruction of aquatic biota (Singh et al. 2011). POME contains high concentration of organics and inorganics materials, and is normally treated in the ponding system with low investment cost (Abdullah & Ahmad, 2016). Raw EFB has a high potential as a substrate to produce methane. The study at the lab scale on cosubstrate addition (EFB and palm kernel) in the anaerobic digestion process of POME in a 500 ml reaction vessel attains maximum specific biogas production rate  $(0.0574 \text{ m}^3/\text{kg})$ chemical oxygen demand per day) and methane level  $(25.6%)$  at  $47.8$ °C operating temperature, 50.4 mL POME volume, and 5.7 g EFB addition (Saleh et al. 2012).

## **4.1. Algal Biomass Co-Utilization**

Conventional treatment of municipal wastewater involves primary and secondary biological treatment but it may only remove a fraction of nitrogen and phosphorus (Orpez et al. 2009). Algal treatment offers more efficient means as it could reduce the eutrophication potential with a more environmentally sound approach (Orpez et al. 2009). In biorefinery, microalgal cultivation is the major and critical step and the use of wastewater (municipal, industrial, agricultural) could reduce the cost substantially due to easy access to substrate and abundantly available free nutrients whilst reducing large amount of freshwater consumption (Pittman et al. 2011; Zhang et al. 216; Abdullah & Ahmad, 2016). It allows sharing of waste management and is one of the viable option to obtain biofuels able to compete with petroleum based ones. As sludge disposal of wastewater treatment plants is one of the major challenges of sustainable wastewater engineering, utilizing and producing algal biomass in excess not only produces an oxygenated effluent whilst remediating the pollutants and eliminating nitrogen, phosphorus or metals without organic carbon requirement, but also becomes a source of biomethane and high-value products (Ruiz et al. 2011; Abdullah et al. 2015a; Abdullah & Ahmad 2016). Contamination may be the major challenge though, that resistance must be considered as fundamental when selecting microalgal strains (Zhang et al. 216; Roux et al. 2017). The selected species must be adapted to large scale cultivation, grow quickly and produce high amount of high quality lipids (Rashid et al. 2014).

#### **Table 3. Box-Behnken design and responses of multi-algal species and EFB anaerobic co-cultivation (Ahmad et al. 2016)**

Anaerobic co-cultivation of mono-culture *N. oculata* at 2 mL mL-1 POME with EFB at 0.12 g mL<sup>-1</sup> POME, attains the highest specific biogas production rate of 0.113–0.114 m<sup>3</sup> kg<sup>-1</sup> COD  $d^{-1}$  and the methane rate of 4606–5018 mL CH<sub>4</sub> L<sup>-1</sup> POME  $d^{-1}$  (Ahmad et al. 2015). However, it is the co-digestion of mono-culture *Chlorella* sp. with EFB, POME and sludge inocula which achieves the highest biomethane  $(5276 \text{ mL L}^{-1} \text{ POME } d^{-1})$  and specific biogas production (0.129 m<sup>3</sup> kg<sup>-1</sup> COD d<sup>-1</sup>) rates at 2 mL mL<sup>-1</sup> POME and EFB of 0.12 g mL<sup>-1</sup>

POME, after 3 days of cultivation, with high removal efficiencies of COD (95  $\sim$ 98%), BOD  $(90 \sim 98\%)$ , TOC  $(80 \sim 86\%)$ , and TN  $(80\%)$  after 7 days treatment (Ahmad et al. 2014). The multi-algal co-cultivation of *N. oculata* and *Chlorella* sp. (each at 1 mL mL-1 POME) with EFB (0.12 g mL<sup>-1</sup> POME) (Table 3) achieves the highest biomethane (4651.9 mL CH<sub>4</sub> L<sup>-1</sup> POME  $d^{-1}$ ) and the specific biogas production (0.124 m<sup>3</sup> kg<sup>-1</sup> COD  $d^{-1}$ ) rates with CO<sub>2</sub>  $(2265.9 \text{ mL } CO<sub>2</sub> L<sup>-1</sup> POME d<sup>-1</sup>)$  (Ahmad et al. 2016). Utilizing *N. oculata*, and *Chlorella* sp. achieve the anaerobic removal of COD (95-98%), BOD (90-98%), TOC (80-86%) and TN (80%), far better than without microalgae (Ahmad et al. 2014; 2015).

POME level	$pH^*$	$\rm COD$	<b>BOD</b>	<b>TOC</b>	<b>TN</b>	Oil and grease
1. Raw						
1%	$6.5 - 7$	627	183	33.4	5.43	30.3
5%	6.2	2974	843	153.1	28.6	144.5
10%	5.5	5839	1642	285.5	56.7	285.1
15%	4.7	8947	2448	456.8	80.3	364.5
2. N. oculate						
1%	$\overline{7}$	63	21	12	0.5	5.3
5%	7.5	145	32	53	4	9.8
10%	7.8	375	47	87	7	15.6
15%	8.3	558	94	115	13	18.7
3. T. suecica						
1%	$\tau$	84	34	19	$\overline{c}$	9.3
5%	6.5	196	47	67	$\overline{7}$	16.7
10%	7.3	463	62	104	12	22.8
15%	7.2	638	114	132	18	31.7

**Table 4. Chemical characteristics of POME at different compositions in sea water before and after inoculation of** *N. oculata* **and** *T. suecica* **(Shah et al. 2016)**

 $*$  All values are in mg  $L^{-1}$  except for pH

Different concentrations of filtered and centrifuged POME in sea water (1, 5, 10 and 15%) has been successfully utilized as an alternative medium for algal cell growth and lipid production (Shah et al. 2016). Both *N. oculata* and *T. suecica* show enhanced cell growth and lipid accumulation at 10% POME with maximum specific growth rate of 0.21  $d<sup>-1</sup>$  and 0.20 d<sup>-1</sup> <sup>1</sup>, and lipid content of 39.1 and 27.0%, respectively, after 16 days of flask cultivation. In comparison, both *I. galbana* and *P. lutheri* also show enhanced cell growth and lipid accumulation but at 15% POME level and with lower maximum specific growth rate  $(0.16 d<sup>-1</sup>)$ and  $0.14$  d<sup>-1</sup>) and lipid content (26.3 and 34.5%), respectively, after 16 days of cultivation (Shah et al. 2014). The TSFA (59.24%, 68.74%), MUFA (15.14%, 12.26%); and PUFA (9.07%, 8.88%) are obtained for *N. oculata* and *T. suecica*, respectively at 10% POME. Both *N. oculata* and *T. suecica* are potential candidates for biodiesel production where *N. oculata* contains high palmitic acid (C16:0) at 28.22% and palmitolic (C16:1) at 9.37%, while *T. suecica* contains high palmitic acid (C16:0) at 36.48% and pentadecanoic acid (C15:0) at 9.21%. Table 4 shows that *N. oculata* and *T. suecica* addition also further reduce the BOD, COD, TOC, TN and oil and grease in POME (Shah et al. 2016).

## **4.2. Cellulose Extraction and the Biocomposite Materials**

EFB and the fibers can be moulded into products for the manufacturing of furniture, building, electronics, packaging and automobile industries (Malaysian Palm Oil Council, 2006). Eco-friendly extraction of Purely-Extracted Cellulose (PEC) from EFB has been achieved by ultrasonic (SONO-CHEM) extraction with  $H_2O_2$  at 40 kHz at room temperature, and autoclave (AUTO-CHEM) extraction with a mixture of  $H_2O_2$  and formic acid and further bleaching with H<sub>2</sub>O<sub>2</sub> at 80<sup>o</sup>C. The AUTO-CHEM yields 64% PEC with the  $\alpha$ -cellulose content of 93.7% and crystallinity of 70%, while the SONO-CHEM yields 49% PEC with the α-cellulose content of 91.3%, and crystallinity of 68.7% (Nazir et al. 2013; Abdullah et al; 2016c). The 25% PEC loading with polypropylene (PP) composites using injection-moulding technique achieves the tensile strength of 26.7-27.3 Mpa, without any addition of coupling agents (Abdullah et al; 2016c). The PECs are also successfully surface-engineered with carboxylic acids where EDTA treatment achieves  $232.9-236.7$  mg/g Pb(II) sorption (Nazir, 2013) and 39.3-54.2 mg  $g^{-1}$  for the Mn(II), Ni(II) and Cu(II) sorptions (Daneshfozoun et al. 2014). The Pb-loaded modified PEC achieves higher sulphur removal from diesel than without metal-modified sorbents (Nazir, 2013). Agro-based magnetic biosorbents (AMBs) from *Ceiba pentandra* (RKF), EFB and PECs have also been developed, using a novel, simple and cost-effective preparation technique for the removal of heavy metal ions from aqueous solutions. The AMBs achieve 97.7-99.4% Pb(II) removal efficiency with 10.3% higher efficiency than the raw sorbents and the regeneration is successfully performed for 5 adsorption/desorption cycles (Daneshfozoun et al. 2017). A novel composite of PEChydroxyapatite (HAp) with graphite has been fabricated into chemically-modified carbon electrode (PEC-HAp-CME) for qualitative and quantitative analysis of Pb(II) ions in aqueous medium, blood serum and POME, employing cyclic voltammetry and square wave anodic stripping voltammetry. The newly developed PEC-HAp-CME possesses favourable electrochemical characteristics for the measurement of  $Pb(II)$  at ppb levels (Ajab 2015).

## **5. BIOPRODUCTS FROM ALGAL FEEDSTOCK**

Bioactive compounds are physiologically active substances with functional properties and effects on human health (Herrero et al. 2013). These include carotenoids, phycocyanins, polyphenols, fatty acids, and polyunsaturated compounds which are of special interest for new products development in medical, pharmaceutical, cosmetic, and food industries (Plaza et al. 2010; de Morais et al. 2015; Abdullah et al. 2017). Biocompounds derived from microalgae like proteins, fatty acids, vitamins, and pigments are often sourced directly from primary metabolism, or from secondary metabolism for compounds with antifungal, antiviral, antialgal, antienzymatic, or antibiotic activities. Cyanovirin, oleic acid, linolenic acid, palmitoleic acid, vitamin E, B12,  $\beta$ -carotene, phycocyanin, lutein, and zeaxanthin from microalgae exhibit antimicrobial, antioxidant, and anti-inflammatory activities, with the potential for the reduction and prevention of diseases (Markou 2013; Ibañez et al. 2013). Most are accumulated intracellularly, but in some cases, these are exometabolites or excreted into the medium. Table 5 summarizes the existing and potential high-value products from microalgae (Borowitzka, 2013).

## **Table 5. Summary of existing and potential high-value products from microalgae (Borowitzka, 2013)**

The PUFAs, especially  $\omega$ -3 and  $\omega$ -6 such as eicosapentaenoic (EPA), DHA, and arachidonic (AA) acids, have been applied in the treatment of chronic inflammation including rheumatism and skin diseases (Barrow and Shahidi 2007). *Nannochloropsis*, *Isochrysis*, *Phaeodactylum, Pavlova, and Thalassiosira* are among species reportedly producing  $\omega$ -3 PUFA as an alternative to fish oil in food. *Nannochloropsis* contains appreciable amount of  $\omega$ -3 fatty acids, mostly in the form of all  $(5Z, 8Z, 11Z, 14Z, 17Z)$ -eicosapenta-5,8,11,14,17enoic acid (Adarme-Vega et al., 2012). The biosynthesis of fatty acids starts from acetyl-CoA, where the stearoylCoA (C18) is released from the chloroplast and is desaturated to produce the MUFA oleoyl-CoA (C18:1n9). This fatty acid is then attached to a glycerol backbone to form mono-, di-, or triglycerides. The lipid oleoyl group is desaturated again to form the linoleoyl (C18:2n6) group. This is the intermediate for the synthesis of  $\omega$ -3 and  $\omega$ -6 fatty acids. Under N-starved conditions, 21.65% and 19.26% of the EPA are found in the polar and phospholipid fractions, respectively, of *Nannochloropsis* sp (Bondioli et al. 2012; Chua & Schenk, 2017). Culture media with decreased iron and zinc contents has the EPA level reduced in *N. gaditana* but reducing molybdenum, manganese, and cobalt does not affect the EPA productivity (Alboresi et al. 2016). Biotin (Vitamin B7) is another important culture component for EPA production, while thiamine (Vitamin B1) and cyanocobalamin (Vitamin B12) can be reduced without affecting the growth and EPA content (Camacho-Rodríguez et al. 2015).

Natural pigments derived from microalgae have neuroprotective properties, with effectiveness in the treatment of neurodegenerative diseases. Vitamin E from marine algae

has preventive effects on neurodegenerative diseases such as multiple sclerosis as well as on atherosclerosis and heart disease (Pangestuti and Kim 2011). Vitamin E (α-tocopherol) production by *N. oculata* has been reportedly achieved under nitrogen limitation (Durmaz 2007). Extracts of *Chlorella* sp. containing  $\beta$ -carotene and lutein significantly prevent the cognitive disability accompanying Alzheimer's disease in rats. Among the pigments with anti-inflammatory activity, fucoxanthin carotenoid found in diatoms, is capable of stimulating apoptosis in human cancer cells (Zhao et al. 2014). Lutein from *Chlorella* also reduces the incidence of cancer, while carotenoids from *C. ellipsoidea* and *C. vulgaris* could restrain the growth of colon cancer (Schepetkin and Quinn 2006).

## **6. COST-ESTIMATION ANALYSES**

Cost estimates for algal production vary based on the systems modeled as each analysis evaluates new and different combinations of technologies, with the industry continuously evolving and moving forward. Over the past few years, many technologies have been developed and tested by NAABB scientists (Perrine et al. 2012; Elliott et al. 2013). The market, at about \$2.5 billion, is expected to grow in the future for *Spirulina*, *Chlorella*, *Dunaliella*, *Nostoc* and *Aphanizomenon*, and many other strains of algae have been screened for their potential use in the food industry (Batista et al. 2013). *Spirulina* and *Chlorella* represent the majority of the microalgal biomass market with an annual production of 3,000 and 4,000 tons, respectively (Masojídek and Prášil 2010). *Nostoc* biomass has been used in the medical field and as a dietary supplement because of its protein, vitamin, and fatty acid content. The medicinal value is evidenced in the treatment of fistula and for some forms of cancer (Temina et al. 2007). *Nostoc* produces several compounds with antimicrobial, antiviral, and anticancer activity and these encourage its cultivation on a large scale, with great economic potential due to its nutritional and pharmaceutical importance (Deng et al. 2008; Abdullah et al. 2017).

The high value protein sources of *Nannochloropsis* would likely drive the economics of a *Nannochloropsis* biorefinery, as up to \$100 per litre of EPA-rich oil may be achievable. Considering approximately 30% lipids in *Nannochloropsis*, a minimum of 3.3 kg biomass would be needed to recover 1 L of oil, for an approximately 2.4 kg of defatted, protein-rich biomass by-product. When compared to other protein-rich feeds such as soybean, the maximum price of \$300/ton can be considered realistic. At a production cost of \$2/kg algal biomass (dry weight), it would cost \$6 to produce 1 L of oil, if the remaining biomass can be sold as animal feed (Chua & Schenk, 2017). The "defatted" biomass may still contain significant amount of EPA for use in aquaculture or as animal feed which typically require supplement such as  $\omega$ -3 fatty acids. The use of whole, unprocessed *Nannochloropsis* as food and/or feed or health supplement addition to food such as bread, pasta and protein bars, is a possible scenario to create highly nutritious functional food to address the general deficiency of  $\omega$ -3 fatty acids and minerals such as zinc. In this way, the best economically-sustainable scenario can be achieved if both, the extracted EPA-rich oil and the high-value protein extracts can be utilized (Chua & Schenk, 2017).

In large scale algal production facilities, the total production costs may range from \$0.15 to \$4.00 per kilogram (\$0.30 to \$7.99 in 2014) of unprocessed biomass. For a privately funded \$20 million program, the algal oil production cost has been estimated at \$84/bbl in 2004 (\$105.08 in 2014) (Huntley et al. 2007). In terms of technical feasibility for biodiesel production, the estimated cost is \$2.95/gallon for open pond, and \$3.80/gallon for PBR in 2006 (\$3.46 and \$4.46 in 2014, respectively) (Chisti, 2007). The co-production of valueadded bioproduct from algal glycerol may help to reduce the biodiesel production cost to as low as \$2.79/GGE (Gong and You 2014). The cost of \$109 and \$77 per gal of bio-oil has been estimated for the open pond and PBR systems, respectively (\$112.18 and \$79.25 in 2014) (Richardson et al. 2014). The biomass production costs in 2016 have been estimated (including dewatering) at 4.95, 4.16, and 5.96  $\epsilon$ /kg for open pond, horizontal PBRs, and flat panel PBRs, respectively (\$7.12, \$5.98, \$8.57 in 2014, respectively) (Norsker et al. 2011). The economic feasibility of open pond and PBR production systems have also been compared based on the differences in biomass production, lipid content, culture crashes, harvesting and extraction costs. Five different production scenarios have been proposed for microalgal biofuel costs:- \$28/bbl, \$0.17/kWh, \$332/bbl, \$0.72/kWh, and \$240/bbl (\$30, \$0.18, \$360, \$0.76, and \$247 in 2014, respectively) (Lundquist et al. 2010). The costs for open pond is \$12.74 per gallon of lipid for open pond and \$32.57 for PBRs, respectively (\$14.52 and \$37.12 in 2014 respectively) (Richardson et al. 2012).

The processing cost of the supercritical technology at \$0.26/gal is nearly half the actual conventional transesterification method (\$0.51/gal). The immediate priority is to demonstrate that the supercritical process technologies can tolerate the complex compositions found in the raw, unprocessed algae with no negative impact on other small metabolites and can be applied in the processing of algae, either whole or just the oil extract, with similar yields and at efficiencies level that can be scaled up to the commercial production (Anitescu et al. 2008). The most profitable scenario is the product selling price of \$17.49 per gallon of algal oil (\$18 in 2014) (Davis et al. 2012). It is therefore, theoretically possible that if the other upstream algal-processing costs could be mitigated through the addition of a transesterification conversion process, the overall algal biorefinery could become cost-competitive with fossil fuels.

## **CONCLUSION**

*Nannochloropsis* sp. has been cultured for biofuel applications due to its high lipid content but with high capital and operating costs. For a more economically and industriallyviable *Nannochloropsis* farming, considerations for high-value products become pertinent as a part of a multi-product biorefinery. *Nannochloropsis* cultivation based on palm oil milling is one of the practical option for the commercial-scale recovery of biomass as a source of renewable biofuels and bioproducts including a high-value food supplement and for animal or aquaculture feed, with co-utilization and conversion of mill residues and the integration of biofixation and waste water treatment to reduce agricultural waste pollutions. The development of a biorefinery setup should consider the biomass productivity of the *Nannochloropsis* strain as the composition of lipids, carbohydrates, proteins, cellulosic material and other high-value compounds will determine the feasibility for extraction and refinement. The market for different products from microalgal cultivation and palm oil milling, and the suitable technological development with regards to the hybrid reactor system

for cultivation and cell harvesting, the hydrothermal liquefaction or supercritical processing for extraction and transesterification reaction, product purification and biomaterials conversion, must all be evaluated. These will determine the economics, sustainability and large-scale applicability of a *Nannochloropsis* biorefinery.

# **TRENDS IN COPEPOD STUDIES**

# *Marco Uttieri*

Department of Integrative Marine Ecology, Stazione Zoologica Anton Dohrn; Department of Science and Technology, University of Naples "Parthenope", Naples, Italy and CoNISMa, Rome, Italy

## **ABSTRACT**

Being present in almost any aquatic system and owing to their ecological role, copepods have been the focus of a large number of studies from taxonomy to global patterns. However, despite the wealth of information available today, our knowledge of their distribution, biology and ecology is still incomplete. Apparently, the more we learn about them, the more we are spurred on to advancing our research on these tiny crustaceans to fully grasp their significance and role. Through the contributions collected, this volume aims at providing new insight in copepod studies and a new foundation for future studies.

**Keywords**: copepods, distribution, biology, ecology

## **1.INTRODUCTION**

The "insects of the sea", the most abundant metazoans on Earth: over the years, copepods have been labelled in several different ways owing to their diversity of life forms and exceptional colonising ability (Huys and Boxshall, 1991; Hardy, 1970; Wiebe *et al.*, 1992). As reviewed by Schminke (2007), copepods are as successful as insects in terms of both absolute success and – equating swimming to flying - relative success thanks to several features including (but not limited to) phylogenetic age, speciosity and size.

### 1444 *Marco Uttieri*

Since Milne Edwards (1840), copepods have been established as a separate class. Huys and Boxshall (1991) identified ten orders, which were subsequently reduced to nine by Boxshall and Halsey (2004) upon the discovery of the Fratiidae family (Ho *et al.*, 1998). Among them, Calanoida are the most effective colonizers of the pelagic environment (Bradford-Grieve, 2002), comprising more than 2,600 species in the marine (Razouls *et al.*, 2005-2017) and approximately 550 species in freshwater (Boxshall and Defaye, 2008) environments.

Figure 1. Ecological role of copepods, linking lower and higher trophic levels, respectively characterised by low  $\langle 2 \rangle$  and high  $\langle 2 \rangle$  Reynolds numbers (Reproduced from Naganuma, 1996, with permission).

Free-living copepods have populated any available habitat, from the pelagic to the subterranean ones (Huys and Boxshall, 1991), through several independent colonisations (Boxshall and Jaume, 2000; Bradford-Grieve, 2002). Copepods are present in any aquatic environment, from deep-ocean trenches to mountain lakes over a vertical range of approximately 20 km (Huys and Boxshall, 1991), and occupy a wide temperature gamut, from polar waters to hydrothermal vents (Walter and Boxshall, 2017).

Copepods represent up to 90-97% of the total biomass of marine zooplankton (Bradford-Grieve *et al.*, 1999), also being abundant in freshwaters (Boxshall and Defaye, 2008). Copepods are primary actors in the functioning and shaping of aquatic ecosystems. They are the linchpin of food webs, preying upon phytoplankton (Marshall, 1973; Turner, 2004) while at the same time representing staple food for higher trophic level organisms, such as chaetognaths (Feigenbaum and Maris, 1984) and fish larvae (Poulet and Williams, 1991). Owing to this, copepods link the viscous and inertial realms, characterised by low and high Reynolds numbers respectively (Naganuma, 1996) (Figure 1). In addition, copepods support the vertical fluxes of carbon through the release of fecal pellets (Fowler and Knauer, 1986), as well as the availability of ammonia to sustain recycled production (Verity, 1985).

Figure 2. Evolution of the number of copepod species. The future projections by Humes (1994) and Schminke (2007) refer to estimates in the total number of species. It is to note the different line ticking before and after the break along the ordinate axis.

The importance of copepods, however, is not just restricted to this. For example, copepods can be used as beacons of climate change (Beaugrand *et al.*, 2002; Richardson, 2008) and as indicators of the effects of ocean acidification on marine biota (Vehmaa *et al.*, 2013). Nearly half of described species live in association with other organisms (Humes,

1994), host pathogens or have parasitic habits (Bron *et al.*, 2011). These crustaceans can also be extremely useful as model animals for ecotoxicological studies and environmental genomics (Raisuddin *et al.*, 2007; Kulkarni *et al.*, 2013), and a great number of species are well documented as invasive (Zenetos *et al.*, 2012; Sabia *et al.*, 2015). Copepods can also be used as control agents of disease vectors (Kalimuthu *et al.*, 2017). Moreover, despite their small size copepods display peculiar swimming behaviour which mediate their interactions with other organisms and with the surrounding environment (Sabia *et al.*, 2014).

Despite all this, our knowledge on the distribution, biology and ecology of copepods is still incomplete. For example, despite the numerous morphological and phylogenomic records available to date, the total number of copepod species is still indefinite. Over the last fifty years, this figure has risen from approximately 7,500 (Kaestner, 1970) to 14,747 (Walter and Boxshall, 2017) (Figure 2), also thanks to the adoption of molecular techniques particularly useful in the identification of cryptic species (Bucklin *et al.*, 2010; Blanco-Bercial *et al.*, 2014). However, considering that Humes (1994) guessed a grand total of 75,374, subsequently raised by Schminke (2007) to the staggering figure of 450,000 (based on the hypothetical Harpacticoida species counts by Seifried, 2004), much more needs yet to be done.

## **2. TRENDS IN COPEPOD STUDIES – SUMMARY OF CONTRIBUTIONS**

When I was proposed to act as editor of a volume on copepods, I asked myself "Do we really need another book on them?"- a question that many readers may equally pose. After initial indecision, I realised that the answer was simply "Yes". As indicated in the previous section, current copepod studies are exploring multiple lines of research at a fast pace. The intended purpose of the present volume is to provide an up-to-date snapshot of some hot topics in the study of the distribution, biology and ecology of these ubiquitous crustaceans. The following chapters focus on a wide range of processes and scales, from global distribution to molecular investigations, witnessing the interest of the scientific community at different levels of investigation.

Wootton *et al.* (this volume) discuss the functioning, policy issues, strengths and limitations of the survey carried out through the Continuous Plankton Recorded (CPR) since its inception in the 1930s. The authors review the copepod taxa collected by the CPR all over the world, including their biological traits and geographical areas of occurrence of each species. The authors then provide examples of applications of CPR data, and discuss about future perspectives and applications of this unique plankton sampler.

Fernández de Puelles *et al.* (this volume) provide a synthesis of the global distribution of copepods from the tropical and subtropical sectors of the Atlantic, Indian and Pacific Oceans (35°N-40°S) over 15 biogeographical provinces. Samples were collected during the Malaspina Circumnavigation Expedition, from the epipelagic to the bathypelagic. The results highlight horizontal and vertical patterns, and point out great similarities in the assemblage composition among the three oceans, depth playing a pivotal role in their distribution.

The chapter by Zagami *et al.* (this volume) is centred on the invasive cyclopoid *Oithona davisae*. The authors first review the biogeographic distribution, habitat characteristics, ecological traits and dispersal mechanisms of this species. Then, they report on the

introduction and establishment of *O. davisae* in two coastal lakes in the Central Mediterranean Sea, where this cyclopoid has become a dominant species in the zooplankton community. Through a one-year study, the sex ratio and the seasonal variation in abundance for adults, copepodites and nauplii are studied and compared with the literature.

Another invasive copepod, the calanoid *Acartia tonsa*, is the focus of the contributions by Villate *et al.* (this volume), Delpy and Pagano (this volume) and Marques *et al.* (this volume). Villate *et al.* (this volume) report on the impact of *A. tonsa* on the Acartidaee assemblage from the estuaries of Bilbao and Urdaibai along the Basque coast (Spain) over a multiannual period (1998-2005). Their results show that both areas were colonised almost contemporaneously since 2003, with a preference for the innermost salinity habitat of both estuaries, but with distribution characteristics dependent upon the specific features of each estuary. The arrival of *A. tonsa* determined a niche shrinking in the native *Acartia clausi* in both sites, and a seaward shift in *Acartia bifilosa* in the estuary of Urdaibai, while the impact on less abundant Acartiidae species was less easily discernible.

Delpy and Pagano (this volume) compare the relationship between *A. tonsa* and *A. clausi* in the Berre Lagoon (southeast France) before and after a rehabilitation period aimed at reducing salinity fluctuations. Following its introduction in the 1980s, *A. tonsa* dominated the zooplankton community restricting *A. clausi* to the neighbouring coastal area. Upon stabilisation of the salinity fluctuations following the rehabilitation of the lagoon, however, *A. tonsa* decreased its abundance, and the two species started to coexist in the Berre Lagoon with a clear seasonal succession. These signs, in the authors' opinion, might be considered an encouraging starting step in the recovery of the lagoon.

Marques *et al.* (this volume) investigate the distribution of *A. tonsa* and *A. clausi* in the Mondego Estuary (Portugal) over a decade (2003-2013). *A. tonsa* was first observed in 1994, efficiently adapting to the newly invaded site. A spatial segregation between the two species was demonstrated, with *A. tonsa* restricted to the inner part of the estuary and *A. clausi* confined seaward. These results confirm *A. tonsa* as an opportunist species, taking advantage of periods of temperature increase and reduction in freshwater flow recorded in the area.

In their contribution, Svetlichny *et al.* (this volume) provide a detailed review of the behavioural and physiological adaptations in key copepod species from the Black Sea. In particular, the authors focus on specific aspects such as salinity tolerance, effect of temperature on physiology and behaviour, and resistance to oxygen limitations. The examples discussed demonstrate the dependence of copepod distribution and vital rates on environmental parameters, which should be always taken into consideration to fully appreciate the ecological role of these tiny crustaceans.

Lenz and Hartline (this volume) present a comprehensive description of the biology of myelin in calanoid copepods. Using examples from different species, they open with a description of the structure and function of myelin, linking its occurrence to the evolution of copepod families. Subsequently, the authors report on the role of myelin in terms of reaction times and localisation of stimuli, and finish by focusing on the niche separation between myelinate and amyelinate species.

The chapter by Gemmell and Buskey (this volume) concentrates upon the escape strategies used by copepods as a response to the predation threat posed by different foes. The processes of predator detection and the mechanism of escape generation are discussed using examples from the available literature, together with a differentiation between the strategies

used by visual and non-visual predators. The role of environmental features (water motion, temperature and viscosity) are also taken into account.

Langhoff *et al.* (this volume) push the boundary of current knowledge on copepod mating, focusing on the detection by male *Temora longicornis* of the ratio of chemical compounds in the pheromone trails released by the female. Through the design of an olfactory apparatus and the implementation of a Simulated Annealing algorithm for the selection of synaptic weights, the authors demonstrate the capability of ratio detection in copepods, opening to further research on this topic.

The closing chapter by Amato and Carotenuto (this volume) reviews the latest "omics" advances in copepod studies. The authors describe the methodologies presently in use, and provide a review of the most recent advances in molecular studies in planktonic copepods, focusing on gene expression approach, metabolomics and proteomics. The chapter closes with some future perspectives on this rapidly evolving field of research.

The contributions collected in this volume point out the latest developments and case studies on a number of research issues, and will promote discussion and stimulate advances in each field of investigation. As editor, I am confident that readers will appreciate the contents of each chapter and will find in them inspiring suggestions for their research, or even just for their curiosity.

## **ACKNOWLEDGMENTS**

I wish to thank all the authors for having accepted the invitation to contribute to this volume. It was a pleasure and an honour to interact with them all, sharing comments and building together the book as you can read it. I also wish to thank all the colleagues and friends with whom, over these years, I discussed about the different aspects of copepod life – listing them all would take many pages! Insightful comments by Maria Grazia Mazzocchi and Geoff A. Boxshall improved an earlier version of this chapter. I also owe a vote of thanks to Carra Feagaiga at Nova Science Publishers, Inc. for supportive feedback during every stage of the publication process. Thanks are also due to Ian Stewart at Inter-Research Science Center for reprint permission of Figure 1.

This work was supported by the MOKA project (Modelling and Observation of zooplanKtonic orgAnisms; ID: RBFR10VF6M), financed by the Italian Ministry of Education, University and Research, and by a grant funded by research awards to Maria Grazia Mazzocchi, Maurizio Ribera d'Alcalà and Diana Sarno from the Stazione Zoologica Anton Dohrn of Naples.

Sir Alister Hardy Foundation for Ocean Science (SAHFOS), The Laboratory, Citadel Hill, Plymouth, United Kingdom

# **ABSTRACT**

The Continuous Plankton Recorder (CPR) Survey, operated by the Sir Alister Hardy Foundation for Ocean Science (SAHFOS), is the longest running, most geographically extensive marine survey in the world. Since its inception in 1931, the Survey has monitored near surface planktonic communities, including pelagic copepods, providing essential baseline information on the state of the marine environment. Initial observations focused on the North Sea. However, today, in cooperation with sister CPR surveys that have started independent monitoring programmes, the scope extends around the globe, operating across basin scales, providing a truly unique and invaluable dataset for the international community.

CPR data have allowed the description of the geographical distribution of almost 700 planktonic taxa across the North Atlantic, North Pacific and Southern Ocean, monitoring their changes over time. Although both phytoplankton and zooplankton are regularly identified in the Survey, a substantial proportion of the routine analysis is dedicated to the group Copepoda (over 300 taxonomic entities) and forms the focus for this chapter. The CPRs multi-decadal time series allows seasonal cycles and natural variation to be disentangled from changes occurring over a much longer period, such as multiannual oscillations and long-term trends of key copepod species. CPR data have provided evidence for northward distributional shifts of indigenous copepod species, range expansions of non-native species and the presence of pathogenic bacteria on copepods' exoskeletons.

 $\overline{a}$

In this chapter we summarise the main findings on pelagic copepods based on CPR data collected all over the world, highlighting the key policy issues that they have contributed to over time. The strengths and limitations of CPR observations will also be discussed.

**Keywords**: *Calanus*, regime-shift, policy, phenology, biogeography, CPR, long-term monitoring

# **1.INTRODUCTION**

In the 1920's, Sir Alister Hardy invented a plankton sampling device designed to demonstrate the patchiness (fluctuations in type and quantity) of plankton that he had observed whilst trying to study young herring in the North Sea. Engineered to collect a continuous line of observations, the sampler was first deployed on the Discovery Antarctic expedition (1925-1927) and was given the name Continuous Plankton Recorder (CPR). In subsequent years the sampler underwent a re-design, tailored towards being towed behind commercial vessels and, apart from some relatively minor modifications, is the CPR we see in operation around the globe today. Although regular deployment of the CPR in the North Sea began in the 1930's, consistent data using present-day methodology is available for the period after the Second World War (*i.e*.*,* post 1948) and represents the longest running and most geographically expansive marine survey in the world.

Figure 1. Schematic longitudinal section of a CPR internal mechanism and external body. Water enters through the front aperture and is filtered by a moving band of silk gauze; a second layer of gauze, moving in synchrony, covers the filtering mesh thereby trapping the captured plankton forming a plankton sandwich. As the tow progresses, driving rollers wind the sample into a storage tank containing buffered formaldehyde (fixing the plankton) allowing for the replenishment of fresh gauze and a new plankton sample to be collected.

Over the last 85 years the Survey has evolved into a unique marine monitoring programme, providing the community with its best long-term measure of the state of oceanic plankton (Richardson *et al*., 2006). Since 1991, the CPR Survey and resulting dataset have been managed by the Sir Alister Hardy Foundation for Ocean Science (SAHFOS, http://www.sahfos.ac.uk), in Plymouth, UK. Today, in cooperation with sister Surveys that have started independent monitoring programs (at present comprised of 12 regional Surveys) the CPR's scope extends around the globe, operating across basin scales, providing a truly unique and invaluable dataset for the international community. Known as the Global Alliance of Continuous Plankton Recorder Surveys (GACS) (http://www.globalcpr.org), this cooperative union of CPR surveys share their data and expertise with the marine community worldwide.

Truly global studies that use a consistent methodology are rare for planktonic organisms, including copepods, and even more so for open ocean regions. The CPR Survey and GACS community aim to address this but gaps in knowledge still exist, in particular for tropical waters. A recent study by Fernández de Puelles *et al*. (this volume) tackles this issue and impressively describes the tropical to subtropical biogeography of copepods in all three major oceans, from the epipelagic to bathypelagic zones.

Figure 2. Map of the number of CPR samples collected between 1958 and 2015 in the North Atlantic, gridded onto a 1 by 1 degree grid. Each sample represents 10 nautical miles (18.5 km) of tow.

A Continuous Plankton Recorder (CPR) is a robust semi-automated sampling device that monitors the near-surface plankton communities over hundreds of nautical miles. Towed at approximately 7-9 m depth (Hays and Warner, 1993) behind a Ship of Opportunity (SoOP) the CPR typically collects epipelagic organisms, including a wide range of copepod taxa. Using a simple and reliable mechanism the CPR collects planktonic organisms using a 270 µm silk mesh, which continuously advances as the CPR is towed through the water, typically at a rate of 10 cm per 10 nautical mile sample (Figure 1). Unlike many other sampling devices, the CPR is capable of towing continuously across 500 nautical miles with minimal supervision; the longest single transect towed to date being 3,000 nautical miles, from Canada to Japan. For a detailed description of sampling and analysis methods please refer to Richardson *et al*., (2006). At present the SAHFOS CPR Survey operates across 10,000

nautical miles of ocean each month on 23 routes passing between 20 different countries, with over 6.5 million miles sampled in total over the history of the Survey (see Figure 2). Having undergone minimal modification in design since 1931, the simple yet efficient design of the CPR means that non-scientists can easily deploy the device. Ships' crews require only brief initial training in CPR deployment and operation before becoming fully competent and part of the CPR Survey fleet. As a result, the Survey is able to operate across an extensive geographical range, on a monthly resolution, at significantly reduced cost compared with relying upon specialised research vessels. The collaboration and support of the shipping community is undoubtedly the key to the success and longevity of this unique time-series.

### **1.1. Why Use a CPR and CPR Methodology?**

There are a variety of monitoring programmes and sampling methods used in the study of copepods, each with their own advantages and disadvantages depending upon the research question being asked. Although a detailed debate about the usefulness and limitations of the numerous types of sampling gear in operation is beyond the scope of this chapter, here we briefly highlight some of the reasons why the CPR and the CPR analysis methodology is a useful tool in copepod research (Owens *et al*., 2013).

As previously mentioned, the CPR is capable of sampling over large distances, up to 3,000 nautical miles at present, unlike traditional net sampling which typically sample a single point in space. Depending upon the CPR Survey, each sample represents either 5 or 10 nautical miles of tow, hence the CPR is the ideal tool for large or basin scale studies.

Typical routine analysis of CPR-collected copepods involves identification down to species or genus level for most taxa. Many programmes and analysis methodologies that are able to collect and process such high volume of samples similar to the CPR Survey (such as the digital identification systems ZooSCAN (Grosjean *et al*., 2004) and FlowCam (Le Bourg *et al*., 2015) are able to record 'bulk' indicators such as total zooplankton, total copepods and large *vs* small copepods, and can provide an estimate of bio-volume (and therefore coarse biomass and size spectra). Bulk indicators can provide a valuable quick general picture of processes that take place, but are often limited by their lack of taxonomic resolution. For example, research by Sydeman *et al*., (2010), using CPR data from the North Pacific, showed that seabird species were more closely related to zooplankton taxonomic groups rather than "bulk" measurements of zooplankton abundance or diversity. Many successful studies have been carried out using these automatic identification tools; however, the use of bulk indicators can often mean that subtle differences and relationships between members of the planktonic community are lost. Ultimately the decision on which level of taxonomic resolution is necessary, and hence choice of methodology, depends on what the data generated is to be used for.

The North Atlantic sibling species *Calanus finmarchicus* and *Calanus helgolandicus* are almost morphologically indistinguishable; however, their presence can indicate different water masses as they both have differing thermal niches (Helaouet and Beaugrand, 2007). For this reason they are currently used as copepod 'indicators' (Edwards *et al*., 2008) and are routinely identified to species level in the SAHFOS CPR Survey. Detailed information about plankton community composition at the species level can only be obtained through microscope-based or molecular analysis. Such detailed information, as provided by the CPR

Survey, is essential in providing an accurate insight into changes in biodiversity, food web dynamics and wider issues such as climate change.

A CPR is a compact, robust and reliable piece of sampling equipment. With an average tow success rate of >90%, a CPR works using simple mechanical engineering. Unlike other devices, such as multiple plankton samplers or the Longhurst-Hardy Plankton Sampler, a CPR is free from electrical firing mechanisms which can commonly cause sampling failure. Many other types of sampling gear need to be deployed and monitored by several skilled operators and are only really suitable for use on specifically designed research vessels. In contrast, a CPR can be deployed by non-scientific staff on non-specialised SoOPs (*e.g*.*,* passenger ferries and container ships), requiring minimal supervision whilst sampling is underway. The body of a CPR also offers a payload area where other sampling equipment can be attached (*e.g*.*,* temperature, chlorophyll and depth sensors). With oceanographic research vessels costs often prohibitive, it is hard to find a more cost efficient and reliable zooplankton sampler than a CPR.

However, as with any piece of equipment and monitoring programme, there are limitations and the CPR is no exception. Volume of water filtered per sample  $(3 \text{ m}^3)$  is relatively small and sampling depth (typically 7 m) is restricted to the upper water column. Despite this apparent shallow depth, it has been speculated that the actual community sampled may be deeper than originally thought. As the CPR is towed behind a vessel at speed, it is probable that with a large ship draft, possessed by ships used in the Survey, enough turbulence will be caused to mix the water down to do approximately 25m, dependant on ship size, thus allowing the CPR to collect plankton from a wider depth range.

Common to many methods of sampling gear, a consistent CPR tow depth is achieved by deploying a set amount of tow-wire. Since the beginning of the CPR Survey, ship speed has undoubtedly increased over time and has raised questions as to its effect on sampling depth. Data gathered from depth sensors attached to CPRs have shown that tow depth is independent of ship speed (Batten *et al*., 2003).

Due to the nature of sample collection and the subsequent analysis process, some planktonic components are less well represented in the CPR dataset than others. For example, the CPR methodology could underestimate components of the plankton, *e.g*.*,* large plankton like euphausiids, delicate gelatinous plankton, and plankton smaller than the 270 μm mesh (a standard WP2 has a mesh size of 200 μm). In terms of copepods, the CPR Survey likely undersamples the smaller species of *Oithona* and *Oncaea* and some juveniles of larger species. The CPR method of sample collection and analysis is indeed somewhat different to other commonly used techniques, yet comparisons made with other types of sampling gear have demonstrated the CPR's ability to measure changes in seasonal cycles in accordance with other samplers (Richardson *et al*., 2004). In addition, when compared with another sampler (Norpac net) using the same 270 μm mesh, both abundance and species composition have been found to be comparable (Hunt and Hosie, 2003). However, direct comparisons of absolute abundances inevitably can vary within and between sampling devices, including the CPR. Regarding the CPR, this has been well documented and users of CPR data are advised of its limitations and help from experienced SAHFOS researchers is always offered in data interpretation (Owens *et al*., 2013).

Unlike many other sampling initiatives, including some long-term programmes, the strength of the Survey lies in its consistency in sampling technique and analysis methodology for over half a century. There have been very little changes in design and analysis

methodology since 1958, and metadata on changes has been kept. Whilst the Survey might underestimate some taxa, it has operated in a consistent manner over the time period, meaning that long term trends in these taxa are still valid. In addition, as new scientific questions arise, plankton taxa can be speciated or grouped according to need, whilst keeping the core dataset intact.

## **1.2. Copepod Taxa Recorded by the Survey**

Of the 700 taxonomic entities (phytoplankton and zooplankton) recorded by the SAHFOS CPR Survey, 306 belong to the subclass Copepoda, many of which are identified to species level (Table 1). To the end of 2015, this dataset amounts to over a quarter of a million samples analysed for plankton taxa. This equates to over 175 million plankton abundance records; just under a third of these records are related to Copepoda. SAHFOS CPR data can be obtained for *bona fide* research (see https://www.sahfos.ac.uk/data/data-request-form/), and are subject to a data licence agreement. Presence only data for all planktonic taxa analysed by SAHFOS can be accessed via the Ocean Biogeographic Information System (OBIS) portal (http://www.iobis.org/) (Copepoda - http://www.iobis.org/explore/#/taxon/ 616102).

Table 1 details the copepod taxa recorded in the SAHFOS CPR Survey and their biological traits. For several taxa of specific interest, sex and copepodite stage are also recorded by the Survey, but for simplicity this information has been omitted from the table. For standard North Atlantic analysis it is general practice to include copepodites and adults in the identification level chosen for that taxon, but only where an accurate identification is possible. For example, a record of *Centropages hamatus* would include males, females and most likely all copepodite stages collected, as identification to species level even in juveniles is relatively simple. However, a record of *Calanus helgolandicus* would only include adult males, females and stage V copepodites, because it is generally thought of as impossible to separate *C. helgolandicus* from its sibling species at younger stages using traditional light microscopy. Each taxon in the CPR database will have with it associated metadata such as this, and should be consulted before any interpretations are made.

Biological traits are used to study functional diversity which provides a link between organisms and their ecosystems. With a wide range of trait descriptors used to characterise the role of a species in terms of ecological functioning, here we list the most common: morphological (body size, measured as total length); trophic position (feeding method, defined as herbivore, omnivore, predator or parasite); physical environment (habitat, defined as neritic, oceanic or cosmopolitan) and distribution (sea areas). It must be noted that many of the feeding method traits have been inferred, as the majority of species have not been specifically studied. In this case, traits have been inferred from similar taxa, *i.e*.*,* species within a genus, or in some cases not explicitly detailed in the reference but alluded to (Johns and Wootton, 2013). Each taxon in the table is also matched with a corresponding Aphia ID, a unique numerical identifier given to each taxon as listed in the World Register of Marine Species (http://www.marinespecies.org/).

# **Table 1. (Continued)**

# **Table 1. (Continued)**

# **2. WHAT CAN CPR DATA BE USED FOR?**

## **2.1. Mapping Copepod Biogeography**

With such a large spatial coverage, data from the CPR Survey is ideally placed to generate biogeographical maps of copepod presence and abundance. Distribution maps are able to be generated for any of the taxa listed in Table 1 and maps of the most common of these taxa in the North Atlantic can be found in Barnard *et al*., (2004).

In addition to sample position, each copepod taxon in the CPR database has metadata associated with it, such as: date taxa first counted, date of collection, abundance, time of collection (day/night). Together, these parameters mean a comprehensive picture of copepod distribution and abundance can be mapped over varying time periods, from short-scale seasonal cycles to long-term decadal or inter-decadal variability, at genus or species level.

Figure 3 shows the average abundances of large  $(>2$  mm) and small  $(<2$  mm) copepods, based on mean adult total length, across the North Atlantic from CPR samples. Although copepods are found throughout the entire region, it can be seen that there is a clear geographical difference in abundance between these two groups, with small copepods dominating in coastal regions. The small cyclopoid copepod *Oithona* is thought to be one of the most abundant and ubiquitous metazoans in the ocean (Gallienne and Robins, 2001), and it is perhaps not surprising that smaller copepods are found widely across the Atlantic. In contrast, the highest abundances of larger copepods seem to be restricted to subarctic waters, notably the Grand Banks and Labrador Sea regions which are known to be amongst the most productive waters in the world.

Figure 3. (Continued).

Figure 3. Map of the average monthly abundance of 'large'  $(22 \text{ mm})$  (a) and 'small'  $(<2 \text{ mm})$ (b) copepods, counted in CPR samples between 1958 and 2015 for the North Atlantic, gridded onto a 1 by 1 degree grid.

Figure 4. Map of copepod species richness recorded from CPR samples between 1958 and 2015 in the North Atlantic, gridded onto a 1 by 1 degree grid.

It is interesting to note that copepod abundance does not necessarily relate to species richness. Figure 4 shows the number of different copepod species recorded for a given area of ocean. Comparing this with Figure 3 demonstrates that the most speciose regions, such as the Sargasso Sea, coincide with lower copepod abundances. With temperature known to be a

crucial environmental variable affecting marine species richness (Tittensor *et al*., 2010), the map displays the classical theory of species number increasing with latitudinal gradient towards low latitudes, and a decrease in species (but an increase in body-size) towards the poles (Rombouts *et al*., 2009). CPR data have shown that rising sea temperatures in the North Sea have been linked with an increase in overall species diversity (Beaugrand *et al*., 2015). With sea temperatures predicted to rise, it will be interesting to see how this map will change over time.

# **2.2. Disentangling Short-Term and Rhythmic Variations from Long-Term Trends**

Long-term (>30 years) marine monitoring datasets are rare (Edwards *et al*., 2010), but are essential in helping disentangle natural variation, *e.g*.*,* seasonal cycles, from changes in the environment, *e.g*.*,* regime shifts. Extensive time-series provide a baseline of data, a form of "yard-stick," against which new measurements can be compared and changes identified. Since its beginning, the CPR Survey has grown and developed with marine management drivers, linking copepod and other plankton abundances with both short-term events (*e.g*.*,* upwelling, diel vertical migration) and long-term events (*e.g*.*,* climate change, fish stock fluctuations) (Edwards *et al*., 2010). For instance, CPR research has shown that the Atlantic Multidecadal Oscillation accounts for the second most important large scale trend in North Atlantic plankton records, and is responsible for habitat switching (abrupt ecosystem/regime shifts) over multi-decadal scales (Edwards *et al*., 2013); without long-term monitoring programmes like the CPR Survey, our understanding of plankton community drivers would be, at best, limited.

#### **2.3. Monitoring Northward Shifts and Range Expansions**

Planktonic copepods are excellent indicators of environmental change (Beaugrand *et al*., 2008). They are quick to respond to changes in their environment, *e.g*.*,* temperature, have rapid generation times and are not generally a harvested resource and consequently they are affected less by direct anthropogenic pressures.

Much of the planktonic research carried out in the North Sea has focused on *Calanus finmarchicus*, a large, lipid rich calanoid copepod (Melle *et al*., 2014). This cold-water species forms the main food source for juvenile cod (Thorisson, 1989) and other fish species, and prefers a temperature range of 0-15°C, with peak abundances from 0-9°C (Melle *et al*., 2014). Its sister species, *Calanus helgolandicus*, similar in size, prefers temperatures between 9-20°C, with peak abundances from 13-17°C (Bonnet, 2005). *C. helgolandicus* abundance has two maxima during the year, the first one from May to June and the second one from September to October (Wilson *et al*., 2016). *C. finmarchicus* on the other hand has its annual maximum around May and is abundant throughout the year (Fromentin and Planque, 1996). Since the 1950s, CPR data have shown a large geographical shift in the distribution of these two species (Beaugrand *et al*., 2001), causing trophic mismatches (Edwards and Richardson, 2004). Notably, there has been a swing in the ratio from a *C. finmarchicus* dominated North Sea to a *C. helgolandicus* dominated North Sea (Figure 5). Coupled with a 70% reduction in

total *Calanus* biomass, this has directly exacerbated the decline in the overexploited Atlantic Cod (*Gadus morhua*) stocks since the mid -1980s (Beaugrand *et al*., 2003), as larvae depend on this prey item for survival (Thorisson, 1989). This step-wise transition, termed a regime shift, is linked to the northward movement of the 9-10°C isotherm in the region and has had effects not only on copepod species biogeography, but on phytoplankton, other types of zooplankton and terrestrial taxa too (Reid *et al*., 2016).

Figure 5. Ratio between the warm-water species (*Calanus helgolandicus*) and the cold-water species (*Calanus finmarchicus*) per month from 1958-2015 in the Central North Sea. Red shades indicate a dominance of the warm-water species and blue the dominance of the cold-water species.

Results from North Atlantic CPR data indicate that the northwards advancement of calanoid copepods is estimated to be 23 Km per year and is closely linked to increasing sea surface temperatures (SSTs) (Beaugrand *et al*., 2009). A similar pattern is also reflected in the North Pacific, with CPR data displaying a close correlation between warm-water copepod species assemblages (examples of taxa incorporated in this grouping include *Mesocalanus tenuicornis*, *Candacia bipinnata* and *Clausocalanus spp.*) and a positive Pacific Decadal Oscillation (PDO). A positive PDO, resulting in warmer SSTs in the northeast Pacific, corresponds with the northward movement of warm water copepod species (Batten and Walne, 2011).

#### **2.4. Observing Phenological Changes**

Phenology is defined as the study of cyclic and seasonal natural phenomena, especially in relation to climate, plant and animal life. CPR data have shown that within the copepod assemblage, seasonal timings of peak abundance can have impacts throughout the marine ecosystem (Burthe *et al*., 2012), and propagate throughout multiple trophic levels, from primary producers to secondary consumers such as fish (Beaugrand *et al*., 2003) and seabirds (Fauchald *et al*., 2011; Reiertsen *et al*., 2014). Due to seasonal variations of the upper-ocean environment, copepods encounter changes that are both intense and prolonged compared to their life spans (Mackas *et al*., 2012). Changes in zooplankton phenology are often correlated with anomalies of one or more environmental variables, including water temperature (Edwards and Richardson, 2004). Most work on phenology in the zooplankton has focused on functional groups as opposed to individual species (Edwards and Richardson, 2004; Thackeray *et al*., 2016). Among copepods, the bulk of studies have concentrated on *Calanus*, due to their keystone position in many marine ecosystems (Melle *et al*., 2014 and references therein).

Figure 6. Time of seasonal peak changes in two species of *Calanus* (*Calanus finmarchicus* (blue) and *Calanus helgolandicus* (red)) in the North Sea (D1: Southern North Sea; C1: Central North Sea) from CPR data (Johns, 2017).

Figure 7. Occurrences of *Pseudodiaptomus marinus* in CPR samples from 2011-2016.

Figure 6 shows the month of seasonal peak for C. *finmarchicus* and C. *helgolandicus*, in two regions of the North Sea (CPR Standard Areas D1, Southern North Sea and C1, Central North Sea). The seasonal peak provides an insight into the phenology of the species in a given year, and the solid lines show long term trends of peak seasonality between 1980 and 2015. It can be seen that although *C*. *finmarchicus* is appearing slightly earlier in the year nowadays, in both areas *C*. *helgolandicus* has pronounced differences, moving earlier in the southern area and shifting to a later occurrence in the more northerly region. Both of these species are extremely important to higher trophic levels, such as fish and seabirds, and shifts in their peak periods of abundance can be propagated through the ecosystem – seasonal timing of prey species are often critical for the successful survival of higher trophic levels. This is known as a 'trophic-mismatch,' with seasonal timings becoming asynchronous. The examination of seasonal timings is crucial when looking at such keystone species as *Calanus*, as long-term trends in abundance only inform on part of the impact.

#### **2.5. Detecting Non-Native Species**

Research has shown the CPR to be a valuable tool in the discovery and monitoring of non-native species. With an extensive history of regular monthly sampling, the CPR Survey is able to provide a baseline for species diversity. In winter 2011 the Survey collected and identified specimens of the non-native copepod *Pseudodiaptomus marinus* in the southern North Sea (Jha *et al*., 2013). Native to north-western Pacific coastal waters, this species was first recorded in the Atlantic Ocean sector and North Sea in 2010 (Brylinski *et al*., 2012). However, the CPR records highlighted its northwards range extension since its arrival in European waters. Thought to have been introduced to the region via ballast water, *P. marinus* is both eurythermal and euryhaline. Not surprisingly, due to its adaptability, this non-native copepod has established itself throughout coastal regions in North America, the Mediterranean and now the North Sea (Sabia *et al*., 2015). Regularly found in North Sea CPR samples, since 2011, the Survey continues to monitor the spread and persistence of *P. marinus* around European waters (Figure 7).

## **2.6. CPR Copepod Data and Policy**

Since the 1930s, the CPR Survey has co-evolved with marine management drivers, from monitoring North Sea plankton blooms for herring fisheries, to ecosystem-based management today (Edwards *et al*., 2010). The uniqueness of the CPR dataset means SAHFOS holds a distinctive position in the marine scientific policy community. The consistent methodology of the Survey allows exploration of long-term datasets that can be interrogated depending on policy questions. For instance, CPR research has contributed to the most recent Intergovernmental Panel on Climate Change (IPCC) reports (Pörtner *et al*., 2014) and the UN's World Ocean Assessment (Malone *et al*., 2015). Assessments such as these provide a mechanism to transfer scientific information on the state of the marine environment to decision makers, to facilitate evidence-based development of monitoring programmes and policy measures. For example, the European Union's Marine Strategy Framework Directive (MSFD) Directive 2008/56/EC (European Parliament and Council, 2008) seeks to achieve Good Environmental Status (GES) of European seas by 2020. By taking a holistic, ecosystem approach to marine management, this Directive relies on a suite of indicators being developed and monitored, at the member state and OSPAR (Oslo-Paris Convention) level, and monitored towards environmental targets which represent GES. Given the pivotal importance of copepods to the marine web, their inclusion as an indicator group for the monitoring of pelagic habitats is crucial. CPR data have played an integral role in the development of indicators at both national and international levels for multiple components of this Directive and, through the CPR Survey, will continue to contribute to the monitoring of these indicators in an effort to attain GES.

# **3. FUTURE OF THE CPR SURVEY**

#### **3.1. Sample Archive and Molecular Methods**

SAHFOS has an extensive sample archive of approximately half a million samples, dating as far back as the late 1950s. Despite samples being preserved in formalin, recently developed molecular techniques have proven to be successful in the genetic analysis of copepod specimens (Kirby *et al*., 2007) as well as other planktonic taxa (Licandro *et al*., 2010). With the development of new techniques, and as interest in how molecular information can inform us about the ecology and physiology of copepods gains momentum (Amato and Carotenuto, this volume), further analyses of these archived samples are possible, thus progressing our understanding of the oceans.

#### **3.2. Copepods and Human Health**

*Vibrio* bacteria are numerous and abundant in the marine environment and are known to be associated with chitinous plankton, such as copepods. Many *Vibrio* species are pathogenic to humans (causing cholera, septicaemia and seafood-related gastroenteritis) as well as causing mass mortality to a range of marine life (Vezzulli *et al*., 2010). *Vibrio* genetic

material has successfully been extracted from archived CPR samples, dating as far back as the 1960s, and has shown that during the last 50 years there has been an increase in the occurrence of *Vibrio* in the North Sea, linked with increased SSTs in the region (Vezzulli *et al*., 2012). Although there are still many questions regarding the relationship between copepod abundance and *Vibrio*-related outbreaks of disease, the predicted rise in climate change induced SSTs can only warrant further investigation into this subject.

#### **3.3. Instrumentation**

To gain a holistic picture of copepod biology and ecology it is important to accurately record many parameters associated within a copepods environment. Since 1994 a range of sensing technologies have been trialled on the CPR, and SAHFOS maintains an archive of these datasets alongside the contemporary presence and abundance data collected. These instruments include miniloggers for temperature and sensors for conductivity, temperature, chlorophyll and depth measurements. Going forward, new techniques are being developed to keep abreast of technological developments. For example, the autonomous Water and Microplankton Sampler (WaMS), which has been developed in collaboration with the Centre for Environment, Fisheries and Aquaculture Science (CEFAS), has already proven its capability to detect bacteria, naked flagellates and other microplankton that would be impossible to be detected with light microscopy alone (Stern *et al*., 2015). SAHFOS has recently invested in a new FlowCam® Macro for copepods and zooplankton, to be used to advance research capabilities. This newly developed instrument will complement microscopic analysis and SAHFOS' proven world-class taxonomic expertise.

## **CONCLUSION**

Since its inception in 1931 the CPR Survey has grown into the world's most geographically extensive and longest running marine biological survey. Despite sampling and recording a variety of phytoplankton and zooplankton taxa, copepods remain at the core of the Survey in terms of both taxonomic and research expertise. The use of consistent methodology coupled with long-term monitoring has allowed long-term trends to be identified from complex spatial and temporal variations, with data showing range shifts and changes in seasonal timing of copepod species in response to warming waters and climate change.

With an extensive sampling effort over large areas of ocean, CPR data are ideally suited to generate abundance and distribution maps for a wide range of species. Information on over 300 copepod taxonomic entities are routinely collected, yet the majority of research, published both by SAHFOS and the wider scientific community, seems to focus on the sister species *Calanus finmarchicus* and *Calanus helgolandicus*. Important to higher trophic organisms and indicators of different regimes, these two species certainly warrant intense study; however, with regional species diversity on the rise in response to a warming planet, the wealth of other copepod taxa stored in the CPR dataset perhaps also deserve attention and investigation.

As national and international leaders begin to realise the importance of the marine environment, policy and decision makers will be looking for suitable metrics to measure and monitor the health of our oceans. The CPR is the only sampler that covers the extent of the Northwestern European shelf, making it extremely useful for long-term and regional assessments of marine health. At a European level, The CPR Survey has been instrumental in the design of such indicators for the pelagic environment, and has been involved in a number of national and international assessments. With marine protection and policy continuing to progress alongside modelling and statistical techniques, it is likely that the use of such longterm vast spatial time-series will develop and they will become increasingly indispensable.

Criticised by some as antiquated, the CPR method of collection and sample analysis is robust and consistent; however, limitations to this method are acknowledged and advances are being made to expand and modernise the CPR's capabilities in the future. Molecular material has successfully been extracted from copepod specimens collected over 50 years ago and research carried out on a range of subjects from human health to population genetics. Hosting the largest known plankton archive in the world, and with the emergence of new techniques and technologies, the CPR Survey holds in its hands a unique and globally significant asset waiting to be explored.

#### **ACKNOWLEDGMENTS**

We would like to thank the owners and crews of the ships that tow the CPRs on a voluntary basis and all the past and present CPR analysts that have contributed to the CPR dataset. We would also like to thank the reviewers for their helpful critical comments which improved the manuscript.

# **ABSTRACT**

Here we show the main distribution characteristics of marine copepods across the subtropical–tropical latitudes and to bathypelagic depths in the Atlantic, Indian and Pacific Oceans (35ºN–40ºS). The copepod samples were collected from December 2010 to June 2011 during the Malaspina Circumnavigation Expedition. Epipelagic (0–200 m), mesopelagic (200–1,000 m) and bathypelagic strata (1,000–3,000 m depth) were sampled using an opening and closing Hydro-Bios Multinet at the following depths: 0–200, 200– 500, 500–1,000, 1,000–2,000 and 2,000–3,000 m. As expected, copepods were the most abundant contributors to the zooplankton community (84%), with more than 290 taxonomic categories identified. Other marine organisms observed were chaetognaths (5%), siphonophores (3%), ostracods (2%) and euphausiids (1%). The general distribution patterns observed included low abundances, irregular spatial distributions across the three oceans, and a large decrease of abundance as the depth of the water increased. The lowest abundance was found in the southern and western regions of the Pacific Ocean, while the highest abundances were found close to the upwelling systems of the northeastern Pacific Ocean, off the Cape Vert Islands and in the Benguela current. Large differences were not observed among oceans where depth played the most important role in the structure of the copepod communities.

# **1.INTRODUCTION**

Marine copepods play a key role in the transfer of matter and energy from the richer upper layers to the deep sea (Gartner, 1997). They are the main components of the zooplankton biomass, they are abundant throughout the whole water column and they are the most abundant group in the marine pelagic ecosystem (Siokou-Frangou *et al*., 2010). They contribute to the ecosystem by transporting organic matter to the deep ocean and egesting faecal pellets during their diel vertical migration (Longhurst, 1995; Hernández-León and Ikeda, 2005). Due to their abundance, biomass, diversity and fast response to environmental fluctuations, they are also good indicators of climate change (Beaugrand *et al*., 2002; Hays *et al.*, 2001). Moreover copepods are one of the most important links to higher trophic levels and a relevant component of the biological pump and the functioning of pelagic food webs (Richardson, 2008). The knowledge of their distribution and structure is useful for the management of marine ecosystems and the assessment of their status and health. Overall distribution and biology in the worldwide oceans are relatively well documented (Razouls *et al*., 2005-2017; Wootton *et al.*, this volume). However, a global-scale baseline assessment of copepod biodiversity and distribution, including long-term monitoring and retrospective analysis, is lacking. Gathering such information will provide a contemporary benchmark that will allow changes in the ocean to be followed over time.

The deep sea is the largest habitat on Earth and also the one that is least known. About 88% of the ocean environment is deeper than 1 km, and 76% of the environment is between a depth of 3 and 6 km (Hering, 2002). The exploration of these zones has been slow because of the inherent difficulties of sampling at great depths. These difficulties are gradually being overcome, which will likely result in an increase in the discovery and identification of new species. Below a depth of 1,500 m, the low abundance of most species requires large volumes of water to be filtered, and sampling takes place over many hours using large systems deployed from research vessels to collect a substantial number of individuals (Bucklin *et al.*, 2010). In addition, zooplankton communities in subtropical–tropical regions are poorly studied, particularly those of the southern hemisphere. They are widely unexplored in comparison to coastal areas, and most studies have been carried out in neritic waters of northern ocean areas (Richardson, 2008). The data on the abundance and distribution of zooplankton is sparse, and it corresponds to different ocean expeditions, mainly in the Atlantic (Gaard *et al*., 2008; Schnack-Schiel *et al*., 2010; Vereshchaka *et al*.*,* 2017). An expedition never covers more than one ocean, and different expeditions use different methodologies, which makes it difficult to compare information about how organisms are distributed and relevant spatial scales. The opportunity to explore three different oceans and to use the same methodologies from surface to the deep ocean in all sampling sites would allow for the generation of a global description of the zooplankton community structure, which is of importance for future studies.

Accordingly, the main goal of this chapter was to give a global view of the copepod distribution down to bathypelagic depths in the subtropical–tropical latitudes in the Atlantic, Indian and the Pacific Oceans. A better understanding of global patterns will provide a baseline for observing future changes.

# **2. MATERIALS AND METHODS**

During the Malaspina Circumnavigation Expedition carried out between December 2010 and July 2011 in the Atlantic, Indian and Pacific Oceans (35ºN–40ºS), samples of zooplankton were collected from 15 biogeographical provinces (Longhurst, 1995), including some poorly studied regions of the Indian and south-western Pacific Oceans (Figure 1). Samples were collected from the surface layer down to a depth of 3,000 m using an opening– closing Multinet that was equipped with a 300 µm mesh. Sample collection took place in five strata at depths of 0–200, 200–500, 500–1,000, 1,000–2,000 and 2,000–3,000 depth m, and samples were always collected during the day (10:00 to 13:00 local time). All samples were preserved on board in 5% buffered formaldehyde. Later, in the laboratory, a total of 38 stations and 198 samples were analysed under a Nikon SMZU stereomicroscope. The main zooplankton groups found were standardized to the number of individuals per  $m^3$  (ind.  $m^{-3}$ ). Copepods were identified at least to the level of genus and, when possible, to the level of species, using published literature from around the world (Bradford-Grieve, 1994; Bradford-Grieve *et al.*, 1999; Conway *et al.*, 2003; Razouls *et al.*, 2005–2017). For the analysis of copepods and main group linkages, the Primer-6 software package was used (Clarke and Warwick, 2005). A similarity matrix was calculated from the copepod abundance using Log  $(x+1)$  and, after averaging main stations by oceans and strata for dendrograms, a cluster analysis was generated based on the Bray–Curtis similarity measure. Due to the particular distribution Benguela station was not included in Figure 5b.

Figure 1. Map of stations and copepod abundance (ind.  $m<sup>-3</sup>$ ) for the five layers sampled at each station (circle) during the Malaspina expedition.

# **3. RESULTS**

#### **3.1. Abundance and Distribution**

A low abundance of zooplankton was generally found across the entire study area (< 50 ind. m<sup>-3</sup>), with the highest values corresponding to the upper 200 m of water in the eastern side of the Atlantic and Pacific Oceans (Figure 1). The spatial variability of the copepod abundance was observed among sampling stations, which covered oligotrophic areas with normal trophic conditions and rich areas and upwelling systems (for example, the northeastern Pacific [NEP], the Costa Rica Dome [CRD], off of the Cape Vert Islands [CV] and the Benguela current [BC]).

A drastic decrease of zooplankton abundance was observed as the depth of the water increased. In the epipelagic strata, only a few areas showed values greater than 200 ind.  $m<sup>3</sup>$ , for example, in the Brazilian waters, NEP and CRD. Large abundances in the mesopelagic strata off of CV and BC were also identified  $(> 80 \text{ ind. m}^{-3})$ . In the bathypelagic strata, very low abundances were generally observed  $(< 2$  ind. m<sup>-3</sup>), with the exception of slightly higher abundances in NEP waters, CRD and BC  $\langle$  <5 ind. m<sup>-3</sup>). When samples from the stations of each ocean and strata were averaged (Figure 2), the epipelagic waters of the Pacific Ocean exhibited a higher percentage of copepods (79%) compared to the Atlantic (67%) or the Indian Oceans (43%). In the mesopelagic strata (200–1,000 m depth), the Atlantic and the Indian Ocean copepods were more abundant than in the Pacific. It was interesting to observe that the upper mesopelagic of the Indian Ocean (200–500 m depth) showed a higher percentage of copepods (31%) than the Atlantic (21%) or the Pacific Oceans (8%). Below a depth of 1,000 m, a very low abundance was found in all three oceans.

Seventeen different zooplankton groups were found, but only seven groups had an abundance higher than 1%. Copepods were the dominant group, and they were always found in an abundance higher than 82% (87% in the Indian Ocean). The main characteristic observed in each strata and ocean was the increase in the contribution of copepods at deep strata (Figure 3). However, in the upper mesopelagic (200–500 m depth), the percentage of copepods was the lowest (75%) because other groups such as chaetognaths, ostracods, siphonophores, pteropods and euphausiids were found in higher densities.

Accordingly, the vertical abundance of copepods in the three oceans defined the vertical pattern of total zooplankton, with a decrease from the epipelagic to bathypelagic strata (Figure 4A). The largest decrease was observed in the Pacific Ocean from the upper (42%) to the mesopelagic strata (19%), while in the Indian Ocean the contribution of copepods was higher in the bathypelagic (59%) than in the epipelagic strata (23%). In the Atlantic, abundance of copepods in the epipelagic and mesopelagic copepod strata was similar (35% and 33%, respectively), with a larger decrease down to the bathypelagic depths (19%).

#### **3.2. Copepod Community Structure**

In this study, 290 taxonomic categories of copepods were observed, and the highest number of species were found in the epipelagic strata, as expected (Figure 4B). In the mesopelagic layer, the number of species decreased sharply, particularly in the Atlantic Ocean; an increase in species was observed at a depth of 500–1,000 m, similar to the number

found in the epipelagic layer. The sampling from the Indian Ocean exhibited a similar pattern to the Atlantic Ocean. In the Pacific Ocean, a higher number of copepod species was found in the upper bathypelagic layer at a depth of 1,000 to 2,000 m. The vertical profiles of the species number were not linear; an increase was observed at mid-depths and also at deeper water depths in the Pacific Ocean than in the Atlantic or in the Indian Oceans.

Figure 2. Average zooplankton abundance and their vertical distribution (as ind. m<sup>-3</sup>) in the Atlantic, Pacific and Indian Oceans (Ap, sal, dol: appendicularians, salps and doliolids).

Figure 3. Vertical distribution (%) of the main zooplankton groups in the Atlantic, Pacific and Indian Oceans.

Figure 4. (A) Comparison of average abundances (ind.  $m^{-3}$ ) and vertical copepod distributions for the Atlantic, Pacific and Indian Oceans. (B) Number of copepod species identified in the Atlantic, Pacific and Indian Oceans.

Although more than 230 species were identified, 55% were consistently rare (less than 1% of abundance). Similar numbers of species were found in the Atlantic and the Pacific Oceans (203 and 206, respectively), and a lower number of species were found in the Indian Ocean (150). Of the calanoids in the epipelagic strata, Clausocalanidae family (16%) had the highest abundance, followed by the Calanidae (14%), Paracalanidae, *Euchaeta* and *Acartia*; all of these accounted around 50% of the total copepods (Table I)*.* Among the non-calanoids, *Oithona* and *Oncaea/Triconia* were dominant (18%). In all three oceans, small cosmopolitan copepods (that is, copepods with a body length  $\leq 1$  mm) were most common.

Although highly dispersed throughout the mesopelagic strata, *Pleuromamma* was the dominant copepod taxa, and among the non-calanoids *Oncaea* and *Oithona*. Some *Clausocalanus*, *Lucicutia*, *Pareucalanus* and *Heterorhabdus* were frequently found in the mesopelagic layer. In the bathypelagic layer, although *Oncaea/Triconia* among the noncalanoids were very abundant, some *Paracalanus*, *Metridia, Lucicutia* and *Monacilla* were also found. It was noteworthy that at a depth below 1,000 m, a large number of *Neocalanus* juveniles and *Calanoides carinatus* were observed in the Atlantic upwelling system.

## **Table 1. Main groups of copepods found at the different strata: epipelagic (0-200 m), mesopelagic (200-1,000 m) and bathypelagic (1,000-3,000 m)**

Figure 5. (A) Clusters of copepod abundances and stations in the Atlantic (At), Indian (In) and Pacific (Pa) (calculated using the Bray–Curtis similarity index after the data  $(x)$  had been transformed to Log  $(x + 1)$ ). (B) Cluster showing copepod abundance at different sampled layers (calculated using the Bray–Curtis similarity index after the data had been transformed to  $Log(x + 1)$ .

A cluster analysis was performed in order to check for similarities between the oceans and the strata by using two way analysis of similarity (ANOSIM; Clarke and Warwick, 2005). Despite the differences in the total abundances between the oceans, the dendograms that resulted from the cluster analysis revealed that at a Bray–Curtis similarity level of 53%, there were more similarities between the Indian and Atlantic Oceans compared to the Pacific Ocean. No significant differences were observed between the three oceans (ANOSIM R: 0.105; significance level of 0.2%) (Figure 5A). However, a significant difference was found between the strata, particularly between the epipelagic layer and other zones (ANOSIM R: 0.508; significance level of 0.1%). The bathypelagic stratum (1,000–3,000 m depth) showed the highest similarity between the upper and the lower strata (40%). The cluster analysis among main stations, copepods and strata (Figure 5B) revealed the presence of three main groups: epipelagic (0–200m), mesopelagic (200–1,000 m) and bathypelagic layers (1,000– 3,000 m).

# **4. DISCUSSION**

We analysed the abundance and composition of the zooplankton, and in particular the copepod community, in the water column  $(0-3,000 \text{ m depth})$  of the subtropical and tropical latitudes. The findings presented in this chapter demonstrate for the first time that three oceans have been sampled using the same methodology. Copepods were always dominant in the three oceans and at all depths  $(> 70\%$  of total zooplankton abundance), as is usually observed in open ocean areas (Longhurst, 2007; Gaard *et al*., 2008). The dominant copepods observed at each depth were similar to what has been reported by other studies (Bradford-Grieve, 1994; Bradford-Grieve *et al*., 1999; Conway *et al.*, 2003; Dias *et al.*, 2010; Razouls *et al*., 2005–2017). The large decrease in abundance that was observed from the epipelagic to the bathypelagic zones was also found by different authors either in the Atlantic or in the Pacific Oceans (Fernández-Álamo and Farber-Lorda, 2006; Schnack-Schiel *et al.*, 2010; Vereshchaka *et al.*, 2017); this vertical discontinuity is a common pattern. Smaller copepods are usually more numerous at the surface layers, while larger copepods are less abundant at the surface layers and are mainly found in deep waters (Deevey and Brooks, 1977; Webber and Roff, 1995; Brugnano *et al.*, 2012).

The high number of copepods observed here is a common pattern in many zooplankton studies, demonstrating the relevance of this group in transferring energy between different levels of the trophic web. They play a key role in the marine plankton food web by controlling primary production and microzooplankton, and by providing food for animals at higher trophic levels (Chank and Fang, 2004). Knowledge of the vertical distribution of copepods and their variations in space are relevant to understanding the dynamics in pelagic communities and the vertical flux of organic matter through the water column.

An overall finding of this study was the high number of copepod species found; however, the majority of them were found in an abundance of less than 1%, as other authors have reported for the Atlantic Ocean (Piontkovski *et al.*, 2003). The number of species and their abundances tended to decrease with increasing depth, which was another general trend that was observed for the distribution of copepods in the pelagic strata (Longhurst, 1995; Angel, 2003). Nevertheless, the decrease in the number of species was not linear, as a peak was

normally found at mid-water and continued to decrease at deeper layers. This was another trait that has already been mentioned with regard to deep oceans and low latitudes (Bucklin *et al.,* 2010). In the present work, the results from the three oceans did not show significant differences between the compositions of copepods, as 50% of species were common for all three oceans; however, depth was the main factor affecting their distribution. In addition, deeper-dwelling copepods were less likely to be endemic (restricted to a particular region) and more likely to be geographically widespread (Bucklin *et al*., 2010; Yamaguchi *et al.*, 2015). Moreover, feeding mode varied across all the strata, with filter-feeding herbivorous copepods observed more frequently in the upper layers and omnivores and carnivores more abundant in deeper layers (Benedetti *et al.*, 2015).

Another finding was the widespread distribution of small copepods, such as *Clausocalanus, Paracalanus, Oithona* and *Oncaea*, which is in contrast to other authors who reported limited distribution (Maycas *et al.*, 1999). As expected from their vertical migratory behaviour, large copepods, such as *Pleuromamma*, *Euchaeta*, *Pareucalanus, Metridia* and *Lucicutia,* were found in deeper layers (Bradford-Grieve *et al.*, 1999; Razouls *et al.*, 2005– 2017). Other copepods, such as *Neocalanus* juveniles with an ontogenetic distribution, were mainly found in upwelling systems and were limited to deep waters and the oxygen-minimum zone (Cavalcanti and Larrazábal, 2004; Fernández-Álamo and Farber-Lorda, 2006; Verheye *et al.*, 2005; Gaard *et al*., 2008; Escribano *et al*., 2009; Teuber *et al.*, 2013).

In summary, we investigated the main characteristics of the copepod community in the subtropical and tropical latitudes (30ºN–40ºS) in the Atlantic, Indian and Pacific Oceans and down to bathypelagic depths. Our results showed irregular spatial abundance from the oligotrophic to the upwelling regions and a large decrease in abundance from the epipelagic to the bathypelagic zones. A large number of copepods were found mainly in the epipelagic layer, but they were also observed at mid-water depths. The overall distribution of copepods in the three oceans was similar; differences between the oceans were mainly due to small differences in genera and species rather than total abundances, and depth was the most relevant factor affecting the copepod distribution. In addition, the oceanic waters were characterized by cosmopolitan small-sized copepods, which dominated the community in the whole water column. In order to understand the role of copepods in the ocean ecosystem, we must expand our knowledge of organisms in deeper water, the patterns of distribution and the diversity of dominant species. This is especially relevant in the deep layers of the subtropical and tropical oceans, which are poorly understood due to the sampling challenges.

#### **ACKNOWLEDGMENTS**

We are very grateful to all of the participants of the Malaspina Expedition and in particular to the main leader of the project C. Duarte, to our zooplankton team with X. Irigoyen as responsible, and to the crew of the R/V Hespérides for their assistance during the seven-month cruise. J. I. González-Gordillo provided us the sample volumes, the UTM/CSIC team assisted with the Hydro-Bios multisampler during the whole cruise and finally, M. C. Iglesias helped with reference transcription. This project was financed by the Spanish Ministry of Economy and Competitiveness (Consolider-Ingenio 2010, CSD2008-00077 and CTM 2012-39587–C04-2).

# **ABSTRACT**

The Asiatic copepod species *Oithona davisae* was initially described from the type locality of the Sacramento San Joaquin Estuary, California, USA (Ferrari and Orsi, 1984). Following recent reports of *O. davisae* in the Black Sea, we researched the biogeographical distribution and ecology of this species, based on original data and on a critical review of the literature. *O. davisae* was not recorded for the Mediterranean Sea before 2003, although it is now becoming established in Italian transitional environments. The literature indicates that *O. davisae* is a typical coastal and estuarine copepod species that was originally endemic in the temperate coastal waters of East Asia, and its spread to other regions was due to human-related vectors. *O. davisae* is less than 1 mm in length, and its abundance has often been underestimated because many sampling programmes have used net mesh sizes of 200 μm or larger, which cannot quantify small cyclopoid species. *O. davisae* has most often been recorded in transitional environments that are characterised by high trophic levels and stable waters, which allow its reproduction throughout the year. In Lakes Faro and Ganzirri, its highest abundance occurs in the late spring to early summer, coincident with the highest abundance of small-sized flagellates. The occurrence of dense populations of *O. davisae* in these transitional environments that are used for aquaculture activities confirms its invasive behaviour, with competitive exclusion of the indigenous species *Oithona nana*. After its introduction, *O. davisae* has become the most abundant species of the copepod assemblage in a short time. To date,

 $\overline{a}$

there do not appear to be negative consequences at the community and ecosystem levels. Ship-ballast waters and bivalve transplants appear to be the main means of dispersion of *O. davisae*.

# **1.INTRODUCTION**

Global human activities have amplified the biogeographical ranges of many invasive species over the last decades. Invasive species are those that are introduced to, and successfully establish themselves in, a region that is outside of their natural range. These have often been considered major threats to ecosystem functions and the maintenance of biodiversity (Carlton, 1989 and 1996; Carlton and Geller, 1993; Ruiz *et al*., 1999; Geller, 1999). The recent increase in studies on such coastal invaders has provided new insights into the human-related vectors, with four main paths of invasion proposed: ship-ballast water, hull fouling, and new connections between water bodies through canals and aquaculture transfers (Ruiz *et al*., 1997; Elston, 1997; Galil, 2009; Zenetos *et al*., 2010). Thus, lagoons, estuaries and coastal marine systems are among the most highly invaded environments for nonindigenous species.

The genus *Oithona* is the most important cyclopoid copepod group in the world oceans in terms of abundance and productivity (Gallienne and Robins, 2001; Turner, 2004). This includes cosmopolitan species, like *Oithona similis* and *Oithona nana*, as well as species with narrower ranges of distribution, such as *Oithona vivida* and *Oithona robusta* (Dahms *et al*., 2015 and references therein). These small-sized oithonids have many ecological roles. They might be an important prey source for the larval stages of some key fishery species (Viñás and Ramirez, 1996), or conversely they might represent energy sinks in metazoan foodwebs (Atkinson and Snÿder, 1997). They directly affect the downward flux of calanoid copepod faecal-pellet material in pelagic zones (González and Smetacek, 1994), contribute to regeneration of nutrients that support primary production (Hiromi, 1995), and facilitate complex trophic interactions between the protozoan and metazoan foodwebs (Nakamura and Turner, 1997). Oithonids differ from better-studied suspension-feeding calanoid copepods in being primarily raptorial predators using hydromechanical signals to detect and capture motile prey (Svensen and Kiørboe, 2000).

*Oithona davisae* was originally endemic to the temperate coastal waters of East Asia. Over the last forty years, it has been recorded in other regions, which now extend from the Pacific and Atlantic Oceans to northern and southern European waters (Nishida *et al*., 1977; Ferrari and Orsi, 1984; Hirakawa, 1988; Lee *et al*., 2001; Saiz *et al.*, 2003; Cordell *et al*., 2009; Lawrence and Cordell, 2010; Temnykh and Nishida, 2012; Cordell *et al*., 2015; Cornils and Wend-Heckmann, 2015; Uriarte *et al*., 2015; Doğan and İşinibilir, 2016). *O. davisae* shows high tolerance to different environments, which allows it to survive and reproduce in many coastal and transitional waters. This ecological plasticity may contribute to its success as an invasive species.

Passive dispersion of *O. davisae* by ship-ballast waters has been widely proposed (Ferrari and Orsi, 1984; Nishida, 1985; Hirakawa, 1988; Cordell *et al*., 2009; Lawrence and Cordell, 2010). Other dispersion vectors have not been considered to have a role in *O. davisae* 

dispersion, although aquaculture transfer as a possible means of introduction and spread of invasive non-indigenous copepod species is a well-known possibility (Carlton, 1992a, b; Naylor *et al*., 2001). Aquaculture activities involving the transport of live shellfish, and especially oysters, have been identified as the most important human vector for the introduction of invasive species into coastal marine and estuarine systems (Molnar *et al*., 2008).

The Mediterranean Sea is particularly vulnerable to ship-transported bio-invasions, which have increased greatly in frequency over the last two decades (Galil, 2009; Coll *et al*., 2010; Costello *et al*., 2010). Among the 955 alien species recorded in the Mediterranean Sea, 42 are planktonic copepods (Zenetos *et al*., 2010), three of which have recently been identified in Lakes Faro and Ganzirri, two coastal lakes located in the Central Mediterranean Sea (Sicily, Italy): *Pseudodiaptomus marinus* Sato, 1913; *Acartia tonsa* Dana, 1849; and *O. davisae* Ferrari and Orsi, 1984 (Brugnano, 2006; Zagami and Brugnano, 2013; Pansera *et al*., 2014; Sabia *et al*., 2014; Sabia *et al*., 2015). These above mentioned species have rapidly invaded many coastal and transitional European sites, showing different patterns of coexistence and/or competitive exclusion with indigenous species (Brugnano *et al*., 2011; Altukhov *et al*., 2014; Uriarte *et al*., 2015; Delpy and Pagano, this volume; Marques *et al*., this volume; Villate *et al*., this volume).

In this contribution we first provide a brief revision of the biogeography and ecology of *O. davisae*. We then present results from a year-long sampling programme in Lakes Faro and Ganzirri, showing the seasonal variations in abundance of this species. For the first time we report the introduction of *O. davisae* through aquaculture rather than ballast water, evidenced by the lack of water exchange among the two lakes and the sea. The dynamics observed in these lakes match those recorded in other sites worldwide, provide evidence for the invasiveness of this species and point to further hypothetical alternative vehicles for dispersion. This information broadens our knowledge of the invasive dynamics of this species, and provides new understanding about its biology and ecology.

# **2. DISTRIBUTION AND ECOLOGY OF** *OITHONA DAVISAE*

## **2.1. Biogeographic Distribution**

*Oithona davisae* is a coastal and estuarine copepod species endemic in the temperate coastal waters of East Asia. *O. davisae* was originally described by Ferrari and Orsi (1984) for Californian estuarine waters, with the type locality of the Sacramento San Joaquin Estuary. It has also been recorded in Chile (Hirakawa, 1988) and in the north-western Mediterranean (Nishida, unpublished observations, cited by Saiz *et al.*, 2003). More recently, *O. davisae* was reported in the Bay of Varna by Mihneva and Stefanova (2013), in the Estuary of Bilbao (eastern Atlantic Ocean, Spain) (Uriarte *et al.*, 2015), Wadden Sea (Cornils and Wend-Heckmann, 2015), Puget Sound (Washington State, USA) (Cordell *et al.*, 2015), Marmara Sea and Golden Horn Estuary (Isinibilir *et al.*, 2016) and Venice Lagoon (northern Adriatic Sea) (Pansera, personal communication) (Figure 1). Data on the literature search on *O. davisae* biogeography are available from Razoul *et al.* (2005-2017) and Walter (2015).

Figure 1. Global distribution of *Oithona davisae* based on the literature data:  $\bullet$  Sacramento San Joaquin Estuary, California (Ferrari and Orsi, 1984); Chile (Hirakawa, 1988); Puget Sound, Washington State (Cordell *et al.*, 2015); ■Eastern Atlantic Ocean, Spain (Uriarte *et al.*, 2015); ▼North-western Mediterranean (Saiz *et al.*, 2003); **A** Venice Lagoon, Adriatic Sea (Pansera, personal communication); Wadden Sea (Cornils and Wend-Heckmann, 2015); Bay of Varna (Mihneva and Stefanova, 2013);  $\blacktriangleright$  Black Sea (Temnykh and Nishida, 2012);  $\blacktriangleright$  Korea (Lee *et al.*, 2001; Orui-Sakaguchi *et al.*, 2011); ◆Japan (Nishida, 1985; Ohtsuka *et al.*, 2008); ▶Lakes Faro and Ganzirri, Central Mediterranean (present work).

It is closely related to *Oithona nana*, *Oithona aruensis* and *Oithona brevicornis* (Nishida and Ferrari, 1983; Ferrari and Orsi, 1984). The morphological features that allow *O. davisae* to be distinguished from these other species are: sharply pointed rostrum; very long distal spine on the first inner lobe of the maxillule; and endopod of the maxillule carries only one seta. Owing to this morphological closeness, *O. davisae* has also been misidentified several times, including as *O*. *brevicornis* f. *minor* (Nishida *et al.*, 1977; Nishida and Ferrari, 1983), *O. aruensis* (Nishida, 1985; Ohtsuka *et al.*, 2008) for the coastal waters of Japan, and as *O. aruensis* in Korea (Lee *et al*., 2001; Orui-Sakaguchi *et al.*, 2011).

It also appears likely that the *O. brevicornis* specimens that have been reported as recently introduced into the Black Sea (Zagorodnyaya, 2002; Gubanova and Altukhov, 2007; Selifonova, 2009) are also *O. davisae*. This is supported by the specimens collected in an offshore area in the Black Sea off the Crimean Peninsula that were previously identified as *O. brevicornis*, and upon re-examination showed to be *O. davisae* (Temnykh and Nishida, 2012).

The geographic distribution of *O. davisae* shows that this species was originally endemic to the temperate coastal waters of East Asia, in contrast to *O. brevicornis*, which was widely distributed in the subtropical-tropical coastal waters of the Indo-Pacific (Giesbrecht, 1891; Nishida, 1985). The recent record in European waters confirms this non-indigenous species as typical of temperate environments. However, the records of the occurrence of *O. brevicornis* in the Mediterranean Sea (Carazzi and Grandori, 1912; Pesta, 1920; Vaisierre and Seguin 1980; Shuvalov, 1980) should be revised, because these studies were not based on description of the morphological characters that are now known to distinguish *O. brevicornis* from the other related species.

# **2.2. Habitat Characteristics**

*O. davisae* has mainly been reported in eutrophic land/sea transitional zones, such as coastal lakes, estuaries, lagoons and coastal marine environments, including near-shore waters, inlets and bays. *O. davisae* can tolerate wide salinities from 12 to 35, and temperatures from -1.8 to 29°C (Ferrari and Orsi, 1984; Kimmerer, 2004; Gubanova and Altukohv, 2007; Temnykh and Nishida, 2012; Mihneva and Stefanova, 2013; Cornils and Wend-Heckman, 2015; Doğan and İşinibilir, 2016; Isinibilir *et al*., 2016), although it appears to thrive in relatively warm conditions (20 to  $25^{\circ}$ C). In the temperate eutrophic inlet of Fukuyama Harbour (Uye and Sano, 1998), in the San Francisco Estuary (Bollens *et al.*, 2011) and inner Estuary of Bilbao (Uriarte *et al*., 2015), *O. davisae* seasonal highest abundances occurred in warmer periods, between late spring and early summer. In Sevastopol Bay (Crimea), the peak abundances of *O. davisae* had high interannual variability, occurring at the end of October (Gubanova and Altukhov, 2007), mid-June and in autumn (Altukhov *et al*., 2014). In the western Black Sea, *O. davisae* abundances peaked during September-October (Mihneva and Stefanova, 2013).

Most of the transitional environments where *O. davisae* has been reported to be abundant, especially in the inner part of estuaries, inlets and semi-enclosed bights, have narrow mouths and shallow channels, limiting water exchange with the sea. This therefore results in little water circulation, eutrophic conditions, and wide salinity variations (Ferrari and Orsi, 1984; Uye and Sano, 1998; Bollens *et al*., 2011; Uriarte *et al*., 2015). These habitat parameters appear to be beneficial for the growth of *O. davisae*. In the Mediterranean Sea, *O. davisae* has only been recorded in some of the many sites that possess these characteristics. One explanation might be that *O. davisae* has often been misidentified as *O. brevicornis* (*e.g*., see Zagami and Brugnano, 2013; Pansera *et al*. 2014), while another might be that the optimal conditions for the success of *O. davisae* invasions are isolated eutrophic environments, resulting in disjunct distributional patterns, and reducing the chances of dissemination of *O. davisae* among coastal transitional environments. In addition, *O. davisae* may have been missed because of the mesh sizes used for copepod sampling. Owing to its small size  $\ll 1$ mm body length), *O. davisae* might not be efficiently collected through the WP-2 plankton net (*i.e*., 200 µm mesh size) (UNESCO, 1968; Sameoto *et al.*, 2000), which remains the most commonly used net for marine zooplankton sampling. This would lead to underestimation of cyclopoid abundances (Gallienne and Robins, 2001; Pansera *et al*., 2014), but not to their total absence.

#### **2.3. Ecology**

With its high egg production rate  $(11.6$  eggs female<sup>-1</sup> d<sup>-1</sup> in summer; Uye and Sano, 1995) and invasiveness, *O. davisae* may require only a short time to become the most abundant copepod species in zooplankton communities of many coastal transitional environments (Uye and Sano, 1998; Bollens *et al*., 2011; Altukhov *et al*., 2014; Cornils and Wend-Heckman, 2015; Uriarte *et al*., 2015). O. davisa*e* shows high numerical peaks in both its original and its newly invaded environments, ranging from  $5.1 \times 10^3$  to  $6.0 \times 10^5$  ind. m<sup>-3</sup> (Uye and Sano, 1995). Its highest numbers were recorded for swarms of adults and copepodites attaining 1.34  $\times$  10<sup>6</sup> ind. m<sup>-3</sup> for the mud flats of Ariake Bay, Kyushu (Hirota and Tanaka, 1985). The reasons for such high *O. davisae* abundance might be the low species diversity and the high primary production that characterise these segregated environments, which can result in little inter-specific competition and sufficient or unlimited food supplies.

In several environments like Sevastopol Bay (Altukhov *et al*., 2014), the Marmara Sea and Golden Horn Estuary (Isinibilir *et al*., 2016), and Estuary of Bilbao (Uriarte *et al*., 2016), *O. davisae* has occupied the niche of the indigenous species *O. nana* and it has become the most abundant species of the copepod assemblage. The preferred food of *O. davisae* consists of motile prey, such as flagellates, ciliates and copepod nauplii (Uchima, 1988; Uchima and Hirano, 1986a, b; Saiz *et al*., 2003; Henriksen *et al*., 2007), with either sinking or jumping considered typical foraging movements (Cheng *et al.*, 2014). Also *O. nana* appears to ingest significant levels of non-motile prey, such as diatoms (Lampitt and Gamble, 1982). *O. davisae* might have a significant role in transferring energy from the nanoflagellates and microflagellates and ciliates to the higher trophic levels in eutrophic environments, such as transitional waters (Uye and Sano, 1998).

The dominance of the invasive species *O. davisae* over *O. nana* might be evidence of competitive exclusion of the indigenous species from the zooplankton community. Laboratory experiments and field studies have highlighted the competitive advantage of *O. davisae* over *O. nana*. *O. davisae* is a widely euryhaline species (Svetlichny and Hubareva, 2015; Svetlichny *et al*., this volume), while *O. nana* is a stenohaline species (Kovalev, 1966). In addition, the frequency and speed of routine jumps, and the maximum escape reaction speed in *O. davisae* are significantly higher than for *O. nana* (Isinibilir *et al*., 2016). Comparisons of the biological attributes between these two species show that, at the same temperature, *O. davisae,* has shorter development time than *O. nana,* 17 days (Uye and Sano, 1998) *vs.* 21-24 days (Haq, 1965), higher daily egg-production rate, 11.6 (Uye and Sano, 1995) *vs.* 7.4 eggs female<sup>-1</sup> day<sup>-1</sup> (Cepeda *et al.*, 2015), and larger clutch size, 28.5 (Uye and Sano, 1995) *vs.* 12.4 eggs female<sup>-1</sup> (Temperoni *et al.*, 2010; Cepeda *et al.*, 2015). All of these factors may indicate the higher adaptive potential of *O. davisae* respect to *O. nana*.

# **2.4. Dispersal**

Previous reports on *O. davisae* have shown that it was originally endemic in temperate Japanese coastal waters. Until now, its occurrence in other regions of the world has been explained exclusively by ship-ballast water transport (Ferrari and Orsi, 1984; Nishida, 1985; Hirakawa, 1988; Cordell *et al*., 2009; Kaysan, 2010; Lawrence and Cordell, 2010). Other human-related vectors have not been considered to play a role in *O. davisae* dispersion. However, ballast transport alone does not completely explain the biogeographic distribution pattern of *O. davisae.* Around the world, *O. davisae* has been found mostly in highly anthropogenic environments, and particularly in segregated coastal features, such as bays, estuaries and lagoons, where it can attain high abundances. The optimal conditions for *O. davisae* growth occur in confined eutrophic environments that are characterised by little water circulation, leading to a varied distribution pattern that reduce the chances of the dispersion of this species. Therefore, *O. davisae* occurs in embayments both with and without ballast water discharge.

# **3.** *OITHONA DAVISAE* **IN THE CENTRAL MEDITERRANEAN SEA (LAKES FARO AND GANZIRRI, SICILY,ITALY)**

#### **3.1. Study Area**

Lakes Faro and Ganzirri are formed by two coastal basins in the central area of the Mediterranean Sea (Figure 2). Lake Faro (38°160' N, 15°380' E) is a small coastal basin (0.263 km<sup>2</sup> ) located in the north-eastern tip of Sicily (Italy), and is connected to the adjacent Lake Ganzirri and to the Strait of Messina by shallow channels. It has a funnel-shaped bottom profile, whereby it has a wide nearshore water area before it reaches its maximum depth of 29 m, in the central part. In this deepest part, Lake Faro is characterised by typical features of a meromictic temperate basin, with its upper oxygenated mixolimnion (up to 15 m in depth) and its lower anoxic and sulphidic monimolimnion (Genovese, 1963; Truper and Genovese, 1968). The nearshore waters of the lake are oxygenated down to the bottom.

Figure 2. Map of the locations of Lakes Faro and Ganzirri.

Lake Faro shows large seasonal fluctuations in physico-chemical parameters, particularly for temperature (10-28 °C) and salinity (28-37) (Crisafi, 1955; Pansera *et al.*, 2014). Its physical and chemical stratification between the surface water and the water column is significant, particularly in summer when anoxia extends up to the lower mixolimnion zone, resulting in large blooms of photosynthetic sulphur bacteria (Sorokin and Donato, 1975).

Lake Ganzirri (38 $\degree$ 150' N, 15 $\degree$ 360' E) has an elongated shape with shallow waters, reaching a maximum depth of 5 m thus maintaining oxygenated bottom waters. Through the year, Lake Ganzirri also has large fluctuations in its physico-chemical parameters, again for temperature and salinity in particular, which range from 10.4  $\degree$ C to 30.1  $\degree$ C, and from 21.2 to 28.7, respectively (Crisafi, 1955; Genovese, 1963; Ferrarin *et al*., 2013).

The very long and shallow channel that connects Lake Ganzirri to the sea results in a low marine water turnover rate. Thus, Lake Ganzirri is characterised by typical brackish waters that are supplied more by the surface rainwater than by marine water (Ferrarin *et al*., 2013). For both lakes, the water movements are influenced by the currents of the Strait of Messina. The marine water turnover rate is higher for Lake Faro than Lake Ganzirri, because of its shorter communication channel with the sea, thus Lake Faro has a more marine character than Lake Ganzirri (Genovese, 1963; Ferrarin *et al*., 2013).

In the segregated sectors of both lakes, very little water exchange occurs, leading to ecotoxicological alterations in the zooplankton communities (Minutoli *et al*., 2008). Lake Faro is an important centre for shellfish aquaculture, whereby living bivalves are imported from many Atlantic (Spain, northern France, The Netherlands) and Mediterranean (Venice Lagoon, Thau Lagoon) sites.

The mesozooplankton of Lakes Faro and Ganzirri include a relatively small number of taxonomic groups, of which copepods constitute by far the dominant species (Genovese, 1963; Crisafi *et al*., 1973; Zagami and Guglielmo, 1995). The permanent copepod communities in Lakes Faro and Ganzirri include only a few copepod species, including *Paracartia latisetosa* Krichagin, 1873, *Acartia margalefi* Alcaraz, 1976, and *Oithona nana* Giesbrecht, 1892. For Lake Faro only, there are also temporary coastal copepod species that enter and exit via tides from the Straits of Messina. A very complex current system driven by the flow of waters from the Ionian Sea to the Tyrrhenian Sea, and *vice versa* (Bossolasco and Dagnino, 1959; Mosetti, 1988), takes place in this area. This flow changes every 6 h, and thus has a large influence on the coastal and Lake Faro zooplankton communities (Zagami and Guglielmo, 1995; Zagami *et al*., 1996; Zagami and Brugnano, 2013).

# **3.2. Materials and Methods**

Zooplankton sampling was carried out in Lakes Faro and Ganzirri at approximately monthly intervals from January to December 2014, at a station in the central, deepest area in each lake (Figure 1, S1, S2, respectively). The samples were collected using a net (mouth area,  $0.125$  m<sup>2</sup>; mesh size,  $80$  µm; Apstein), with a digital flowmeter (Hydro-Bios, Kiel) mounted on the mouth of the net to calculate the filtered water volume. For Lake Faro, each net tow was vertical and taken within the oxygenated layer, from 15 m depth to the surface. For Lake Ganzirri, because of its lesser depth, each net tow was horizontal in the subsubsurface layer of the water column (*i.e*., 0-1.5 m in depth). A multiparametric conductivity, temperature and depth probe (ISY 6600V2) was used to measure the temperature and salinity at each sampling station. In the laboratory, the zooplankton samples were fixed in 4% neutralised formalin in lake water, and *Oithona davisae* specimens were counted under a stereomicroscope (Wild MDG-17). The body appendages (*i.e*., mandible, maxillule) were removed under a stereomicroscope and mounted on microscope slides for taxonomic identification based on morphological comparisons according to Giesbrecht (1891) and Ferrari and Orsi (1984).

# **3.3. Results**

#### *3.3.1. Seasonal Variations of Environmental Factors*

For Lake Faro, the surface water temperature ranged from  $12.8^{\circ}$ C in January to  $29.0^{\circ}$ C in August, and a similar range occurred in Lake Ganzirri, 12.5°C to 28.8°C in January and August, respectively (Figure 3). No significant temperature differences were recorded between these two lakes (Student's t-test;  $p = 0.89$ ;  $n = 24$ ).

For Lake Faro the salinity varied from 26.5 in March to 35.0 in October, while for Lake Ganzirri it varied from 21.3 in April to 28.9 in September. (Figure 4). In general, only salinity showed significant differences between Lakes Faro and Ganzirri (Student's t-test, *p* < 0.01; n  $= 24$ ).

Figure 3. Seasonal variations of surface water temperatures for Lakes Faro and Ganzirri, from January to December 2014.

Figure 4. Seasonal variations of surface water salinity for Lakes Faro and Ganzirri, from January to December 2014.

#### *3.3.2. Seasonal Variations in Abundance of Oithona davisae*

*O. davisae* was found in Lakes Faro and Ganzirri during the entire sampling period. Females carrying ovisacs and nauplii were also seen throughout the year, and the two lakes had similar seasonal abundance dynamics. In terms of the mean density of *O. davisae* including adults plus all copepodite stages, abundances at Lake Faro were lowest in winter (January), at 3,312 ind. m<sup>-3</sup>. From May to June, abundances increased exponentially, peaking in June at  $116,512$  ind.  $m^{-3}$ . Thereafter, from summer to winter, the abundances decreased gradually (Figure 5).

Figure 5. Seasonal variations in the abundance of *Oithona davisae* in Lake Faro.

For Lake Ganzirri, the abundances also increased from winter  $(970 \text{ ind. m}^{-3} \text{ in January})$  to spring, when they increased exponentially through May to June, peaking at  $211,617$  ind.  $m<sup>-3</sup>$ . Abundances remained high all summer, and then decreased rapidly beginning in September, to the lowest for the year in December, at  $92.6$  ind.  $\text{m}^3$  (Figure 6).

Figure 6. Seasonal variations in the abundance of *Oithona davisae* in Lake Ganzirri.

In both lakes, the naupliar abundances followed similar seasonal trends to the adults and copepodites. The nauplii abundance for Lake Faro peaked in May, at  $13,000$  ind.  $m^{-3}$ , and for Lake Ganzirri in June, at  $242,692$  ind. m<sup>-3</sup>. Females always outnumbered males, with annual means of 85.4% females for Lake Faro and 87.2% females for Lake Ganzirri. Ovigerous females occurred throughout the year for both Lakes Faro and Ganzirri, although they showed

greater relative abundance in spring/early summer (28.7%, 30.2%, respectively) than in winter (16.7% and 17.4%, respectively). Overall, the total annual mean *O. davisae* population for Lake Faro (19,141  $\pm$  34,423 ind. m<sup>-3</sup>) was lower than for Lake Ganzirri (55,420  $\pm$  78,470 ind. m<sup>-3</sup>), although this difference was not statistically significant (paired Student's t-test, *p*=0.19; n=20). The contribution of *O. davisae* to the total mean copepod abundance was also lower for Lake Faro compared to Lake Ganzirri (Figure 7). During the periods of peak abundance of *O. davisae*, its relative abundance in terms of the total copepod densities reached 98.3% and 99.6% for Lakes Faro and Ganzirri, respectively.

Figure 7. Mean annual contribution of *Oithona davisae* to the total copepod abundance in Lakes Faro and Ganzirri.

## **CONCLUSION**

The passive dispersion of *Oithona davisae* due to synanthropic introduction in many regions of the world has rapidly widened its biogeographical distribution, with a circumglobal, though scattered distribution pattern. *O. davisae* occurs mostly in temperate waters of the boreal hemisphere. It is also found in both cold-temperate latitudes, as the northern Wadden Sea, and austral hemisphere, as southern Pacific Ocean (Chile).

The new records of *O. davisae* in Lakes Faro and Ganzirri confirm that this invasive species is typical of temperate environments. These lakes have physical characteristics similar to those of other locations where this species has been reported. The specimens identified as *Oithona nana* by Zagami and Guglielmo (1995) in these lakes were re-examined and confirmed to be only *O. nana*. In contrast, the specimens identified as *O. nana* and *Oithona brevicornis* by Brugnano (2006); Zagami and Brugnano (2013) and Pansera *et al.* (2014) in Lake Faro showed only a few specimens of *O. nana*, and high numbers of *O. davisae*. All of the *Oithona* specimens collected during the present study were identified as *O. davisae.* It thus appears that *O. davisae* has eliminated *O. nana* in Lakes Faro and Ganzirri.

Differences in abundances between Lakes Faro and Ganzirri can be ascribed to the different sampling methodologies employed: vertical and horizontal tows, respectively. The highest abundances were recorded in the sub-superficial layer (Pansera *et al*. 2014), so the vertical sampling throughout all the water column may have underestimated abundances.

In Lakes Faro and Ganzirri, the sex ratio of *O. davisae* is female skewed, with values close to those reported in literature (Uye and Sano, 1995; Ceballos and Kiørboe, 2011). Females can reproduce throughout the year, and thus across temperatures ranging from 12.5 to 29.0°C. The high abundance peaks of the adults, copepodites and nauplii, the relatively high proportions females carrying ovisacs, and the occurrence of brooding females and nauplii during winter, all indicate that this invasive species has become a permanent component of Lakes Faro and Ganzirri. As reported elsewhere (Uye and Sano, 1995), the specific egg production rate of *O. davisae* increases linearly with increasing temperature, up to  $\sim$  22 °C, although at temperatures > 22 °C this rate no longer increases, and can even decrease.

The density peaks of *O. davisae* in Lakes Faro and Ganzirri were recorded in late spring, when water temperatures were from 23  $\degree$ C to 25  $\degree$ C, in agreement with records from other temperate environments (Uye and Sano, 1998; Bollens *et al.*, 2011; Uriarte *et al*., 2016). These also co-occurred with the seasonal peaks of flagellates, both autotrophic and heterotrophic (Giuffrè and Pezzani, 2005), and ciliates (Saccà and Giuffrè, 2013), so *O. davisae* might have an important role as a predator in the regulation of an eventual dystrophic crisis, due to recurrent summer blooms of flagellates. Conversely, *O. davisae* summer decreases were inversely correlated with temperatures over 25 °C.

Before 1992, *O. davisae* was not recorded from Lakes Faro and Ganzirri (Crisafi *et al*., 1973; Zagami and Guglielmo, 1995). However, recent studies on the zooplankton community in Lake Faro in 2004-2005 showed gradual decreases eventually resulting in almost total disappearance of *O. nana*, with progressive replacement by *O. davisae*, although the latter was largely misidentified as *O. brevicornis* (Brugnano, 2006; Zagami and Brugnano, 2013). Therefore, *O. davisae* appears to have penetrated into Lake Faro between 1993 and 2004. However, it might have been present in Lake Faro earlier, but the absence of regular zooplankton monitoring in these lakes does not allow pinpointing the year of its introduction. After a few years of coexistence between *O. nana* and *O. davisae*, the non-indigenous *O. davisae* excluded the indigenous *O. nana*, which has not been reported since 2009 (Pansera *et al*., 2014; Zagami, personal observations). The replacement of *O. nana* by *O. davisae* agrees with reports from other locations (Altukhov *et al*., 2014; Isinibilir *et al*., 2016; Uriarte *et al*., 2015).

In Lakes Faro and Ganzirri, the low resilience of the *O. nana* native population to *O. davisae* invasion might have been caused by short anomalous high peaks in the water temperatures. These exceeded 32 °C in both lakes, with Lake Faro also showing upwelling of the bottom anoxic waters during the summer period for some of the years over the last decade. These effects resulted in the death of the entire zooplankton community, and also bivalve cultures (Zagami, personal observations). The resulting temporarily empty niche in the zooplankton community might have favoured *O. davisae* establishment in Lakes Faro and Ganzirri, also enhanced by human activities.

Coastal estuarine and marine environments are heavily subjected to non-indigenous species invasions. Ecological and evolutionary consequences of invasions can be observed at species, community and ecosystem levels. After its introduction, an invader must either find a niche that is not occupied or it must compete for an occupied niche (Di Castri, 1990). In Lakes Faro and Ganzirri, *O. davisae* has become the most abundant species of the copepod assemblage in a short time. To date, no negative consequences appear to have been reported for the ecosystem functioning of these lakes, apart from the disappearance of the indigenous species *O. nana*. Small proportions of the *O. nana* and *O. davisae* numbers enter the planktonic foodweb as prey for the pelagic fish species *Atherina boyeri*, as seen from gutcontent observations (Zagami personal observations), whereas the major proportions of *O. nana* and *O. davisae* are not consumed by pelagic predators, but instead flow into the benthic systems to maintain the microbial loop (Nakamura and Turner, 1997).

Lakes Faro and Ganzirri are shallow-water environments, closed to transoceanic ship traffic. Due to their shallow channels, and the weak *O. davisae* adaptation to the strong currents of the Messina Strait (Mosetti, 1988), it is improbable that this species was introduced by ship ballast waters. Furthermore, *O. davisae* has not been reported in recent samplings of the adjacent Ionian and Tyrrhenian Seas (Zagami, personal observations), and its introduction from adjacent basins is thus highly improbable. In addition, Lake Faro is an important importation centre for living bivalve**s** coming from many Atlantic and Mediterranean sites, thus it is more probable that aquaculture activities are responsible for *O. davisae* introduction. Monitoring of imported molluscs and further samplings in the Messina harbour would provide further evidence in support of this hypothesis. Recently, the identification of new copepod species for Lake Faro (Baviera *et al.*, 2007; Zagami *et al*., 2008; Brugnano *et al*., 2010) and reports of not only plankton species typical of different biogeographic regions (Zagami *et al*., 2005; Cosentino *et al*., 2009; Cosentino and Giacobbe, 2011; Saccà and Giuffrè, 2013; Sabia *et al.* 2014 and 2015) can probably be ascribed to the importation of these molluscs for aquaculture. Indeed the Thau Lagoon, a shallow water system on France's Mediterranean coast, is one of the major hotspots of marine species invasions in the world (Verlaque, 2001), and also an important exportation centre of living bivalves to other aquaculture sites. Consequently, the high numbers of non-indigenous species introduced into Thau Lagoon has a high probability of being transported to other shellfish farming sites in Europe. Thus, it is likely that *O. davisae* was introduced into Lakes Faro and Ganzirri via aquaculture acitivities. The passive dispersion of *O. davisae* by ballast water has already been widely demonstrated (Ferrari and Orsi, 1984; Nishida, 1985; Hirakawa, 1988; Cordell *et al*., 2009; Kaysan, 2010; Lawrence and Cordell, 2010) and the present study represents the first record of the introduction of *O. davisae* through aquaculture.

#### **ACKNOWLEDGMENTS**

Our thanks go to Mr Vincenzo Bonanzinga (Department of Chemical, Biological, Pharmaceutical and Environmental Sciences, University of Messina, Italy) for zooplankton and environmental parameter graphical elaboration. Thanks go to Dr Christopher Paul Berrie for English revision of the manuscript. We are also grateful to Referees for their helpful discussions and criticism of the manuscript.

# **IMPACT OF THE INVASIVE SPECIES** *ACARTIA TONSA* **ON THE DISTRIBUTION OF AUTOCHTHONOUS ACARTIIDAE SPECIES IN ESTUARIES OF THE BAY OF BISCAY**

*Fernando Villate1,\* , Ibon Uriarte<sup>2</sup> and Arantza Iriarte<sup>2</sup>*

<sup>1</sup>Department of Plant Biology and Ecology, Faculty of Science and Technology, University of the Basque Country (UPV/EHU), Leioa, Spain <sup>2</sup>Department of Plant Biology and Ecology, Faculty of Pharmacy, University of the Basque Country (UPV/EHU), Gasteiz, Spain

# **ABSTRACT**

The impact of the settlement of the invasive copepod species *Acartia tonsa* on the spatial and temporal (seasonal and interannual) distribution of native Acartiidae species in two estuaries of the Bay of Biscay of contrasting morphology, hydrology, and level of pollution, namely the estuaries of Bilbao (polluted) and Urdaibai (weakly polluted), was assessed. Until the arrival of the non-indigenous species *A. tonsa* in 2001-2002 and its occurrence in high density in the inner zone of both estuaries in 2003, *Acartia clausi* dominated the assemblage of Acartiidae species in the estuary of Bilbao, whereas in the estuary of Urdaibai *A. clausi* dominated in the high salinity zone and the brackish species *Acartia bifilosa* in the low salinity zone. The settlement of *A. tonsa* caused (directly or indirectly) the spatial distribution of *A. clausi* to shrink in both estuaries, the latter species being almost driven out from the 30 salinity zone in the estuary of Bilbao. Low oxygen levels in the low salinity zone of the estuary of Bilbao may have helped the settlement of *A. tonsa*, which is more tolerant to hypoxic conditions than *A. clausi*. In the estuary of Urdaibai, which has a wider range of salinity habitats to sustain brackish planktonic copepods, the *A. tonsa* population optimum was at a lower salinity than in the estuary of Bilbao, and there was large overlapping of the spatial and temporal distributions of *A. tonsa* and *A. bifilosa*. Competitive pressure of *A. bifilosa* likely restricted the seasonal

 $\overline{a}$ 

<sup>\*</sup> Corresponding Author's Email: fernando.villate@ehu.eus.

distribution of *A. tonsa*, and contributed to its decline from 2003 to 2005, a period during which temperature decreased. Conversely, the settlement of *A. tonsa* caused the displacement of the annual maximum of *A. bifilosa* from summer to late spring, as well as its spatial displacement seaward. The impact of *A. tonsa* on other Acartiidae species that are scarce in the estuaries of Bilbao (*Acartia discaudata* and *Acartia margalefi*) and Urdaibai (*Paracartia grani*) could not be clearly assessed. *A. discaudata* and *A. margalefi* almost disappeared when *A. tonsa* settled, but the concomitant deterioration of environmental conditions for the former species argues against the hypothesis of a biotic interaction with *A. tonsa* as the main cause for their decline. In contrast, the summertime species *P. grani* was the only one that showed highest abundance at the same time as *A. tonsa*, likely as a common positive response to temperature increase.

**Keywords**: *Acartia tonsa*, invasive species, Acartiidae assemblages, estuaries, Bay of Biscay

# **1.INTRODUCTION**

After habitat loss or degradation, biological invasions are the major challenge for the conservation of biodiversity and natural resources (MEA, 2005). Non-indigenous species are able to become invaders because they may displace or replace indigenous species, and affect ecosystem structure and functioning, causing losses of native genotypes, habitat changes, and alterations in community structure, food web properties and ecosystem processes. They can thus prevent the provision of ecosystem services, resulting in negative effects on human health and large economical losses (Grosholz, 2002; Perrings *et al.*, 2002; Wallentinus and Nyberg, 2007; Molnar *et al.*, 2008; Vilà *et al.*, 2010). In a globalized world like today's, the fast increase in trading, travelling and transportation over the last decades has accelerated marine biological invasions, notably in estuaries due to their vulnerability (Nehring, 2006), through maritime transport (e. g. ballast water discharge, biofouling), channel construction for navigation, aquaculture and use of aquariums (Hulme 2009; Katsanevakis *et al.*, 2013).

The Convention on Biological Diversity (CBD, 2000) has recognized the need to compile and spread the information about non-indigenous species which threaten ecosystems, habitats, or native species, in order to use them in a context of prevention and mitigation actions. CBD (2000) has also issued a call to intensify research on the impact of non-indigenous species on biological diversity. In the case of the European Union, the Marine Strategy Framework Directive (EU, 2008) considers non-indigenous species as the main threat to biodiversity and ecosystems health in Europe.

*Acartia tonsa* is among the listed non-indigenous species that can become invasive in European marine systems and can have a high impact on ecosystems services or diversity, although both positive and negative impacts have been attributed to this species (Katsanevakis *et al.*, 2014). *A. tonsa* competes with native copepods, especially congenerics, and may become dominant in zooplankton communities. It may also modify food webs and trophic flows within invaded ecosystems (Katsanevakis *et al.*, 2014), as it can be a significant prey for pelagic fish (Detwyler and Houde, 1970) and it can control algal blooms (Leppäkoski *et al.*, 2002).

This species has become widespread across the world, but it is reported to be native to American and Indo-Pacific waters (Leppäkoski and Olenin, 2000). *A. tonsa* has been colonising new coastal areas and estuaries by self-propagation and/or anthropogenic

introduction, due mainly to its ability to cross geographic barriers owing to its capacity to develop resistance stages (Belmonte and Potenza, 2001) and to tolerate wide ranges of environmental factors (Holste and Peck, 2006). This species has become a well-known nonindigenous species in European waters since the early 1900s (Brylinski, 1981).

In the Bay of Biscay, *A. tonsa* has been reported since 1983 in the Gironde estuary (David *et al.*, 2007), the largest estuary flowing into this bay. In the small estuaries of the Basque coast, however, it was detected for the first time only in 2001 in the estuary of Bilbao, where it has become the dominant zooplankton calanoid in the inner estuary since 2003 (Aravena *et al.*, 2009). *A. tonsa* was observed for the first time in the nearby estuary of Urdaibai later than in the estuary of Bilbao, in 2003 (Aravena, 2009). In addition, *A. tonsa* has shared from the beginning the occupation of the upper reaches of both estuaries with *Oithona davisae*, a typical coastal and estuarine species that has been found to be a rapid invader of transitional environments in the Mediterranean (Zagami *et al.*, this volume), and since 2010 with *Pseudodiaptomus marinus* in the estuary of Bilbao (Uriarte *et al.*, 2016). The last two non-indigenous species are both native to the Indo-Pacific region (see Mihneva and Stefanova, 2013; Sabia *et al.*, 2015).

In this chapter we aim to show the impact of the arrival of the non-indigenous *A. tonsa* in the estuaries of Bilbao and Urdaibai on the spatial and temporal distribution of the other Acartiidae species inhabiting these areas. Since these two estuaries differ largely in morphological and hydrological properties, as well as in the level of human pressure and system health, we have also dealt with the role of system inherent characteristics in constraining or enhancing the impact of the non-indigenous species on co-occurring Acartiidae species.

# **2. MATERIAL AND METHODS**

# **2.1. Study Area**

The estuary of Bilbao (also known as Ibaizabal-Nerbioi estuary or Nervión estuary; 43º23'N, 03º07'W) and the estuary of Urdaibai (also known as Gernika estuary, Mundaka estuary or Oka estuary; 43º22'N, 02º43'W) are located in the Basque coast (inner Bay of Biscay) (Figure 1). Because of their proximity to each other, they share a temperate-oceanic climate. However, they differ largely in geomorphology, hydrodynamic characteristics, and level of anthropogenic impact, which result in differences in their water environments (Iriarte *et al.*, 2016).

#### *2.1.1. Estuary of Bilbao*

The estuary of Bilbao has two clearly different areas: a funnel-like harbour (23 km long, 3.8 km wide (on average) and 10-25 m deep) called Abra, and a man-made channel (15 km long, 50-150 m wide and 2–9 m deep) that extends from this harbour area up to the Ibaizabal river. The estuary is partially mixed in the outer area and highly stratified in the inner area. High salinity waters  $(>=30)$  usually penetrate up to the inner reaches at the bottom, whilst freshwater flows seaward at surface and is progressively mixed with seawater. This results in a two-layer circulation with landward net flux in bottom layers and seaward net flux in surface layers, and much higher residence time in waters below the halocline (3-12.6 days)

than in waters above the halocline (0.5-3 days) (Uriarte *et al.*, 2014). The original features of the estuary were dramatically modified due to (i) land reclamation for urban, industrial and port developments, and (ii) channelization and dredging works to make navigation easier. As a result of these, the estuary has lost most of its original intertidal areas (Cearreta *et al.*, 2004). By the 1970s, the channelled area was extremely polluted with high heavy metal and organic matter concentrations, and hypoxic/anoxic conditions in waters and sediments (Cearreta *et al.*, 2000), which gave rise to extensive benthic areas devoid of fauna (González-Oreja and Saiz-Salinas, 1998). Since 1979 the estuary is in a rehabilitation process, as a consequence of the industrial decline in the area surrounding the estuary, the treatment of wastewaters from the Metropolitan Area of Bilbao and new environmental protection policies, resulting in a significant decrease in heavy metal, ammonia and organic matter loadings, and an increase in oxygenation and biodiversity (García-Barcina *et al.*, 2006; Borja *et al.*, 2010; Pascual *et al.*, 2012; Villate *et al.*, 2013).

Figure 1. Map and location of the estuaries of Bilbao and Urdaibai, showing the 26, 30, 33, 34 and 35 salinity zones where samplings were carried out in each estuary.

The first plankton studies in this system, carried out around 1980, were restricted to the Abra harbour, where both phytoplankton biomass and neritic zooplankton abundance where shown to strongly decrease toward the inner-eastern zone due to the effect of the polluted estuarine plume coming from the channel mouth (Villate, 1991a and 1994). In these studies, *Acartia clausi* was the only species of Acartiidae found. Later studies initiated in 1996 also included the channelled zone and reported the occurrence in low numbers of two more Acartiidae species, *i.e.*, *Acartia margalefi* and *Acartia discaudata*, which were observed landward from the area occupied by *A. clausi* (Uriarte, 2001).

#### *2.1.2. Estuary of Urdaibai*

The estuary of Urdaibai, with a maximum and minimum width of 1.2 km and <20 m in the outer area and the inner channel respectively, is shorter (12.5 km), shallower (mean depth of 3 m) and physically less modified (*e.g.*, less channelized, with less land reclamation) than the estuary of Bilbao. Reed beds and salt marshes at its upper and middle reaches border the central channel, and relatively extensive intertidal flats of mainly muddy (in the inner part) and sandy (in the outer part) sediments occupy the outer half of the estuary. The watershed area is small and river inputs are usually low when compared to the tidal prism. As a consequence, most of the estuary is seawater-dominated at high tide, while a stronger axial gradient of salinity is only found in the upper reaches, where it receives freshwater inputs from its main tributary, the Oka river (Villate *et al.*, 2008). In the outer zone, tidal flushing is so high that waters of salinities >34 are flushed out of the estuary at each tidal cycle. The outer half of the estuary remains well mixed most of the time, while the inner half is partially stratified. In the upper reaches, the estuary receives relatively large amounts of nutrients and organic matter from an old primary waste water treatment plant (Franco *et al.*, 2004). Nevertheless, this estuary is among the healthiest coastal systems of the Basque coast, and constitutes the most valuable natural resource of the Biosphere Reserve of Urdaibai.

The first plankton studies in this system, in the early 1980s, showed the presence of three Acartiidae species segregated along the salinity gradient: the neritic *A. clausi*, dominant in the highest salinity waters; the brackish *Acartia bifilosa*, dominant in <33 salinity waters; and *Paracartia grani* (*Acartia grani* in previous publications), which was less abundant than the former two species, and occurred in an intermediate spatial position (Villate, 1991b and 1995). The abundance of the latter species has been shown to be much lower since 1996 when studies on zooplankton were resumed (Uriarte and Villate, 2005).

# **2.2. Data Source**

Zooplankton and environmental data shown in this chapter come from an ongoing monitoring program carried out in the estuaries of Bilbao and Urdaibai since 1997, and correspond to the time-series of the period 1998–2005, for which zooplankton identification and counting has been completed for all salinity sites in both estuaries at present. Data were obtained from monthly samplings (usually during the last week of the month) conducted at high tide during neap tides at the 35, 34, 33 and 30 salinity zones of the estuary of Bilbao, and at the 35, 33, 30 and 26 salinity zones of the estuary of Urdaibai (Figure 1), using a Lagrangian type of sampling strategy. This consisted in obtaining the biological and environmental information in water masses of a given salinity instead of at spatially fixed

sampling sites (see Kimmerer *et al.*, 1998; Modéran *et al.*, 2010). The salinity zones were selected according to previous studies (*e.g.*, Villate, 1991b; Uriarte, 2001), which allowed to define the main salinity habitats within each estuary on the basis of the distribution of main zooplankton species. Water masses of around 30 salinity constitute the innermost salinity habitat occupied by mesozooplankton copepods in the estuary of Bilbao, while water masses of around 26 salinity represent the optimal inner limit for brackish mesozooplankton copepods in the estuary of Urdaibai (Villate *et al.*, 1993).

Zooplankton samples were obtained from below the halocline by 2–3 min. horizontal tows using a 200 µm mesh size net (mouth diameter 0.25 m) equipped with a Digital Flowmeter, and preserved in 4% buffered formalin. Zooplankton counting and identification to the lowest possible taxonomic level was made under a stereomicroscope Olympus IX70. In Acartiidae species, female, male and copepodite stages were distinguished, but for the purposes of the chapter only the total abundance of each species was taken into account. Vertical profiles of salinity, water temperature and dissolved oxygen saturation (DOS) were measured *in situ* using a WTW LF 197 thermosalinometer and a YSI 55 oxymeter, but only data from the depth of zooplankton sampling are presented in this chapter. Water samples were collected also at the depth of zooplankton sampling using a Niskin bottle for measuring chlorophyll *a* (Chl *a*), which was determined spectrophotometrically in triplicate samples according to the monochromatic method with acidification (Jeffrey and Mantoura, 1997). Secchi disk depths (SDDs) were also recorded to assess water turbidity at each sampling site.

Salinity stratification was calculated from salinity profiles obtained at each sampling site in each sampling day as the maximum difference in salinity at 0.5 m depth intervals in the water column ( $\Delta$  salinity). This calculation has been put forward as an index to reflect the sharpening of the salinity gradient associated to the narrowing of the halocline layer, and was found to explain dissolved oxygen saturation dynamics below the halocline in the estuary of Bilbao better than a stratification index calculated from the difference between bottom and surface salinities (Villate *et al.*, 2013).

River flow data for the Ibaizabal-Nerbioi river (main tributary of the estuary of Bilbao) and for the Oka river (main tributary of the estuary of Urdaibai) were obtained from the Provincial Council of Bizkaia. In the case of the Oka river, missing values were filled with values obtained using a regression model (y =  $0.3892x$ , R<sup>2</sup> = 0.9333) performed with data from the nearest station (Oleta (LE02) hydro-meteorological station) with a complete series. Daily values of river flow were averaged for each month.

### **2.3. Data Treatment**

The impact of *A. tonsa* and the effect of environmental variables on Acartiidae species were assessed. To that purpose, the spatial (in relation to salinity) and temporal (seasonal and interannual) variations of abundance of all Acartiidae species, together with the niche breadth and overlap based on distribution of the dominant species (*A. clausi*, *A. bifilosa* and *A. tonsa*) were compared for three periods in the 1998-2005 data time series. The first two periods correspond to years prior to the large increase of *A. tonsa* abundance, but with different environmental conditions, *i.e.*, the 1998-2000 and the 2001-2002 periods. The third period extends from 2003 to 2005 and was characterized by the dominance of *A. tonsa* in the low

salinity waters of both estuaries at least during one month of the year. Prior to data analysis, Acartiidae species abundances were log-transformed (log  $(x+1)$ ).

Principal components analysis (PCA) was used to assess the influence of environmental factors on spatial and seasonal changes in Acartiidae species abundance. The eigenvectors allowed identification of the variables contributing most to the principal components of environmental variability. The three first principal components were used to describe the main environmental gradients in each estuary. The plot of Acartiidae species within the space configured by such environmental gradients was used to describe the segregation of Acartiidae populations along environmental gradients and determine the ecological niche of these species in each estuary.

Data normality was tested by means of the Kolmogorov-Smirnov test. Data comparisons were carried out by Kruskal-Wallis and Mann-Whitney U tests. Relationships between variables were assessed by Spearman rank order correlations and regressions (linear and quadratic).

Spatial (salinity sites) and seasonal (monthly) uniformity of distribution of individuals of the dominant Acartiidae species for each time period was estimated by Levins' standardized niche breadth ( $B_A$ ), suggested by Hurlbert (1978):

$$
B_A = \frac{B-1}{n-1} \text{ being } B = \frac{1}{\sum p_i^2} \tag{1}
$$

where:

 $B_A$  = Levins' standardized niche breadth n = number of possible resource states  $B =$ Levins' measure of niche breadth  $p_i$  = proportion of individuals found in or using resource state j

Additionally, to measure spatial (salinity sites) and seasonal (monthly) niche overlap between *A. tonsa* and *A. clausi* in the estuary of Bilbao, and *A. tonsa*, *A. clausi* and *A. bifilosa* in the estuary of Urdaibai for each time period, the simplified Morisita index proposed by Horn (1966) was calculated:

$$
C_{H} = \frac{2\sum_{i}^{n} p_{ij} p_{ik}}{\sum_{i}^{n} p_{ij}^{2} + \sum_{i}^{n} p_{ik}^{2}}
$$

where:

 $C_H$  = simplified Morisita index of overlap between species j and species k  $p_{ij}$  = proportion of individuals *i* of species *j* found in resource state  $p_{ik}$  = proportion of individuals *i* of species *k* found in resource state  $n =$  total number of resource states

(2)

# **3. RESULTS**

## **3.1. Environmental Conditions**

Table 1 summarizes the abiotic and biotic data considered to describe and compare the environmental conditions in the estuaries of Bilbao and Urdaibai during the 1998-2005 study period. None of the variables showed normal distribution (Kolmogorov-Smirnov; *p* < 0.001).

The variations of river flow and salinity stratification index were similar in both estuaries (Figure 2), showing the typical seasonal patterns of river flow and stratification, with highest values in late autumn-winter and lowest values in summer. However, a clear anomaly in the autumn-winter period of 2001-2002 occurred, when river flow and salinity stratification were unusually low. In addition, summer river discharge and stratification were higher (Kruskal-Wallis test;  $p = 0.005$  in 2002 than in the other years of the series. Between-estuary differences were evident in terms of fresh water discharges into the estuary and degree of stratification, both being much higher in the estuary of Bilbao than in Urdaibai (Table 1) due to the characteristics of the tributaries (much extensive watershed in the estuary of Bilbao) and morphological features of the estuarine basin (deeper and channelized in the estuary of Bilbao).

**Table 1. Mean (± standard deviation, SD), minimum and maximum values of environmental variables obtained for the estuaries of Bilbao and Urdaibai during 1998-2005.** *P***-values of Mann-Whitney U tests for between-estuary differences are also shown**

		<b>Estuary of Bilbao</b>		Estuary of Urdaibai

Figure 3 shows the spatiotemporal variation of abiotic (salinity, temperature, DOS and SDD) factors and chlorophyll *a* (a variable that indicates food availability for zooplankton) () in the two estuaries during the period 1998-2005. Salinity values were almost constant at each sampling site over the study period as a result of the Lagrangian-type of sampling method. Salinity ranged from 35.5 at the 35 salinity site to 28.1 at the 30 salinity site in the estuary of Bilbao, and from 35.6 at the 35 salinity site to 23.3 at the 26 salinity site in the estuary of Urdaibai. Temperature showed the typical seasonal pattern in temperate areas with summer maxima and winter minima (Figure 3 and Table 1), but with a wider range of variation in low salinity waters (14.1ºC and 18.3ºC in the estuary of Bilbao and Urdaibai, respectively) than in high salinity ones (11.2°C and 14.3°C in the estuary of Bilbao and Urdaibai, respectively).

Figure 2. (a) Temporal variations of the monthly mean river flow  $(m^3 s^{-1})$  of the main tributaries of the estuary of Bilbao (Ibaizabal-Nerbioi river) and Urdaibai (Oka river), and (b) spatiotemporal variations of the salinity stratification (Δ salinity) along the salinity gradient of the estuaries of Bilbao and Urdaibai, for the 1998-2005 period. Arrows indicate the division between the three periods distinguished in the series. (c) Seasonal pattern of the river flow  $(m^3 s<sup>-1</sup>)$  of the main tributaries of the estuary of Bilbao (Ibaizabal-Nerbioi river) and Urdaibai (Oka river) and (d) seasonal pattern of the salinity stratification index (SSI) in the estuaries of Bilbao and Urdaibai. Results of the quadratic regressions are showed.

Figure 3. Spatiotemporal variations of salinity, temperature (ºC), dissolved oxygen saturation (DOS; %), Secchi disk depth (SDD; meters) and concentration of chlorophyll *a* (μg L-1 ) along the salinity gradient of the estuaries of Bilbao and Urdaibai for the 1998-2005 period. Vertical dashed lines indicate the limits between the three periods distinguished in the series.

Between-year differences were similar in both estuaries. In the period 1998-2000 temperature showed smaller differences between years (range of variation – maximum temperatures: 0.7°C and 1.6°C; minimum temperatures:  $1.2$ °C and  $1.6$ °C, in the estuaries of Bilbao and Urdaibai, respectively) than in the second period (range of variation – maximum temperatures: 2.1°C and 4.2°C; minimum temperatures: 1.7°C and 3.6°C, in the estuaries of Bilbao and Urdaibai, respectively), the latter being characterized by an increase of summer temperatures in 2001 followed by a decrease in 2002. The highest summer temperatures of the series were found in the last period, with maximum values of 24.2°C and 26.3°C in the

estuaries of Bilbao and Urdaibai, respectively, in 2003. DOS showed higher values and lower differences between salinities in the estuary of Urdaibai (with a range from 29.8% to 137.6%) than in the estuary of Bilbao (with a range from 0.3% to 152.9%). DOS values were more homogenous in the estuary of Urdaibai than in the estuary of Bilbao. Hypoxic conditions (<30% of DOS) were frequent during the warm season in the 30 salinity site of the estuary of Bilbao in the first (1998-2000) and last (2003-2005) periods. In the middle period, at the lowest salinity site of this estuary the highest values of DOS were observed in 2002. Turbidity increased, in general, with decreasing salinity in both estuaries (Spearman rank correlation: R  $= -0.603$ ,  $p < 0.001$  in the estuary of Bilbao and R =  $-0.698$ ,  $p < 0.001$  in the estuary of Urdaibai), but was clearly higher in the estuary of Bilbao (Table 1). Chlorophyll *a* showed a clear decreasing trend with increasing salinity in the estuary of Urdaibai (Spearman rank correlation:  $R = -0.309$ ,  $p < 0.001$ ), whereas in the estuary of Bilbao its distribution was rather uniform along the salinity gradient (Spearman rank correlation:  $R = -0.094$ ,  $p = 0.065$ ) and showed seasonally well defined cycles with maxima in summer. In addition, chlorophyll *a* fluctuated from year to year without a clear trend in the estuary of Bilbao ( $\mathbb{R}^2 = 5 \times 10^{-5}$ ,  $p =$ 0.881), but showed a slight but significant increasing trend over the study period in the estuary of Urdaibai ( $R^2 = 0.029$ ,  $p = 0.001$ ).

#### **3.2. Spatial and Temporal Distribution of Acartiidae Species**

The densities of Acartiidae species (*Acartia clausi*, *Acartia discaudata*, *Acartia margalefi*, *Paracartia grani*, *Acartia bifilosa* and *Acartia tonsa*) in the estuaries of Bilbao and Urdaibai in each salinity zone and in the three periods distinguished in the time series are summarized in Table 2 and Table 3, respectively.

	<b>Estuary of Bilbao</b>						
<b>Species</b>	35	34	33	30			
A. clausi	793.7±1267.5	$777.6 \pm 1563.4$	$213.6 \pm 539.4$	$50.4 \pm 120.1$			
A. discaudata	$3.1 \pm 9.2$	$9.2 + 32.3$	$3.7 \pm 12.9$	$0.6{\pm}2.3$			
A. margalefi	$0.5 \pm 1.9$	$5.8 \pm 20.1$	$4.4 \pm 13.1$	$3.1 \pm 12.1$

**Table 2. Mean±standard deviation of the density (ind. m-3 ) of the Acartiidae species at the 35, 34, 33 and 30 salinity sites in the estuary of Bilbao and the 35, 33, 30 and 26 salinity sites in the estuary of Urdaibai**

# **Table 3. Mean±standard deviation of the density (ind. m-3 ) of the Acartiidae species of the estuaries of Bilbao and Urdaibai for each of the three periods distinguished in the time series**

The dominant neritic species *A. clausi* showed a decrease of abundance with decreasing salinity in both estuaries (Spearman rank correlation:  $R = 0.425$ ,  $p < 0.001$  in the estuary of Bilbao and  $R = 0.410$ ,  $p < 0.001$  in the estuary of Urdaibai) (Figures 4 and 5). In addition, the seasonal cycle of this species showed the annual maximum earlier (in March) and was more constrained to the spring period in the estuary of Urdaibai than in the estuary of Bilbao, where it peaked between April (during the first and the third period) and June (in the second period) (Figure 6). Throughout the study period, *A. clausi* fluctuated from year to year without a clear temporal trend until 2003 in both estuaries, but showed a clear decrease during the last period (2003-2005) in waters of salinities below 35 (Kruskal-Wallis test;  $p < 0.001$ , for both estuaries), this decrease being more evident at the lowest salinity zone of the estuary of Bilbao (Figure 4).

*A. discaudata* and *A. margalefi* appeared in low abundances in the estuary of Bilbao during the first period (1998-2000). They reached highest densities, mainly *A. margalefi*, during the second period, in 2002, and were rarely observed since 2003 (Figure 4). In most of the years, *A. discaudata* and *A. margalefi* showed the highest density in late winter-early spring (February-March), although the seasonal distribution of both species was extended throughout the year during the second period, in 2002, when secondary peaks in early summer or autumn were also observed (Figure 6). Spatially, both species peaked at lower salinities than *A. clausi*, but the distribution of *A. discaudata* in the estuary skewed toward high salinity, whereas that of *A. margalefi* skewed toward low salinity (Figures 4 and 5). *A. discaudata* was also found in the estuary of Urdaibai, but only in one occasion during each period of the series (Figure 4).

*P. grani* was only recorded in the estuary of Urdaibai: in the first two periods it was found occasionally, but in the last period it was found in relatively high abundance in 2003 and in much lower abundance in 2004 (Figure 4). Seasonally, the occurrence of *P. grani* was restricted to the warmest period, mainly to July and August (Figure 6), showing a spatial preference for intermediate salinity (33-30) sites (Figure 5).

Figure 4. Spatiotemporal distribution of the density ( $log(x+1)$ , individuals m<sup>-3</sup>) of (a) *Acartia clausi*, (b) *Acartia discaudata*, (c) *Acartia margalefi*, (d) *Paracartia grani*, (e) *Acartia bifilosa* and (f) *Acartia tonsa* along the salinity gradient of the estuaries of Bilbao and Urdaibai from 1998 to 2005. Vertical dashed lines indicate the division between the three periods distinguished in the time series.

The brackish species *A. bifilosa* was only observed in the estuary of Urdaibai, where it dominated the assemblage of Acartiidae species in low salinity waters (Figures 4 and 5). *A. bifilosa* showed a rather variable seasonal pattern during the period of study (Figure 6) and marked interannual variations, with lowest abundances and atypical seasonal distributions in the second period (Figure 4). The seasonal increase and annual maximum were found to occur earlier in the last period, from 2003 to 2005.

*A. tonsa* was recorded for the first time in autumn 2001 in the estuary of Bilbao, and from 2003 onward it became very abundant in this system (Figure 4). In the estuary of Urdaibai it also occurred in high density in 2003, but in contrast with observations in the estuary of Bilbao it showed a marked decrease in 2005. The population of this species decreased with increasing salinity in both systems (Spearman rank correlation:  $R = -0.368$ ,  $p < 0.001$  in the estuary of Bilbao and  $R = -0.294$ ,  $p < 0.001$  in the estuary of Urdaibai), where the highest densities were observed at the lowest salinity sites of 30 and 26 in the estuaries of Bilbao and Urdaibai, respectively (Figure 5). Seasonally, *A. tonsa* showed maxima in the warm period, but with a wider seasonal distribution in the estuary of Bilbao (Figure 6).

# **3.3. Species Segregation in Environmental Gradients**

Three main modes of environmental variation were extracted by the PCA of environmental variables in each estuary (Table 4). The first one was mainly explained by salinity, DOS and SDD in opposition to stratification in the estuary of Bilbao (37.07% of variance), and by salinity and SDD in opposition to stratification in the estuary of Urdaibai (30.85% of variance), reflecting the spatial gradient of salinity in both estuaries. The second one was mainly explained by river flow in opposition to temperature in the estuary of Bilbao (27.51% of variance) and by temperature and chlorophyll *a* in the estuary of Urdaibai (22.35% of variance), while the third one was mainly explained by chlorophyll *a* in the estuary of Bilbao (14.94% of variance) and by river flow in opposition to DOS in the estuary of Urdaibai (17.38% of variance). Both the second and the third factors reflected temporal environmental variations.

The plot of species abundance in the space configured by the three main factors of environmental variability in the two estuaries showed the spatial and temporal segregation pattern of Acartiidae species along environmental gradients (Figure 7). In the estuary of Bilbao, the segregation of species along the spatial gradient determined by salinity, DOS, stratification and turbidity showed the succession *A. clausi* – *A. discaudata* – *A. margalefi* – *A. tonsa* from the outer to the inner estuary; however, *A. clausi* and *A. tonsa* showed a wider distribution along this gradient than *A. discaudata* and *A. margalefi*. Along the seasonal gradient related to river flow and temperature, *A. clausi*, *A. discaudata* and *A. margalefi* were all similarly positioned under conditions of higher river flow and lower temperature than *A. tonsa*, which was more restricted to low river flow and high temperature conditions. By contrast, *A. clausi* showed a wider distribution along this environmental gradient than the other three species. Similarly, *A. clausi* had a wider distribution than the other congeneric species along the trophic gradient accounted for by chlorophyll *a* concentration.

**Table 4. Loadings of environmental variables for the three main rotated components extracted by PCA in the estuaries of Bilbao and Urdaibai. Percentage of variance explained by each component is shown in parentheses**

In the estuary of Urdaibai, the segregation of species along the spatial gradient determined by salinity, turbidity and stratification showed the succession *A. clausi* – *A. discaudata* – *P. grani* – *A. bifilosa* – *A. tonsa* from the outer to the inner estuary. The spatial segregation between the outermost species *A. clausi* and the innermost species *A. tonsa* was more marked than in the estuary of Bilbao. Along the environmental gradient driven mainly by temperature and secondarily by chlorophyll *a* concentration, *A. bifilosa* showed the widest distribution, whereas more restricted distributions and a clear segregation along temperature gradients were found for *P. grani* and *A. tonsa*, associated to highest temperatures, and *A. discaudata*, associated to low temperatures.

Figure 7. Plot of density values (log (x+1), individuals m<sup>-3</sup>) of (a) *Acartia clausi*, (b) *Acartia discaudata*, (c) *Acartia margalefi*, (d) *Paracartia grani*, (e) *Acartia bifilosa* and (f) *Acartia tonsa* in the space configured by the first and second factors (left figures) and the second and third factors (right figures) of environmental variability in the estuaries of Bilbao and Urdaibai during the 1998-2005 period.

#### **3.4. Niche Breadth and Overlap**

The niche breadths estimated in relation to salinity sites (spatial) and months (seasonal) of the three dominant species *A. clausi*, *A. bifilosa* and *A. tonsa* in the estuaries of Bilbao and Urdaibai for each of the three periods distinguished in the time series are shown in Table 5.

The spatial niche of *A. clausi* was reduced from the first two periods to the third in both estuaries. The spatial niche breadth of *A. bifilosa* in the estuary of Urdaibai did not differ largely between periods, but it was lowest in the second period, this coinciding with the highest spatial niche breadth of *A. clausi*. In the third period, when *A. tonsa* was established in both estuaries, the spatial niche breadth of *A. tonsa* was smaller than of *A. clausi* in the estuary of Bilbao and than of *A. bifilosa* in the estuary of Urdaibai.

# **Table 5. Levin's niche breadth (BA) of** *Acartia clausi***,** *Acartia bifilosa* **and** *Acartia tonsa* **in relation to salinity (spatial) and months (seasonal) in the estuaries of Bilbao and Urdaibai for each of the three periods distinguished in the time series**

		Niche breadth $(B_A)$							
	Period	Spatial			Seasonal				
		A. clausi	A. bifilosa	A. tonsa	A. clausi	A. bifilosa	A. tonsa		
<b>Estuary of Bilbao</b>	1998-2000	0.997	$- - -$	---	0.985	---	---		
	2001-2002	0.960	$- - -$	---	0.951	---	$- - -$		
	2003-2005	0.706	---	0.652	0.887		0.687		
Estuary of Urdaibai	1998-2000	0.501	0.702	---	0.771	0.878	---		
	2001-2002	0.622	0.607	---	0.763	0.876	$- - -$		
	2003-2005	0.273	0.679	0.539	0.870	0.916	0.451		

**Table 6. Simplified Morisita Index for spatial niche overlap (CH), in relation to salinity (spatial) and months (seasonal) between** *Acartia clausi* **(c),** *Acartia bifilosa* **(b) and** *Acartia tonsa* **(t) in the estuaries of Bilbao and Urdaibai for each of the three periods distinguished in the time series**

The seasonal niche of *A. clausi* diminished from the first two periods to the third in the estuary of Bilbao, the niche breadth in the third period being higher than that of *A. tonsa.* In the estuary of Urdaibai, however, the seasonal niche of both *A. clausi* and *A. bifilosa* expanded in the third period, when the niche breadth of *A. tonsa* was much lower than those of the two former species.

Results of niche overlap between the three dominant species *A. clausi*, *A. bifilosa* and *A. tonsa* in the estuaries of Bilbao and Urdaibai for each of the three periods distinguished in the time series, in relation to salinity (spatial) and months (seasonal) are shown in Table 6. The spatial niche overlap between *A. clausi* and *A. tonsa* was much higher in the estuary of Bilbao than in Urdaibai, and that between *A. bifilosa* and *A. tonsa* in the latter estuary was the highest found between the dominant *Acartia* species in any of the two estuaries. Seasonally, the highest niche overlap was obtained between *A. clausi* and *A. bifilosa* in the estuary of Urdaibai, and the overlap between *A. tonsa* and *A. clausi* was higher in the estuary of Bilbao than in Urdaibai. In addition, in the 2003-2005 period the spatial overlap between *A. clausi* and *A. bifilosa* decreased while the seasonal overlap increased in the estuary of Urdaibai.

#### **CONCLUSION**

Before the arrival of the non-indigenous species *Acartia tonsa* in the estuaries of Bilbao and Urdaibai, the Acartiidae assemblage was constituted by the perennial neritic species *Acartia clausi* and the occasional species *Acartia discaudata* and *Acartia margalefi* in the estuary of Bilbao, and by the perennial neritic species *A. clausi*, the perennial brackish species *Acartia bifilosa* and the occasional species *A. discaudata* and *Paracartia grani* in the estuary of Urdaibai. This indicates that each estuary, in spite of the geographic proximity, was inhabited by different assemblages of Acartiidae species. Such differences cannot be attributed only to differences in the health status, but also to the extent of salinity habitats able to support perennial brackish species populations. The role of system features in the composition of the Acartiidae assemblage is corroborated by the variety of species combinations reported in different types of estuarine systems of the Bay of Biscay and nearby European Atlantic coasts. Without taking into account the invasive *A. tonsa*, for example, *A. clausi*, *A. bifilosa* and *A. discaudata* have been reported in the Ems estuary (Baretta and Malschaert, 1988), *A. clausi*, *A. bifilosa*, *A. discaudata* and *A. margalefi* in Southampton Water (Muxagata, 2005), *A. clausi*, *A. bifilosa*, *A. discaudata* and *A. grani* in the Marennes-Oléron Bay (Sautour and Castel, 1993), and *A. clausi*, *A. discaudata*, *A. margalefi* and *A. grani* in the Ría de Vigo (Alcaraz, 1983).

*A. tonsa* reached high abundances in the estuaries of Bilbao and Urdaibai at the same time, in 2003. This may have been favoured by a common environmental event in both systems, such as the marked increase of temperature in 2003 after the dry period of 2001- 2002. In fact, already by this period *A. tonsa* was occasionally found in the estuary of Bilbao. The most plausible hypothesis is that *A. tonsa* arrived in this estuary (maybe even repeatedly) via ballast water from ships that brought it to the outer port area of the Abra harbour. In 2002 the penetration of this species to the upper reaches was presumably favoured by the decrease of river flow, which enabled a higher penetration of marine waters upstream, a mechanism reported for this species in the Gironde estuary too (David *et al.*, 2007). There is no commercial shipping transport in the estuary of Urdaibai but small boat circulation between this estuary and that of Bilbao is frequent, being likely responsible for carrying plankton organisms between them. This has been claimed to be an important way of secondary spread for crustacean zooplankton (Kelly *et al.*, 2013). Although the exact mechanism by which *A. tonsa* arrived in the estuaries of Bilbao and Urdaibai cannot be known for certain, genetic analysis of individuals from both estuaries suggested a secondary invasion from a European source to Basque estuaries (Albaina *et al.*, 2016).

*A. tonsa* reached the highest population growth in the innermost salinity habitats of both estuaries in spite of the differences in salinity range, which was wider in the estuary of Urdaibai. *A. tonsa* is found to be an extremely euryhaline species well adapted to instantaneous variations of salinity (Svetlichny *et al.*, this volume), with high reproductive success over wide ranges of temperature and salinity (Holste and Peck, 2006) and optimal adaptation to salinities between 15 and 22 (Cervetto *et al.*, 1999). It is abundant from oligohaline (0.5-5 salinity) to polyhaline (18-30 salinity) waters, with usual maxima in the mesohaline (5-18 salinity) region of large estuaries like Chesapeake Bay and the Gironde (Kimmel and Roman, 2004; David *et al.*, 2007). Thus, *A. tonsa* population settled preferentially in the available innermost salinity habitat of the estuaries of Bilbao and Urdaibai which were in the limit between euhaline and polyhaline waters (around 30 salinity) in the former, but in polyhaline (18-30 salinity) waters in the latter. This shows the ability of this species to adapt to different salinity habitats in transitional waters of estuarine systems, depending on their availability.

The colonization of *A. tonsa* seems to be facilitated by environmental conditions close to its temperature and salinity optima (Chaalali *et al.*, 2013). However, although salinity conditions in the estuary of Urdaibai were nearer to the optimal, the settlement of *A. tonsa* was more successful in the estuary of Bilbao than in Urdaibai, where this species showed a more restricted seasonal presence and decreased from 2003 to 2005. This may be the result of the combined effect of biotic and abiotic factors, such as competition, temperature and ecosystem health. The lack of perennial brackish *Acartia* species in the inner estuary of Bilbao, in contrast to the development of a large population of *A. bifilosa* in the inner estuary of Urdaibai, suggests a stronger competitive pressure for *A. tonsa* in the estuary of Urdaibai, which could be enhanced when environmental conditions were less favourable for this species than for *A. bifilosa*. *A. tonsa* is well known as a warm-water species (Katajisto, 2006) which reaches its maximum abundances and dominance in summer-early autumn in a wide variety of estuaries and coastal systems (Soetaert and Rijswijk, 1993; Mouny and Dauvin, 2002; David *et al.*, 2005; Purcell and Decker, 2005; Marques *et al.*, 2007; Feike and Heerkloss, 2008; Mackas *et al.*, 2012; Rowshan *et al.*, 2014), and usually disappears from the water column in winter or winter-spring for long periods in which it stays on the bottom as resting eggs (David *et al.*, 2005; Katajisto, 2006; Milligan *et al.*, 2011). The absence or lower abundance of this species during the cold season may be caused by low water temperature, high river discharge and high water export from the estuary (Mortazavi *et al.*, 2000). River flow is also reported to govern *A. tonsa* dynamics in the inner Mondego estuary by advective transport and turbulence (Marques *et al.*, this volume). *A. bifilosa*, however, has been found to have a wide thermal niche, and it is usually a perennial species which may peak from spring to summer depending on the year (our own results; Hernroth and Ackefors, 1979; Viitasalo, 1992; David *et al.*, 2005). *A. tonsa* decreased as temperature decreased from 2003 to 2005 in the estuary of Urdaibai but not in the estuary of Bilbao, this suggesting that the temperature decrease which can be unfavourable in itself for this species could have an additional negative effect by enhancing the competitive pressure by *A. bifilosa*. In the estuary of Bilbao, on the contrary, *A. tonsa* increased from 2003 to 2005, likely due to the lack of brackish competitors and to the deterioration of oxygen conditions in the estuary of Bilbao, which were found to confer a competitive advantage to *A. tonsa* over the neritic species *A. clausi* in this system (Aravena *et al.*, 2009). At very low dissolved oxygen concentrations, *i.e.*, 0.5 mL L-1 , *A. tonsa* shows high mortality, but it can tolerate dissolved oxygen concentrations as low as  $1.0 \text{ mL L}^{-1}$ and adapt well to hypoxia (Decker *et al.*, 2003; Kimmel *et al.*, 2009). The differences observed in the colonising success of *A. tonsa* in the inner estuarine habitats of the estuaries of Bilbao and Urdaibai corroborate the finding that both natural and anthropogenic forcings can explain the successful settlement of this species in estuaries, as reported in the Gironde estuary (David *et al.*, 2007). Our results also exemplify the plasticity of this species, a property which helps to explain why *A. tonsa* is a key species in many estuaries around the world (Derisio *et al.*, 2014). Once this species is established, its replacement by other *Acartia* species might require strong environmental changes such as reported for Berre lagoon, where rehabilitation processes resulting in an increase of salinity have led to the replacement of *A. tonsa* by *A. clausi* (Delpy and Pagano, this volume). The ongoing rehabilitation processes in

the estuary of Bilbao may also lead to changes in the relative abundances of these species, but possibly linked to modifications in trophic and/or water quality parameters rather than to unlikely changes of salinity due to anthropogenic activities in the system.

Another difference in the distribution of *A. tonsa* attributable to the peculiarities inherent to the system was that its abundance decreased seaward with increasing salinity in both estuaries, but dropped sharply in 35 salinity waters of the estuary of Urdaibai, as the abundance of *A. bifilosa* did. This may be related to the much stronger effect of tides on the dynamics of water masses in the estuary of Urdaibai, where water masses of 35 salinity are removed from the estuary at low tide during each semidiurnal tidal cycle, thus enhancing dispersal of brackish species populations. The marked differences in environmental and plankton dynamics of the 35 salinity site of the estuary of Urdaibai compared to lower salinity sites have also been emphasized for dissolved oxygen and phytoplankton biomass (Villate *et al.*, 2008; Iriarte *et al.*, 2014).

The settlement of *A. tonsa* in the estuaries of Bilbao and Urdaibai caused an impact on the spatial and seasonal distribution of Acartiidae species that coexisted in these estuaries before its arrival, in different ways depending on the estuary characteristics and the brackish or neritic origin of species. The spatial distribution of *A. clausi* was displaced seaward and its salinity niche breadth shrank in both estuaries after the settlement of *A. tonsa*, but the direct effect was more evident in the estuary of Bilbao, where both the spatial and the seasonal niche overlaps between *A. clausi* and *A. tonsa* were higher than in the estuary of Urdaibai. This was the result of the smaller spatial salinity range available for the distribution of these two species in the estuary of Bilbao and of the wider seasonal distribution of both species as compared to the estuary of Urdaibai. Therefore, a strong spatial segregation can be expected when salinity habitat range increases and both species coexist in time, as it has been reported also for the Mondego estuary and the Ria de Aveiro (Azeiteiro *et al.*, 2005; Leandro *et al.*, 2014). In the estuary of Urdaibai, however, the seasonal occurrence of *A. tonsa* was more restricted than in the estuary of Bilbao, and *A. clausi* showed a longer period of coexistence with *A. bifilosa*. This latter species showed higher spatial and seasonal niche breadth, and higher spatial and seasonal overlap with *A. clausi* than *A. tonsa*. Consequently, a greater effect of *A. bifilosa* – than of *A. tonsa* – in the spatial and seasonal distribution of *A. clausi*  can be expected in the estuary of Urdaibai. Since both the spatial and seasonal distributions of *A. bifilosa* changed when *A. tonsa* settled in the estuary of Urdaibai, the likely impact of *A. tonsa* on *A. clausi* could be better understood as an indirect effect via the impact of *A. tonsa* on *A. bifilosa*. Our results indicate that *A. bifilosa* population maximum was displaced seaward along the salinity gradient, from 26 to 30 salinity, and the seasonal maximum came earlier, being displaced from summer to late spring. This was due to the fact that *A. tonsa*  occupied preferentially the lowest salinity habitat and reached the annual maximum in summer when it colonized the estuary of Urdaibai. The spatial segregation pattern of *A. tonsa* and *A. bifilosa* observed in this estuary agrees with that observed in other estuaries where both species coexist after the colonization by the former*.* For instance, Soetaert and Rijswijk (1993) reported that *A. bifilosa* occupied preferentially the central part and *A. tonsa* the upstream part of the Westerschelde estuary, and that *A. bifilosa* could not penetrate more upstream in summer because of the occurrence of *A. tonsa* in this area. Seasonally, *A. bifilosa* also showed a phenological change upon *A. tonsa* establishment in the Gironde estuary, with the production period occurring one month earlier than before, which resulted in a clear seasonal segregation between the two species (David *et al.*, 2007; Selleslagh *et al.*, 2012). In an interannual context, after the occurrence in large numbers of *A. tonsa* in 2003, this species showed a decline in the estuary of Urdaibai, while the congeneric brackish species *A. bifilosa* recovered from lower abundances during the period prior to the occurrence of *A. tonsa*. This is in contrast with observations in the Gironde estuary, where the colonization process of *A. tonsa* was more progressive and consisted in a succession of long phases from its initial occurrence in low numbers in 1983 to the point of becoming more abundant than *A. bifilosa* from 1999 onward (Chaalali *et al.*, 2013). In any case, the period of coexistence of *A. tonsa* and *A. bifilosa* analyzed in the estuary of Urdaibai is still short to be able to explain the pattern of joint population dynamic of these species in this system, and an extension of the study to include more years is needed. Changes in environmental conditions may also play a key role in the variations of brackish species in the estuary of Urdaibai as inferred from the strong decline of *A. bifilosa* prior to the occurrence of *A. tonsa*, in the period characterized by the anomalous river flow regime during 2001-2002 and low summer temperatures in 2002.

The impact of *A. tonsa* on the much less abundant and occasional Acartiidae species, such as *A. discaudata* in both estuaries, *A. margalefi* in the estuary of Bilbao and *P. grani* in the estuary of Urdaibai, could not be easily assessed on the basis of our data. These species show an intermediate spatial position in the salinity gradient between the neritic species *A. clausi* and the brackish species *A. bifilosa* and *A. tonsa*, but they also appear spatially (*A. discaudata* and *A. margalefi* in the estuary of Bilbao) or seasonally (*A. discaudata* and *P. grani* in the estuary of Urdaibai) segregated among them. In the estuary of Bilbao, both *A. discaudata* and *A. margalefi* increased in the period prior to the settlement of *A. tonsa*, coinciding with an improvement of water environmental conditions in the inner estuary, and they almost disappeared after the settlement of *A. tonsa*. The arrival of *A. tonsa* has been suggested as the cause for the disappearance of the formerly abundant *A. margalefi* in some Mediterranean systems (Sei *et al.*, 1996; Sei and Ferrari, 2008) and the Black Sea (Gubanova *et al.*, 2014). However, it is difficult to attribute the strong decline of *A. discaudata* and *A. margalefi* to the negative impact of *A. tonsa* in the estuary of Bilbao when it coincided with a general deterioration of environmental conditions, namely a decrease in dissolved oxygen and an increase in river flow and temperature. Such conditions were similar to those found in the period 1998-2000, in which *A. tonsa* was not present but *A. discaudata* and *A. margalefi* were also scarce. The sensitivity of *A. margalefi* to environmental changes is corroborated by results from other studies. In the lagoon of Venice *A. margalefi* density also declined with the introduction of *A. tonsa*, but the reported simultaneous disappearance of this species from other Italian estuarine and lagoon systems, as discussed in Ribera d'Alcalà *et al.* (2004), suggested that larger scale environmental changes might be responsible (Bandelj *et al.*, 2008).

The case of *P. grani* in the estuary of Urdaibai was clearly different, as this species showed a very weak presence until 2003 when it showed the highest abundance at the same time as *A. tonsa* did. This only allows concluding that the occurrence of *P. grani* was linked to high temperatures, and that it responded to this factor in the same way as *A. tonsa* did. The presence of *P. grani* in the plankton also appears restricted to the summer period in Mediterranean lagoon systems (Boyer *et al.*, 2013). At an interannual scale, the occurrence of *P. grani* in the estuary of Urdaibai was erratic and with long periods of absence. Its highest abundance and seasonal presence were recorded in previous studies during the years 1981- 1982 and the summer of 1990 (Villate, 1982; Uriarte *et al.*, 2000), but it was almost absent from 1997 until 2003. Similarly, this species was reported in the 1960s but not in more recent studies (2001-2002) in Southampton Water (Muxagata, 2005). This indicates that this species

might be undergoing a long term decline in these systems. However, the present scarcity of *P. grani* in the estuary of Urdaibai precluded the analysis of competitive relationships with other Acartiidae species, as is the case of the invading *A. tonsa*.

Figure 8. Synoptic diagram of the spatial and temporal distribution of Acartiidae species in the estuaries of Bilbao and Urdaibai, with indication of the observed effects of species competition and hydroclimatic factors in the variations in abundance of *Acartia clausi*, *Acartia discaudata*, *Acartia margalefi*, *Paracartia grani*, *Acartia bifilosa* and *Acartia tonsa* during the 1998-2005 period. Continuous lines: competitive interactions resulting in reduction or displacement of spatial and/or seasonal distributions, or changes in abundance between periods (1: 1998-2000, 2: 2001-2002 and 3: 2003-2005). Dashed lines: negative effect of river flow and positive effect of temperature.

In summary, the colonization of the inner salinity habitats of the estuaries of Bilbao and Urdaibai by the non-indigenous copepod *A. tonsa* since 2003 was found to be directly or indirectly responsible for spatial and temporal changes in the distribution of the autochthonous dominant neritic species *A. clausi* in both systems, and the autochthonous dominant brackish species *A. bifilosa* in the estuary of Urdaibai. No clear impact of *A. tonsa* on the less abundant and occasional species *A. discaudata*, *A. margalefi* and *P. grani* was observed, presumably because the development of these species was primarily limited by environmental constraints. Differences in the spatial, seasonal and interannual distribution of *A. tonsa* between the two estuaries showed that population dynamics were affected by biotic and abiotic features specific to each system, and that *A. tonsa* benefited from the worse environmental conditions and the lack of a dominant brackish species in the inner estuary of Bilbao. The synoptic scheme shown in Figure 8 summarizes the role of specific competition and hydroclimatic factors in the changes observed for Acartiidae species throughout the 1998- 2005 period in the estuaries of Bilbao and Urdaibai. Results are preliminary because they cover a short period of time after the occurrence of *A. tonsa* in the estuaries of Bilbao and

Urdaibai. An extension of the study encompassing more years would be advisable to obtain a more robust picture of changes in the Acartiidae congenerics, and determine the invasive character of *A. tonsa* in these systems. For this last purpose, future studies should be expanded to address also the impact of this species at the ecosystem level, considering ecosystem services too. Comparative studies covering a wide variety of systems colonized by *A. tonsa* would also be desirable in order to determine how system typology and level of anthropogenic disturbance affect the invasive character of this species. In addition, long term studies based on ongoing time series to analyse the response of *A. tonsa* to current modes of climate variation should be promoted. They could provide useful information to predict future impacts of this species under different climate change scenarios.

#### **ACKNOWLEDGMENTS**

We thank the Provincial Council of Bizkaia for providing hydro-meteorological data. This research was funded by the University of the Basque Country, UPV/EHU (GIU16/69).

# **CAN CHANGES IN THE DISTRIBUTION OF TWO CONGENERIC COPEPODS (***ACARTIA CLAUSI VS. ACARTIA TONSA***) CONSTITUTE A SIGN OF RECOVERY FOR THE ANTHROPIZED BERRE LAGOON (FRANCE, MEDITERRANEAN SEA)?**

# **ABSTRACT**

The impact of rehabilitation processes on *Acartia* distributions in the anthropized Berre Lagoon was investigated comparing a study performed in 2010-12 to ones achieved before the rehabilitation period. In 1966, the opening of a hydroelectric powerplant led to the establishment of a strong unidirectional salinity gradient. The invasive copepod *Acartia tonsa*, introduced in the 1980's, dominated a low-diversity zooplankton community with another common brackish species, the rotifer *Brachionus plicatilis*. At that time, *Acartia clausi* was restricted to the adjacent coastal area. Initiated since the mid 1990's, the rehabilitation processes have managed to reduce salinity fluctuations and maintain it above 15. The time and space partitioning of both *Acartia* species was modified, since *A. tonsa* and *A. clausi* coexisted over the whole lagoon. A seasonal succession pattern was then outlined throughout the year, with *A. clausi* dominant from winter to spring and *A. tonsa* from summer to autumn. Likewise, a spatial segregation was observed in the entire lagoon, as *A. clausi* remained in more marine areas. *A. tonsa*  was less abundant, highlighting that a balance seemed established between these two congeneric species. However, environmental variables did not display any clear direct relationship with these distributions, suggesting more complex mechanisms, such as trophic interactions. Nevertheless, these changes in the distribution of *Acartia* species following the rehabilitation processes constitute a sign of a hoped recovery.

# **1.INTRODUCTION**

Due to their short generation time, copepods, as other zooplankton organisms, quickly respond to environmental changes, a response that could be considered useful to appreciate the health status of aquatic ecosystems and assess their variability at distinct space and time scales (Cairns *et al.*, 1993; Beaugrand, 2005; Fernández de Puelles *et al.*, this volume; Wootton *et al.*, this volume). Community structure modifications (*e.g.*, species composition, size spectra) following perturbations, as well as changes in the spatial distribution of 'steno' species depending on different types of gradients (haline, trophic, pollution, *etc.*), are often considered tools to acknowledge the variability of marine, coastal and brackish water environments (Etilé *et al.*, 2009; Delpy *et al.*, 2012; Serranito *et al.*, 2016; Svetlichny *et al.*, this volume). For instance, at large scale, alterations in copepod communities have been associated to hydroclimatic changes in the North Atlantic Ocean (Beaugrand and Reid, 2003). At the regional scale, the impact of pollution, water quality, eutrophication and brief climatic events have been evidenced on copepod communities (Vincent *et al.*, 2002; Etilé *et al.*, 2009; Delpy *et al.*, 2012; Serranito *et al.*, 2016). Their monitoring may thus represent a powerful tool for a sustainable management of coastal lagoons, which are major sites of socioeconomic interests (*e.g.*, artisanal fisheries, aquaculture, tourism, various aquatic leisure activities). They represent  $\sim$ 13% of worldwide coastlines and are highly impacted by various anthropogenic pressures (*e.g.,* urbanization, chemical industries, agriculture, marine commercial traffic) which combine with natural forcing such as temperature and salinity variations matching seawater and/or freshwater inputs. Coastal lagoons are then very selective to copepods, and particularly to species which may be considered reliable bio-indicators (Capuzzo, 1980; Bianchi *et al.*, 2003; Marcus, 2004; Beaugrand, 2005; Etilé *et al.*, 2009; Delpy *et al.*, 2012; Falcão *et al.*, 2012; Serranito *et al.*, 2016).

Among the noteworthy copepod families, Acartiidae represent typical coastal and brackish water copepods that have been used to characterize water quality and hydrological changes in coastal ecosystems (*e.g.*, Alcaraz, 1983; Bianchi *et al.*, 2003; David *et al.*, 2007; Aravena *et al.*, 2009; Etilé *et al.*, 2009; Marques *et al.*, this volume; Villate *et al.*, this volume). In this chapter, we focus on the only two *Acartia* species (*Acartia tonsa* Dana, 1849 and *Acartia clausi* Giesbrecht, 1889) observed in a French Mediterranean coastal lagoon (Berre Lagoon), which has been particularly impacted by major hydrological changes. Berre Lagoon has been subject to strong anthropogenic pressures for several decades (Warner, 2012). The development of chemical and petrochemical industries (1920-70), as well as a massive urbanization of surrounding cities (1973-90), led to large inputs of organic and inorganic pollutants. This was in addition to the contribution of three small tributaries (*i.e.,* Touloubre, Durançole and Arc) which drained a watershed of  $\sim$ 1,300 km², bringing annually 275 tons of N-NO<sub>3</sub> and 36 tons of P-PO<sub>4</sub> into the lagoon (Gouze *et al.*, 2008; Warner, 2012). In 2005-06, floods were responsible for supplying up to 33% of nitrate, 53% of phosphate and 99% of suspended matter (Gouze *et al.*, 2008). Moreover, strong winds (*i.e.,* Mistral and East wind) contributed to the release of stored phosphorus within the sediment. In 1966, a

derivation canal of the Durance River into the northern part of the lagoon was built to supply a hydroelectric powerplant. Releases of freshwater  $(3.3 \times 10^9 \text{ m}^3 \text{ y}^{-1}, 3.7 \text{ times}$  Berre volume) and silt  $(520,000 \t{t} y<sup>-1</sup>)$  were realized with no or very few controls causing intense eutrophication (Minas, 1976a; Gaudy *et al.*, 1995; Gouze *et al.*, 2008) and significant anoxia events (Minas, 1976b; Nerini *et al.*, 2000). In 1994, the rehabilitation processes were initiated with a reduction in freshwater (1.2 x  $10^9$  m<sup>3</sup> y<sup>-1</sup>) and silt (100,000 t y<sup>-1</sup>) inputs through Barnier Plan. However, these restrictions were not enough as large fluctuations of salinity and eutrophication were still observed. In 2006, a litigation of the European Union imposed stricter limitations with a further reduction of silt inputs ( $< 60,000$  t y<sup>-1</sup>) and a mandatory smoothing of both freshwater and silt releases over a weekly basis. The objective was the maintenance of salinity above 15.

As other coastal environments, Berre Lagoon was also impacted by the introduction of several alien species probably *via* ballast waters of commercial ships (Gaudy and Vinas, 1985; Delpy *et al.*, 2012 and 2016). Among them, two species (the copepod *A. tonsa* and the ctenophore *Mnemiopsis leidyi*) were known to be particularly invasive, modifying food webs drastically (Gaudy *et al.*, 1995; Katsanevakis *et al.*, 2014; Albaina *et al.*, 2016; Delpy *et al.*, 2016). Thus, *A. tonsa* can alter trophic fluxes to higher trophic levels competing with native copepods, and exert a potential control on primary producers (Chaalali *et al.*, 2013; Katsanevakis *et al.*, 2014; Marques *et al.*, this volume; Villate *et al.*, this volume). In Berre Lagoon, *A. tonsa* was observed for the first time in the 1980's (Gaudy and Vinas, 1985) and then co-dominated the zooplankton community with another euryhaline and eurythermal species, the rotifer *Brachionus plicatilis* (Cervetto, 1995; Gaudy *et al.*, 1995). Conversely, *A. clausi* was an autochtonous species observed in Berre Lagoon before 1966 when it had the characteristics of a marine environment (Blanc *et al.*, 1967). Afterwards, the introduction of *A. tonsa* and the powerplant-induced freshwater discharges drove it out from the lagoon, limiting it to the adjacent coastal area where it represented one of the most abundant species (Cervetto, 1995; Cervetto *et al.*, 1995). While *A. tonsa* and *A. clausi* exhibited an opposite spatial distribution in the lagoon and its adjacent coastal waters before any rehabilitation effort (Cervetto, 1995; Gaudy *et al.*, 1995 and 2000), they now coexist in both areas (Delpy *et al.*, 2012; unpublished data).

Several environmental parameters may be responsible for the maintenance of *A. tonsa* within invaded areas. Temperature, salinity and diet (*i.e.,* type and amount of available food) can differently influence the metabolism of congeneric species, particularly in terms of reproductive success and feeding activity (Jeffries, 1962; Gaudy *et al.*, 2000; Calliari *et al.*, 2006; Boyer *et al.*, 2013; Marques *et al.*, this volume; Svetlichny *et al.*, this volume; Villate *et al.*, this volume). For instance, *A. clausi* and *A. tonsa* are known to accept a wide range of salinity (1-65 and 1-72, respectively), but with different optimal values (24-30 and 15-22) (Cervetto *et al.*, 1995 and 1999). Therefore, the presence of many *Acartia* species in the same area generally matched a seasonal succession (Jeffries, 1962; Lee and McAlice, 1979; Wooldridge and Melville-Smith, 1979) and/or a spatial segregation especially in brackish environments presenting a unidirectional salinity gradient (Greenwood, 1981; Alcaraz, 1983; Azeiteiro *et al.*, 2005; Aravena *et al.*, 2009; Falcão *et al.*, 2012; Leandro *et al.*, 2014). These segregations, whether temporal and/or spatial, highlighted that *A. tonsa* presents competitive advantages compared to other species, regarding the production of resistance stages (Belmonte and Potenza, 2001; Svetlichny *et al.*, this volume) and its large tolerance to low oxygen concentrations (Decker *et al.*, 2003; Kimmel *et al.*, 2009).

In this context, the present chapter, based on a comparison of our current results and studies achieved before the rehabilitation period (Gaudy *et al.*, 1995; Cervetto, 1995), aims at: (1) analyzing the relationships between *A. clausi* and *A. tonsa* abundances and their responses to environmental conditions, and (2) evaluating the effects of the rehabilitation processes on the respective distribution of these species. This comparison shows in particular that, linked to strong environmental changes after the rehabilitation, the two *Acartia* species are now cohabiting within the lagoon, representing a sign of recovery, but display seasonal succession and spatial segregation.

# **2. METHODS**

#### **2.1. Study Site and Sampling Strategy**

Located northwest off Marseille (southeast France), Berre Lagoon is a large (155 km²) and shallow (7 m average depth) brackish water basin composed of two parts: the main lagoon and Vaïne Lagoon in the east (Figure 1). Freshwater inflows are concentrated in the northern part with three small rivers (*i.e.,* Touloubre, Durançole and Arc) and the man-made Durance River derivation canal supplying a hydroelectric powerplant at Saint-Chamas. In the southwestern part, Caronte Canal is its only connection to the Mediterranean Sea.

Between 1966 and 1994, releases of freshwater by the hydroelectric powerplant into Berre Lagoon were realized with no or very few controls leading to large fluctuations of salinity (4.0 to 28.0). Since 1994, rehabilitation processes (*i.e.*, gradual reduction and smoothing of inputs) were performed to maintain the salinity above 15. To evaluate the responses of *Acartia clausi* and *Acartia tonsa* distributions to these different environmental conditions, we compared a recent study we performed in 2010-12 (referred to "after rehabilitation") to previous ones by Gaudy *et al.* (1995) and Cervetto (1995) conducted in 1985 and 1992-93, respectively just before the first rehabilitation efforts (referred to "before rehabilitation").

In our study, monthly sampling was realized from January 2010 to January 2012 (39 samplings) at three mooring stations in Berre Lagoon (SA1, SA2 and SA3) and at Port de Bouc (PdB) (Figure 1). Located in the northern part, SA1  $(43^{\circ}29.735^{\circ}N / 5^{\circ}2.953^{\circ}E, 6.9 \text{ m})$ deep) is impacted by freshwater inflows. In the middle, SA2 (43°27.598'N / 5°5.404'E, 7.8 m deep) represents an intermediate situation. In the southern part, SA3 (43°25.300'N / 5°6.219'E, 9.5 m deep) is influenced by bottom inflows of marine water through the Caronte Canal. Situated at the mouth of the Caronte Canal, PdB  $(43^{\circ}23.944^{\circ}N / 4^{\circ}59.299^{\circ}E, 6.5^{\circ}m)$ deep) presents almost typical marine characteristics of the Mediterranean Sea with a minimal influence of brackish water surface inflows from the Berre Lagoon.

In Gaudy *et al.* (1995), data were collected in February, June, October and November 1985 at stations close to SA1, SA2 and SA3 (G1, G2 and G3, Figure 1). In Cervetto (1995), sampling was performed between March 1992 and March 1993 (22 samplings) at a station slightly southeast of SA3 and another one close to PdB (C3 and C4, Figure 1). Thus, Gaudy *et al.* (1995)'s dataset allowed a seasonal comparison of the spatial distribution of *Acartia*

assemblages over the whole lagoon, while Cervetto (1995) was used to evaluate the impact of the rehabilitation processes on their higher-frequency temporal distribution in the south of the lagoon and its adjacent coastal area.

Figure 1. Map of Berre Lagoon and its adjacent coastal area. Station location: SA1, SA2, SA3 and PdB sampled in 2010-12; G1, G2 and G3 in 1985 (Gaudy *et al.*, 1995); C3 and C4 in 1992-93 (Cervetto, 1995).

#### **2.2. Environmental Parameters**

In our study, each mooring station in Berre Lagoon was equipped with multiparametric probes CTD SBE37 (Seabird) located at  $\sim$ 1 m from the surface and the bottom. Daily averages of temperature and salinity were computed from a high frequency sampling (96 times per day) dataset. At PdB, vertical profiles of temperature and salinity were realized with the multiparametric probe CTD SBE19+ (Seabird) at each sampling date.

To estimate chlorophyll *a* (Chl *a*) concentrations, water was collected at sub-surface (0.5 m) and at  $\sim$ 1 m from the bottom using an 8 L Niskin bottle. Triplicate samples of 20-100 mL were filtered directly onboard onto GF/F filters  $(0.7 \mu m)$ , then frozen with liquid nitrogen and stored at -20°C until further analysis. Chlorophyll *a* content was extracted using acetone (90%) in the dark, at 4°C, for 24 h. Measurements were performed by fluorimetry (Turner Design – TD700 fluorimeter) according to Lorenzen (1967). Chlorophyll *a* concentrations were obtained by averaging triplicate values.

Temperature and salinity were measured by Gaudy *et al.* (1995) in the surface and deeper layers using a salinograph YTECH, whereas Cervetto (1995) realized vertical profiles with a multiparametric probe (ME Hydrodata). In both studies, chlorophyll *a* concentrations were evaluated at the same depths using a fluorimetric method.

#### **2.3. Metazooplankton Community**

In our study, to sample metazooplankton (defined as planktonic metazoans), a haul was performed at each station with a modified WP2 plankton net (1.2 m long, 50 cm diameter of opening area and 80 µm mesh size). The net was towed vertically, from bottom to surface, at a speed of  $\sim$ 1 m s<sup>-1</sup>. The cod-end content was immediately fixed with a formaldehyde buffered seawater solution (4% final). Sub-samples (1-20%) were realized with micropipettes (1 and 5 mL) and analyzed using a dissecting microscope (Leica MZ6). An average of 948 individuals were counted per sample and the enumeration error was estimated at  $\pm$  6.5% (Postel *et al.*, 2000). The metazooplankton community of Berre Lagoon presented only two *Acartia* species: *A. clausi* and *A. tonsa*. Adults of these two congeneric copepods were identified and counted according to Rose (1933) and Razouls *et al.* (2005-2017). *Acartia* copepodite stages were counted, but they could not be discriminated at the species level. Abundances of remaining metazooplankton were also estimated and expressed as ind. m<sup>-3</sup>.

In Gaudy *et al.* (1995) and Cervetto (1995), metazooplankton was collected in the surface and deeper layers with a Clarke Bumpus type net  $(80 \,\mu m)$  and a WP2 plankton net  $(60 \,\mu m)$ , respectively. Data were averaged over the water column to allow relevant comparisons.

#### **2.4. Data Analysis**

Only the dataset obtained from Cervetto (1995) allowed a higher-frequency comparison matching our dataset and was used for statistical analyses.

Non-parametric Mann-Whitney U tests (MWU thereafter; Mann and Whitney, 1947) were used to evaluate differences between studied periods, stations and depths. Environmental parameters (*i.e.,* temperature, salinity and chlorophyll *a* concentrations) and biological data (*i.e.,* abundance and relative abundance) were not normally distributed (Shapiro-Wilk test) and considered independently of one another.

The relationships between environmental variables (*i.e.,* temperature, salinity and chlorophyll *a* concentrations) and zooplankton (*A. clausi* and *A. tonsa*, other - *i.e.,* non-*Acartia* - copepods, meroplanktonic larvae and other zooplankton organisms) were assessed using principal component analyses (PCA) performed on log-transformed data of 1992-93 and 2010-12 for the two shared stations (C3/SA3 and C4/PdB) using ADE4 software (Thioulouse *et al.*, 1997). Partial correlation analyses were also carried out on logtransformed data to explore the relationships between the two *Acartia* species and the same environmental and zooplankton variables. In these multivariate analyses, abundances of *Acartia* species were estimated by cumulating abundance of adults and copepodites. As *Acartia* copepodite stages could not be discriminated at the species level, their abundance in each species was estimated at the *pro rata* of adult abundance.

Furthermore, two dimensional surface plots were drawn to show the effects of salinity and chlorophyll *a* concentrations on *A. clausi* and *A. tonsa* abundances. They were performed on pooled datasets of 1992-93 and 2010-12 with least square adjustment using Statistica software 7.1.

# **3. RESULTS**

#### **3.1. Environmental Parameters**

Before and after the rehabilitation processes, temperature displayed comparable range values (4.7 to 26.2°C in Berre Lagoon, 6.5 to 23.8°C at Port de Bouc) and similar seasonal pattern with higher values in summer and lower ones in winter (Figures 2 and 3). These observations corresponded to the typical seasonal cycle in temperate areas.

Figure 2. Temporal variations of temperature (°C), salinity and chlorophyll *a* concentrations (µg Chl *a*  $L^{-1}$ ) in the south of Berre Lagoon (C3/SA3) before (1992-93 – Cervetto, 1995) and after (2010-12 – this study) the rehabilitation efforts.

For both periods, salinity displayed a clear seasonal pattern that matched the temperature pattern (Figures 2 and 3). Lower values were observed in winter corresponding to higher freshwater inputs related to increased activity of the hydroelectric powerplant to fulfill heating requirements (Warner, 2012). However, in the lagoon (C3/SA3 stations), this temporal variability was significantly lower after the rehabilitation efforts, particularly regarding surface values (4.0 to 28.0 in 1992-93 *vs.* 16.6 to 26.5 in 2010-12; MWU, *p*<0.001) (Figure 2). A lower vertical stratification was also observed after the rehabilitation compared to before (difference bottom-surface: 6.2 to 29.0 in 1992-93 *vs.* 0.4 to 17.1 in 2010-12; MWU, *p*<0.001). At Port de Bouc (C4/PdB stations), surface salinity significantly increased after the rehabilitation (13.0 to 32.2 in 1992-93 *vs.* 21.0 to 35.4 in 2010-12; MWU, *p*<0.001) (Figure 3). This salinity change matched the gradual reduction in freshwater released by the powerplant since 1994 and the mandatory smoothing over a weekly basis realized since 2006 (Delpy *et al.*, 2012; Warner, 2012). They led also to lower brackish water outputs through the Caronte Canal into the adjacent coastal area.

Figure 3. Temporal variations of temperature (°C), salinity and chlorophyll *a* concentrations (µg Chl *a*  $L^{-1}$ ) at Port de Bouc (C4/PdB) before (1992-93 – Cervetto, 1995) and after (2010-12 – this study) the rehabilitation efforts.

Chlorophyll *a* concentrations presented no clear seasonal pattern during both periods. In Berre Lagoon, significantly lower values were observed after the rehabilitation (7.0  $\pm$  6.8 µg Chl *a* L<sup>-1</sup> in 2010-12) compared to before  $(10.7 \pm 10.5 \text{ µg Chl } a \text{ L}^{-1}$  in 1992-93) (MWU, *p*<0.05) (Figure 2). However, very high concentrations were occasionally observed in 1992- 93 (53.5 μg Chl *a* L<sup>-1</sup> in December 1992), and even in 2010-12 (45.0 μg Chl *a* L<sup>-1</sup> in September 2011). At Port de Bouc, chlorophyll *a* concentrations presented a significant decrease after the rehabilitation processes with mean values of  $1.8 \pm 1.9$  µg Chl *a* L<sup>-1</sup> in 2010-12 *vs.*  $3.2 \pm 2.9$  µg Chl *a* L<sup>-1</sup> in 1992-93 (MWU,  $p$ <0.001) (Figure 3). The maximum value observed in 1992-93 was 14.5 µg Chl  $a L<sup>-1</sup>$ , whereas it was only 8.5 µg Chl  $a L<sup>-1</sup>$  in 2010-12. Accompanying the drastic changes in salinity conditions, a modification of the trophic status

was then observed with lower chlorophyll *a* concentrations in 2010-12. It is worth noticing that the persistence of high peaks of chlorophyll *a* concentrations is typical of coastal and shallow ecosystems. In this type of environments, development of phytoplanktonic blooms depended also on short-term episodic weather events like heavy rainfall and strong winds (*i.e.,* Mistral and East wind in the studied area), and not only on traditional seasonal variations in plankton succession (Cloern, 1996; Pinazo *et al.*, 2004; Cook *et al.*, 2010; Liess *et al.*, 2016).

# **3.2. Spatiotemporal Variations of Zooplankton Community and**  *Acartia* **Populations**

At all stations, total zooplankton abundance followed a clear seasonal pattern before and after the rehabilitation efforts. Minimal values were observed in winter, followed by a progressive increase in spring to maximal values reached in early summer (from 0.8 to 200.6  $x$  10<sup>3</sup> ind. m<sup>-3</sup>) (Figure 4), matching seasonal variations of temperature previously described (Figures 2 and 3). Before the rehabilitation, peaks of total zooplankton abundance were characterized by an increase of *Acartia* abundance (copepodites, *A. clausi* and *A. tonsa* adults) (Figure 4). After the rehabilitation, *Acartia* assemblages were particularly abundant in winter/early-spring, as well as in summer but to a lesser extent.

Figure 4. Temporal variations of abundances (x10<sup>3</sup> ind. m<sup>-3</sup>) of *Acartia* spp. (black), non-*Acartia* copepods (grey) and other zooplankton organisms (dark grey) before (1992-93 – Cervetto, 1995) and after (2010-12 – this study) the rehabilitation efforts, in the south of Berre Lagoon (C3/SA3) and at Port de Bouc (C4/PdB).

In the lagoon (C3/SA3 stations), seasonal pattern and range of abundance were not significantly different between both periods  $(40.0 \pm 43.1 \times 10^3 \text{ ind. m}^{-3}$  in 1992-93 *vs.* 42.0  $\pm$ 34.6 x  $10^3$  ind. m<sup>-3</sup> in 2010-12; MWU,  $p > 0.05$ ). Zooplankton communities presented comparable structures with comparable relative abundances for copepods  $(43.6 \pm 26.0\%)$  in 1992-93 *vs.*  $40.5 \pm 28.8\%$  in 2010-12) and other zooplankton organisms  $(56.4 \pm 26.0\%$  in 1992-93 *vs.* 59.5 ± 28.8% in 2010-12) (MWU, *p*>0.05). At Port de Bouc (C4/PdB stations), the same seasonal pattern was observed whereas total zooplankton abundance nearly doubled after the rehabilitation processes  $(32.1 \pm 24.8 \times 10^3 \text{ ind. m}^3 \text{ in } 1992\text{-}93 \text{ vs. } 56.0 \pm 41.7 \times 10^3 \text{ m}^3 \text{ m}^3$ ind. m<sup>-3</sup> in 2010-12; MWU,  $p<0.01$ ). Maximal value was 99.7 x 10<sup>3</sup> ind. m<sup>-3</sup> in 1992-93 and reached 200.6 x  $10^3$  ind. m<sup>-3</sup> in 2010-12. Compared to the lagoon, copepods contribution to total abundance was significantly higher  $(54.8 \pm 17.6\%$  in 1992-93 *vs.*  $68.3 \pm 17.1\%$  in 2010-12) and occurred at the expense of other zooplankton organisms  $(45.2 \pm 17.6\%$  in 1992-93 *vs.*  $31.7 \pm 17.1\%$  in 2010-12) (MWU,  $p < 0.05$ ).

The relative contributions of *A. tonsa* and *A. clausi* to total Acartiidae revealed a clear change before and after the rehabilitation processes (Figure 5). In 1992-93, *A. tonsa* was almost the only *Acartia* species in the lagoon (C3) representing up to 100% almost year round. Conversely, at Port de Bouc (C4), *A. clausi* and *A. tonsa* successively dominated the *Acartia* population. In 2010-12, a similar temporal pattern was observed at both stations (SA3 and PdB). At the spatial scale, *A. clausi* presented a higher relative abundance at Port de Bouc (63.1  $\pm$  41.6%), while *A. tonsa* displayed a correlative higher one in the lagoon (65.1  $\pm$ 39.4%) (MWU, p<0.05). Nevertheless, at Port de Bouc, it is worth noticing that in 2010-12 the main predominance periods of each species (winter to spring for *A. clausi vs.* summer to autumn for *A. tonsa*) were longer than in 1992-93 exhibiting alternation of five dominance peaks for each species.

Figure 5. Temporal variations of relative abundance (% of total Acartiidae) of *A. tonsa* (dark) and *A. clausi* (grey) adults before (1992-93 – Cervetto, 1995) and after (2010-12 – this study) the rehabilitation efforts, in the south of Berre Lagoon (C3/SA3) and at Port de Bouc (C4/PdB).

The spatial distribution of *Acartia* populations in Berre Lagoon at both periods was compared to salinity variations in Figure 6. Before the rehabilitation, the salinity presented a clear seasonal variation with lowest values  $({\sim}6)$  observed in winter in the northern part of the lagoon and highest ones (~18) in summer in the southern part (Figure 6 bottom). *A. clausi* was already absent from Berre Lagoon (G1-G2-G3), whereas adults of *A. tonsa* dominated the zooplankton community with a mean abundance of  $3,458 \pm 4,352$  ind. m<sup>-3</sup> from June to November. In February, low abundance  $(2.1 \pm 3.2 \text{ ind. m}^{-3})$  corresponded to the development of a large population of the rotifer *Brachionus plicatilis* (Gaudy *et al.*, 1995). After the rehabilitation, the salinity presented the same seasonal variations, but to a lesser extent, with a range of values from 17 to 28 (Figure 6 bottom). The mean abundance of *A. tonsa* was twice higher than the one of *A. clausi* (469  $\pm$  1,632 ind. m<sup>-3</sup> and 221  $\pm$  536 ind. m<sup>-3</sup>, respectively). Despite the inter-annual variability, our study emphasizes that highest abundances of *A. clausi* occurred in winter/early-spring, and those of *A. tonsa* in summer following the same trend as in 1985 (Figures 4 and 6). Even if the two *Acartia* species were present over the whole lagoon, a spatial segregation was generally observed with a predominance of *A. tonsa* in the northern and intermediate parts (SA1-SA2) and a strong presence of *A. clausi* in the southern area (SA3). A reverse trend was only observed from January to April 2010.

Figure 6. Bubble plots representing abundances of *A. tonsa* (black) and *A. clausi* (grey) adults before (1985 – Gaudy *et al.*, 1995) and after (2010-12 – this study) the rehabilitation efforts from North (G1/SA1) to South (G3/SA3) of Berre Lagoon. Size of bubbles is proportional to the range of abundance (ind.  $m^{-3}$ ). The bottom graph represents the temporal variations of the salinity (average of surface and bottom values) gradient within the lagoon.

#### **3.3. Effects of Environmental Factors on** *Acartia* **Distribution**

The PCA analyses on the lagoon data before and after the rehabilitation processes explained 57.5% and 54.6% of the variance, respectively (Figure 7 top). Before the rehabilitation, *A. clausi* was poorly correlated with the first axis (33.5%) contrarily to *A.* 

*tonsa.* These two congeneric species, together with other copepods and meroplankton, were opposed to high chlorophyll *a* concentrations. On the second axis (24.0%), both species, together with the other zooplankton groups and chlorophyll, were opposed to high temperature and salinity. After the rehabilitation, the first axis (30.2%) opposed the two *Acartia* species to high temperature and salinity, whereas the second axis (24.3%) opposed *A. tonsa*, temperature and salinity to chlorophyll.

The PCA on Port de Bouc data before and after the rehabilitation explained 60.5% and 58.2%, respectively (Figure 7 bottom). Before the rehabilitation, the first axis (42.3%) opposed high abundances of meroplankton and copepods (including both *Acartia* species) to high chlorophyll, whereas the second axis (18.2%) opposed *A. clausi* to *A. tonsa*. After the rehabilitation, on the first axis (34%), non-*Acartia* copepods and other holoplankton were associated to high temperature and opposed to *A. clausi* and chlorophyll. The second axis (24.4%) clearly opposed the two *Acartia* species with *A. tonsa* associated to high salinity. Thus, the role of temperature, salinity and chlorophyll on the two *Acartia* species did not appear very clearly on the basis of the PCA analyses.

Figure 7. Principal component analyses (PCA) realized on datasets obtained before (1992-93 – Cervetto, 1995) and after (2010-12 – this study) the rehabilitation efforts in Berre Lagoon (C3/SA3) and at Port de Bouc (C4/PdB). T°C: temperature, S: salinity, Chl: chlorophyll *a* concentrations, *A. tonsa*: *A. tonsa* adults and copepodites, *A. clausi*: *A. clausi* adults and copepodites, Other Cop: non-*Acartia* copepods, Mero: meroplanktonic larvae and Other Zoo: other zooplankton organisms.

The partial correlation analysis confirmed this tendency as no correlation was found with temperature, salinity or chlorophyll for both species in the lagoon at the two periods (Table 1). However, in Port de Bouc, after the rehabilitation, both species were negatively correlated with temperature, whereas *A. tonsa* was also positively correlated to salinity. Furthermore, the analysis showed high positive correlation between *Acartia* and non-*Acartia* copepods in the lagoon, for the different situations considered (before and after the rehabilitation and pooled data of the two periods) in the case of *A. tonsa* and only after the rehabilitation processes in the case of *A. clausi.* The two *Acartia* species were negatively correlated in both sites (Berre and Port de Bouc) after the rehabilitation or when considering pooled data of the two periods. Before the rehabilitation, negative correlation between the two species was only found when considering pooled data of the two sites, which illustrated the reverse spatial trend at this period with *A. clausi* only present in PdB and *A. tonsa* quite exclusively present in Berre.

Figure 8. Surface plots of *A. tonsa* and *A. clausi* abundances (ind. m<sup>-3</sup>) depending on salinity and chlorophyll *a* concentrations ( $\mu$ g Chl *a* L<sup>-1</sup>). Datasets of 1992-93 (C3 and C4 – Cervetto, 1995) and 2010-12 (SA3 and PdB – this study) were pooled in these analyses.

In summary, if the negative relationship between the two *Acartia* species illustrated their space and/or time partitioning, the absence of clear direct relationship with environmental variables suggests complex mechanisms as interaction or competition to explain these distributions.

To better explore this issue and better understand the effects of salinity and trophic changes after the rehabilitation, we represented, on the same surface plots, the *Acartia* abundances relative to salinity and chlorophyll *a* concentrations by combining the data obtained in 2010-12 and in 1992-93 (Figure 8). The two species showed different patterns. *A. tonsa* presented clear optimal ranges with higher abundances at low salinity (< 10) and medium chlorophyll *a* concentrations (5 to 25  $\mu$ g Chl *a* L<sup>-1</sup>). The abundance of *A. clausi* was also dependent on these two environmental parameters with a peak outlined at medium salinity (5 to 25) and low chlorophyll *a* concentrations (< 10 µg Chl *a* L<sup>-1</sup>). The start of another slight peak can be observed at medium salinity (5 to 25) and very high chlorophyll *a* concentrations ( $>$  50 µg Chl *a* L<sup>-1</sup>).

# **CONCLUSION**

In the anthropized Berre Lagoon, the rehabilitation processes did not seem to have any significant effect on seasonal pattern of zooplankton abundance. Thus, the rough community structure remained unchanged with similar relative contributions of copepods and other zooplankton organisms, despite the lower chlorophyll *a* concentrations observed after the rehabilitation processes. Conversely, at Port de Bouc, total zooplankton abundance increased significantly in 2010-12 reaching values as high as in the lagoon. Copepods gained prominence in the zooplankton community reaching relative contributions (*ca.* 70%) that are currently observed in coastal marine conditions (Siokou-Frangou *et al.*, 2010). The effects of the rehabilitation processes were then perceived as far as the adjacent coastal area, confirming a lower influence of surface brackish water originating from Berre Lagoon. Environmental restorations have already shown positive impacts on plankton communities, and particularly on copepod assemblages. For instance, in a coastal marine system of Tunisia, the removal and containment of phosphogypsum has allowed a diversification of several plankton compartments (Kobbi-Rebai *et al.*, 2012; Rekik *et al.*, 2015). Likewise, the taxonomic composition of zooplankton has drastically changed in Berre Lagoon after the rehabilitation, with a more diverse community including several typical coastal marine species as evidenced by Delpy *et al.* (2012) for the copepods *Centropages typicus*, *Paracalanus parvus* and *Acartia clausi*. The lower variability in salinity likely allowed the development of these marine species brought into the lagoon through the Caronte Canal. Even if both *Acartia tonsa* and *A. clausi* were present in the entire studied area, they tended to succeed one another over time and space.

A clear succession of predominance periods was observed in Berre, as well as at Port de Bouc, with *A. clausi* dominating from winter to spring and *A. tonsa* from summer to autumn. Thus, the reappearance of *A. clausi* in Berre Lagoon and its predominance in winter/spring coincided with the disappearance of the rotifer *Brachionus plicatilis* which had been reported missing after the rehabilitation processes (Gaudy *et al.*, 1995; Delpy *et al.*, 2012). These observations corresponded to the well-defined influence of temperature on the population dynamics of both species (Jeffries, 1962). *A. clausi* is preferentially present in winter/spring as its growth rate increased with increasing temperature and food level (Klein Breteler and Schogt, 1994). In summer, egg production of *A. clausi* was negatively impacted by high temperature (Boyer *et al.*, 2013). This matched the development of the warm-water species *A. tonsa,* mainly depending on production and hatching time of its resting eggs (Katajisto, 2006; Mackas *et al.*, 2012; Svetlichny *et al.*, this volume).

At both periods, a spatial segregation of both *Acartia* species occurred along the salinity gradient from the northern part of Berre Lagoon to Port de Bouc. Before the rehabilitation processes, *A. clausi* was restricted to the marine coastal area, while *A. tonsa* occupied the entire brackish lagoon. This opposite distribution was highlighted in many estuarine systems with *A. clausi* observed downstream and *A. tonsa* upstream (Alcaraz, 1983; Azeiteiro *et al.*, 2005; Aravena *et al.*, 2009; Leandro *et al.*, 2014; Marques *et al.*, this volume; Villate *et al.*, this volume). After the rehabilitation, increasing salinity allowed *A. clausi* penetration into Berre Lagoon, as highlighted in the Mondego estuary by Marques *et al.* (this volume). *A. tonsa* dominated *Acartia* assemblages in most of the lagoon, except in the southern part where *A. clausi* was more abundant, matching optimal salinity range of both species (Cervetto *et al.*,

1995 and 1999; Svetlichny *et al.*, this volume). In the adjacent coastal area, *A. clausi* was still predominant, but followed closely by *A. tonsa*. Falcão *et al.* (2012) showed that restoration measures can lead to a relative homogenization of zooplankton community downstream of the Mondego estuary.

A focus on the two environmental factors modified by the rehabilitation processes (*i.e.*, salinity and chlorophyll *a* concentration) highlighted the first signs of ecological niche for *A. tonsa* and *A. clausi*. After the rehabilitation processes, *A. clausi* co-dominated *Acartia* assemblages with the non-indigenous species *A. tonsa*. The drastic change in salinity conditions may partly explain this evolution, although the salinity effect was not shown in the multivariate analyses in Berre Lagoon. Higher salinity (mean value of 23.6) was less favorable for *A. tonsa*, whose optimal adaptation for metabolism (respiration and excretion) was found at 15-22 (Cervetto *et al.*, 1999; Gaudy *et al.*, 2000; Calliari *et al.*, 2006). The decrease in *A. tonsa* abundance in 2010-12 also corresponded with the installation of *A. clausi* population throughout Berre Lagoon. Its penetration into the lagoon was also linked to salinity increase as *A. clausi* was shown to exhibit reduced ingestion and highly elevated cost of growth at low salinity (< 20) (Calliari *et al.*, 2006). Its optimal salinity range was found to be 24-30, matching the new salinity conditions observed in the lagoon (Cervetto, 1995; Gaudy *et al.*, 2000). Short-term variations of salinity may also explain the spatial segregation observed in Berre after the rehabilitation processes. Following this hypothesis, due to its higher tolerance to sudden salinity variations (Cervetto *et al.*, 1999; Hubareva *et al.*, 2008) and its ability for osmoregulation (Svetlichny *et al.*, this volume), *A. tonsa* would be better adapted to the northern part, which suffered influences of freshwater releases in surface. *A. clausi* would prefer the southern part with marine conditions closer to that observed in the adjacent coastal area.

Concerning chlorophyll, Boyer *et al.* (2013) showed that this factor played a far lower importance than salinity and temperature on egg production of *Acartia* species in another Mediterranean coastal lagoon (Thau Lagoon). However, the following development stages of *A. tonsa* selected their prey according to their physiological need: P-rich prey for the rapid growth of nauplii and N-rich prey for the slower growth of copepodites (Meunier *et al.*, 2015). For *Acartia* adults, the feeding behavior is even more complex since they are omnivorous (Kleppel, 1993; Tiselius, 1989). Even if the peaks of *A. tonsa* and *A. clausi* abundances appeared in Berre Lagoon at medium and low chlorophyll *a* concentrations respectively, the quality of prey could be more important than its quantity. While the feeding regime of *A. tonsa* was more oriented toward proteinic food than *A. clausi,* no relationship between ingestion and food concentration was observed for both species (Gaudy *et al.*, 2000). Thus, *A. tonsa* could be present in less eutrophic environments as it exhibits a fast response to food and a strong efficiency to remain inside ephemeral and thin patches (Tiselius, 1992). Likewise, *A. clausi* also occurred in hyper eutrophic environments in African sites (Arfi *et al.*, 1989). Nevertheless, in 2011, the succession of predominance periods was less evident with a higher relative contribution of *A. tonsa* from April. This predominance coincided with chlorophyll *a* concentrations twice higher in surface waters (MWU, *p*<0.05), values close to those observed before the rehabilitation processes (Cervetto, 1995; Gaudy *et al.*, 1995). Increased abundances of *A. tonsa* have often been associated to increase in chlorophyll and turbidity in other coastal systems (Derisio *et al.*, 2014; Biancala *et al.*, 2014).

The role of temperature, salinity and chlorophyll appeared not to be so obvious, as described in other coastal ecosystems (Jeffries, 1962; Alcaraz, 1983; Gaudy *et al.*, 2000;

Calliari *et al.*, 2006; Boyer *et al.*, 2013; Marques *et al.*, this volume; Svetlichny *et al.*, this volume; Villate *et al.*, this volume). Kimmel *et al.* (2012) showed that environmental and food web changes can be involved together to explain the decline in *A. tonsa* population in the central Chesapeake Bay. Then, a combination of site-specific factors has to be considered to explain modifications in *Acartia* assemblages (Lakkis, 1994; Calliari *et al.*, 2006). Trophic interactions, like competition and predation, can move out species from their optimal temporal and/or spatial distribution. Villate *et al.* (this volume) emphasized a restricted seasonal distribution of *A. tonsa* due to a competitive pressure with *Acartia bifilosa* in the estuary of Urdaibai.

In conclusion, the rehabilitation processes have managed to reduce salinity fluctuations and maintain it above 15. These modifications led to a space and time partitioning of *A. tonsa* and *A. clausi* along the salinity gradient as described in other brackish water systems. Changes in the distribution of *Acartia* species following the rehabilitation processes constitute a sign of a hoped recovery. Thus, even if Acartiidae constitute an important link to higher trophic levels in brackish environments (Alcaraz, 1983; Azeitero *et al.*, 2005; Werbrouch *et al.,* 2016; Villate *et al.*, this volume), the contribution of both *Acartia* species to the food web may be different. Werbrouch *et al.* (2016) highlighted that the replacement of *A. clausi* by *A. tonsa* is detrimental for higher trophic levels as *A. tonsa* presents a lower content of fatty acids (*i.e.,* DHA and EPA) in membrane lipids for the same body size. In Berre Lagoon, the cephalothorax length of *A. tonsa* was significantly lower than the one of *A. clausi* with mean values of  $0.98 \pm 0.12$  cm (n = 272 ind. for the 2010-12 survey) and  $1.08 \pm 0.06$  cm (n = 419 ind. for the 2010-12 survey), respectively (MWU,  $p<0.001$ ; data not shown). Before the rehabilitation processes, the energy transfer was then likely less effective since *A. tonsa* was the only Acartiidae observed in the lagoon. The arrival of *A. clausi* in Berre Lagoon, resulting from salinity increase, could eventually drive to a rich and diverse pelagic ecosystem which is actually very damaged by the anthropogenic pressures of these last decades. For the moment, a positive influence on higher trophic levels is still expected as food web is dominated by gelatinous zooplankton considered as a trophic dead end, particularly the indigenous scyphozoan *Aurelia* sp. (Marques *et al.*, 2015) and two alien species (*i.e.,* the ctenophore *Mnemiopsis leidyi* (Delpy *et al.*, 2016) and the hydrozoan *Gonionemus vertens* (F. Delpy, June 2013, pers. obs.). Nonetheless, the presence of some planktivorous fish whether inhabiting the lagoon (*e.g.,* goby and atherine) or coming from the Mediterranean Sea through Caronte Canal (*e.g.,* sardine and anchovy) can offer hopes for a next improvement (GIPREB, pers. com.). These results constitute a very first step in the long road to Berre recovery.

#### **ACKNOWLEDGMENTS**

The present study was supported by the GELAMED project funded by the MEEDDM (Ministere de l'Ecologie, de l'Energie, du Developpement Durable et de la Mer) (Programme 189 –"Recherche"18902 C) and the Total foundation (P.I. D. Bonnet), and by a Ph.D. fellowship for F. Delpy from the Provence-Alpes-Côte d'Azur Region. This project aimed to monitor gelatinous zooplankton in three lagoons and four coastal stations along the French Mediterranean coast (Marques *et al.*, 2015; Delpy *et al.*, 2016). We would like to thank the GIPREB and the crew of the N.O. Antedon II for their assistance, as well as EDF for

providing temperature and salinity data. We would like to express our gratefulness to the editor of this book Marco Uttieri and our Reviewers, especially one of them for his/her huge synthesis work on *Acartia* chapters.

## **ABSTRACT**

This chapter aimed to identify the role of natural environmental factors in the distribution of the congeneric species *Acartia tonsa* and *Acartia clausi* in the Mondego estuary, central Iberian Peninsula, over the period 2003-2012. *A. tonsa* was the dominant species during the study period, representing 84% of the total abundance of *Acartia*. The distribution patterns of *Acartia* species revealed a spatial segregation along the estuary, with *A. tonsa* confined to upstream areas, while *A. clausi* was restricted downstream. Both species showed seasonal variation, peaking during warmer months. Since 2007, *A. tonsa* exibithed yearly averages consistently above the long-term mean abundance. The results identified a clear effect of temperature warming on the ecosystem, favoring and accelerating the settlement of the non-indigenous species *A. tonsa* at an unexpectedly rapid rate.

<sup>\*</sup> Corresponding Author's Email: sonia.cotrim@ipma.pt.

STATICO analysis revealed that 2007, 2010 and 2011 were years with strong temporal patterns, which best fitted the compromise analyses between *Acartia* abundance and environmental parameters. *A. tonsa* showed an overall positive relationship with temperature, salinity, and total suspended solids (TSS), while *A. clausi* presented a positive association with chlorophyll *a*. Local variability of freshwater flow was the dominant signal in the present time-series, and explained the observed dynamics in *Acartia* populations structure at shorter temporal scales. However, this effect could be masked by larger time-scale phenomena occurring simultaneously, such as a rise in water temperature, leading to a higher abundance of opportunistic tolerant-species, as *A. tonsa*.

These results suggest that copepods living in highly dynamic ecosystems are prone to shifts in community equilibria that show complex, non-linear responses to climatic oscillations.

**Keywords**: *Acartia tonsa*, *Acartia clausi*, Mondego estuary, environmental variability

## **1.INTRODUCTION**

Zooplankton constitutes the ocean's essential secondary producers, representing a key link between primary producers and higher trophic levels (Turner, 2004). Their spatial and temporal variability are known to be linked with hydrological patterns, seasonal fluctuations, trophic status and pollution (*e.g.*, Kimmerer, 1993; Lawrence *et al.*, 2004; Uriarte *et al.*, 2005; Aravena *et al.*, 2009). Often, zooplankton communities are reported as more sensitive indicators of change than environmental variables themselves (Taylor *et al.*, 2002, Hays *et al.*, 2005), acting as integrators of hydroclimatic forcing and providing an accurate diagnosis of the ecosystem state (Beaugrand, 2005). Zooplankton is highly sensitive to short-term environmental variability, with studies reporting changes in zooplanktonic communities according to seasonal*,* tidal, and diurnal variations (*e.g.*, Kimmerer, 1993; Roman *et al.*, 2001; Lawrence *et al.*, 2004; Marques *et al.*, 2009; Menéndez *et al.*, 2012; Leandro *et al.*, 2014). Furthermore, zooplankton communities have been useful to track large-scale climate-driven environmental changes (Hays *et al.*, 2005; Richardson, 2008; Aravena *et al.*, 2009; Edwards *et al.*, 2013), and recent evidences of long-term studies indicate variations in the seasonal window and timing around the world (*e.g.*, Hinder *et al.*, 2012; Mackas *et al.*, 2012), as well as the reduction and redistribution of several species (*e.g.*, Hinder *et al.*, 2012; Edwards *et al.*, 2013; Gubanova *et al.*, 2014).

Global climate change has led to a sustained increase in ocean temperatures in the last decades. In the North Atlantic, for instance, sea surface temperature (SST) has increased by about 0.5 °C during the past 50 years (IPCC, 2013). Copepods play a fundamental role in the energy transfer to higher trophic levels, in the transport of organic matter to depth (*via* fecal pellets), in the dynamics of their main prey (phyto- and microzooplankton), and in the mineralisation of nitrogen and carbon *via* grazing (Turner, 2004). Thus, it is mandatory to know how these communities are affected by this increased climatic variability. Further, the phenotypic plasticity and tolerance to hydrological variability will also determine the zooplankton community structure in highly unstable ecosystems, such as estuaries (Dam, 2013).

Copepods clearly dominate the numerical abundance of zooplankton, particularly calanoid copepods (Mauchline, 1998). These small microcrustaceans graze upon phytoplankton and microzooplankton, including nauplii of their own class (Turner, 2004).

Among calanoids, members of the genus *Acartia* exhibit a clear supremacy in the plankton communities across several temperate and subtropical estuaries (Brylinski, 1981; David *et al.*, 2007; Marques *et al.*, 2007) and other semi-enclosed marine areas (Kimmerer, 1993; Roman *et al.*, 2001; Leandro *et al.*, 2014). Their spatial and temporal variability are known to be linked with hydrological patterns, seasonal fluctuations, trophic status and pollution (*e.g.*, Kimmerer, 1993; Lawrence *et al.*, 2004; Uriarte *et al.*, 2005; Aravena *et al.*, 2009). Recently, non-native species of *Acartia* are efficiently colonizing many coastal areas and estuaries, increasing the pressure on autochthonous copepod communities (*e.g.*, Comaschi *et al.*, 2000; Seuront, 2005; David *et al.*, 2007; Delpy *et al.*, this volume; Villate *et al.*, this volume). The increase in ocean temperature has been pointed out as an important factor for the successful establishment of these non-native species (Aravena *et al.*, 2009; Chaalali *et al.*, 2013; David *et al.*, 2007). Non indigenous *Acartia* species have beeen responsible for changing the seasonal distribution pattern of zooplankton leading to a phenological shift in the native copepod *Acartia bifilosa* production period at the Gironde estuary (David *et al.*, 2007), the decreased abundance of the autochtonous *Acartia clausi* in the estuary of Bilbao (Aravena *et al.*, 2009; Villate *et al.*, this volume), or the complete replacement of formerly abundant *Acartia margalefi* in the South Adriatic Sea (Brugnano *et al.*, 2011). Changes in the ecosystem also favoured the non-native *Acartia* species to the detriment of the indigenous copepods in the early 1970s in the Black Sea (Gubanova *et al.*, 2014): in this case, increased pollution and eutrophication have been identified as the main factors determining the replacement of native species, rather than the increase in temperature (Gubanova *et al.*, 2014). Also, changes in salinity proved to be unfavorable for the autochthonous species of *Acartia* congeners in the Gironde estuary (David *et al.*, 2007) and in the estuary of Bilbao (Aravena *et al.*, 2009). Non-native species are extremely efficient at colonizing brackish waters, which are more vulnerable to the establishment of alien species owing to the greatest natural 'indigenous species minimum' (Paavola *et al.*, 2005).

Relevant interannual variability observed in the weather conditions over the Iberian Peninsula attests to the decreasing trend in annual precipitation in Portugal (Rodrigo and Trigo 2007; Santos *et al.*, 2010). In the particular case of the Mondego estuary, located in the Portuguese Atlantic coast, lower annual precipitations have led to a reduction in river flow, influencing also the extent of the estuarine salinity gradient and of the spatial distribution of planktonic species (Marques *et al.*, 2008, 2014; Primo *et al.*, 2011, 2015). This highlights the strong influence of water exchanges with the Atlantic Ocean on the composition and dynamics of local pelagic communities (Bento *et al.*, 2016; D'Ambrosio *et al.*, 2016). As in other temperate estuaries, *Acartia tonsa* represents the main species of planktonic communities of this estuary, only outreached by its congener *A. clausi* (Marques *et al.*, 2006; Primo *et al.*, 2009). The congeners present different seasonal and spatial distributions patterns in the estuary and are generally linked with estuarine and marine water masses, respectively.

The main aim of this contribution was to identify the role of natural environmental factors in the populations of the coexisting species *A. tonsa* and *A. clausi* in the Mondego estuary over a 10-year period (2003-2012). To answer this objective, we analysed and described the influence of environmental factors (hydrology and biology) on *Acartia* species dynamics and assessed the effects of different environmental regimes on congeneric spatial segregation. Our approach reveals that variability of freshwater flow explained the observed dynamics in *Acartia* populations structure at shorter temporal scales. However, this effect

could be masked by an increase in water temperature, leading to a higher abundance of opportunistic tolerant-species as *A. tonsa*.

## **2. METHODS**

### **2.1. Study Area**

The Mondego estuary  $(40^{\circ} 08' N, 8^{\circ} 50' W)$  is located in a warm temperate region on the west coast of Portugal (Figure 1). This system experiences a Mediterranean temperate climate and is classified as a mesotidal estuary. About 7 km from the sea, the river branches into 2 arms (northern and southern), which converge again near the mouth. The two branches exhibit different hydrographic characteristics: the northern branch presents a low residence time (<1 day, Kenov *et al.*, 2012), is deeper (4–8 m during high tide), and is the location of the Figueira da Foz harbour, constituting the main navigation channel and being subjected to regular dredging activities. The southern branch is shallower (2–4 m deep, during high tide) with longer residence time (2–8 days) (Kenov *et al.*, 2012).

Figure 1. Map of the Mondego estuary showing the location of the sampling sites. M (mouth site), S1 and S2 (southern arm sites), N1 and N 2 (northern arm sites).

#### **2.2. Environmental and Biological Data**

Data on the abundance of *Acartia clausi* and *Acartia tonsa* cover a 10 year period (2003 to 2012) and were obtained from monthly samples at 5 stations distributed throughout both branches (M – mouth, N1 and N2 – northern branch, S1 and S2 – southern branch; M, S1 and  $N1$ – downstream areas, S2 and  $N2$  – upstream areas) (Figure 1). This constitutes a unique time series dataset for an estuarine system of the West Iberian coast (which started in 2003), considering the consistency in the sampling methods and number of samples. Zooplankton samples were collected by subsurface horizontal hauls, using a 335 μm mesh bongo net (mouth diameter: 0.5 m). Subsequently, all collected organisms were fixed and stored with buffered formaldehyde (4%). The zooplankton analysis was carried out under a Leica M80 stereomicroscopice and subsamples (a minimum of 500 individuals were counted) were obtained for numerical abundance using a Folsom-splitter. Records of *Acartia* were only based on adults, since the mesh size used under-estimates the early life stages. Abundance data were standardized as the number of ind. m-3 .

*In situ* surface salinity and water temperature were recorded with appropriate sensors (WTW Cond 330i) simultaneously to zooplankton sampling. Water samples were also collected for determination of total suspended solids (TSS, mg l<sup>-1</sup>; APHA, 1992) and chlorophyll *a* concentration (Chl *a*, mg m-3 ; Parsons *et al.*, 1984) as a measure of total phytoplankton biomass.

#### **2.3. Statistical Analysis**

Interannual variability of biological and environmental variables was represented by standardised anomalies (z-scores), computed as deviations from the mean of the time-series divided by the respective standard deviation. Additionally, the relationship between environmental variables was determined using the Spearman's non parametric correlation ρ, using SigmaPlot v12.5 (Systat Software). When applicable, results were presented as mean  $\pm$ standard deviation (STD).

In order to investigate the influence of the environmental conditions on *Acartia* populations, species abundance and environmental parameters (temperature, salinity, Chl *a* and TSS) for each year and sampling site were combined to generate two series of tables: one for the environmental parameters and another for *Acartia* species densities. Each pair of tables corresponded to the same sampling year (in rows). Therefore, both tables (biological and environmental) were composed of 10 matrices (2003-2012). Prior to calculations, *Acartia* abundance was  $log(x+1)$  transformed, in order to minimize the dominant effect of exceptional values, and environmental data were normalized.

In order to detect change points in *Acartia* abundance and environmental parameters, the cumulative sum (CUSUM) of the deviations from the mean of the reference period 2003 to 2012 were computed. The interpretation was based on the sign and steepness of the slopes, which reflect the deviation of a period from the time-series mean value (Ibañez *et al.,* 1993).

The STATICO method (Simier *et al.*, 1999; Thioulouse *et al.*, 2004) was carried out to analyze the two series of tables (Figure 2). In this chapter, the common structure between environmental and *Acartia* abundance tables and the stability of this structure over the sampling period were assessed. The samples, which must be the same for both paired tables but may vary between the pairs, correspond to a monthly sampling. The STATICO method proceeds in three steps: (1) the interstructure, which is achieved by performing a PCA for analyzing each table by a one table method (normed for the the environmental variables and centred for the species data); (2) the compromise analysis gives an ordination of the environmental parameters and an ordination of the *Acartia* species representing the average *Acartia*-environment relationship across the years; the compromise analysis links each pair of table Co-inertia analysis (Dolédec and Chessel, 1994) providing an average image of the costructure (species-variables cross-table); and (3) the trajectories analysis involves the projection of the individual tables onto the axes of the compromise. This step allows visualisation of the similarities and differences amongst the years' structures, *i.e.*, environmental and *Acartia* cycles. A Partial Triadic Analysis (Thioulouse and Chessel, 1987)

was used to analyze the series of species and environmental variables cross-tables. STATICO allows building compromise maps composed of compromise axes on which observation (*i.e.*, monthly samples), species abundance and environmental factors from each original table are projected. Hence, it is possible to observe the correlation between species distribution and environmental factors. Calculations and graphs shown in this work were done using ADE-4 software (Thioulouse *et al.*, 1997; available at http://pbil.univ-lyon1.fr/ADE-4).

Figure 2. STATICO scheme. The data structure is a sequence of K paired ecological tables.  $X_k$  and  $Y_k$ are respectively the species (dimension  $n_k$  x p) and environmental (dimension  $n_k$  x q) tables in the pair.  $Z_k$  is the cross-table at k occurences; p is the number of species, q is the number of environmental variables,  $n_k$  is the number of rows at k different dates. (1) Basic analyses (PCA for species abundance and environmental tables) are performed on each table; (2) Co-inertia analyses allow linkage of the pairs of PCA-PCA, producing a sequence of K cross-tables; (3) PTA is finally used to analyze this sequence.

All data regarding precipitation and freshwater runoff were acquired from the Portuguese Water Institute (INAG, www.snirh.inag.pt) stations Soure 13/01G and Açude Ponte de Coimbra 12G/01A (nearby the city of Coimbra, since no meteorological station was present in the study area). In accordance with the reports of the Portuguese Institute for Sea and Atmosphere (IPMA, https://www.ipma.pt/pt/), three major drought events were considered during the study period: 2004-2005, 2007-08 and 2012 (García-Herrera *et al.*, 2007; Trigo *et al.*, 2013).

## **3. RESULTS**

#### **3.1. Variabilty of Environmental Parameters and** *Acartia* **Abundance**

The years sampled included a very wide range of environmental conditions, encompassing extreme climate events (Figure 3). Compared to the mean precipitation regime for central Portugal during 1981-2010 (winter: 92.4 mm; spring: 58.3 mm; summer: 8.8 mm; autumn: 87.1 mm, http://www.ipma.pt/pt/oclima/normais.clima), it was possible to distinguish three periods where drought regimes prevailed, namely 2004-2005, 2007-2008 and 2012 (García-Herrera *et al.*, 2007; Trigo *et al.*, 2013). According to IPMA, 2009 was considered a regular to dry year, while 2010 and 2011 regular years. The drought episode of 2004-2005 was considered the most severe in terms of meteorological data, extent of the area affected, and impacts on different socio-economic and environmental sectors (https://www.ipma.pt/pt/).

Figure 3. Seasonal precipitation (mm) and runoff  $(dam<sup>3</sup>)$  for the 10-year study period (2003-2012) in the Mondego estuary. Shaded areas represent drought periods. Black circles – precipitation (mm), white circles – average precipitation for 1981-2010, and grey bars – runoff  $(dam<sup>3</sup>)$ .

Figure 4. Standardized anomalies of mean annual (A) salinity (surface), (B) water temperature, (C) chlorophyll *a* (Chl *a*) and (D) total suspended solids (TSS).

The variations of freshwater discharge into the Mondego estuary were clearly influenced by precipitation (Figure 3), showing a highly significant positive relationship between these two parameters (Spearman rank,  $p < 0.001$ ,  $R = 0.67$ , Table 1). Maximum salinity values were typically observed during the lowest runoff periods described above, especially in 2004- 2005, due to a drought started in 2004 and extended to an extreme event in 2005 (Figure 4A). In comparison, low salinity values were observed in 2003, 2006 and 2010, concomitant with the years of highest river runoff registered during the study period. The salinity anomalies values exhibited a highly significant negative correlation with runoff ( $p < 0.001$ , R = -0.81, Table 1) and precipitation ( $p < 0.001$ , R = -0.61, Table 1). Dealing with water temperature, the ten years presented the typical annual pattern for temperate ecosystems, with lower values in winter  $(9.0-15.2^{\circ}\text{C})$  and higher in summer  $(15.4-26.7^{\circ}\text{C})$  (data not shown). Positive anomalies were recorded in 2006 (particularly downstream), with highest positive deviation in 2008-09 and 2011-12 (Figure 4B).

Figure 5. Variability of (A) *Acartia tonsa* and (B) *Acartia clausi* abundance (ind. m-3 ) over the 2003-2012 period.

Chlorophyll *a* values varied between 0.9 and 29.9 mg m<sup>-3</sup> (mean =  $6.7 \pm 5.4$  mg m<sup>-3</sup>) during the 2003–2012 period. This parameter was generally above the long-term average in 2007 (downstream), 2008 (upstream), and 2012 (downstream) (Figure 4C). Higher positive average of TSS were recorded between 2003 and 2005, and in 2009-2010, more pronounced at upstream, while the lowest were observed in 2007 and 2011-12. The correlation between TSS anomalies and water temperature anomalies was highly significant ( $p < 0.001$ , R =  $-$ 0.41, Table 1).

Figure 6. Z-scores of (A) *Acartia clausi* and (B) *Acartia tonsa,* abundance in the Mondego estuary over the 2003-2012 period (winter-Wi, spring- Sp, summer – Su, autumn-Au).

Over the 2003-2012 period, *Acartia tonsa* was the dominant species, making up 84% of the total abundance of *Acartia* (Figure 5). The distribution pattern of *Acartia* species revealed a spatial segregation along the estuary. On one hand, *A. tonsa* was confined to the upstream areas, with an average annual density of  $540.5 \pm 401.0$  ind. m<sup>-3</sup> (Figure 5A). The anomalies in *A. tonsa* abundance revealed a cyclical variation, with peaks during the warming seasons (Figure 6A). After 2007, *A. tonsa* abundance increased considerably, with yearly averages consistently above the long-term mean. In autumn 2007-2008, 2010 and 2012, the species exhibithed higher amplitude of its seasonal maxima compared to other years (max. 4.089, 2.618, 2.075, 1.605 ind. m<sup>-3</sup>, respectively) and extended its period of presence until winter in 2010 and 2012. On the other hand, its congener *Acartia clausi* was more restricted to the lower estuary (mean =  $67.2 \pm 58.0$  ind. m<sup>-3</sup>). A clear general pattern was observed over time, with a bimodal increase of *A. clausi* abundance in spring and summer. The highest positive anomalies were detected in summer 2007 (377 ind.  $m^{-3}$ ), spring 2009 (1,235 ind.  $m^{-3}$ ), spring and winter 2012 (291 and 287 ind.  $m<sup>-3</sup>$ , respectively) (Figure 6B). Noticeable changes also occurred in the phenology of *A. clausi*, with an earlier timing of seasonal peak after 2007, with the occurrence of major abundance peaks in late winter/early spring.

### **3.2.** *Acartia* **Variability in Relation to Environmental Parameters**

#### *3.2.1. CUSUM Analysis of Time-Series*

Regarding environmental variability, water temperature showed two main periods, delimited by a breakpoint in 2008 (Figure 7A). The first period (2003-08) was characterized by lower seasonal values. Afterwards, an upward change in temperature was observed. Salinity showed higher variability: two main periods of positive slope, 2005-early 2006 and late 2007 until 2010, were highlighted by the cumulative sums (Figure 7B). Chl *a* presented a clear upward trend after 2007 (Figure 7C), while TSS showed positive slope in 2006-07 and during the period 2009-2012 (Figure 7D). As for *Acartia*, the abundance of both species exhibited a synchronized increase after 2006 and 2007, for *A. tonsa* and *A. clausi*, respectively (Figures 7E, F).

Overall, despite the variability in the CUSUM analysis, a significant positive correlation was observed between water temperature and Chl  $a$  ( $R = 0.43$ ,  $p < 0.001$ ), which may have also played a role in influencing the changes in *Acartia* abundance, since a positive correlation was also detected between them and Chl *a* (*A. clausi, R* = 0.57, *p* = 0.001 and *A. tonsa,*  $R = 0.70$ ,  $p = 0.001$ . TSS showed negative significant correlations with *A. clausi* ( $R = 0.70$ ,  $p = 0.001$ ). TSS showed negative significant correlations with *A. clausi*  $-0.59$ ,  $p = 0.001$ ) and *A. tonsa* (R =  $-0.53$ ,  $p = 0.001$ ).

#### *3.2.2. Interstructure Analysis of the Years*

The first axis represented 94.5% of the total inertia (3.4% for the second axis, Figure 8A). Therefore, no structure inversion was evidenced from one sample to the other, and distribution patterns of *Acartia* were (at least partially) common to all sampling years. Weights (reflecting the contribution of each sub-matrix in the construction of the compromise) and  $\cos^2$  (indicating of how much the compromise expresses the information contained in each table) values (Table 2) showed that each year shared characteristics with the compromise, despite this has some individual features. From the analysis of the correlation and weights (Table 1, Figure 8), the common temporal pattern appeared to be stronger in 2007, 2011, 2010 and 2006 (higher weight and longer arrows), exhibiting a strong association with PC1; this in turn indicated similar structures and meant that the compromise would be more influenced by these years. The years of 2004, 2005, 2008, 2009, 2012 presented lower weight (short arrows) indicating that their corresponding tables were less structured and consequently their contribution to the compromise was lower.

#### *3.2.3. Compromise Analysis*

The factor map of the first two axes are shown for the *Acartia* populations (Figure 9A) and environmental variables (Figure 9B). Axis 1 accounted for 53.9% of the explained variance and differentiated the samples with higher and lower abundance, whilst Axis 2 (10.63% of the explained variance) indicated a clear separation in the distribution patterns of *A. clausi* and *A. tonsa* within the estuary (Figure 9A). As can be seen from the environmental compromise analysis (Figure 9B), water temperature and salinity were displayed on the positive section of Axis 1, confirming that high abundance were typically observed in years of higher salinity and temperature. Overall, chlorophyll *a* was positively linked to Axis 2, whereas TSS was negatively associated to this axis.

Figure 7. Cumulative sums of normal standard deviates of (A) water temperature, (B) salinity, (C) clorophyll *a* (Chl *a*), (D) total suspended solids (TSS), (E) *Acartia clausi* abundance (F) *Acartia tonsa* abundance; 2003 to 2012 (winter -w, spring - sp, summer-s and autumn-a).

**Table 2. Correlation matrix and typological value indices: Weights = weights of tables in the compromise; cos<sup>2</sup> = square cosine between table and approximated compromise**

Year											Weights	$\cos^2$
2003	1000										0.277	0.629
2004	230	1000									0.116	0.081
2005	712	293	1000								0.273	0.621
2006	601	65	571	1000							0.387	0.572
2007	623	61	611	496	1000						0.456	0.645
2008	434	70	378	383	412	1000					0.206	0.250
2009	440	200	447	524	354	175	1000				0.245	0.400
2010	573	306	571	509	509	410	592	1000			0.403	0.622
2011	589	269	638	503	666	393	420	501	1000		0.407	0.640
2012	476	247	537	462	555	241	422	569	525	1000	0.218	0.477

Figure 8. Results from the interstructure analysis. (A) Histogram of eigenvalues. (B) Factorial map for years. The contribution of sampled years to the compromise map is indicated by the strength of association with each principal component (PC1, x-axis; PC2, y-axis) extracted from the analysis. The y-axis is the second principal component (PC2). Scales for axes is given in the bottom right corner.

Figure 9. Compromise factor maps of the STATICO analysis. This plot represents the typical (A) *Acartia* population structure and (B) environmental structure in the Mondego estuary. Ato – *Acartia tonsa*, Acl– *A. clausi*, CHLA – chlorophyll *a*, TEMP – water temperature, SAL – Salinity, TSS – total suspended solids. The scales for axes are given in the right upper corner.

In the downstream areas of the estuary (sites M, S1, N1), the higher abundance of *Acartia*  were associated to *A. clausi*, whereas in the upstream areas (sites S2 and N2) they were associated to *A. tonsa*. These results confirmed the positive relationship between *Acartia*  abundance with temperature and salinity. Axis 2 also permitted to evidence the positive association between Chl *a* and *A. clausi*, while *A. tonsa* was more related with TSS.

#### *3.2.4. Trajectories Analysis*

The projection of the environmental variables and *Acartia* abundance on the compromise axes is showed in the factorial map of trajectories (Figure 10). High interannual variability in the *Acartia* populations and environmental conditions was evidenced, and differences between years were predominantly driven by variablity of salinity and temperature. The characteristic structure of the species-environmental dynamics, revealed by the compromise analysis, was well expressed in 2007, 2010 and 2011, which corresponded to the highest abundance peaks of *A. tonsa*. A different scenario emerged in 2003, 2005 and 2009, when a spatial segregation in *Acartia* species abundance was not so evident.

The co-structure analysis (divided according to sampling years) clearly showed the dynamics of the *Acartia* species-environment relationships and highlighted seasonal differences (Figure 11). Whatever the date, the species points (circles) were more stable than the environmental points. This expresses the steady establishment of the *Acartia* assemblages, despite the high environmental variability (salinity and water temperature, in particular). The end of the arrows (environmental variables) had comparatively different values (generally presented separated) and simultaneously close *Acartia* abundances (the circles were in general in the same area). Indeed, considering the species, the sites were regularly projected on the right-hand side of the first axis, characterized by the highest *Acartia* abundances (see Figure 9A).

In general, and notwithstanding the strong dispersion of the environmental points and a poor fit between the *Acartia* species and environment parameters (long arrows), summer, autumn and winter were regularly grouped together, expressing a better consensus in the species-environment relationship. In fact, this was most clear (in general) for 2007, 2010 and 2011. Overall, in winter the environmental points (given by the end of arrows) were located on the left-hand side of the first axis, corresponding to "lower environmental values". On the other hand, environmental points (end of arrows) corresponding to summer (followed by autumn) were located on the right-hand side of the first axis, which means "higher environmental values". In sum, species and environmental parameters denote the absence of a clear coupling between environmental and copepod trajectories.

## **CONCLUSION**

Estuaries are higly dynamic and variable environments, which promote not only a low level of species diversity, but also the co-existence of congeneric species. Our results revealed considerable complexity in the processes structuring the dynamics of the two congeneric *Acartia* species, *Acartia clausi* and *Acartia tonsa*, which represent nearly 60% of the total zooplankton abundance of the Mondego estuary (Marques *et al.*, 2006), a shallow coastal ecosystem under the influence of river discharge. In these ecosystems, zooplankton abundance is characterized by a high degree of spatial and temporal variability (Kimmel, 2011). Our results showed the existence of a spatial segregation between congeneric species: *A. clausi* was restricted to the downstream areas where salinity is relatively higher, while *A.* 

*tonsa* occurred at upstream sections of the estuary. Environmental pressures characterized in the present chapter (*e.g*., salinity, temperature and chlorophyll *a*), together with biotic and physiological aspects already observed by other authors (*e.g.*, Gaudy *et al.*, 2000; Leandro *et al.*, 2014), explain the spatial distribution pattern for these two species at the Mondego estuary.

Figure 10. Factorial map of trajectories for species (grey) and environmental parameters (white). Depicted are annual projections of *Acartia* abundance and environmental variables along the two principal components of STATICO analysis. Scale for axes are given at the top right corner.

Figure 11. Trajectories factor plots of the STATICO analysis: projection of the samples in respect to seasons on the first factorial plan of the compromise analysis. Each sample is represented by two points: one is the projection of the row of the *Acartia* table (circle: origin of arrows), and the other is the projection of the row of the environmental table (end of arrows). The length of the connecting line reveals the disagreement or the consensus between the two profiles (*Acartia*–environment), *i.e.*, the length of the line is proportional to the divergence between the datasets. When the datasets strongly agree, the arrows will be short. Likewise, a long arrow demonstrates a locally weak relationship between the environment and *Acartia* features for that case. The scales for axes are given in the right lower corner.

*A. tonsa* was first observed in the estuary in 1994 by Azeiteiro *et al.* (1999), and since then persistent proliferation and swarming demonstrate the adaptive behavior of this species. In this sense, Gaudy *et al. (*2000) described the influence of temperature and salinity on the metabolism of *A. clausi* and *A. tonsa* and concluded that, for several temperatures tested, at the salinity of 35 psu, respiration rates were lower in *A. clausi* than in *A. tonsa*, with the contrary being observed at the lowest salinity. High respiration rates reflect the existence of some physiological constrains (*e.g.*, osmotic pressure) that are overtaken through costly energetic processes. If more energy is available for growth and reproduction, that will be reflected on the population structure of a given copepod species – higher abundance and high reproductive rate. A dense population of *A. tonsa* occurring at a specific location as a result of the combination of optimal environmental conditions (temperature, salinity and food) will have a negative effect on other pelagic copepod population like *A. clausi* given its predatory impact on other copepod species.

Results from the present work corroborate findings suggesting that *A. tonsa* is an opportunistic-tolerant species, which can take advantage of thermal increase. An increment in water temperature has been suggested as a key factor to explain the introduction of *A. tonsa* in some estuarine ecosystems (Kimmel and Roman, 2004; David *et al.*, 2007). According to Leandro *et al. (*2006 a, b), *A. tonsa* has a stronger response to temperature than the majority of marine and estuarine calanoid copepods, including *A. clausi*, exhibiting higher growth rates and lower developmental times. By developing faster, *A. tonsa* populations will be able to dominate the estuarine zooplankton community. Coastal waters have warmed during the last century, leading to profound consequences for the dynamic regime of coastal ecosystems (Scavia *et al.*, 2002; Goberville *et al.*, 2010). In fact, the abundance of this species showed an increase after 2007-2008 in the inner upstream areas of the estuary, concomitantly with an increase in water temperature and chlorophyll *a* concentration. In the western Iberian coast, previous studies showed that hydrographic modifications covary with the secular trend of both sea surface temperatures and the North Atlantic Oscillation (NAO) (Pérez *et al.*, 2010). Indeed, the interannual changes of the NAO showed enhanced variance (twofold higher) after 2008 that encompassed a dramatic drop in the NAO during 2010–2011, followed by a marked reversal change of the signal (Marques *et al.*, 2017). In turn, the physical environment in the Mondego estuary showed prominent monthly variations of hydrological conditions that exhibited a larger variance around 2007–2010 as well. This suggests a close link between the environmental conditions at the Mondego estuary and the NAO through the influence of the later on regional atmospheric variables in the Northeast Atlantic coast, such as temperature, atmospheric pressure, wind and precipitation, and whose variability permeated into the environmental conditions in the estuary, as suggested by the temporal patterns of autotrophic and heterotrophic communities (Marques *et al.*, 2017). Overall, the observed structural change in the *Acartia* populations lies in the direction of pervasive structural changes in Northeast Atlantic coastal ecosystems. Indeed, increased abundances of copepod cosmopolitan species in the western English Channel have been shown to be linked to hydroclimate changes acting in the North Atlantic Ocean (Reygondeau *et al.*, 2015).

The STATICO approach used in this work proved to be an efficient tool to analyse sequences of paired ecological tables. This technique has previously been used by Simier *et al.* (2006) to study the spatial and seasonal variability of fish assemblages in Gambia estuary. Recently, Mazzocchi *et al.* (2012) applied this statistical method in planktonic communities in order to describe the variability of copepod assemblages in relation to local environmental dynamics. In both works, it was possible to visualize the variations in the species distribution and abundance patterns as a function of different environmental scenarios. As already demonstrated by Mendes *et al.* (2011), the STATICO advantage over other classical methods, such as canonical correspondence analysis (CCA) and redundancy analysis (RDA) commonly used in community ecology, is that it provides a complete and consistent analysis framework and the results presented are thus interesting and important for understanding estuarine dynamics. The findings reported in the STATICO compromise analysis suggested that water temperature and salinity were key factors determining the inter-annual occurrence and abundance of *Acartia* species in the Mondego estuary. In estuaries with a wide range of brackish habitats, salinity is thought to determine the spatial segregation of *Acartia* species (*e.g.*, David *et al.*, 2007; Aravena *et al.*, 2009; Leandro *et al.*, 2014). During regular years (in sense of precipitation) the Mondego Estuary presented a dynamic horizontal salinity gradient, with values increasing gradually from the inner to the lower estuary. These hydrographical conditions induced a spatial segregation in the distribution of *A. tonsa* and *A. clausi*.

*A. clausi* is a neritic species that occurs in the Mondego estuary as a result of water mass transport, namely advection during the flood, and its population dynamics is not directly dependent on the hydrological estuarine characteristics. The relatively stability of nertitic waters is reflected on the constant occurrence of *A. clausi* at the most downstream station of Mondego estuary between 2003-2012. Despite the evidence that *A. clausi* can tolerate a broad range of salinities (*e.g.*, Cervetto *et al.*, 1999; Gaudy *et al.*, 2000), our results indicate that a decrease in salinity had an unfavourable effect on *A. clausi* populations, which was revealed by their distribution restricted to the outer part of the estuary. This agrees with observations in other estuarine systems of the European Atlantic coast, where *A. clausi* populations reach higher densities at higher salinity areas (*e.g.*, Uriarte *et al.*, 2005; Albaina and Irigoien, 2007).

In Portugal, a high inter-annual variability and irregular distribution of precipitation was observed between 2003 and 2012, which was responsible for altered hydrological regimes in the Mondego estuary. As a result, drought conditions gave rise to prolonged periods of reduced freshwater inflow. This is in accordance with regional climate models that estimate sligh precipitation decreases for southern Europe by the end of the 21st century (Miranda *et al.*, 2006; IPCC 2007), including in the Iberian Peninsula (Lehner *et al.*, 2006). The reduced river flow, caused by the general evolution of climate conditions, was an important factor that induced the observed trends in *A. tonsa* and *A. clausi* dynamics in the Mondego estuary. First, it is well known that the diffusive and advective properties of freshwater discharge play a critical role in the population distribution patterns and richness, as well as in their temporal variability (*e.g.*, Licandro and Ibanez, 2000; Sundby, 2000; Roman *et al.*, 2001; Lindley and Daykin, 2005). During dry years, the lower advective transport also allowed stabilization of the environmental estuarine conditions, and the recolonization of important species such as *A. tonsa* (Marques *et al.*, 2007).

However, the success of an invader population over time cannot be linked solely to abiotic parameters such as temperature or salinity. Other important factors in the Mondego estuary were total suspended solids and clorophyll *a*. These can be helpful to explain the lower abundance of *A. tonsa* at the downstream stations. The low concentrations of appropriate food in seawater (Paffenhöfer and Stearns, 1988) and the qualitative nature of food (less proteinic material in marine seston) (Gaudy *et al.*, 2000) could explain the difficulties of *A*. *tonsa* to develop in coastal marine waters, because of its inability to filter sufficient food at lower concentrations. Therefore, it is reasonable to consider that processes such as interspecific competition and distinct feeding strategies might also have played a significant role in the observed distribution patterns of the two copepod species.

In sum, local variability of freshwater flow was the dominant signal in the present timeseries, and explained the observed dynamics in *Acartia* populations structure at shorter temporal scales. However, this effect could be masked by larger time-scale phenomena occurring simultaneously, such as a rise in temperature, leading to a higher abundance of opportunistic tolerant-species as *A. tonsa*. Indeed, more than one mechanism was probably operating simultaneously, thus establishing the complex nonlinear relationships between climate variability and zooplankton dynamics (Hays *et al.*, 2005), an issue that needs to be assessed based on longer observation periods.

#### **ACKNOWLEDGMENTS**

We wish to thank two anonymous reviewers and the Editor for their most helpful and constructive comments on the chapter. The present work was supported by FCT (Portuguese Foundation for Science and Technology) through the Postdoctoral grants attributed to SC Marques (SFRH/BPD/110400/ 635 2015) and AL Primo (SFRH/BPD/91030/2012), the Investigador FCT programme attributed to F. Martinho (IF/01410/2012), with funds from European Social Fund and POPH (Human Potential Operational Programme) and the COMPARE Project (FCOMP-01-0124-FEDER- 020850) with funds from the POPH (Portuguese Operational Human Potential Program), the QREN Portugal (Portuguese National Strategic Reference Framework), the MCTES (Portuguese Ministry of Science, Technology, and Higher Education).
