Brief Contents

UNIT I

Supporting the Patient Through the Health Care System

- 1 Using Evidence in Nursing Practice, 1
- 2 Admitting, Transfer, and Discharge, 11
- 3 Communication, 28
- 4 Documentation and Informatics, 47

UNIT II

Vital Signs and Physical Assessment

- 5 Vital Signs, 65
- 6 Health Assessment, 104

UNIT III

Infection Control

- 7 Medical Asepsis, 166
- 8 Sterile Technique, 181

UNIT IV

Activity and Mobility

- 9 Safe Patient Handling, Transfer, and Positioning, 197
- 10 Exercise and Ambulation, 220
- 11 Orthopedic Measures, 249
- 12 Support Surfaces and Special Beds, 273

UNIT V

Safety and Comfort

- 13 Safety and Quality Improvement, 295
- 14 Disaster Preparedness, 322
- 15 Pain Assessment and Basic Comfort Measures, 345
- 16 Palliative Care, 375

UNIT VI

Hygiene

- 17 Personal Hygiene and Bed Making, 391
- 18 Pressure Ulcer Care, 433
- 19 Care of the Eye and Ear, 453

UNIT VII

Medications

- 20 Safe Medication Preparation, 472
- 21 Oral and Topical Medications, 492
- 22 Parenteral Medications, 538

UNIT VIII

Oxygenation

- 23 Oxygen Therapy, 587
- 24 Performing Chest Physiotherapy, 613

- 25 Airway Management, 624
- 26 Closed Chest Drainage Systems, 655
- 27 Emergency Measures for Life Support, 676

UNIT IX

Fluid Balance

- 28 Intravenous and Vascular Access Therapy, 693
- 29 Blood Transfusions, 737

UNIT X

Nutrition

- 30 Oral Nutrition, 754
- 31 Enteral Nutrition, 775
- 32 Parenteral Nutrition, 796

UNIT XI

Elimination

- 33 Urinary Elimination, 809
- 34 Bowel Elimination and Gastric Intubation, 842
- 35 Ostomy Care, 866

UNIT XII

Care of the Surgical Patient

- 36 Preoperative and Postoperative Care, 880
- 37 Intraoperative Care, 908

UNIT XIII

Dressings and Wound Care

- 38 Wound Care and Irrigations, 920
- 39 Dressings, Bandages, and Binders, 942
- 40 Therapeutic Use of Heat and Cold, 976

UNIT XIV

Home Care

- 41 Home Care Safety, 994
- 42 Home Care Teaching, 1015

UNIT XV

Special Procedures

- 43 Specimen Collection, 1052
- 44 Diagnostic Procedures, 1097

Answer Key, 1129

Appendix, 1153

Glossary, 1156

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

BOOK AID
International

Sabre Foundation

As always, this book is dedicated to my children. To be their mother brings more joy, honor, and sense of pride than I could ever imagine. They and their loved ones are truly my shining stars. As they grow, things change, and I now dedicate this book to:

My daughter, Rebecca Lacey Perry Bryan, her husband, Robert Donald Bryan, their three daughters Cora Elizabeth Bryan, Amalie Mary Bryan, and Noelle Anne Bryan, and their son Shepherd Charles Bryan; and to my son, Horace Mitchell "Mitch" Perry and his partner Samuel Jacob Cox.

Anne G. Perry

I wish to dedicate this new edition of our text to the incredible friends, work colleagues, and scholars I have been so fortunate to associate with throughout my career.

Patricia A. Potter

For my husband, who believes in me, even when I do not believe in myself.

Wendy R. Ostendorf

About the Authors

ANNE GRIFFIN PERRY, RN, MSN, EdD, FAAN

Dr. Anne G. Perry, Professor and Associate Dean for Academic Programs at Southern Illinois University—Edwardsville, is a Fellow in the American Academy of Nursing. She received her BSN from the University of Michigan, her MSN from Saint Louis University, and her EdD from Southern Illinois University—Edwardsville. Dr. Perry is a prolific and influential author and speaker. Her work includes four major textbooks (*Basic Nursing*, *Fundamentals*

of Nursing, *Nursing Interventions and Clinical Skills*, and *Clinical Nursing Skills and Techniques*), 24 journal articles, 10 abstracts, and 12 nursing research and education grants. She has presented more than 50 papers at conferences across the United States. She has acted as an editorial board member of numerous

journals (*Journal of Nursing Measurement*, *Intensive Care Medicine*, *AACN Clinical Issues*, and *Perspectives in Respiratory Nursing*), and she was one of a few key consultants on *Mosby's Nursing Skills Videos*, and *Mosby's Nursing Skills Online*. Dr. Perry currently serves on the NANDA board of directors and on the advisory board for Louis and Clark Community College School of Nursing.

Dr. Perry has been involved in the front lines of nursing education since 1973, first as an instructor and then through various roles of leadership at Saint Louis University Hospital and School of Nursing and now at Southern Illinois University—Edwardsville. As a clinician and researcher, Dr. Perry's contributions to pulmonary nursing and nursing language development involve both research and policy making. She has investigated and published findings regarding topics that include weaning from mechanical ventilation, uses of the therapeutic intervention scoring system, critical care, and validation of nursing diagnoses.

PATRICIA A. POTTER, RN, MSN, PhD, FAAN

Dr. Patricia Potter received her BSN at the University of Washington in Seattle, and her MSN and PhD at Saint Louis University in St. Louis, Missouri. A groundbreaking author for more than 25 years, her work includes four major textbooks (*Basic Nursing*, *Fundamentals of Nursing*, *Nursing Interventions and Clinical Skills*, and *Clinical Nursing Skills and Techniques*) and more than 20 journal articles. She has been an unceasing advocate of

evidence-based practice and quality improvement in her roles as administrator, educator and, more recently, director of research.

Dr. Potter has devoted a lifetime to nursing education, practice, and research. She spent a decade teaching at Barnes Hospital School of Nursing and Saint Louis University. She entered into a variety of managerial and administrative roles, ultimately becoming the director of nursing practice at Barnes-Jewish Hospital. In that capacity she sharpened her interest in the development of nursing practice standards and the measurement of patient outcomes in defining nursing practice. Her most recent passion has been in the area of nursing research, specifically cancer family caregiving, the cancer patient symptom experience, and the effects of compassion fatigue on nurses. Dr. Potter is currently a director of research for patient care services at Barnes-Jewish Hospital.

WENDY R. OSTENDORF, RN, MS, EdD, CNE

Dr. Wendy R. Ostendorf received her BSN from Villanova University, her MS from the University of Delaware, and her EdD from the University of Sarasota. She currently serves as an associate professor of nursing in the Division of Nursing and Health Sciences at Neumann University in Aston, Pennsylvania. She has contributed more than 20 chapters to multiple nursing textbooks and has served as section editor for two major textbooks

Nursing Interventions and Clinical Skills, and *Clinical Nursing Skills and Techniques*. She has presented more than 25 papers at conferences at the local, national, and international levels.

Professionally, Dr. Ostendorf has a diverse background in pediatric and adult critical care. She has taught at the undergraduate and graduate level for 30 years. With decades of practice as a clinician, her educational experiences have influenced her teaching philosophy and perceptions of the nursing profession. Dr. Ostendorf's current interests include the history and image of nursing as it has been represented in film, which she has developed into an undergraduate nursing course.

Preface to the Student

Numerous features are built into this text to help you identify key pieces of information and study more efficiently. Additional study tools and review questions may be found on the companion Evolve site: <http://evolve.elsevier.com/Perry/skills>

Evolve media resources are available for every chapter.

Key Terms call attention to critical terminology.

Objectives highlight key information to follow.

22 Parenteral Medications

SKILLS AND PROCEDURES

- Skill 22-1 Preparing Injections: Ampules and Vials, p. 544
- Procedural Guideline 22-1 Mixing Parenteral Medications in One Syringe, p. 549
- Skill 22-2 Administering Intradermal Injections, p. 552
- Skill 22-3 Administering Subcutaneous Injections, p. 555
- Skill 22-4 Administering Intramuscular Injections, p. 562
- Skill 22-5 Administering Medications by Intravenous Bolus, p. 568
- Skill 22-6 Administering Intravenous Medications by Piggyback, Intermittent Infusion Sets, and Mini-Infusion Pumps, p. 574
- Skill 22-7 Administering Continuous Subcutaneous Medications, p. 580

MEDIA RESOURCES

- Evolve <http://evolve.elsevier.com/Perry/skills>
- Review Questions
- Video Clips
- Audio Glossary
- Nursing Skills Online

KEY TERMS

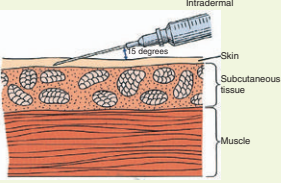

Adverse reaction	Compatibility	Induration	Parenteral
Air embolus	Continuous subcutaneous infusion (CSOI or CSCI)	Infiltration	Phlebitis
Allergic reaction	Diluent	Infusion	Piggyback infusion
Ampule	Extravasation	Injection	Saline lock
Anaphylactic reaction	Hematemesis	Intradermal (ID) injection	Subcutaneous injection
Aqueous	Hematuria	Intramuscular (IM) injection	Vial
Aspirate	Hypodermoclysis	Intravenous (IV) injection	Volume-control administration set (Volutrol)
Blunt-tip vial access cannula	Incompatibility	Medication administration record (MAR)	Z-track method
Bolus			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Correctly prepare injectable medications from a vial and an ampule.
- Identify advantages, disadvantages, and risks of administering medications by each injection route.
- Evaluate the effectiveness and outcomes of administering medications by each injection route.
- Explain the importance of selecting the proper-size syringe and needle for an injection.
- Discuss factors to consider when selecting injection sites.
- Discuss ways to promote patient comfort while administering an injection.
- Correctly administer intradermal, subcutaneous, and intramuscular injections.
- Compare the risks of three different intravenous routes.
- Correctly administer an intravenous infusion by intravenous piggyback, intermittent infusion, or bolus through a hanging intravenous line or saline lock.
- Initiate, maintain, and discontinue a continuous subcutaneous infusion.

554 CHAPTER 22 Parenteral Medications

STEP	RATIONALE
<ul style="list-style-type: none"> • Inject medication slowly. Normally you feel resistance. If not, needle is too deep; remove and begin again. <p>Clinical Decision Point It is not necessary to aspirate because dermis is relatively avascular.</p> <ul style="list-style-type: none"> d While injecting medication, note that small bleb (approximately 6 mm [$\frac{1}{4}$ inch]) resembling mosquito bite appears on skin surface (see illustration). • After withdrawing needle, apply alcohol swab or gauze gently over site. <p>15 Help patient to comfortable position.</p> <p>16 Discard uncapped needle or needle enclosed in safety shield and attached syringe in puncture- and leak-proof receptacle.</p> <p>17 Remove gloves and perform hand hygiene.</p> <p>18 Stay with patient for several minutes and observe for any allergic reactions.</p>	<p>Slow injection minimizes discomfort at site. Dermal layer is tight and does not expand easily when you inject solution.</p> <p>Bleb indicates that you deposited medication in dermis.</p> <p>Do not massage site. Apply bandage if needed.</p> <p>Gives patient sense of well-being. Prevents injury to patients and health care personnel. Recapping needles increases risk for a needlestick injury (OSHA, 2012). Reduces transmission of microorganisms. Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.</p>
 <p>STEP 14b Intradermal needle tip inserted into dermis.</p>	 <p>STEP 14d Injection creates small bleb.</p>
	
<p>EVALUATION</p> <ol style="list-style-type: none"> 1 Return to room in 15 to 30 minutes and ask if patient feels any acute pain, burning, numbness, or tingling at injection site. 2 Ask patient to discuss implications of skin testing and signs of hypersensitivity. 3 Inspect bleb. <i>Optional:</i> Use skin pencil and draw circle around perimeter of injection site. Read TB test site at 48 to 72 hours; look for induration (hard, dense, raised area) of skin around injection site of: <ul style="list-style-type: none"> • 15 mm or more in patients with no known risk factors for tuberculosis. • 10 mm or more in patients who are recent immigrants; injection drug users; residents and employees of high-risk settings; patients with certain chronic illnesses; children less than 4 years of age; and infants, children, and adolescents exposed to high-risk adults. <p>Continued discomfort could indicate injury to underlying tissues. Patient's ability to recognize signs of skin testing helps to ensure timely reporting of results. Determines if reaction to antigen occurs; indication positive for TB or tested allergens.</p> <p>Degree of reaction varies based on patient condition. Site must be read at various intervals to determine test results. Pencil marks make site easy to find. You determine results of skin testing at various times, based on type of medication used or type of skin testing completed. Manufacturer directions determine when to read test results.</p>	

Clinical Decision Points highlight points to consider when performing skills to ensure effective outcomes and promote safety.

Extensive illustrations demonstrate step-by-step procedures for more thorough understanding.

Quick Response codes may be scanned to link to video clips directly from the text page.

STEP	RATIONALE
8 Dispose of supplies in puncture- and leak-proof container.	Prevents accidental needlesticks (OSHA, 2012).
9 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
10 Stay with patient for several minutes and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.

EVALUATION	
1 Observe patient for signs or symptoms of adverse reaction.	IV medications act rapidly.
2 During infusion periodically check infusion rate and condition of IV site.	IV must remain patent for proper drug administration. Infiltration at IV site requires discontinuing infusion.
3 Ask patient to explain purpose and side effects of medication.	Evaluates patient's understanding of instruction.

Unexpected Outcomes	Related Interventions
1 Patient develops adverse or allergic reaction to medication.	<ul style="list-style-type: none"> Stop medication infusion immediately. Follow agency policy or guidelines for appropriate response to allergic reaction (e.g., administration of antihistamine such as diphenhydramine [Benadryl] or epinephrine) and reporting of adverse medication reactions. Notify patient's health care provider of adverse effects immediately. Add allergy information to patient record per agency policy.
2 Medication does not infuse over established time frame.	<ul style="list-style-type: none"> Determine reason (e.g., improper calculation of flow rate, poor positioning of IV needle at insertion site, infiltration). Take corrective action as indicated.
3 IV site shows signs of infiltration or phlebitis (see Chapter 28).	<ul style="list-style-type: none"> Stop IV infusion and discontinue access device. Treat IV site as indicated by agency policy. Insert new IV catheter if therapy continues. For infiltration determine how harmful medication is to subcutaneous tissue. Provide IV extravasation care (e.g., injecting phentolamine [Regitine] around IV infiltration site) as indicated by agency policy or consult pharmacist to determine appropriate follow-up care.

Recording and Reporting

- Immediately record medication, dose, route, infusion rate, and date and time administered on MAR or computer printout. Include initials or signature.
- Record volume of fluid in medication bag or Volurol on intake and output (I&O) form.
- Report any adverse reactions to patient's health care provider.

Special Considerations

Teaching

- Review all IV medications with patient and significant others, including why patient is receiving the medication and potential adverse effects, including allergic responses.
- Teach patient and/or significant others not to alter the ordered rate of infusion without consulting the prescriber. IV medications need to be infused at a specified rate to achieve their desired effect and avoid adverse effects.
- Teach patient and/or significant others to report any adverse effects immediately.

Pediatric

- Infants and young children are more vulnerable to alterations in fluid balance and do not adjust quickly to changes in fluid

balance. Therefore, to assess fluid balance, monitor I&O carefully when infusing IV medications (Hockenbery and Wilson, 2011).

Gerontologic

- Altered pharmacokinetics of medications and the effects of polypharmacy place older adults at risk for medication-related errors. Carefully monitor the response of older adults to IV medications (Touhy and Jetz, 2010).
- Older adults are at risk for developing fluid volume overload and require careful assessment for signs of overload and heart failure.

Home Care

- Patients or significant others who administer IV medications at home require education about the steps of medication administration. The patient or significant other needs to perform several return demonstrations of IV medication administration before performing this skill independently. In addition, patients and significant others need to know signs of IV medication administration complications such as phlebitis and infiltration and what to do for any problems.

Unexpected Outcomes/Related Interventions help you anticipate problems and respond appropriately.

Recording and Reporting guidelines for each skill detail what to document and report.

Special Considerations indicate special teaching considerations, as well as procedure modifications needed for pediatric, gerontologic, and home care populations.

NSO icon links to online course lessons.

Home Care

- Self-administration of an IM injection is difficult, especially in the vastus lateralis. Teach a significant other to identify and administer injections at this site.
- Instruct adult patients who require frequent injections to apply EMLA cream to the injection site before administration.

- Patients need instruction in safe disposal of syringes and needles (see Skill 22-3, Home Care Considerations).
- See Skill 41-1 for information about modifying safety risks in the home.

SKILL 22-5 Administering Medications by Intravenous Bolus

NSO IV Medication Administration Module 1 Lesson 4

In the past nurses often mixed medications into large volumes of intravenous (IV) fluids (500 to 1000 mL). However, today's safety standards and evidence-based practice no longer support this practice on a routine basis (Infusion Nurses Society [INS], 2011; ISMP, 2011; TJC, 2012). Many patient safety risks such as incorrect calculation, poor aseptic technique, incorrect labeling, pump programming errors, lack of medication knowledge, and mix-up with another medication occur when nurses have to prepare medications in IV containers on patient care units. There are a number of current best practices for preparation and administration of IV medication (Box 22-4).

An IV bolus is one method of medication administration currently practiced on patient care units. It introduces a concentrated dose of a medication directly into a vein by way of an existing IV access. An IV bolus or "push" usually requires small volumes of fluid, which is an advantage for patients who are at risk for fluid

overload. Administering medications by IV bolus is common in emergencies when you need to deliver a fast-acting medication quickly. Because these medications act quickly, it is essential that you monitor patients closely for adverse reactions. Agencies have policies and procedures that identify the medications that nurses are allowed to administer by IV push and other IV routes. These policies are based on the medication, compatibility and availability of staff, and type of monitoring equipment available. There are advantages and disadvantages to administering IV push medications (Box 22-5).

The IV bolus is a dangerous method to administer medications because it allows no time to correct errors. Administering an IV push medication too quickly can cause death. Therefore be very careful in calculating the correct amount of the medication to give. In addition, a bolus may cause direct irritation to the lining of blood vessels; thus always confirm placement of the IV catheter or needle. Never give an IV bolus if the insertion site appears edematous or reddened or if the IV fluids do not flow at the ordered rate. Accidental injection of some medications into tissues surrounding a vein can cause pain, sloughing of tissues, and abscesses.

Verify the rate of administration of IV push medication using agency guidelines or a medication reference manual. The Institute for Safe Medication Practices (ISMP, 2011) has identified the

BOX 22-4 Best Practices for Administration of Intravenous Solutions and Medications

- Use standardized concentrations and dosages of medication.
- Use standardized procedures for ordering, preparing, and administering intravenous (IV) medications.
- Administer solutions and medications prepared and dispensed from the pharmacy or as commercially prepared when possible.
- Never prepare high-alert medications (e.g., heparin, dopamine, dobutamine, nitroglycerin, potassium, antibiotics, or morphine) on a patient care unit.
- Use standardized infusion concentrations of "high-alert" medications.
- Standardize the storage of IV medications.
- Use the mnemonic CATS-PRRR to help remember safety checks for administering IV medications: C, compatibilities; A, allergies; T, tubing correct; S, site checked; P, pump safety checked; R, right rate; R, release clamps; R, return and reassess the patient (Billings & Kowalski, 2005).
- Use standardized label practices. Bold patient name, generic drug name, and patient-specific dose.
- Correctly use technology such as intelligent-infusion devices, bar code-assisted medication administration, and electronic medication administration record.

BOX 22-5 Advantages and Disadvantages of the Intravenous Push Method

Advantages	Disadvantages
<ul style="list-style-type: none"> There is rapid onset of medication effects, which is useful in patients experiencing critical or emergent health problems. Medications can be prepared quickly and given over a shorter time than by intravenous (IV) piggyback. Doses of short-acting medications can be titrated based on a patient's needs and responses to the drug therapy. This is important for infants, children, and older patients. Method provides a more accurate dose of medication delivered because no medication is left in intravenously. 	<ul style="list-style-type: none"> Not all medications can be delivered by IV push. There is higher risk for infusion reactions; some are mild to severe because the medication action peaks quickly. When giving medication quickly (e.g., less than 1 minute), there is very little opportunity to stop the injection reaction if an adverse reaction occurs. Risk for infiltration and phlebitis is increased, especially if a highly concentrated medication, a small peripheral vein, or a short venous access device is used. Hypersensitivity reaction can cause an immediate or delayed systemic reaction to a medication, requiring supportive measures.

Mosby's Nursing Video Skills, Student Version, 4th edition contains 130 entirely new, high-definition video skills.

Preface to the Instructor

The evolution of technology and knowledge influences the way we teach clinical skills to nursing students and improves the quality of care possible for every patient. However, the foundation for success in performing nursing skills remains a competent, well-informed nurse who thinks critically and asks the right questions at the right time. That outcome is the driving factor behind this new edition.

In this eighth edition of *Clinical Nursing Skills & Techniques* we have adapted our headings to bring content relevant to the *Quality and Safety Education for Nurses* (QSEN) initiative to the forefront. You will now find sections on *Evidence-Based Practice*, *Patient-Centered Care*, *Safety*, and *Documentation and Collaboration*, making the related content even more visible. The opening chapter on *Using Evidence in Nursing Practice* prepares the student to understand and use the evidence-based practice information included in every chapter.

New content areas include **Communicating with a Cognitively Impaired Patient** (Skill 3-5), **Adverse Event/Incident Reporting** (Procedural Guideline 4-4), **Caring for Patients with Multidrug-Resistant Organisms (MDRO) and *Clostridium difficile*** (Procedural Guideline 7-1), and **Wheelchair Transfer Techniques** (Procedural Guideline 9-1). All other topics have been updated to the most recent standards in nursing practice.

Your students will find that *Clinical Nursing Skills & Techniques* provides a comprehensive resource that will serve them well through their nursing training and right into their clinical practice careers.

CLASSIC FEATURES

- **Over 200 basic, intermediate, and advanced nursing skills and procedures.**
- **Five-step nursing process** format provides a consistent presentation that helps students apply the process while learning each skill.
- **Skills and Procedures list, Objectives, and Key Terms** open each chapter.
- **Over 1200 full-color photos and drawings** help students master the material covered.
- **Evidence-Based Practice** in each chapter presents students with the newest scientific evidence for the procedures and protocols presented. Recent research findings are discussed, and their implications for patient care are explored.
- **Rationales** are given for steps within skills so students learn the *why* as well as the *how* of each skill. Rationales include citations from the current literature.
- **Clinical Decision Points** alert students to key steps that affect patient outcomes and help them modify care as needed to meet individual patient needs.
- **Recording and Reporting** sections follow the evaluation discussion and alert students to what information should be documented in each situation.
- **Delegation and Collaboration** defines communication within the patient care team and the nurse's responsibility when delegating to assistive personnel.
- **Unexpected Outcomes and Related Interventions** remind students to be alert for potential problems and help them determine appropriate nursing interventions.
- **Special Considerations** sections include additional considerations when performing the skill for specific populations of patients or in specific settings and may include:
 - **Teaching Considerations**
 - **Pediatric Considerations**
 - **Geriatric Considerations**
 - **Home Care Considerations**
- **Glossary** defines all key terms.

NEW TO THIS EDITION:

- **Quick Response codes** (scan with smartphone or tablet with camera to view video clips) on the text pages link video clips to the appropriate skill or procedure, allowing students to view the video immediately after reading the implementation section of the skill.
- **NSO icon** links text content with the new edition of *Nursing Skills Online*, which has been simultaneously revised with the textbook to provide completely coordinated information.
- **Patient-Centered Care** section in each chapter prepares nurses to recognize the importance of having patients partner in performing skills in a compassionate and coordinated way based on respect for patient's preferences, values, and needs (QSEN core competency).
- **Safety Guidelines** section in each chapter covers global recommendations on the safe execution of the particular skill set covered (QSEN core competency).
- **Expanded and improved end-of-chapter exercises** include a case study as well as review questions.
- **Additional review questions on Evolve** include a brand new set of unique questions for every chapter.
- **TEACH for RN** instructor manual helps you capitalize on the all new clinical material in the text, new skills video series, and online course. Additional case studies and discussion questions unique to the TEACH manual expand the in-class material available to you.
- For the first time, an **Image Collection is available** with *Clinical Nursing Skills & Techniques*.

Contents

UNIT I

Supporting the Patient Through the Health Care System

- 1 Using Evidence in Nursing Practice, 1**
Patricia A. Potter, RN, MSN, PhD, FAAN
A Case for Evidence, 2
Steps of Evidence-Based Practice, 2
Impact of Evidence-Based Practice on Nursing, 9
- 2 Admitting, Transfer, and Discharge, 11**
Wendy R. Ostendorf, RN, MS, EdD, CNE
Skill 2-1 Admitting Patients, 12
Skill 2-2 Transferring Patients, 19
Skill 2-3 Discharging Patients, 22
- 3 Communication, 28**
Jacqueline Raybuck Saleeby, PhD, RN, BCCS
Skill 3-1 Establishing the Nurse-Patient Relationship, 30
Skill 3-2 Communicating with an Anxious Patient, 36
Skill 3-3 Communicating with an Angry Patient, 38
Skill 3-4 Communicating with a Depressed Patient, 41
Skill 3-5 Communicating with a Cognitively Impaired Patient, 43
- 4 Documentation and Informatics, 47**
Kathleen Gerhart-Gibson, MSN, RN, CCRN
Procedural Guideline 4-1 Giving a Hand-Off Report, 60
Procedural Guideline 4-2 Documenting Nurses' Progress Notes, 61
Procedural Guideline 4-3 Adverse Event/Incident Reporting, 62

UNIT II

Vital Signs and Physical Assessment

- 5 Vital Signs, 65**
Susan Jane Fetzer, RN, BSN, MSN, MBA, PhD
Skill 5-1 Measuring Body Temperature, 67
Skill 5-2 Assessing Radial Pulse, 77
Skill 5-3 Assessing Apical Pulse, 81
Procedural Guideline 5-1 Assessing Apical-Radial Pulse Deficit, 85
Skill 5-4 Assessing Respirations, 86
Skill 5-5 Assessing Arterial Blood Pressure, 90
Procedural Guideline 5-2 Assessing Blood Pressure Electronically, 99
Procedural Guideline 5-3 Measuring Oxygen Saturation (Pulse Oximetry), 101
- 6 Health Assessment, 104**
Wendy R. Ostendorf, RN, MS, EdD, CNE
Skill 6-1 General Survey, 112
Skill 6-2 Head and Neck Assessment, 120
Skill 6-3 Thorax and Lung Assessment, 125
Skill 6-4 Cardiovascular Assessment, 132
Skill 6-5 Abdominal Assessment, 143
Skill 6-6 Genitalia and Rectum Assessment, 151

Skill 6-7 Musculoskeletal and Neurologic Assessment, 154
Procedural Guideline 6-1 Monitoring Intake and Output, 161

UNIT III

Infection Control

- 7 Medical Asepsis, 166**
Ruth M. Curchoe, RN, MSN, CIC
Skill 7-1 Hand Hygiene, 168
Skill 7-2 Caring for Patients Under Isolation Precautions, 172
Procedural Guideline 7-1 Caring for Patients with Multidrug-Resistant Organisms (MDRO) and *Clostridium difficile*, 178
- 8 Sterile Technique, 181**
Ruth M. Curchoe, RN, MSN, CIC
Skill 8-1 Applying and Removing Cap, Mask, and Protective Eyewear, 183
Skill 8-2 Preparing a Sterile Field, 186
Skill 8-3 Sterile Gloving, 191

UNIT IV

Activity and Mobility

- 9 Safe Patient Handling, Transfer, and Positioning, 197**
Rita Wunderlich, MSN, PhD
Skill 9-1 Using Safe and Effective Transfer Techniques, 199
Procedural Guideline 9-1 Wheelchair Transfer Techniques, 209
Skill 9-2 Moving and Positioning Patients in Bed, 210
- 10 Exercise and Ambulation, 220**
Rita Wunderlich, MSN, PhD
Procedural Guideline 10-1 Performing Range-of-Motion Exercises, 222
Skill 10-1 Performing Isometric Exercises, 227
Skill 10-2 Continuous Passive Motion Machine, 231
Procedural Guideline 10-2 Applying Elastic Stockings and Sequential Compression Device, 234
Skill 10-3 Assisting with Ambulation and Use of Canes, Crutches, and Walker, 236
- 11 Orthopedic Measures, 249**
Pamela A. Cupec, RN, MS, ONC, CRRN, ACM; Wendy R. Ostendorf, RN, MS, EdD, CNE
Skill 11-1 Assisting with Cast Application, 251
Procedural Guideline 11-1 Care of a Patient During Cast Removal, 257
Skill 11-2 Care of a Patient in Skin Traction, 258
Skill 11-3 Care of a Patient in Skeletal Traction and Pin Site Care, 263
Skill 11-4 Care of a Patient with an Immobilization Device, 268
- 12 Support Surfaces and Special Beds, 273**
Kristin L. Mauk, PhD, DNP, RN, CRRN, GCNS-BC, GNP-BC, FAAN
Procedural Guideline 12-1 Selection of Pressure-Reducing Support Surfaces, 276
Skill 12-1 Placing a Patient on a Support Surface, 278

- Skill 12-2 Placing a Patient on an Air-Suspension or Air-Fluidized Bed, 283
- Skill 12-3 Placing a Patient on a Bariatric Bed, 287
- Skill 12-4 Placing a Patient on a Rotokinetic Bed, 289

UNIT V

Safety and Comfort

13 Safety and Quality Improvement, 295

Patricia A. Potter, RN, MSN, PhD, FAAN

- Skill 13-1 Fall Prevention in a Health Care Agency, 297
- Skill 13-2 Designing a Restraint-Free Environment, 304
- Skill 13-3 Applying Physical Restraints, 307
- Procedural Guideline 13-1 Fire, Electrical, and Chemical Safety, 312
- Skill 13-4 Seizure Precautions, 315
- Procedural Guideline 13-2 Conducting a Root Cause Analysis, 319

14 Disaster Preparedness, 322

Paula Ann Stangeland, PhD, RN, CRRN

- Skill 14-1 Care of a Patient After Biologic Exposure, 330
- Skill 14-2 Care of a Patient After Chemical Exposure, 336
- Skill 14-3 Care of a Patient After Radiation Exposure, 340

15 Pain Assessment and Basic Comfort Measures, 345

Cathy E. Flasar, MSN, APRN; Anne Griffin Perry, RN, MSN, EdD, FAAN

- Skill 15-1 Providing Pain Relief, 348
- Skill 15-2 Patient-Controlled Analgesia, 353
- Skill 15-3 Epidural Analgesia, 358
- Skill 15-4 Local Anesthetic Infusion Pump for Analgesia, 363
- Skill 15-5 Nonpharmacologic Pain Management, 366

16 Palliative Care, 375

Valeria J. Yancey, PhD, RN, HNC, CHPN

- Skill 16-1 Supporting Patients and Families in Grief, 378
- Skill 16-2 Symptom Management at the End of Life, 380
- Skill 16-3 Care of a Body After Death, 385

UNIT VI

Hygiene

17 Personal Hygiene and Bed Making, 391

Pamela L. Ostby, RN, MSN, OCN®

- Skill 17-1 Bathing a Patient, 395
- Procedural Guideline 17-1 Perineal Care, 403
- Procedural Guideline 17-2 Use of Disposable Bed Bath, Tub, or Shower, 404
- Skill 17-2 Oral Hygiene, 405
- Procedural Guideline 17-3 Care of Dentures, 410
- Skill 17-3 Performing Mouth Care for the Unconscious or Debilitated Patient, 411
- Skill 17-4 Hair Care—Combing and Shaving, 414
- Procedural Guideline 17-4 Hair Care—Shampooing, 418
- Skill 17-5 Performing Nail and Foot Care, 420
- Skill 17-6 Care of a Patient's Environment, 425
- Procedural Guideline 17-5 Making an Occupied Bed, 428
- Procedural Guideline 17-6 Making an Unoccupied Bed, 430

18 Pressure Ulcer Care, 433

Janice C. Colwell, RN, MSN, CWOCN, FAAN

- Skill 18-1 Risk Assessment, Skin Assessment, and Prevention Strategies, 437
- Skill 18-2 Treatment of Pressure Ulcers, 444

19 Care of the Eye and Ear, 453

Anne Griffin Perry, RN, MSN, EdD, FAAN

- Procedural Guideline 19-1 Eye Care for Comatose Patients, 455
- Procedural Guideline 19-2 Taking Care of Contact Lenses, 455
- Procedural Guideline 19-3 Taking Care of an Artificial Eye, 458
- Skill 19-1 Eye Irrigation, 460
- Skill 19-2 Ear Irrigation, 463
- Skill 19-3 Care of Hearing Aids, 466

UNIT VII

Medications

20 Safe Medication Preparation, 472

Roberta L. Harrison, PhD, RN, CRRN

- Patient-Centered Care, 473
- Pharmacologic Concepts, 473
- Types of Medication Action, 474
- Routes of Administration, 477
- Medication Distribution, 477
- Systems of Medication Measurement, 478
- Safe Medication Administration, 480
- Medication Preparation, 485
- Evidence-Based Practice, 485
- Nursing Process, 488
- Special Handling of Controlled Substances, 489
- Reporting Medication Errors, 489
- Patient and Family Teaching, 489

21 Oral and Topical Medications, 492

Nicole Bartow, RN, MSN; Anne Griffin Perry, RN, MSN, EdD, FAAN

- Skill 21-1 Administering Oral Medications, 494
- Skill 21-2 Administering Medications Through an Enteral Feeding Tube, 500
- Skill 21-3 Applying Topical Medications to the Skin, 505
- Skill 21-4 Instilling Eye and Ear Medications, 509
- Skill 21-5 Administering Nasal Instillations, 516
- Skill 21-6 Using Metered-Dose Inhalers, 520
- Procedural Guideline 21-1 Using Dry Powder Inhaled Medications, 525
- Skill 21-7 Using Small-Volume Nebulizers, 526
- Skill 21-8 Administering Vaginal Instillations, 529
- Skill 21-9 Administering Rectal Suppositories, 533

22 Parenteral Medications, 538

Wendy R. Ostendorf, RN, MS, EdD, CNE

- Skill 22-1 Preparing Injections: Ampules and Vials, 544
- Procedural Guideline 22-1 Mixing Parenteral Medications in One Syringe, 549
- Skill 22-2 Administering Intradermal Injections, 552
- Skill 22-3 Administering Subcutaneous Injections, 555
- Skill 22-4 Administering Intramuscular Injections, 562
- Skill 22-5 Administering Medications by Intravenous Bolus, 568
- Skill 22-6 Administering Intravenous Medications by Piggyback, Intermittent Infusion Sets, and Mini-Infusion Pumps, 574
- Skill 22-7 Administering Continuous Subcutaneous Medications, 580

UNIT VIII**Oxygenation****23 Oxygen Therapy, 587***Jeanne Marie Papa, MBE, MSN, ACNP-BC, CCRN*

- Skill 23-1 Applying a Nasal Cannula or Oxygen Mask, 590
- Skill 23-2 Administering Oxygen Therapy to a Patient with an Artificial Airway, 595
- Skill 23-3 Using Incentive Spirometry, 597
- Skill 23-4 Care of a Patient Receiving Noninvasive Positive-Pressure Ventilation, 600
- Procedural Guideline 23-1 Use of a Peak Flow Meter, 604
- Skill 23-5 Care of a Patient on a Mechanical Ventilator, 604

24 Performing Chest Physiotherapy, 613*Anne Griffin Perry, RN, MSN, EdD, FAAN*

- Skill 24-1 Performing Postural Drainage, 615
- Procedural Guideline 24-1 Using an Acapella Device, 619
- Procedural Guideline 24-2 Performing Percussion, Vibration, and Shaking, 620

25 Airway Management, 624*Kelly Jo Cone, RN, PhD, CNE*

- Skill 25-1 Performing Oropharyngeal Suctioning, 626
- Skill 25-2 Airway Suctioning, 629
- Procedural Guideline 25-1 Closed (In-Line) Suction, 638
- Skill 25-3 Performing Endotracheal Tube Care, 639
- Skill 25-4 Performing Tracheostomy Care, 644
- Skill 25-5 Inflating the Cuff on an Endotracheal or Tracheostomy Tube, 650

26 Closed Chest Drainage Systems, 655*Kelly Jo Cone, RN, PhD, CNE*

- Skill 26-1 Managing Close Chest Drainage Systems, 659
- Skill 26-2 Assisting with Removal of Chest Tubes, 668
- Skill 26-3 Autotransfusion of Chest Tube Drainage, 671

27 Emergency Measures for Life Support, 676*Nelda K. Martin, RN, CCNS, ANP-BC*

- Skill 27-1 Inserting an Oropharyngeal Airway, 677
- Skill 27-2 Use of an Automated External Defibrillator, 680
- Skill 27-3 Code Management, 683

UNIT IX**Fluid Balance****28 Intravenous and Vascular Access Therapy, 693***Virginia Strootman, RN, MS, CRNI*

- Skill 28-1 Initiating Intravenous Therapy, 697
- Skill 28-2 Regulating Intravenous Flow Rate, 708
- Skill 28-3 Changing Intravenous Solutions, 713
- Skill 28-4 Changing Infusion Tubing, 716
- Skill 28-5 Changing a Short Peripheral Intravenous Dressing, 719
- Procedural Guideline 28-1 Discontinuing a Short Peripheral Intravenous Access, 723
- Skill 28-6 Caring for Central Vascular Access Devices, 724

29 Blood Transfusions, 737*Virginia Strootman, RN, MS, CRNI*

- Skill 29-1 Initiating Blood Therapy, 742
- Skill 29-2 Monitoring for Adverse Transfusion Reactions, 750

UNIT X**Nutrition****30 Oral Nutrition, 754***Terry L. Wood, PhD, RN, CNE*

- Skill 30-1 Performing a Nutritional Assessment, 760
- Skill 30-2 Assisting the Adult Patient with Oral Nutrition, 764
- Skill 30-3 Aspiration Precautions, 768

31 Enteral Nutrition, 775*Patricia H. Worthington, MSN, RN, CNSC*

- Skill 31-1 Inserting and Removing a Small-Bore Nasogastric or Nasoenteric Feeding Tube, 777
- Skill 31-2 Verifying Feeding Tube Placement, 782
- Skill 31-3 Irrigating a Feeding Tube, 786
- Skill 31-4 Administering Enteral Nutrition: Nasoenteric, Gastrostomy, or Jejunostomy Tube, 788
- Procedural Guideline 31-1 Care of a Gastrostomy or Jejunostomy Tube, 793

32 Parenteral Nutrition, 796*Charlene Compher, PhD, RD, CNSC, LDN, FADA; Phyllis Ann Schiavone, MSN, CRNP*

- Skill 32-1 Administering Parenteral Nutrition Through a Central Line, 801
- Skill 32-2 Administering Parenteral Nutrition Through a Peripheral Line, 804

KEY TERMS

Clinical guidelines	Peer reviewed
Evidence-based practice (EBP)	PICOT question
Hypothesis	Variable

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Define the key terms listed.
- Discuss how evidence improves the relevance and accuracy of nursing skills.
- Describe the six steps of evidence-based practice.
- Explain the components of a PICOT question.
- Discuss the process for evaluating evidence in the literature.
- Identify the elements to review when critiquing a scientific article.
- Discuss ways to apply evidence in nursing practice.
- Explain the importance of identifying outcomes in the evaluation of an evidence-based practice change.

Cathy works on a medical oncology unit where patients undergo chemotherapy and radiation for leukemia, lymphoma, and other forms of cancer. Because of their chemotherapy, many patients experience a drop in their platelet count and clotting factors, increasing their risk for bleeding. Cathy recently cared for a 42-year-old woman who fell while trying to get to the bathroom and hit her head against the bed frame, resulting in a serious intracranial bleed. Cathy discusses the situation with two nurse colleagues and asks, "How can we reduce the number of falls and injuries to our patients on the oncology unit?" The nurse specialist for the unit tells Cathy, "I heard about an approach to fall prevention on one of the surgical floors; it involves hourly rounding. Let's ask this question, *"In adult oncology patients, will the use of hourly rounding compared with the current fall prevention protocol affect the incidence of falls during hospitalization?"* Feeling frustrated that their existing fall prevention protocol was not effective in reducing falls, the group agrees that the question is the right one to search in the literature.

This clinical case study highlights how professional nurses address problems in their practice. Evidence-based practice (EBP) is a process of making informed decisions about the way you care for patients. It all begins with asking clinical questions. Clinical questions lead nurses like Cathy and her colleagues to find evidence from the research literature, quality improvement data, risk management trends, and the opinions of nurse experts. Nurses then apply the evidence to make relevant and informed changes in practice such as fall prevention in the case study.

There are elements of all nursing procedures within this textbook that are evidence based. For example, the length of time necessary to wash hands, the technique for determining the position of a feeding tube in the stomach, and the technique for giving an intramuscular injection are based on evidence. Clinical research led to the answers for how these nursing procedures should be performed. The use of such evidence in practice enables clinicians like Cathy to provide the highest quality of care to their patients and families. EBP requires nurses to always think about their practice, raise pertinent clinical questions, search for the evidence that pertains to their questions, apply relevant evidence in practice changes, and evaluate the outcomes.

A CASE FOR EVIDENCE

One of the key messages in the 2010 report of the Institute of Medicine (IOM), *The Future of Nursing: Leading Change, Advancing Health*, is for nurses to be full partners with physicians and other health care professionals in redesigning health care in the United States (IOM, 2010). Nursing is well positioned to lead change and advance health through the use of EBP, a process that makes nurses more autonomous in changing health care practices. The IOM recommends that nurses be accountable for their own contributions to delivering high-quality care and work collaboratively with leaders from other health professions. The EBP process is a perfect vehicle to achieve that aim.

EBP is a guide for making accurate, timely, and appropriate clinical decisions. It is an interdisciplinary process that results in applying the newest knowledge available in health care sciences to the bedside. It is important to translate best evidence into best practices at a patient's bedside. For example, using a sliding board to transfer a patient from bed to stretcher instead of lifting and using the research-based Braden scale to routinely assess a patient's risk for skin breakdown are examples of using evidence at the bedside. Evidence-based practice is a problem-solving approach to the delivery of health care that integrates the best evidence from scientific studies and patient care data along with clinicians' expertise and patient preferences and values (Melnyk et al., 2009). In this textbook you learn that use of evidence in nursing procedures or skills provides scientific guidelines for how to perform skills more effectively and improve patient outcomes.

As a professional nurse you need to stay informed and aware of the most current evidence. Typically new students diligently read their textbooks and assigned scientific articles. A good textbook incorporates current evidence into the practice guidelines and nursing skills at the time it is published. However, because a textbook relies on the scientific literature, a portion of the book can become outdated by the time it is published. Articles from nursing and the health care literature are available on almost any topic involving nursing practice. New research is reported every day. Although the scientific basis of nursing practice has grown, some practices are still not "research based" (based on findings from well-designed research studies) because findings are inconclusive or researchers have not yet studied the practices. For example, in the past nurses changed intravenous (IV) site dressings daily and applied antibiotic ointment to reduce the incidence of infection at a site. However, there was no evidence at the time to support this practice. IV care was based on tradition. Recent research has shown that topical antibiotics offer no benefit and daily dressing changes are not beneficial unless a dressing becomes soiled or compromised. In addition, a current standard of care is to cleanse an adult's IV site with chlorhexidine antiseptic solution, not antibiotic ointment (Infusion Nurses Society [INS], 2011). The challenge is to obtain the very best, most current information at the right time, when you need it for patient care.

The best evidence comes from well-designed, systematically conducted research studies found in scientific journals. Unfortunately much of that evidence does not reach the bedside. Many health care settings do not have a process to help staff adopt new evidence in practice. Nurses in practice settings, unlike educational settings, may not have easy access to databases for scientific literature. Instead they often care for patients on the basis of tradition, preferences, or convenience. Because there are often obstacles to research-based practice in clinical settings, it is important for administrators to provide a supportive environment and adequate facilitation of change. Researchers have found that

implementation of EBP is enhanced when organization leaders commit to improving practices and there are links to management structures and processes to support change (VanDeusen et al., 2010).

Research evidence alone is often not enough to justify a change in practice (Melnyk et al., 2010). You must also use sources of evidence that include quality improvement and risk management data, infection control data, retrospective or concurrent chart review, and clinicians' expertise. Nonresearch-based evidence is very valuable to fully inform you of practice issues in your setting. But remember, it is important that you not rely on nonresearch-based evidence alone. Research-based evidence is more likely to be timely, accurate, and relevant. When you face a clinical problem, seek out all sources of evidence to find the best solution in caring for patients.

Even when you use the best evidence available, application and outcomes will differ based on your patients' values, preferences, concerns, and/or expectations. As a nurse you develop critical thinking skills to determine whether evidence is relevant and appropriate to your patients and to a clinical situation. For example, some research suggests that therapeutic massage is effective in promoting sleep and reducing fatigue in patients who undergo coronary artery bypass surgery (Nerbass et al., 2010). However, if you care for a patient from a culture in which touch is a taboo, the use of massage is inappropriate. Using your clinical expertise and considering patients' cultures, values, and preferences ensure that you apply new evidence in practice both ethically and appropriately. EBP requires good nursing judgment; it is not finding research evidence and applying it blindly.

STEPS OF EVIDENCE-BASED PRACTICE

The multistep EBP process requires a spirit of inquiry (i.e., an ongoing curiosity about the best evidence to make clinical decisions) (Melnyk et al., 2009). Using a step-by-step approach ensures that you will obtain the strongest available evidence to apply in patient care. With a spirit of inquiry in place, there are six steps of EBP (Melnyk and Fineout-Overholt, 2010):

- 1 Ask a clinical question.
- 2 Search for the most relevant and best evidence that applies to the question.
- 3 Critically appraise the evidence you gather.
- 4 Apply or integrate evidence along with your clinical expertise, patient preferences, and values in making a practice decision or change.
- 5 Evaluate the practice decision or change.
- 6 Communicate your results.

Ask the Clinical Question

Every day nurses perform interventions (e.g., changing dressings, giving medications, providing comfort measures) that stimulate questions such as, "Why do we use this approach?" or "Is there a better way?" Always think about your practice when caring for patients. Question what does not make sense to you and what you think needs clarification. It is also important to include colleagues from all disciplines to give their perception of the clinical problem or issue. As shown in the previous case study, think about a patient care problem or an area of interest that is time consuming, costly, or not logical. Often The Joint Commission (TJC) standards (e.g., the annual patient safety goals) spark questions for you to pose about your patients. Clinical questions often arise as a result of either a problem- or a knowledge-focus trigger. A problem-focused trigger develops as you care for a patient or notice a trend on a

nursing unit. For example, a problem-focused trigger might arise while caring for an unconscious patient: “Which is the best anti-infective solution to use when giving oral care to unconscious patients?” Examples of problem-focused trends include the increase in number of pressure ulcers or incidence of urinary tract infections on a nursing unit. A knowledge-focused trigger arises when you ask a question regarding new information about a topic. For example, “What is the current evidence to reduce bloodstream infection in central venous catheters?” Important knowledge sources often include standards and practice guidelines available from national agencies such as the Agency for Healthcare Research and Quality (AHRQ), the Infusion Nurses Society (INS), and the American Association of Critical Care Nurses (AACN).

There are two types of clinical questions: background and foreground (Stillwell et al., 2010a; Nollan et al., 2010; Straus, 2011). A background question is broad and general. For example, “Which interventions are effective in reducing falls in oncology patients?” The answer to the question provides general knowledge about the problem or topic of interest. A background question has the advantage of allowing you to explore a vast array of options for your area of interest. In contrast, a foreground question is specific and relevant to a practice issue (Stillwell et al., 2010a). It is a question that must be asked to decide which of two interventions is likely the more effective in addressing a practice issue. For example, “In adult oncology patients, will the use of hourly rounding compared with a standard fall prevention protocol affect the incidence of falls?” When you ask a question and search the scientific literature, you do not want to read 100 articles to find the handful that are most helpful. This happens if you ask a background question. If you ask a foreground question, you are able to identify a few select articles that specifically address your practice question.

A foreground question is clearly worded when you use a PICOT format (Melnyk and Fineout-Overholt, 2010). Box 1-1 summarizes the five elements of a PICOT question. The key words of a PICOT question make it easier to search for evidence in the scientific literature. Examples of PICOT questions follow: *In abdominal surgery patients (P), does epidural analgesia (I) compared with patient-controlled analgesia (C) affect pain severity (O) in the first 48 hours after surgery? In oncology patients (P) does the use of a case management model (I) compared with a telephone call-back system (C) improve patient adherence to chemotherapy (O) during the first 3 months (T)?*

BOX 1-1 Developing a PICOT Question

P = Patient population of interest	<i>Identify your patients by age, gender, ethnicity, disease, or health problem.</i>
I = Intervention or issue of interest	<i>Which intervention do you think is worthwhile to use in practice (e.g., a treatment, diagnostic test, prognostic factor)?</i>
C = Comparison intervention or issue of interest	<i>Which standard of care or current intervention do you usually use now in practice?</i>
O = Outcome	<i>Which result do you wish to achieve or observe as a result of an intervention (e.g., change in patient's behavior, physical finding, change in patient's perception)?</i>
T = Time	<i>How long does it take for an intervention to achieve the outcome?</i>

A well-designed PICOT question does not have to include all five elements. For example, a comparison intervention is not pertinent when a PICOT question is about meaning such as, “Do family caregivers (P) of hospice patients feel anxiety (O) when providing hands-on care? A time element is also not always required (Stillwell et al., 2010a). However, the elements of Population, an Intervention or issue of interest, and Outcome are essential for a well-designed PICOT question.

A clearly stated PICOT question helps to identify knowledge gaps for a specific clinical problem or situation. When you form well-thought-out questions, the type of evidence you lack for clinical practice becomes clearer when you search the literature. Examples of different knowledge gaps include the following:

- **Diagnosis:** Questions about the selection and interpretation of diagnostic tests. *Example:* Does the use of a disposable oral thermometer compared with an electronic oral thermometer measure body temperature accurately in a patient with an endotracheal tube?
- **Prognosis:** Questions about a patient's likely clinical outcome. *Example:* Is there a difference in the incidence of deep vein thrombosis in surgical patients wearing sequential compression stockings compared to those who wear elastic stockings?
- **Therapy:** Questions about the selection of the most beneficial treatments. *Example:* Which bowel regimen is most effective in relieving constipation caused by the administration of opioid therapy in oncology patients with chronic pain?
- **Prevention:** Questions about screening and prevention methods to reduce the risk of disease. *Example:* Does performance of a prostate-specific antigen (PSA) test in an older adult who is asymptomatic of prostate disease decrease his risk for mortality from prostate cancer?
- **Education:** Questions about best teaching strategies for colleagues, patients, or family members. *Example:* Is the use of visual aids compared with low-literacy teaching booklets more effective to educate low-literacy adults about therapeutic diets?
- **Meaning:** Questions that seek understanding of a phenomenon. *Example:* How do patients with cervical cancer perceive their quality of life?

Search for the Best Evidence

In the case study the nurse specialist conducts a literature search on the basis of the PICOT question. Key words from the question direct the search, including “falls,” “cancer,” “injury,” “rounding,” and “adult.” The literature search results in four articles pertaining to risk factors for falls and outcomes from hourly rounding.

Once you have a clear and concise PICOT question, you are ready to search for evidence. Evidence exists in quality or performance improvement data, existing clinical practice guidelines, or computerized bibliographical databases. Do not hesitate to ask for help from faculty or expert nurses to find appropriate evidence. When you are assigned to a health care setting, consider using advanced practice nurses, staff educators, risk managers, and infection control nurses as resources.

When searching the scientific literature for evidence, seek the assistance of a medical librarian who knows the relevant databases (Box 1-2). A database is an electronic library of published scientific studies, including peer-reviewed research. A peer-reviewed article is one that has been evaluated by a panel of experts familiar with the topic or subject matter of the article. The librarian translates the elements of your PICOT question into the language or key

BOX 1-2 Searchable Scientific Literature Databases and Sources

CINAHL	Cumulative Index of Nursing and Allied Health Literature. Includes studies in nursing, allied health, and biomedicine http://www.cinahl.com
MEDLINE	Includes studies in medicine, nursing, dentistry, psychiatry, veterinary medicine, and allied health http://www.ncbi.nlm.nih.gov
EMBASE	Biomedical and pharmaceutical studies http://www.embase.com
PsycINFO	Psychology and related health care disciplines http://www.apa.org/psycinfo
Cochrane Database of Systematic Reviews	Full text of regularly updated systematic reviews prepared by the Cochrane Collaboration; includes completed reviews and protocols http://www.cochrane.org/reviews
National Guidelines Clearinghouse	Repository for structured abstracts (summaries) about clinical guidelines and their development; also includes condensed version of guideline for viewing http://www.guideline.gov
PubMed	Health science library at the National Library of Medicine; offers free access to journal articles http://www.nlm.nih.gov

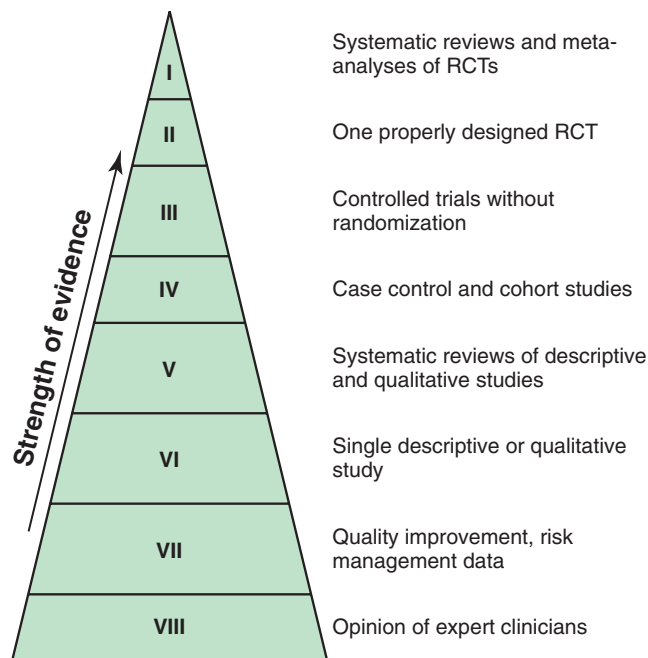

FIG 1-1 The evidence pyramid. RCT, Randomized controlled trial.

words that yield the best evidence search. For example, consider this PICOT question: “Does the use of computerized home instruction compared with a group class improve oncology patients’ adherence to oral chemotherapy 3 months following treatment?” The key words include *oncology patient*, *computerized instruction*, *adherence*, and *chemotherapy*. A good librarian recommends using the indexing language or controlled vocabulary of the database that you are searching. This means that, by using the words that the database contains, you will likely have a more inclusive search (Stillwell et al., 2010b). In the previous example the word *oncology* might be entered instead as “cancer” to fit the database language. When conducting a search, you enter and manipulate the different key words until you get the combination that gives you the articles about your question that you want to read. When you enter a key word to search a database, be prepared for some confusion in the evidence that you obtain. The vocabulary within published articles is often vague. The word that you select sometimes has one meaning to one author and a very different meaning to another. Each key word generates a set of articles. For example, in the PubMed database *oncology patient* generates 122,000 articles, *adherence* generates 64,878 articles, and *chemotherapy* generates over 2 million articles. That’s a lot of reading. In addition, you want to read only articles that address all three of the topics. If you combine the key terms of a search using the Boolean connector *and*, the combination of “oncology patient *and* chemotherapy *and* adherence” generates 274 articles. A librarian can also show you how to limit a search by categories such as the time frame during which the article was

written, types of studies, or age of patients. This reduces the number of articles further to give you a more manageable number to review for your PICOT question (Stillwell et al., 2010b).

CINAHL, PubMed (which includes MEDLINE), and the Cochrane Database of Systematic Reviews are among the most comprehensive databases and represent the scientific knowledge base of health care (Melnyk and Fineout-Overholt, 2010). Some databases are available through vendors at a cost, some are free of charge, and some offer both options. Nursing students and nurses who work in academic medical centers usually have access to an institutional subscription through a vendor. One of the common vendors is OVID, which offers several different databases. Some databases such as PubMed are available free on the Internet. The Cochrane Database of Systematic Reviews is a valuable source of synthesized evidence (i.e., preappraised evidence). It includes the full text of regularly updated systematic reviews and protocols for reviews that are currently in progress. The National Guidelines Clearinghouse (NGC) is a database supported by the AHRQ. It contains clinical guidelines (i.e., systematically developed statements about a plan of care for a specific set of clinical circumstances involving a specific patient population). The NGC is a valuable source when you want to develop a plan of care for a patient.

The pyramid in Fig. 1-1 represents a hierarchy for rating available scientific evidence. It is important to learn about the types of studies to help you know which ones have the best scientific evidence. The strongest evidence is at the top of the pyramid; the weakest is at the bottom. You can use the rating scale of I to VIII when you later critique each article that you obtain in your search of the literature. Table 1-1 describes types of studies in the evidence hierarchy, beginning with the study at the top of the hierarchy, a systematic review.

If your PICOT question leads you to a systematic review, celebrate! A systematic review is the perfect answer to a PICOT question. Basically a researcher has asked the same PICOT question you have asked and then examined all of the well-designed relevant randomized controlled trials (RCTs) that ask the same question. A systematic review explains if the evidence for which you are searching exists and whether there is good cause to change

TABLE 1-1 Types of Studies in the Evidence Hierarchy

Study Type	Description	Example
Systematic review or meta-analysis	An author or panel of experts reviews the evidence from randomized controlled trials about a specific clinical question and summarizes the state of the science. In a meta-analysis, there is the addition of a statistical analysis that combines data from all studies.	35 studies were examined to evaluate the outcomes of case-managed, integrated home and community care services for older persons, including those with dementia. Evidence from RCTs showed that case management improves function and appropriate use of medications, increases use of community services, and reduces nursing home admission (Low, Yap, and Brodaty, 2011).
Randomized controlled trial (RCT)	A researcher tests an intervention against the usual standard of care. Participants are randomly assigned to either a control group (receives standard care) or a treatment group (receives the experimental intervention), with both measured on the same outcomes to see if there is a difference.	Researchers conducted an RCT among 125 critically ill patients receiving tube feedings. The study determined the effect of returning (treatment) or discarding gastric residual volume (GRV) on gastric emptying delays and feeding, electrolyte, and comfort outcomes. Findings showed a lower incidence and severity of delayed gastric emptying when GRV was returned. No significant differences were found for feeding delays, electrolyte imbalance, or changes in vital signs. The study findings support that the return of gastric content aspirated improved GRV management without increasing the risk for potential complications (Juvé-Udina et al., 2009).
Case control study	Researchers study one group of subjects with a certain condition (e.g., obesity) at the same time as another group of subjects who do not have the condition to determine if there is an association between the condition and predictor variables (e.g., exercise pattern, family history, history of depression).	In a historical case control, researchers studied a group of 19,951 children who had been admitted to an emergency department for asthma attacks. The researchers compared the effectiveness of the use of inhaled beta-agonists given via a metered-dose inhaler (MDI) with spacers versus the use of nebulizers. This was part of an evidence-based asthma pathway. The use of an MDI with spacer was effective in the management of acute asthma (Goh et al., 2010).
Descriptive study	Study describes the concepts under study. It sometimes examines the prevalence, magnitude, and/or characteristics of a concept.	A convenience sample of 100 patients and 100 unrelated family caregivers were surveyed to examine their perceptions of the caregiving skills they perform, the difficulty they experience in performing certain skills, and their associated learning needs (Potter et al., 2010).
Qualitative study	Study examines individuals' experiences with health problems or life experiences and the contexts in which the experiences occur.	Researchers asked 392 nurses to discuss a care episode from their practice. Cases describing patients with cancer involved nurses' use of powerful emotive language. The influence of patients' cancer experience affects nurses personally and professionally (Kendall, 2007).
Quality improvement data, risk management information	Data collected within a health care agency offer important trending information about clinical conditions and problems. Staff in the agency review the data periodically to identify problem areas and seek solutions.	Article reviews the results of a 2-year quality improvement campaign involving physicians and nurses at a teaching hospital to improve the identification and accurate documentation of pressure ulcers (Dahlstrom et al., 2011).
Clinical experts	Accessing clinical experts on a nursing unit is an excellent way to learn about current evidence. Clinical experts often write clinical articles on topics that require application of evidence in the literature.	Clinical article describes an evidence-based practice project. The practice change involved interventions, including a campaign to raise geriatric awareness, the creation of "falls tool boxes," education of staff and family, and implementation of a structured hourly patient rounds schedule (Murphy et al., 2008).

practice. In the Cochrane Library all entries include information on systematic reviews.

Individual RCTs have been the gold standard for research (Padian et al., 2010; Titler et al., 2001). An RCT is a formal experiment for testing therapies and establishing cause and effect. Historically few RCTs have been conducted in nursing, but this is changing. The nature of nursing causes researchers to ask questions that are not always answered best by an RCT. Nurses care for patients' responses to disease or health problems. For example, they assist patients with problems such as knowledge deficit, symptom management, and coping with psychological distress and with the problems in these areas that often occur simultaneously. An RCT cannot easily be designed to learn how patients handle such complex health problems.

More often you find articles in the nursing literature that involve controlled trials without randomization (i.e., descriptive studies). Even though these types of studies represent a lower level of evidence, if a study results in relevant findings, it helps you decide if your PICOT question can be answered.

The use of clinical experts is at the bottom of the evidence pyramid, but do not consider clinical experts a poor source of evidence. Expert clinicians frequently use evidence as they build their own practice, and they are rich sources of information for clinical problems.

Critique the Evidence

In the case study the nurses on the oncology unit conduct their unit-based practice committee (UPC) meeting. During

the meeting Cathy and her colleagues decide that it is important to include key members of their interdisciplinary team (pharmacy and physical therapy). The UPC then reviews the articles carefully, using a rapid-appraisal checklist. After the group evaluates the articles for the strength of evidence and synthesizes the findings, they decide that there is evidence for implementing hourly rounding with focused patient assessment to prevent falls. The staff notes that one of the articles recommends hourly rounding during daytime hours and rounding every 2 hours during evening and night hours. Another article summarizes fall risks for patients in an acute care hospital and highlights factors to include in a nursing assessment such as medications (e.g., antihistamines, sedatives, analgesics, and antiemetics).

Once you have found research articles that address your PICOT question, the next step is to review the articles critically to determine if there is evidence that answers your question. It is important to use an approach that does not bog you down by reviewing every single element of each article. Melnyk et al. (2010) recommend the use of a rapid critical appraisal (RCA) that answers three important questions:

- What are the results of the study, and are they important?
- Are they valid?
- Will the results help you care for your patients?

Many organizations use an RCA checklist (Fig. 1-2) for recording article reviews. You begin an article review by determining if the research study was valid or conducted in a well-designed way. This

Example of a Rapid Critical Appraisal Form

- Why was the study done? (Is there a clear explanation of the study purpose?)
- Are the study findings valid?
 - How were study participants chosen? How many were chosen?
 - Are the study instruments valid and reliable?
 - Does the research approach fit the purpose of the study?
 - How were accuracy and completeness of data ensured?
 - Do the study findings fit the data that were generated?
- What are the results of the study, and are they important?
 - Yes
 - No
 - Unknown
- Is the finding from the study clearly identified?
- Are the results logical, consistent, and easy to follow?
- Are the results plausible and believable?
- How do the results fit with previous research in the area?
- Will the results help me in caring for my patients?
- Do the results apply to my patients?
- How would I use the findings in my practice?
- How would patient and family values be considered in applying these results?
- Do we have the resources to apply this in our practice setting?

FIG 1-2 Example of a rapid critical appraisal form. (Adapted from Melnyk B, Fineout-Overholt E: Evidence-based practice in nursing and health care: a guide to best practice, Philadelphia, 2010, Lippincott Williams & Wilkin; Fineout-Overholt E et al: Evidence-based practice step by step: critical appraisal of the evidence, Part 1, AJN 110(7):47, 2010.)

requires knowing the type of study using the evidence pyramid. For example, if you have an RCT to review, were subjects randomized? Does the sample of subjects appear to be large enough to test the intervention effectively? Were all subjects measured for the same outcomes? In contrast, if you read a qualitative study, did the researcher study a sufficient representation of subjects, and did the approach allow for a thorough and objective review of findings? As you read each article, you ask the second question: What are the results and were they important? If you have an RCT, you want to know if an intervention worked or not. If you have a descriptive study, is the information relevant to your PICOT question?

You might also choose to review a clinical article that explains a clinical practice topic relevant to your PICOT question. A clinical article is not rated for its level of evidence; but it can offer useful information, especially if you decide to implement a change related to the practice topic. To learn how to read research and clinical articles, know each of the common elements. This will help you decide if an article is complete and well explained. Articles should include the following elements:

- **Abstract:** A brief summary of the article that tells you if the article is research or clinically based. An abstract summarizes the purpose of the study or clinical topic, the major themes or findings, and the implications for nursing practice.
- **Introduction:** Contains information about the purpose of the article and the importance of the topic for the audience who reads it. The introduction usually contains brief supporting evidence as to why the topic is important from the author's point of view.

After reading the abstract and introduction, you will decide if you want to continue to read the entire article. You will know if the topic of the article is similar to your PICOT question or related closely enough to provide you useful information. Remember that the research question does not need to be the same as yours but close enough to offer useful information. If this is the case, continue to read the next elements of the article:

- **Literature review or background:** A good author offers a detailed background of the level of scientific or clinical information that exists about the topic of the article. The review offers an explanation about what led the author to conduct a study or report on a clinical topic. Perhaps the article itself does not address your PICOT question the way you desire but possibly leads you to other more useful articles. The literature review gives you a good idea of how past research led to the researcher's question.
- **Article narrative:** The "middle section" or narrative of an article differs according to the type of evidence-based article, either clinical or research (Melnyk and Fineout-Overholt, 2010). A clinical article describes a clinical topic, which often includes a description of a patient population, the nature of a certain disease or health problem, how it affects patients, and the appropriate nursing therapies. Clinical articles often describe how to use a therapy or new technology. A research article describes the conduct of a research study, including its purpose; how the study was designed; and the results. A narrative of a research article contains several standard subsections:
 - **Purpose statement:** Explains the focus or intent of a study. It identifies which concepts will be researched.
 - **Methods or design:** Explains how a research study is organized and conducted to answer the research question(s). This is where you learn the type of study (i.e., RCT, case control, or qualitative). You also learn how many subjects or persons are in a study. In health care studies subjects

BOX 1-3 Common Statistical Terms

Sample Size: Number (n) of individuals in a study.

Significance: A measure that gives the likelihood that a finding or a result is caused by the intervention being tested and not by chance. Most researchers set the level of significance at a p value of 0.05 or 0.01. For example, if the effects of an intervention are significant at $p < 0.05$, it means that the likelihood of the effect occurring by chance is less than 5%; thus it is more likely that the intervention made a true difference.

Confidence interval (CI): The range (e.g., range of a mean score) in which clinicians can expect to get results if they present an intervention as it was in a study (Fineout-Overholt et al., 2010). The CI tells you the precision of a study. A 95% CI means that clinicians can be 95% confident that their findings will be within the range given in the study.

Effect size: When the effect of an intervention is statistically significant, it does not necessarily mean that it is big, important, or helpful in decision making. It simply means that you can be confident that there is a difference. An effect size greater than 0.05 is considered a large effect.

sometimes include patients, family members, or health care staff. The language in the methods section is sometimes confusing if it explains details about how the researcher designs the study to minimize bias so as to obtain the most accurate results possible. Use your faculty member as a resource to help interpret this section.

- **Results or conclusions:** Clinical and research articles have a summary section. In a clinical article the author explains the clinical implications for the topic. In a research article the author explains the results and whether a research question is answered. For example, in a qualitative study there is a thorough summary of the descriptive themes and ideas that arise from the researcher's analysis of data. A quantitative study includes a full description of the study subjects and a statistical analysis of findings. It is important to learn some of the common statistical terms (Box 1-3). A good author discusses limitations to a study in the results section. The information on limitations helps you decide if you want to use the evidence with your patients.
- **Clinical implications:** A research article includes a section that explains if the findings from the study have clinical implications. The researcher explains how to apply findings in a practice setting for the type of subjects studied.

As you critique each article, complete your RCA checklist. You may choose to rate each article by its level and strength of evidence, using the scale of I to VIII from the evidence pyramid (see Fig. 1-1). It also helps to review multiple articles with a group of colleagues involved in the EBP process. Each person can review a single article; then you can come together as a group to review your total findings. At that time you discuss the third important question: Will the results help you care for your patients?

Use critical thinking to consider the scientific rigor of the evidence and how well it answers your area of interest. Scientific rigor is the extent to which the findings of a study are valid, reliable, and relevant to a patient population of interest. Consider the evidence in light of your patients' concerns and preferences. Your review of articles offers a snapshot conclusion based on combined evidence about one focused topical area. As a clinician judge whether to use the evidence for a particular patient or group of

patients who usually have complex medical histories and patterns of responses (Melnyk and Fineout-Overholt, 2010). Ethically always consider evidence that will benefit patients and do no harm. Decide if the evidence is relevant, is easily applicable in your setting of practice, and has the potential for improving patient outcomes.

Apply the Evidence

Based on their experience and a review of their unit fall index reports, the staff on the oncology unit know that patients on the unit fall during all hours of the day and night. The unit practice committee recommends starting a new hourly rounds program using a focused fall screening tool and nursing assessments for key fall risk factors. Registered nurses (RNs) will round on patients on all even hours and conduct focused assessments of fall risk factors such as weakness, pain, or the need to go to the bathroom. If a patient is found to be at high fall risk, the physical therapists will be asked to consult and assess patients' lower-extremity strength and overall balance. Pharmacy will place alerts on medication administration records so nurses can monitor patients receiving antihistamines before blood transfusions. Nursing assistive personnel (NAP) will round on odd hours and do follow-up observations to be sure that patients have their toileting needs met, are comfortable, and have no further needs. Each hour the nursing staff will inform patients that someone from the nursing team will return in an hour for another check. The unit practice committee plans to have a staff orientation and set a date for the start of the hourly rounding protocol.

After reviewing all of the evidence, you decide if it answers your PICOT question. If so, your next step is to implement a plan to apply evidence into practice. One important step for an individual or an interdisciplinary EBP committee to address is the resources needed for a practice change project. Are added costs or new equipment involved with a practice change? Do you have adequate staff to make the practice change work as planned? Do management and medical staff support you in the change? If the barriers to practice change are excessive, adopting a practice change can be difficult, if not impossible.

In the case study the oncology UPC involves other disciplines and their managers in planning their project. The committee forms a plan for implementing their hourly rounding protocol. There are key steps for applying evidence into practice:

- 1 Plan how to collect baseline data on the outcomes that will evaluate the effect of your practice change (e.g., the oncology nurses will be able to refer to fall index data collected during the 6 months before implementation of the protocol). The nurses will continue to collect the fall index and the fall-related injury rate once the new protocol begins.
 - a Know which outcomes to measure and how to collect them (e.g., to measure pain acuity use a self-report pain scale; to measure ambulation determine the distance a patient walks each time).
 - b Be sure that the outcomes are measurable. Use scales (e.g., Pain and Braden scales), physiologic measures (e.g., temperature, blood pressure, pulse oximetry), or survey tools.
 - c Choose outcomes that are not costly to collect. Use existing equipment if you can.
 - d Who will collect the data? It is usually best to limit the number of staff who collect data to ensure better accuracy

and consistency in measurement. Be sure that each person collects data the same way and accurately.

- e Establish a way to record all data.
- 2 Test your practice change in a pilot project. This means that you implement the change in practice for a set period of time (e.g., 3 to 6 months). Consider how long it will take to show that your practice change made a difference (Poe and White, 2010). Apply evidence in a manner that integrates well with existing practice for all affected disciplines. Consider how you can introduce your practice change into existing policies, standards of care, and assessment or clinical protocols.
- 3 Involve all staff in the patient care area or unit where you work. An interdisciplinary approach brings together ideas from different perspectives. This is very important for creating a climate of EBP.
- 4 Be sure to educate all nurses or other staff who will be involved in the project before you begin implementation. Also keep them informed of the progress of the change.

The goal of any EBP change is to ensure the highest quality of care by using evidence that promotes the best outcomes (Poe and White, 2010). Proper planning is essential before implementing your practice change. Once you implement your intervention, monitor the project closely and consider how staff and patients are responding.

Evaluate the Practice Decision or Change

On the oncology unit the UPC made sure that outcome measures were in place when the protocol began. A fall index rate was collected monthly. The staff decided to add a monthly report of injuries from falls to the outcome data. Three months after implementing the protocol the medical oncology unit was cautiously optimistic. The average fall index for the unit dropped from 5.1 to 3.7, and the injury rate also dropped. The nurses observed a decline in patients' use of call lights, which was attributed to their knowing that nurses and assistive personnel would visit frequently. The UPC members surveyed nursing and physical therapy staff about the change and found that the majority were enthused and agreed that hourly rounding needed to be a routine part of their unit practice. The nursing staff is able to see that use of the protocol improves patient outcomes and gives them more time to coordinate care because of fewer distractions from patient calls.

After implementing a practice change, your next step is to evaluate the effect. You do this by analyzing the outcome data that you collect during the pilot project. Outcome evaluation tells you if your practice change improved conditions, created no change, or worsened conditions. For examples, after using a new, transparent IV dressing, the staff analyzed their audits, which included the incidence of dislodged IVs and the incidence and rating of phlebitis. Their findings showed reduction in the number of catheters that became dislodged and in onset and severity of phlebitis. After using a new approach to educating clinic patients about medications and administration schedules, follow-up phone calls to patients found an improved understanding of doses and times to administer. However, patients were not able to explain which side effects to expect. Once an evaluation is complete, you must decide to continue the EBP, make a revision, or discontinue the practice change. Analysis of an EBP change may require assistance from statisticians if you or your team members collect extensive data. Be sure to use reliable resources and be thorough in examining all data.

Communicating a Practice Change

Six months after starting the new fall prevention protocol, the fall index of the oncology unit continues to remain low. An added outcome is an improvement in patient satisfaction scores. Cathy submits the protocol for an abstract in the hospital publication, *Nursing Research Day*. Her abstract, “Using Evidence To Prevent Falls,” is well accepted by her peers and becomes a standard for other nursing units in the hospital.

After applying evidence, it is important to communicate the change in practice and the results to nursing and other health care colleagues. This is true whether the results are successful or unsuccessful. There are many ways to communicate the outcomes of EBP: talking with a colleague, sharing results in staff meetings, presenting in workshops or seminars, submitting an abstract for a poster presentation, and publishing an article. As a professional you are responsible for communicating important information about nursing practice. Sharing evidence and the effects of any

practice change motivates others within a health care setting and makes them excited about potential practice improvements on their work units. When you successfully adopt an EBP way of thinking, it becomes very natural to talk about available evidence and continue seeking solutions for problems in patient care.

IMPACT OF EVIDENCE-BASED PRACTICE ON NURSING

This chapter provides a brief introduction to EBP. Of all of the initiatives introduced in health care, EBP may be the most important. With the rapid, ongoing expansion of research knowledge in health care, it is essential to remain accountable by applying evidence in patient care. When evidence exists about ways to improve patient outcomes, it becomes important for that evidence to reach the bedside. Your patients expect nursing professionals to be informed and to use the safest and most appropriate interventions. Use of evidence enhances nursing, improving patients’ perceptions of excellent nursing care.

Critical Thinking Exercises

Maria Gonzalez is a 45-year-old Hispanic woman who is admitted to the hospital with inflammatory bowel disease, which she has had for 2 years. The disease is an inflammation of the intestines. As a result, Maria has a recurrence of bloody diarrhea, abdominal cramping, and a fever. During her hospital stay Maria receives IV fluids, corticosteroids, and antiinfective drugs. Jeanne is the nurse assigned to coordinate Maria’s discharge home. Jeanne is concerned about Maria’s diet at home and wonders how it might affect her disease, particularly the frequency of diarrhea. She learns that Maria eats three large meals a day with a diet high in carbohydrates. In consultation with her instructor, Jeanne asks if a low-carbohydrate diet might be best for Maria. The instructor suggests that Jeanne conduct a literature search to see what the most current evidence suggests.

- 1 Given this clinical case study, write the PICOT question that is the basis of Jeanne’s inquiry.
- 2 The librarian helps Jeanne conduct a literature search. Among the articles located in the search is a systematic review. Explain why a systematic review is the best source of evidence.
- 3 One of the articles found by the librarian describes a study in which a researcher studied 45 patients with inflammatory bowel disease and 52 patients with normal intestinal function to determine if there is an association between frequency of diarrhea and ingestion of high-carbohydrate intake. Which type of study did this researcher conduct?

REVIEW QUESTIONS

- 1 Place the steps of evidence-based practice in the correct order:
 - 1 _____ Search the literature for evidence.
 - 2 _____ Evaluate outcomes of the practice change.
 - 3 _____ Communicate the findings.
 - 4 _____ Apply evidence in making a practice change.
 - 5 _____ Ask a PICOT question.
 - 6 _____ Critique the available evidence.

- 2 A nurse is talking with colleagues and shares what she learned at a recent conference on wound care. She suggests that the group discuss which is the best antiinfective solution to use to clean infected incisions? Which type of trigger for a clinical question is this?
 - 1 Problem-focused
 - 2 Knowledge-focused
 - 3 Peer-focused
 - 4 PICOT-focused
- 3 Which question contains the primary components of a PICOT question?
 - 1 Are oral steroids effective for female adults with adult-onset asthma?
 - 2 Which steroid preparations are best for male teenagers with activity-induced asthma who play sports?
 - 3 Does the use of inhalers improve bronchial air flow?
 - 4 Does the use of medication via an inhaler versus a nebulizer affect oxygen saturation in asthmatic children?
- 4 A group of nurses on an obstetric unit are discussing the results of their patient satisfaction scores. They’ve noticed the scores dropping over the last 3 months. Their manager has expressed concern as to why the female patients do not think that nurses are responsive to their needs. The nurses decide to address the issue in their EBP committee where they will form a PICOT question. This scenario is an example of which type of trigger for an EBP question?
 - 1 Administrative-focused
 - 2 Knowledge-focused
 - 3 Problem-focused
 - 4 Time-focused
- 5 The nurses on the obstetric unit have identified a PICOT question to address the patient satisfaction problem, “Does hourly rounding improve female obstetric patients’ perceptions of satisfaction with nursing care?” Place each element of the PICOT question in the correct category.
 - 1 P _____
 - 2 I _____
 - 3 C _____
 - 4 O _____
 - 5 T _____

- 6 A nurse has developed a clinical question, “Do oncology patients feel hopelessness when experiencing side effects of chemotherapy?” Which type of research article should the nurse be sure to include in her search for evidence on this topic?
- 1 Case study
 - 2 Systematic review
 - 3 Quality improvement project
 - 4 Qualitative study
- 7 A staff nurse is talking to a clinical nurse specialist on a surgical unit. The nurse specialist is helping the nurse identify the clinical question that interests her most. The nurse explains that she is interested in using guided imagery to help patients gain better pain relief. She believes that it would be most effective beginning 24 hours after surgery through discharge because pain would be less acute during that time frame. The nurse specialist asks the nurse which outcome she would want to achieve. What would be the nurse’s best answer?
- 1 Ability of patients to follow coaching while performing guided imagery
 - 2 Patients’ reported level of pain severity
 - 3 The frequency patients ask for pain medication after surgery
 - 4 The time it takes to perform the guided imagery exercise
- 8 Which of the following is a background question?
- 1 What is the most effective method for teaching patients with diabetes how to self-administer insulin?
 - 2 Does the use of chewing gum compared with NPO reduce postoperative ileus in a patient undergoing colon resection?
 - 3 Does a low-fat diet reduce incidence of postoperative nausea in patients undergoing colon resection?
 - 4 Does the use of demonstration versus viewing a DVD program affect the ability of patients with diabetes to self-administer insulin?
- 9 A UPC on a medicine unit is planning to pilot an EBP change. Which of the following steps would enhance involvement of all staff on the unit in the practice change? (Select all that apply.)
- 1 Involve only nurses familiar with the practice issue.
 - 2 Educate all nurses or other staff who will be involved in the project before implementation.
 - 3 Keep all staff on the unit informed of the progress of the change.
 - 4 Include all staff involved in collecting outcome information.
- 10 A UPC is planning to adopt a new type of pulse oximeter to improve accuracy of measurement and reduce patient discomfort while wearing the device. Which resources should the committee consider before beginning a pilot evaluation of the oximeter? (Select all that apply.)
- 1 The accuracy of the device
 - 2 Cost of the device
 - 3 Support from doctors for the change
 - 4 The patients’ satisfaction with the device

KEY TERMS

Advance directives	Health Insurance Portability and Accountability Act (HIPAA)	Patient's rights Patient Self-Determination Act	The Joint Commission (TJC) Transitional care
Condition of participation			
Continuum of care			
Discharge planning			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe a nurse's role in maintaining continuity of care through a patient's admission, transfer, and discharge from an acute care facility.
- Explain the purpose and importance of advance directives.
- Identify the ongoing needs of patients in the discharge planning process.
- Explain the role of a patient's family in the admission, transfer, or discharge process.

Patients entering the health care system have unique and individual health needs. It is important for patient care to be integrated across a variety of settings, services, health care practitioners, and care levels to maintain a continuum of care. The Joint Commission (TJC) (2012a) defines the continuum of care as matching an individual's ongoing needs with the appropriate level and type of medical, psychological, health, or social care or services within an organization or across multiple organizations. This continuum flows from preadmission to admission, throughout the acute care hospitalization as the discharge plan is developed, through care transition, and after hospitalization on discharge home or to another health care setting. Essential in promoting continuity of patient care is the need for transitional care. Transitional care consists of nursing actions implemented to ensure coordination and continuity of care for patients who are transferring between different care settings or care levels (McLeod and others, 2011).

A nurse plays a key role in coordinating resources for a patient's care from admission to discharge or from one level of care to the next. He or she identifies patients' ongoing health care needs and anticipates physical, psychological, and social deficits that have implications for resuming normal activities. In addition, a nurse involves family and significant others in a plan of care, provides health education, and assists in making health care resources available to patients. To

separate the processes of admission and discharge is a critical error; the two are simultaneous and continuous. Discharge planning begins at the time of admission. Patients and families need to be involved in the planning and decision making. They also need to understand the implications of any health problems and the responsibilities for continued care either in the home or next level of care setting.

EVIDENCE-BASED PRACTICE

Evidence shows that effective communication is an essential component of the admission, transfer, and discharge of patients. Evidence also indicates that poor communication can lead to misunderstandings, clinical errors, and poor outcomes (Pope et al., 2008). Research shows that the development of admission, discharge, and transfer teams within both adult and pediatric facilities improves the emergency department (ED) admission process, patient care productivity, and nurse-patient satisfaction (Giangiulio et al., 2008). The keys to good communication include:

- Knowing when, how, and what to communicate regarding patient issues (Krautscheid, 2008).
- Patient comprehension of accurate, timely, complete, and unambiguous information from providers (TJC, 2012a).

- Concise and specific documentation of information.
- Use of a combination of verbal and written information to provide patient teaching.
- Use of computer-generated summaries of pertinent discharge information to improve patient care after discharge. Provide patients with copies of the pertinent information at time of discharge.
- Use of medication reconciliation to avoid medication errors such as omissions, duplications, dosing errors, or drug interactions (TJC, 2012a).
- Use of electronically reconciled medication lists to provide patients with a better understanding of medication administration instructions and potential adverse effects of the discharge medication.
- High-quality discharge teaching that improves a patient's readiness for discharge.
- Use of a discharge-planning checklist to help patients and family members consider practical aspects of being discharged home.

PATIENT-CENTERED CARE

Communication and culture function together, preserving tradition and influencing verbal and nonverbal expressions (Giger, 2013). Research demonstrates that patients may experience a decrease in safety, health outcomes, and quality of care based on their race, ethnicity, language, disability, and sexual orientation (TJC, 2011). When admitting, transferring, or discharging patients, it is important to understand their cultural beliefs and practices. Be aware of the cultural variables that will affect your patient and family assessment, approach to nursing care, and teaching during admission or discharge. Common cultural

variations include perception of time or acceptance of bodily contact. For example, some cultures consider touch taboo, whereas others are highly tactile.

To promote effective communication and plan care, it is beneficial to learn about a patient's cultural background. Modify your communication approaches to meet a patient's cultural needs and ensure that he or she understands your communication. For example, schedule the admission, transfer, or discharge of Orthodox Jewish patients so they can begin observance of the Sabbath (sundown on Friday to sundown on Saturday) undisturbed.

Safety Guidelines

- 1 Identify whether a patient has a sensory or communication need.
- 2 Identify if a patient uses any assistive devices.
- 3 Screen all patients on admission to a health care setting for possible discharge needs to ensure that appropriate teaching is completed.
- 4 Include the patient, family, and relevant health care professionals early in planning to promote successful transition through the health care system.
- 5 Consider a patient's educational background, health literacy level, and ability to understand instructions.
- 6 Coordinate the health care providers who contribute to a patient's care needs to develop a plan of care for discharge to ensure a safe transition to home or an alternate care facility.
- 7 Assist other health care personnel in assessing appropriate resources needed as patient's transition through the health care system.

SKILL 2-1 Admitting Patients

A patient may enter the health care system in a variety of ways (e.g., hospital, clinic, or physician's or health care provider's office). The admission process is typically the first point of contact a patient has with a health care agency. There are common procedures for admitting patients to these settings (Box 2-1). Most patients enter the health care system through a scheduled admission process. However, some patients require emergency admission. For example, a patient admitted through the ED is often not able to undergo the same registration process that takes place in a hospital admission office. Family members usually provide pertinent information for the hospital records while the staff are caring for the patient. In contrast, an older-adult patient with self-care

limitations undergoes extensive screening before being accepted as a nursing home resident.

Admission officers, secretaries, and technicians are the personnel involved in the preliminary admission process such as interviewing patients and reviewing information about insurance, demographic data, and agency procedures. Technicians usually collect routine specimens and perform screening procedures such as electrocardiograms (ECGs). A nurse performs the admission assessment.

Role of the Admission Personnel

The admission personnel initiate and maintain a courteous and professional relationship with patients while providing their safety, legal rights, and privacy. A private interview area gives patients and families a place to reveal important identifying information, including a patient's full legal name, age, birth date, address, next of kin, health care provider, religious preference, occupation, and type of insurance. If a patient does not speak English or has a severe hearing impairment, an interpreter assists during the admission procedure.

At this time the admission personnel secure an identification (ID) band legibly stating the patient's full legal name, hospital or agency number, health care provider, and birth date to the patient's wrist. Health care providers use the ID band to identify a patient when performing treatments or procedures. If a patient is unconscious, you cannot perform identification until family members arrive. Hospital staff provide a patient who has been a victim of

BOX 2-1 Common Procedures for Admission to the Health Care System

- Placement of patient in appropriate receiving area
- Explanation of patient's rights and elements of advance directives
- Orientation to relevant health care agency's policies and procedures
- Assessment of patient's health care problems and needs
- Preliminary testing and screening (specific for each agency and patient's condition)
- Development of an individualized plan of care
- Determination of patient's payment source for health care

crime with an anonymous name under the agency's "blackout" or "do not publish" procedure.

A patient's legal rights are met by instructing the patient or legal guardian to read the general consent form for treatment. During admission all patients receive information regarding their rights related to health care services. This information should be available in multiple languages and alternate formats (e.g., audio, visual, or written). In 1999 the Centers for Medicare and Medicaid Services (CMS) introduced a Patients' Rights Condition of Participation that all hospitals are required to meet to receive Medicare and Medicaid reimbursement. The condition requires hospitals to notify each patient of his or her rights (Box 2-2). Other regulatory agencies such as TJC also require agencies to provide for specific patient rights (Box 2-3). Each agency has policies and procedures describing a patient's rights and the role of the nurse in ensuring those rights.

The Patient Self-Determination Act, effective December 1, 1991, requires all Medicare- and Medicaid-recipient hospitals to

provide patients with information about their right to accept or reject medical treatment. At the time of registration patients receive information about advance directives and are referred to appropriate resources if they want to discuss advance directives or receive help in completing an advance directive document (Box 2-4).

Patients must also receive information about the Health Insurance Portability and Accountability Act (HIPAA). HIPAA is a federal law finalized in 2003, designed to protect the privacy of patient health information and referred to as *protected health information (PHI)* (U.S. Department of Health and Human Services [USDHHS], 2003). Three key concepts of HIPAA are: (1) agencies are required to inform patients of the privacy rights they have and how the agency will handle their PHI; (2) the agency and the health care providers are to use or disclose a patient's PHI only for the purposes of treatment, payment, or health care operations; and (3) health care providers disclose only the minimum amount of PHI necessary, on a need-to-know basis, to accomplish the

BOX 2-2 Patients' Rights Provided for by CMS

Code of Federal Regulations Title 42, Chapter IV, Part 482, Sec. 482.13 Condition of Participation: Patients' Rights

Standard 1: Notice of Rights

- A hospital must protect and promote each patient's rights.
- A hospital must inform each patient whenever possible or, when appropriate, the patient's representative of the patient's rights in advance of furnishing or discontinuing patient care.
- The hospital must have a process for prompt resolution of patient grievances and must inform each patient whom to contact to file a grievance.

Standard 2: Exercise of Rights

- The patient has the right to participate in the development and implementation of his or her plan of care.
- The patient or his or her representative has the right to make informed decisions regarding his or her care.
- The patient's rights include being informed of his or her health status, involved in care planning and treatment, and able to request or refuse treatment. This right must not be construed as a mechanism to demand the provision of treatment or services deemed medically unnecessary or inappropriate.
- The patient has the right to formulate advance directives and have hospital staff and practitioners who provide care in the hospital comply with these directives.
- The patient has the right to have a family member or representative of his or her choice and his or her own health care provider notified promptly of his or her admission to the hospital.

Standard 3: Privacy and Safety

- The patient has the right to personal privacy.
- The patient has the right to receive care in a safe setting.
- The patient has the right to be free from all forms of abuse or harassment.

Standard 4: Confidentiality of Patient Record

- The patient has the right to the confidentiality of his or her clinical records.
- The patient has the right to access information contained in his or her clinical records within a reasonable time frame.

Standard 5: Restraint or Seclusion

- The patient has the right to be free from physical or mental abuse and corporal punishment.
- The patient has the right to be free from restraints or seclusion of any form that are not medically necessary or are used as a means of coercion, discipline, convenience, or retaliation by staff. A restraint is any manual method or physical or mechanical device, material, or equipment attached or adjacent to the patient's body that he or she cannot easily remove that restricts freedom of movement or normal access to one's body. A drug used as a restraint is a medication used to control behavior or to restrict the patient's freedom of movement and is not a standard treatment for the patient's medical or psychiatric condition. Seclusion is the involuntary confinement of a patient alone in a room or area from which the patient is physically prevented from leaving.
- A restraint or seclusion can only be used if needed to improve the patient's well-being and less restrictive interventions have been determined to be ineffective.
- The use of a restraint or seclusion must be selected only when other less restrictive measures have been found to be ineffective to protect the patient or others from harm and in accordance with the order of a physician or other licensed independent practitioner.
- This order must never be written as a standing order or on an as-needed basis (i.e., prn). The order must be followed by consultation with the patient's treating physician, as soon as possible, if someone other than the patient's treating physician or health care provider ordered the restraint or seclusion.
- The use of a restraint or seclusion must be:
 - In accordance with a written modification to the patient's plan of care.
 - Implemented in the least restrictive manner possible.
 - In accordance with safe and appropriate restraining techniques.
 - Ended at the earliest possible time.
- The condition of the restrained or secluded patient must be assessed, monitored, and reevaluated continually.
- All staff who have direct patient contact must have ongoing education and training in the proper and safe use of restraints and seclusion.

BOX 2-3 The Joint Commission Patients' Rights Standards

- Right to an appropriate level of care
- Right to receive safe care
- Respect for cultural values and religious beliefs
- Privacy
- Consent obtained for recording or filming made for purposes other than the identification, diagnosis, or treatment of patients
- Confidentiality of information
- Recognition and prevention of potential abuse situation
- Notification of unanticipated outcomes
- Involvement in care decisions
- Information on risks and benefits of investigational studies
- End-of-life care
- Advance directives
- Organ procurement
- A right to have advance directives and to have them followed
- Freedom from unnecessary restraints
- Informed consent for various procedures
- The right to refuse care
- The right to have their pain believed and relieved
- Communication with administration
- Education

From The Joint Commission: *Comprehensive accreditation manual for hospitals*, Chicago, 2012, The Joint Commission.

BOX 2-4 Advance Directives

- An advance directive is a document that gives a patient's directions about future medical care or designates another person(s) to make medical decisions if the individual loses decision-making capacity.
- An advance directive conveys the patient's choice in continuing medical care when the patient is unable to speak or make decisions.
- Advance directives may include a living will, power of attorney for health care, or notarized handwritten document.
- A copy of the document should be available in the patient's medical record. If not available, the substance of the advance directive should be documented in the medical record, and a family member should be asked to bring the advance directive to the hospital.
- The attending health care provider is notified of the patient's advance directive.
- Witnesses for an advance directive document should not be medical personnel, nor should they be related to the patient or heirs to the patient's estate. A social worker often fulfills this requirement.

FIG 2-1 Nurse explains HIPAA regulations to patient.

purpose of the use. In addition to existing laws, new proposals include allowing patients to know who has accessed their information (USDHHS, 2011).

The HIPAA privacy regulations also give patients the right to access their records, request amendments to the PHI contained in their records, request restriction of certain uses or disclosures of their PHI, request that they be sent information at an alternative address or telephone number, and request an accounting of PHI disclosures (Fig. 2-1). Know your agency-specific policies and procedures related to HIPAA.

Role of the Nurse

On admission nurses complete a thorough nursing assessment, review any advance directives, and ensure that necessary diagnostic testing is completed. If patients were receiving health care before admission (e.g., home health care, long-term care), a nurse provides for continuity of care when a patient is admitted. Admitting

personnel consult with nursing staff to ensure that a patient's room assignment is based on the patient's condition, health care needs, developmental level, activity level, expected length of stay, and personal preferences. For example, the best room for an older patient who is acutely ill, at risk for falls, and receiving multiple treatments is one close to the nurses' station. The nurse identifies any known allergies and, if any exist, places an allergy band on the patient and properly documents the known allergies in the medical record.

When a patient is admitted through the ED, the nurse notifies the nursing division and reports on the patient's admission information, including his or her name; admitting physician or health care provider; chief complaint; and any treatments or testing completed and the outcome, diagnosis, and pertinent information related to the patient's condition (e.g., initial vital signs, allergies, level of consciousness, and intravenous [IV] fluid infusing). An escort takes the patient and family members to the nursing division

and introduces them to the nurse assuming the patient’s care. The ED nurse shares pertinent observations about the patient’s behavior (e.g., anxiety, fear, or level of knowledge regarding need for health care) with the nursing staff to foster continuity of care and assist the patient and family in coping with a new environment and procedures.

Patients admitted on the morning of a surgical procedure or treatment are “same day” admissions. A nurse provides basic instructions about the purpose of the surgery or treatment, preparatory procedures, and postsurgical or posttreatment care. Admission and consent forms, diagnostic tests, patient teaching, and instructions are usually completed before the actual day of surgery. Nurses use a variety of resources such as classes, videotapes, information booklets, and calls to home for patient teaching.

Nurses are active in coordinating the initial admission process for all patients. A patient’s condition influences the extent and type of admission activities. Always note the patient’s level of fatigue and comfort. For example, when a critically ill patient reaches a hospital nursing division, he or she undergoes extensive examination and treatment procedures immediately. Little time is available for you to orient the patient and family to the division or learn of the patient’s fears or concerns. When a patient enters a hospital for elective treatment, you have more time to prepare him or her psychologically for hospitalization. Early psychological preparation when the patient is still at home prepares patients for hospitalization.

Delegation and Collaboration

The skill of completing the nursing assessment during admission to a health care agency cannot be delegated to nursing assistive personnel (NAP). Do not delegate admission vital signs because a nurse must conduct the baseline assessment. The nurse directs the NAP to:

- Prepare the patient’s room with equipment needed before admission.
- Gather and secure the patient’s personal care items.
- Escort and orient the patient and family to the nursing unit.
- Collect ordered specimens.

Equipment

- Hospital gown
- Bedpan and urinal (if needed)
- Washbasin, bath towel, and washcloth
- Toiletry items (e.g., soap, toothpaste, hand lotion; *optional* in some hospitals)
- Facial tissues
- Water pitcher and drinking cup
- Kidney or emesis basin
- Disposable thermometer (see agency policy)
- Sphygmomanometer
- Stethoscope
- Pulse oximeter (*optional*)
- Documentation forms (see agency policy)

STEP **RATIONALE**

ROOM PREPARATION

- | | |
|--|--|
| <p>1 Perform hand hygiene and prepare room equipment and furniture. Prepare bed by adjusting it to the lowest horizontal position if patient is ambulatory. Place bed in high position if patient is arriving by stretcher. Turn down top sheet and bedspread. Arrange room furniture for easy access to bed. Adjust lights, temperature, and ventilation.</p> <p>2 Be sure that equipment is in working order. Assemble any special equipment (e.g., suction, oxygen supplies, or IV pole) in patient’s room.</p> | <p>Promotes patient’s comfort by preventing delays during care. Proper position of bed lessens likelihood of patient fall during transfer and back injuries to staff assisting patient into bed.</p> <p>Prevents delays in delivering immediate treatment and provides for smooth transition between caregivers.</p> |
|--|--|

ASSESSMENT

- | | |
|--|--|
| <p>1 Greet patient and family cordially by name. Introduce yourself by name and job title; explain your responsibilities in patient’s care.</p> <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient’s identification bracelet.</p> <p>3 If patient does not speak English or has a severe hearing impairment, arrange for a translation service so you are able to conduct a nursing assessment.</p> <p>4 Assess patient’s general appearance, noting signs or symptoms of physical distress (see Chapter 6).</p> | <p>Providing personalized care reduces anxiety about admission, clarifies staff roles, and expedites patient requests.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (2012b).</p> <p>Translation services are preferable to using family members to ensure correct translation of medical terminology.</p> <p>Provides baseline assessment.</p> |
|--|--|

Clinical Decision Point *If patient is having acute physical problems, postpone routine admission procedures until you meet his or her immediate needs. Complete a focused assessment at this point.*

- | | |
|--|---|
| <p>5 Determine patient’s ability to understand and implement health information by asking a health literacy question.</p> | <p>This supports patient’s ability to understand information and allows you to use appropriate teaching methods such as the “teach back” method (TJC, 2011a).</p> |
|--|---|

STEP	RATIONALE
6 Assess patient's and family's psychological status by noting verbal and nonverbal behaviors and responses to greetings and explanations.	Anxiety influences how well patient adapts to a health care environment and retains instruction.
7 Assess vital signs (see Chapter 5) and height and weight (see Chapter 6).	Provides baseline measurement to compare future findings. Determines alterations from normal range.
8 Assess for fall risk using scale with grading criteria per agency policy. Consider patient's risk factors (e.g., neurologic disorders; history of previous fall; urinary urgency or incontinence; use of sedatives, antihypertensives, and analgesics; history of unsteady gait; use of assistive devices; history of orthostatic hypotension; memory deficits) (Kulik, 2011).	Provides data to determine patient's risk for injury and whether patient needs to be placed on fall precautions.
9 Have family or friends leave room unless patient wishes to have them assist with changing into a hospital gown or pajamas. Close door and curtains. Help patient undress and assist patient into comfortable position.	Provides for privacy and prepares patient for examination.
10 Obtain nursing history as soon as possible after patient's arrival to nursing division. Apply standards of nursing care adopted by hospital (e.g., functional health patterns). Data include:	Each patient is to have an admission assessment prepared by a registered nurse (RN) (TJC, 2012a). Each agency sets a time frame for completion of admission assessment (maximum time 24 hours).
a Patient's perception of illness and health care needs.	Establishes a baseline of patient's clinical status.
b Past medical history.	Identifies signs and symptoms in case the patient's condition deteriorates.
c Presenting signs and symptoms and reason for hospitalization.	A comprehensive health history provides a holistic view of patient's health problems and response to those problems.
d Completion of a review of health status based on standards such as elimination, nutrition and metabolism, activity and exercise, self-concept, values and beliefs, cultural factors, social support, and cognitive function.	Allows you to institute preventive care measures and educate patient about health promotion behaviors.
e Risk factors for illness.	Patients often have sensitivity to a drug or substance rather than a true allergy; this needs to be clarified. Specify all allergens to prevent accidental exposure.
f History of allergies, including type of substance and a description of the reaction that patient has previously experienced.	
Clinical Decision Point Provide patient with allergy arm band listing allergies to foods, drugs, latex, or other substances; document allergies according to hospital policy.	
g Detailed medication history, including prescribed, over-the-counter (OTC), and alternative therapies such as herbs and hormones.	Assesses potential for drug interactions and often explains patient's presenting signs and symptoms.
h Patient's knowledge of health problems and expectations of care.	Enables you to recognize and meet patient expectations when possible.
11 Conduct physical assessment of appropriate body systems (see Chapter 6). If not obtained in admitting, instruct patient to provide a urine specimen. Inform patient if collecting blood specimens or performing tests.	Provides objective data for identifying health problems. When unannounced procedures are performed, patients become anxious. Preparation of patient relieves anxiety.
12 Check health care providers' orders for treatment measures to initiate immediately.	Delay causes deterioration of patient's condition.
13 Orient patient to nursing division.	Helps patient recognize caregivers. Shows respect for patient.
a Introduce staff members who enter room. Always introduce patient by last name unless patient indicates otherwise.	Provides means for patient to communicate problems.
b Tell patient and family the name of the nurse manager in charge of the division and explain that person's role in solving problems.	Provides knowledge and increases willingness to observe policy for visiting hours, which ensures that patient receives adequate rest.
c Explain visiting hours and their purpose.	A hospital-wide smoking policy that prohibits the use of smoking materials throughout the hospital is required. Some hospitals may have a designated smoking area.
d Discuss smoking policy and identify smoking areas for patient and family if available.	

STEP	RATIONALE
e Demonstrate use of equipment (e.g., bed, over-bed table, lighting).	Patient's safety depends on patient understanding correct use of equipment.
f Show patient how to use nurse call light and position it in a convenient place. Have patient demonstrate use of light. Discuss with patient any specific fall risks and encourage him or her to ask for assistance when getting out of bed.	Ensures that patient knows how to call for assistance.
g Escort patient to bathroom (if able to ambulate).	Patient's safety depends in part on understanding how to use toilet facilities.

Clinical Decision Point *Ensure that patient knows how to call for assistance while in bathroom. (An emergency call light is usually in bathrooms.)*

h Explain hours for mealtime and nourishments to patient and family.	Family often wishes to visit during evening to help with meals.
i Describe services available (e.g., chaplain, beauty shop, activity therapy).	Offers patient options for making decisions.

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding hospital procedures and planned therapies
- Fear
- Ineffective coping, individual or family
- Powerlessness
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient is able to explain purpose and schedule of planned treatments and procedures. • Patient demonstrates how to call for nurse when assistance is needed. • Patient is able to ambulate (if condition permits) in room free of obstacles. • Patient can safely and efficiently use equipment in the room. 	<p>Understanding treatment plan gives patient a better sense of control and reduces anxiety about the unknown.</p> <p>Falls commonly occur when patients attempt to get out of bed without assistance.</p> <p>Ensures patient safety and mobility in room.</p> <p>Equipment used in care of patient frequently poses hazards; assists in reducing some anxiety.</p> <p>Knowledge of hospital policies assists patient in adapting to the health care environment.</p>
<ul style="list-style-type: none"> • Patient verbalizes understanding of smoking policy, visiting hours, mealtimes, and services available. 	

IMPLEMENTATION

1 Complete patient medication reconciliation by checking home medication list for duplication, omission, or potential drug interactions with newly ordered medications. Update medication list based on health care provider's orders for treatment.	Medication reconciliation on admission helps to make sure that patient is taking the correct medications and avoid medication errors (TJC, 2012a).
2 Inform patient about procedures or treatments scheduled for the next shift or day (e.g., visits by health care provider or dietitian). These vary based on nature of patient's condition.	Patient has right to be informed of any scheduled procedures or treatments. Being able to anticipate planned therapies minimizes anxiety.
3 Complete learning needs assessment for patient and family.	Identifies patient's and family's educational needs and learning preferences.
4 Give patient and family chance to ask questions about procedures or therapies. (If patient is unresponsive or unable to understand, review with family.)	Provides opportunity to clarify expectations and misconceptions.
5 Collect valuables that patient chooses to keep at agency. Complete clothing and valuables listing sheet (see agency policy). Have patient or family member sign it. Place valuables in agency safe or send home with family.	Accounts for placement of valuables and prevents loss.
6 Ensure that patient and family have time together alone if desired.	Admission is often stressful and fatiguing. Allows time for decision making.
7 Be sure that call light is within easy reach and bed is in low position. (Check agency policy regarding use of side rails.)	Provides for patient's safety. Side rails enhance patient's ability to position in bed but are considered a restraint if they obstruct patient's ability to get out of bed when desired (TJC, 2012a).
8 Perform hand hygiene.	Reduces spread of microorganisms.

STEP

RATIONALE

EVALUATION

- 1 Have patient explain own fall risks, hospital policies, tests, and procedures through discussion and questions.
- 2 Have patient demonstrate use of call light.
- 3 Monitor patient's ability to ambulate independently.
- 4 Check patient's room setup regularly.

Patient demonstrates learning and understanding through feedback.

Return demonstration confirms learning.

Provides data to judge patient's safety in ambulating without injury.

Determines if care area is free of obstacles.

Unexpected Outcomes

- 1 Patient denies understanding hospital policies or knowing purpose or schedule for tests and procedures.
- 2 Patient becomes restless, expresses concerns, or displays tension in body movements.
- 3 Patient falls or is injured.

Related Interventions

- Schedule a follow-up session with patient.
- Keep information focused and specific to patient's situation. Include family if helpful.
- Give patient time to discuss fears and concerns.
- Show caring and compassion so patient becomes willing to communicate openly.
- Attend to patient's immediate physical needs, inform health care provider of the injury or fall, reassess patient's environment, alter care plan as needed, ensure that the environment is free of safety hazards, and complete incident report (see [Chapter 13](#)).

Recording and Reporting

- Record history and assessment findings in nurses' notes, electronic health record (EHR), or on appropriate forms. Begin to develop nursing plan of care. Confer with patient and family as needed.
- If patient has an advance directive, place copy in the medical record. In the absence of the actual advance directive, document the substance of the directive in the medical record ([TJC, 2012a](#)).
- Notify health care provider of patient's arrival; report any unusual findings. Secure admission orders if not previously provided.

Special Considerations

Teaching

- Explain to patient that a different nurse provides care on each shift. Explain time frame for how assignments are made.
- Teaching occurs throughout the admission process. Provide information regarding physical assessment findings, risks for falling, nature of patient's illness, planned diagnostic and treatment procedures, medications, and hospital routines. Do not begin a formal teaching plan until you have completed the assessment and developed a care plan.
- In an emergency situation or if patient is unable to perform aspects of his or her care, instruct family members in the rationale for any procedures and routines to be used in patient's care.

Pediatric

- Hospitalization is a major crisis for children who feel stress from separation, loss of control, bodily injury, and pain. Separation anxiety is most common from middle infancy throughout the

toddler years, especially ages 16 to 30 months. Preschoolers are better able to tolerate brief periods of separation, but their protest behaviors are more subtle than those in younger children (e.g., refusal to eat, difficulty sleeping, withdrawing from others). School-age children are able to cope with separation but have an increased need for parental security and guidance ([Hockenberry and Wilson, 2011](#)). Explain the rooming-in and visiting policies of the agency. Allow and encourage parental involvement in the child's care. Allow parents to assist with routine care activities (e.g., bathing, eating) and when possible to remain with the child during procedures.

- Parental input during admission assessment is essential because they can provide input on the child's normal behavior and deviations caused by illness ([Moorey, 2010](#)).
- Incorporate the child's usual routines such as favorite food, bedtime practices, and toileting into the plan of care. Encourage the parent to bring a favorite toy, blanket, or other items to make child feel more comfortable in the unfamiliar setting.

Gerontologic

- Hospitalized older adults often experience functional declines such as new-onset incontinence, malnutrition, pressure ulcers, and falls. Interventions that retain functional status (e.g., physical therapy, nutrition consultation) include providing coordinated interdisciplinary care ([Touhy and Jett, 2010](#)).
- Patients who typically fall in the hospital are those who have been admitted recently and are unfamiliar with surroundings, have acute illness, take four or more medications, or have been relocated recently. Visual changes that occur with aging often lead to falls in hospitalized older-adult patients ([Touhy and Jett, 2010](#)).

SKILL 2-2 Transferring Patients

Patients transfer to different patient care units and agencies to receive alternate forms and levels of therapy and services and to have essential care continued closer to home. When patients transfer, you need to ensure continuity of nursing care and improve transitions across the continuum of care. The goal is to continue health care to avoid therapeutic interruptions or omissions that may hinder progress toward recovery. Collaborate early with health care providers and members of the interdisciplinary team to ensure efficient patient transfer with optimal patient outcomes. There is evidence that interprofessional teams provide more integrated care than individual providers, particularly for patients with complex physiological, psychological, and social needs (Blewett and others, 2009). Open collaboration and effective communication help to ensure that quality patient care is realized.

When transferring a patient from one patient care unit to another within an agency, it is important to complete the process without interrupting care activities when possible. When providing a “hand off” of a patient to another unit, it is essential that information about the patient’s care, treatment, services, and current condition and any recent or anticipated changes are communicated accurately to meet patient safety goals (TJC, 2012a). Policies and procedures are usually similar throughout an agency. A nurse first provides a telephone report to the receiving nurse. This allows the receiving nurse to prepare for the patient (e.g., preparing the room and securing necessary equipment). As clinically appropriate, a nurse or technician accompanies the patient during transport, providing the receiving nurse with the patient’s medical record; introducing the patient to the receiving nurse; and providing an updated report, including any changes in clinical status or plan of care.

In the Emergency Department (ED), when a patient is transferred from one agency to another, a nurse completes the transfer in compliance with the Emergency Medical Treatment and Labor Act (EMTALA) (CMS, 2011). EMTALA is a federal law intended to protect patients from being transferred against their wishes and thus defines how an appropriate facility-to-facility transfer is accomplished. An appropriate transfer includes:

- Informing the patient of the risks and benefits of the transfer.
- Obtaining the patient’s written consent for transfer.
- Having the transferring hospital provide medical treatment within its capacity.
- Having available space and qualified personnel for treatment of the patient at the receiving agency and an agreement to accept transfer of the patient and provide treatment.
- Making copies of all relevant medical records, including a transfer form, sent by the transferring agency to the receiving facility.
- Transporting the patient using qualified personnel and transportation equipment (e.g., ambulance with advanced cardiac life support [ACLS] versus basic life support [BLS]).

Although this law primarily affects the ED, know EMTALA policies and transfer policies for inpatient transfers of the agency. Many agencies follow the same policies for all patient transfers.

Delegation and Collaboration

The skill of assessment and decision making conducted during transfers cannot be delegated to nursing assistive personnel (NAP).

The nurse directs the NAP to:

- Assist the patient with dressing.
- Gather and secure the patient’s personal belongings and any equipment that goes with the patient.
- Escort the patient to the nursing unit or transport area.

Equipment

- Transfer forms
- Copies of documents such as medical records, radiology films, laboratory test results (as appropriate)
- Special equipment as needed: wheelchair or stretcher, emesis basin, bedpan and urinal, oxygen tank and tubing, IV pole, cardiac monitor, and emergency medications

STEP

RATIONALE

ASSESSMENT

- 1 Obtain transfer order from sending health care provider. Order includes name of receiving agency (when applicable), receiving health care provider’s name, and statement of patient’s stability for transfer.
- 2 In collaboration with health care provider and members of the interdisciplinary team, assess reason for patient’s transfer (e.g., change in condition, services available at agency, patient or family preferences regarding patient’s location).
- 3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient’s identification bracelet.
- 4 Assess individuals at high risk for transitional care problems (e.g., older adults with multiple health issues, depression, non-English speakers, and low-income patients).

Health care provider is legally responsible for releasing patient from medical care and arranging for receiving health care provider. Patient has legal right to refuse transfer against medical advice.

Patient needs to have access to agency with best resources to meet health care needs. Health care provider determines patient’s physical stability for transfer.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012b).

Identifying patients at risk for transitional care problems allows for better continuity of care and improved patient outcomes (Touhy and Jett, 2010). Patients may require consultation with needed resources (e.g., care manager, psychologist).

STEP	RATIONALE
5 Explain purpose of transfer thoroughly and provide time to discuss patient's and family's feelings about the change in care setting. As necessary, obtain patient's written consent to transfer. If patient is unable to consent, patient's family provides this consent.	Patients need to be informed of transfer plans in a timely manner (TJC, 2011). A patient requires adequate psychological preparation. In the event of a clinical emergency in which patient and patient's family are unable to consent, this consent is waived, and patient is transferred to a higher level of care based on the clinical judgment of the health care provider requesting the transfer.
6 Assess patient's current physical condition and determine method for transport. When transferring to new agency, assess method of transport to transferring vehicle (e.g., wheelchair or stretcher) (consult agency policy).	Patient's condition often changes quickly and influences stability for transfer and type of support needed during transport.

Clinical Decision Point Determine if patient's status and safety require life-support equipment. Staff assisting with transfer needs training in life-support measures. When transporting to new agency, a vehicle equipped with life-support equipment is necessary.

7 Assess if patient requires pain relief or other medications for symptom management.	Ensures patient's comfort during transfer.
8 Ensure that staff have notified patient's family or significant others of transfer as desired by patient.	Provides adequate communication with family or significant others to assist with patient's emotional and psychological adjustment to the transfer (TJC, 2011).

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding transfer procedure
- Fear
- Pain, acute and chronic
- Powerlessness
- Relocation stress syndrome
- Risk for relocation stress syndrome

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient's vital signs and physiologic status remain the same following transfer. • Patient incurs no injury during transport procedures. • Patient or family explains purpose of transfer and procedure for transport. • Receiving nursing staff acquire and confirm written plan of care. • Patient socializes with family members, staff, and/or other residents. 	Treatments are planned so as not to interrupt physical support of patient during transfer. Safety measures are successful in transferring patient from wheelchair or stretcher to transport vehicle. Understanding provides patient with sense of control.
2 Arrange for patient's transport to an agency by chosen vehicle (social worker involvement may be necessary).	Ensures continuity of care.
3 When transfer is to a new agency, contact the agency and arrange for bed in appropriate setting. Confirm willingness of agency to accept patient (usually social worker or discharge coordinator completes).	Identifies that patient has not developed relocation stress syndrome.
	Transfer needs to occur without delays so patient has access to all needed resources at all times.
	Prevents delays when patient arrives at destination. Receiving hospital ensures that there is available space and qualified personnel to treat patients. Hospital also agrees in advance to transfer.

IMPLEMENTATION

1 Make sure that documentation in patient's record is complete with care plan that has individualized nursing care measures.	Accurate information is necessary for receiving agency to assume patient's care.
2 Complete nursing care transfer form according to agency policy. (When transfer is to a different nursing unit, entire medical record accompanies patient.)	Form summarizes patient's pertinent nursing care needs to ensure continuity of care and prevent unnecessary duplication of services.
3 Complete medication reconciliation per agency policy. Check patient's current orders against the most recent medication administration record and the original home medication list. Communicate updated medication list to next provider of care.	Ensures that patient receives correct medications at new facility and decreases medication errors (TJC, 2012a).
4 Have NAP gather patient's personal care items, clothing, and valuables. Check the entire room and all storage areas. Secure in suitcase or container.	Prevents loss of articles during transfer.

STEP	RATIONALE
5 Anticipate problems that patient frequently develops just before or during transfer. Perform necessary nursing therapies such as suctioning or changing a dressing.	Ensures patient's comfort and safety during transport.
6 Assist in transferring patient to stretcher or wheelchair using safe patient-handling techniques (see Chapter 9).	It is easier to move patient transported to outside agency by stretcher into transport vehicle.
7 Perform and document final assessment of patient's physical stability.	Minimizes risk of patient developing complications during transfer.
Clinical Decision Point <i>Priority assessment includes vital signs, clear airway, patency of IV lines and accuracy of infusion rate, and patient's level of consciousness.</i>	
8 When transfer occurs to an outside agency, accompany patient to transport vehicle.	Ensures that medically qualified personnel are in attendance until patient leaves agency/unit.
9 Call receiving agency/unit and notify of impending transfer and patient's status (check agency policy).	Notification of nurse in charge or nurse assuming care of patient ensures better continuity of care at time of patient's arrival.

EVALUATION

1 During the final assessment compare data with the previous findings.	Determines if patient's condition is changing.
2 Inspect patient's alignment and positioning on stretcher/wheelchair.	Proper alignment and positioning reduce risk of an injury occurring during transport.
3 Ensure that equipment needed for transfer is functioning.	Equipment such as oxygen must last through transport for patient safety.
4 Confirm that patient understands transfer and procedures through discussion and questions.	Feedback helps to ensure learning.
5 Determine if receiving agency/nurse has questions about patient's care.	Provides for clear communication and continuity of care.
6 Evaluate patient for inappropriate behaviors (e.g., acting out, refusing medication).	Provides information about relocation adaptation.

Unexpected Outcomes

- 1 Patient's physical status deteriorates during preparation.
- 2 Patient sustains injury during transfer to wheelchair or stretcher.
- 3 Patient is confused or uncertain about transfer.
- 4 Receiving staff misinterpret directions for patient's care.
- 5 Patient will not socialize and demonstrates inappropriate behaviors.

Related Interventions

- Call health care provider immediately.
- Initiate necessary interventions to stabilize patient's condition.
- Stabilize patient and call health care provider.
- Complete incident (occurrence) report (see Chapter 4).
- Provide clarification or additional explanation.
- Sending agency has nurse or health care provider call to confirm that there are no questions regarding patient's care.
- Include patient in developing plan of care.
- Identify previous coping mechanisms.
- Ensure that all caregivers introduce themselves.

Recording and Reporting

- Nurse sending patient documents patient's status, including vital signs and other assessment findings, nursing plan of care, date and time of transfer, and method of transport.
- Nurse receiving patient documents patient's arrival at agency by recording date and time of arrival, reason for transfer, method of transport, patient's condition, and care provided at time of arrival.

Special Considerations

Teaching

- A transfer frequently creates anxiety for a patient and family members. Carefully repeat instructions about the transfer when patient and family are better able to understand your explanation. In this situation be sure to have patient restate any critical information.

Pediatric

- Children need their parents' comfort and security; thus make sure that parents are well informed. Involve older children in any discussion regarding transfers. Allow a parent to accompany the child in the transfer.

Gerontologic

- When transferring an older-adult patient to a new facility, relocation is stressful. Ensure that significant support persons are still accessible and that patient is thoroughly oriented to new surroundings. Also make sure that patient is able to take important memorabilia and has an opportunity to make decisions about care (Touhy and Jett, 2010).

Long-Term Care

- It is important that patients receive the level of services appropriate to their physical and mental health needs. Participation of social worker or discharge planner in transfer process ensures that transfer to a long-term care facility is appropriate.

- On patient's arrival at long-term care facility, complete a Resident Assessment Instrument (RAI). The RAI consists of the minimum data set (MDS), resident assessment protocols, and utilization guidelines specified in state operations guidelines (Touhy and Jett, 2010).
- Essential components of successful transfer to a long-term care facility are accurate communication of medication lists and advance directives. Possible use of a standardized transfer form can assist in accurate communication (LaMantia and others, 2010).

SKILL 2-3 Discharging Patients

Discharge planning facilitates the transition of a patient from a health care agency to the most independent level of care, whether that is home or another agency. The overall goal of discharge planning is to provide the most appropriate level and quality of care throughout all stages of a patient's illness. The discharge planning process is comprehensive and multidisciplinary, including all caregivers who are involved in the care of the patient. Every hospitalized patient requires discharge planning. The trend toward a shortened length of stay in the acute care setting makes discharge planning increasingly difficult, but all the more essential. The Joint Commission identifies the elements of a comprehensive discharge planning model (Box 2-5).

Development of a discharge plan with outcomes mutually accepted by a patient and caregivers and ongoing communication about its progress are essential (TJC, 2011, 2012a). Effective discharge planning can decrease hospital readmission and increase

patient satisfaction (Rose and Haugen, 2010). The discharge process is simple or complex and occurs in three phases: acute, transitional, and continuing care. In the acute phase medical attention dominates discharge planning efforts. During the transitional phase the need for acute care is still present, but its urgency declines, and patients begin to address and plan for their future health care needs. In the continuing care phase patients are able to participate in planning and implementing continuing care activities needed after discharge.

The greatest challenge in effective discharge planning is communication. Communication issues are minimized when an organization has a discharge coordinator or case manager responsible for discharge planning. Staff members in these roles are responsible for thoroughly assessing a patient's health care needs at discharge, identifying available and needed resources, and linking the patient and family to the proper resources. Staff are also responsible for coordinating services (as appropriate) and following up on patients' progress after discharge.

Discharge from an agency is stressful for a patient and family. Before a patient is discharged, the patient and family need to know how to manage care in the home and what to expect in regard to any continuing physical problems. Without the necessary equipment and professional resources, a patient risks loss of rehabilitation gains made before discharge. Failure to understand restrictions or implications of health problems often causes a patient to develop complications. Poor discharge planning ignores a patient's needs within the home and increases the chance of the patient needing to reenter the health care system prematurely.

Delegation and Collaboration

The skill of assessment, care planning, and instruction included in discharging patients cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Gather and secure the patient's personal items and any supplies that accompany him or her.
- Transport the patient to the discharge transport vehicle.

Equipment

- Wheelchair or stretcher
- Discharge documentation forms (see agency policy)
- Patient instruction sheets
- Plastic bag for personal belongings

BOX 2-5 The Joint Commission Recommendations for Discharge Planning Process

- Address patient communication needs during discharge. This includes the patient's preferred language and any sensory or communication impairments.
- Ensure that language services are available during discharge for both patient and family members.
- Engage patients and families in discharge planning and instruction.
- Provide discharge instruction that meets patient needs.
 - Instruction may involve use of pictures, diagrams, or models to illustrate instruction.
 - Use discharge instruction that meets health literacy needs. Materials should be at fifth grade or lower reading level.
- Identify follow-up providers who can meet unique patient needs.
 - Create a list of follow-up providers that offer services and accommodations that meet the patient's communication, cultural, religious, mobility, and other needs.
 - Refer patients to appropriate care provider (e.g., community clinic).

Modified from The Joint Commission: *Advancing effective communication, cultural competence, and patient- and family-centered care: a roadmap for hospitals*, Oakbrook Terrace, 2011, The Joint Commission.

STEP

RATIONALE

ASSESSMENT

1 From time of admission, assess patient's discharge needs using nursing history and discussions with patient and health care provider. Use care plan to focus on ongoing assessments of patient's physical health, functional status, psychosocial support system, financial resources, health values, cultural and ethnic background, level of education, and barriers to care that are needed.

Planning for discharge begins at admission and continues throughout patient's stay in agency. Discharge planning interventions focus on helping patients achieve maximum functioning.

STEP	RATIONALE
<p>2 Identify patient using two identifiers (e.g., name and birthday or name and account number) according to agency policy). Compare identifiers with information on patient's identification bracelet.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012a).</p>
<p>3 Assess patient's and family's need for health teaching related to how to perform home therapies, use of home medical equipment, restrictions resulting from health alterations, and possible complications.</p>	<p>Improves understanding of health care needs and ability to achieve self-care at home. Inclusion of family member in teaching sessions provides patient with available resource.</p>
<p>4 Assess for barriers to learning (e.g., fatigue, pain, lack of motivation).</p>	<p>Determines timing and approach to instruction. Different types of educational materials are effective with different individual learning styles. If printed material is to be used, be sure that material at proper reading level is available.</p>
<p>5 Assess for environmental factors within the home that interfere with self-care (e.g., size of rooms, doorway clearances, steps, bathroom facilities). (A home care nurse is usually available on referral to assist with assessment.)</p>	<p>Environmental factors within patient's home pose safety risks or problems for self-care. For example, throw rugs are a fall hazard for a patient discharged with crutches or a walker (see Chapter 41).</p>
<p>6 Collaborate with health care provider and interdisciplinary team (e.g., physical therapy) in assessing need for referral for skilled home care services or extended care facility.</p>	<p>Patients eligible for home care must be confined to home as a result of illness, are under a health care provider's care, and require skilled nursing care on an intermittent basis.</p>
<p>7 Assess patient's and family's perceptions of continued health care needs outside the hospital. Include an assessment of family caregivers' perceived ability to provide care to patient, including ability to adjust to demands of patient care, impact of care demands on their lives (e.g., providing hands-on care, preparing special diets), and potential ongoing nature of patient's needs.</p>	<p>Patients and family members often disagree on health care needs of patient after discharge. Identifying discrepancies early helps in more accurately developing the discharge plan. Family caregiving is a highly stressful experience. Family members who are not properly prepared for caregiving are frequently overwhelmed by patient's needs, which can lead to unnecessary hospital readmissions (Sobolewski, 2011).</p>

Clinical Decision Point *It is often necessary to talk with patient and family separately to learn about true concerns or doubts.*

<p>8 Assess patient's acceptance of health problems and related restrictions.</p>	<p>Affects willingness to follow therapies and restrictions.</p>
<p>9 Consult other health care team members (e.g., dietitian, social worker) about anticipated needs after discharge. Make appropriate referrals in a timely manner.</p>	<p>Members of all health care disciplines collaborate to determine patient's needs and functional abilities.</p>

NURSING DIAGNOSES

- Anxiety
- Caregiver role strain
- Deficient knowledge regarding home care restrictions
- Impaired home maintenance
- Interrupted family processes
- Relocation stress syndrome
- Self-care deficit: feeding, toileting, dressing/grooming, bathing/hygiene

Related factors are individualized based on patient's condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient or family caregiver explains how health care is to continue in home (or other facility), which treatments or medications patient needs, and when to seek medical attention for problems. 	<p>Increases likelihood of care not being interrupted in home (or other facility).</p>
<ul style="list-style-type: none"> • Patient is able to demonstrate self-care activities (or family member is able to administer care measures). 	<p>Feedback ensures learning.</p>
<ul style="list-style-type: none"> • Obstacles to patient's mobility and hazards to ambulation in home setting are removed. 	<p>Patient is often physically weakened or has physical changes resulting from illness that predispose to injury.</p>

STEP

RATIONALE

IMPLEMENTATION

<p>1 Preparation before day of discharge:</p> <ul style="list-style-type: none"> a Suggest ways to change physical arrangement of home to meet patient's needs (see Chapter 41). b Provide patient and family with information about community health care resources (e.g., medical equipment companies, Meals on Wheels, adult day care). Referrals are usually made while patient is in hospital. c Conduct teaching sessions with patient and family as soon as possible during hospitalization (e.g., signs and symptoms of complications, information regarding medications, use of medical equipment, follow-up care, diet, exercise, restrictions imposed by illness or surgery). Review and give patient discharge materials such as pamphlets, books, or multimedia resources. Refer patient to reliable and current resources on the Internet. d Communicate patient's and family's response to teaching and proposed discharge plan to other health care team members. 	<p>Maintains patient's level of independence and ability to retain function within safe environment.</p> <p>Community resources offer services that patient or family cannot provide.</p> <p>Gives patient opportunities to practice new skills, ask questions, and obtain necessary feedback to ensure learning.</p> <p>A combination of written and verbal information is effective in improving patient satisfaction and knowledge (TJC, 2011).</p> <p>Facilitates development of individualized discharge plan.</p>
<p>2 Procedure on day of discharge:</p> <ul style="list-style-type: none"> a Let patient and family ask questions or discuss issues related to home care. A final opportunity to demonstrate learned skills is helpful. b Check health care provider's discharge orders for prescriptions, change in treatments, or need for special medical equipment. (Make sure that orders are written as early as possible.) Arrange for delivery and setup of equipment (e.g., hospital bed, oxygen) before patient arrives home. c Determine whether patient or family has arranged for transportation. d Provide privacy and assistance as patient dresses and packs all personal belongings. Check all closets and drawers for belongings. Obtain copy of valuables list signed by patient and have security or appropriate administrator deliver valuables to patient. e Complete medication reconciliation per agency policy. Check discharge medication orders against the medication administration record and home medication list. Provide patient with prescriptions or pharmacy-dispensed medications ordered by health care provider. Offer a final review of information needed to facilitate safe medication self-administration. f Provide information on follow-up appointments to health care provider's office. Provide phone number of unit. g Contact agency business office to determine whether patient needs to finalize arrangements for payment of bill. Arrange for patient or family to visit business office. h Acquire utility cart to move patient's belongings. Obtain wheelchair for patient. Transport patients leaving by ambulance on ambulance stretchers. i Assist patient to wheelchair or stretcher using safe patient handling and transfer techniques (see Chapter 9). Escort patient to entrance of agency where source of transportation is waiting (see agency policy) (see illustrations). Lock wheelchair wheels. Assist patient in transferring into transport vehicle. Help place personal belongings in vehicle. 	<p>Allows for final clarification of information previously discussed. Helps relieve anxiety.</p> <p>Only a health care provider is able to authorize a discharge. Early check of orders permits nurse to attend to any last-minute treatments or procedures well before discharge.</p> <p>Patient's condition at discharge determines method of transport.</p> <p>Prevents loss of personal items. Patient's signature verifies receipt of items and relieves nursing department of liability for losses.</p> <p>Medication reconciliation decreases risk of medication errors and ensures that patient is receiving correct medication at home (TJC, 2012a). Review of drug information provides feedback to determine patient's success in learning about medications.</p> <p>Provides patient with contact for questions that arise after discharge. Ensures continuity of care to prevent rehospitalization.</p> <p>Source of concern for many patients is whether agency has accepted insurance or other payment forms.</p> <p>Provides for safe transport.</p> <p>Prevents injury to nurse and patient. Agency policy requires escort to ensure patient's safe exit. Agency's liability ends once patient is safely in vehicle.</p>

STEP

RATIONALE

- j Return to division. Notify admitting or appropriate department of time of discharge. Notify housekeeping of need to clean patient's room.

Allows agency to prepare for admission of next patient.

STEP 2i A, Nurse escorts patient to transport vehicle at time of discharge via a wheelchair.
 B, Many patients are discharged via stretcher.

EVALUATION

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Ask patient or family member to describe nature of illness, treatment regimens, and physical signs or symptoms to be reported to a health care provider. 2 Have patient or family member perform any treatments that will continue in the home. 3 Home care nurse inspects home, identifies obstacles that pose risks for patient, and recommends revisions. | <p>Measures patient's or family's learning.</p> <p>Return demonstrations allow you to evaluate level of learning.</p> <p>Provides continuity of care.</p> |
|--|---|

Unexpected Outcomes

- 1 Patient or family is unable to explain self-care measures.
- 2 Patient or family demonstrates treatment measures incorrectly.
- 3 Environmental risks are still present in home.
- 4 Patient or family resists discharge plans and refuses assimilation of new roles needed for home care.
- 5 Patient refuses continued treatment and asks to leave the hospital before planned discharge.

Related Interventions

- Provide immediate clarification or offer additional instruction.
- Plan additional time to demonstrate treatment measures.
- Ask patient to explain which aspect of procedure is difficult to perform and why.
- If patient or family continues to be unable to correctly demonstrate treatment measures, request referral for home care services.
- Reassess reason for changes not being implemented.
- Home care nurse attempts to problem solve and seek appropriate solution.
- Contact additional resources (e.g., social work, home care, pastoral care).
- Talk with patient to determine reason for request to leave the hospital. Attempt to resolve the pressing issue for patient; involve family and social worker as appropriate.
- Notify health care provider to talk with patient and explain the risks of leaving the hospital with unresolved health care needs and the benefits of continued treatment.
- Inform patient that his or her health insurance provider may not pay for hospitalization as a result of leaving against medical advice (AMA).
- Request that patient sign discharge AMA form documenting that he or she understands the risk involved in leaving.
- Complete incident report and document thoroughly all communications/actions taken in attempt to have patient continue treatment (see Chapter 4).

Recording and Reporting

- Complete documentation of patient's discharge on discharge summary form (Box 2-6). Give patient a signed copy of form.
- Document unresolved problems and description of arrangements made for resolution in nurses' notes and electronic health record (EHR).
- Document patient's vital signs and status of health problems at time of discharge in nurses' notes and EHR.

BOX 2-6 Elements of a Written Discharge Summary Form

- Mode of discharge: Ambulatory, wheelchair, stretcher
- Instructions for self-care activities: Activity, diet, medications, special treatments such as wound care, self-catheterization, tracheostomy care
- Reconciled list of discharge medications with dose, frequency, route, reasons for change in medication or for newly prescribed medications
- Signs and symptoms of complications or drug reactions for which to be observant
- Signs and symptoms that the patient should consider normal
- Correct settings for any equipment required
- Planned follow-up appointment at health care provider's office, clinic
- Name and contact information of health care provider and/or nursing unit
- Explanation of pertinent emergency procedures
- Patient's signature, showing understanding of instructions

Modified from Loudon K: Creating a better discharge summary, *ACP Hospitalist* 3:1, 2009; National Quality Forum (NQF): *National voluntary consensus report, standards for public reporting of patient safety information: a consensus report*, Washington, DC, 2010, NQF.

Special Considerations

Teaching

- Assess patient's fatigue and pain levels before beginning any instruction. Keep focused on the important teaching topics to cover.

Pediatric

- Once family members have learned how to perform any necessary caregiver skills, have them assume care before child returns home. Many hospitals incorporate a trial period requiring family to manage care before child's discharge home (Hockenberry and Wilson, 2011).
- Discharge planning should be completed in partnership with children and parents. Over 80% of pediatric discharges are simple and do not require complex teaching or planning (Gibbens, 2010).

Gerontologic

- Older adults are interested in more information about community resources and social supports once discharged (Price, 2011).
- Older adults and their families often overestimate their ability to manage care after discharge. They also disagree about what postdischarge care includes. Make referrals to home care to address needs associated with functional decline and help prevent readmission to the hospital.

Home Care

- Assess availability and skill of primary family caregiver (e.g., spouse or friend): assess time availability, ability and willingness to give care, emotional and physical stamina, and knowledge of caregiving. Assess additional resources, including friends or neighbors who are available to help.
- Refer patients who meet the eligibility criteria to home care agencies for assistance.
- Inform patient or family member and patient's health care provider as to decision to accept or not accept patient for admission to home care agency.

Critical Thinking Exercises

Mrs. Hampton, a 68-year-old retired school teacher, is transferring from intensive care to your nursing unit following a cerebrovascular accident. She entered the ED 2 days ago with slurred speech and weakness of the right arm and leg. She has a history of primary hypertension, coronary artery disease, and type 2 diabetes mellitus. Her condition is stabilized. The intensive care nurse calls you to give a report on Mrs. Hampton. The nurse notes the admitting diagnosis, vital signs, pain level, and transferring health care provider's orders.

- 1 Which other information would you like to have about Mrs. Hampton?
- 2 The nurse arrives with Mrs. Hampton in a wheelchair; she is accompanied by her husband. Which interventions would you select to reduce Mr. and Mrs. Hampton's anxiety related to the transfer out of the intensive care unit?
- 3 Mr. Hampton states that his wife has an advance directive. What is the role of a nurse in understanding a patient's advance directive?
- 4 Mr. Hampton tells you that his wife is going home in a few days because she is doing so well. She will be going home using a walker. He says that he hopes he will be able to take care of her once she is at home. How do you respond to Mr. Hampton? Which interventions do you need to take before Mrs. Hampton's discharge?

REVIEW QUESTIONS

- 1 In which of the following steps of the admission process can the admission personnel participate? (Select all that apply.)
 - 1 Explaining information about a patient's rights to health care services
 - 2 Attaching an ID band after verifying that the information is correct
 - 3 Reviewing the details of a patient's advance directive for clarity
 - 4 Explaining how HIPAA is enforced in the agency
 - 5 Printing a patient's allergies on the allergy band before attaching it to the patient
 - 6 Helping a patient know what is included in the basic admission process
- 2 Who is responsible for developing a patient's discharge plan?
 - 1 The primary nurse
 - 2 The medical social worker
 - 3 The nurse caring for the patient the longest
 - 4 The patient's health care team

- 3 Which statement *best* explains why it is essential to assess and document the clinical status of a patient immediately before transfer or at time of discharge?
- 1 Increased reimbursement to the hospital occurs because of additional diagnosis codes.
 - 2 Potential changes in a patient's clinical needs may require nursing interventions to provide for patient safety during transport.
 - 3 Hospital documentation requirements could prevent transfer of a patient unless the information is current.
 - 4 The necessary information needs to be reflective of a discharge plan for visiting accrediting agencies.
- 4 A toddler is hospitalized for the first time. Which strategy is most effective to make the child feel more comfortable?
- 1 Have the parents visit only sporadically so the toddler does not get upset.
 - 2 Have the child bring a favorite blanket for comfort.
 - 3 Ask the parents what time the toddler usually goes to bed.
 - 4 Find out the toddler's favorite foods and beverages.
- 5 You are caring for a hospitalized patient who requires transfer to a skilled nursing facility. Which of the following interventions *best* facilitates a referral to a skilled nursing facility?
- 1 Providing teaching and instruction that supports the patient's continued independence
 - 2 Providing a variety of options for skilled care facilities to the patient and family
 - 3 Matching the services provided at the skilled care facility with the patient's needs
 - 4 Providing accurate information about the patient to the skilled care facility so nurses have a clear understanding of patient's needs
- 6 When completing an admission on a patient from a different culture, the nurse needs to:
- 1 Speak slowly and clearly so the patient can understand the nurse.
 - 2 Respect the patient's health beliefs and customs.
 - 3 Get all information about the patient from the family members.
 - 4 Use common slang terms that the culture understands.
- 7 When a patient arrives on the nursing division for admission to his or her room, what is the first thing the nurse should do?
- 1 Complete the admission assessment
 - 2 Orient the patient to the room
 - 3 Order all the patient's medication
 - 4 Complete all ordered diagnostic tests
- 8 You are caring for a patient in the ED who decides to leave without completion of his medical treatment. Which type of patient discharge should the nurse document?
- 1 Against medical advice (AMA)
 - 2 Patient-initiated discharge (PID)
 - 3 Voluntary discharge (VD)
 - 4 Without physician or health care provider order (WPO)
- 9 _____ are nursing actions implemented to ensure coordination and continuity of care for patients who are transferring between different care settings or care levels.
- 10 When determining the health literacy of your patient before beginning discharge teaching, it is essential that the information is at which appropriate reading level?
- 1 Sixth grade
 - 2 Tenth grade
 - 3 Fifth grade
 - 4 College level

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify guidelines to use in therapeutic communication.
- Explain the communication process.
- Identify the purposes of therapeutic communication, communication in various phases of the nurse-patient relationship, and special issues related to communication.
- Develop skills for therapeutic communication in various phases of the nurse-patient relationship.
- Develop therapeutic communication skills for communicating with anxious, angry, and depressed patients.
- Develop therapeutic communication skills for communication with cognitively impaired patients.

Effective communication positively influences nursing care. A nurse's responsibility to effectively communicate extends beyond the patient to include family members/significant others and members of the health care team. This chapter does not intend to give a complete introduction to the complicated process of communication. Rather the purpose is to provide a framework for you to develop therapeutic skills that are essential to the communication process.

Communication is an interaction between two or more persons that involves the exchange of information between a sender and a receiver (Fig. 3-1). It is an essential component of the human experience, involving the expression of emotions, ideas, and thoughts through verbal (words or written language) and nonverbal (behaviors) exchanges. Therapeutic communication is an application of the process of communication to promote the well-being of a patient.

Verbal communication includes both spoken and written words. To send an accurate message the sender of verbal communication needs to be aware of the tone, volume, and cadence (pace or rate) of his or her voice. In addition, he or she needs to be aware of cultural differences between sender

and receiver such as the use of dialect or slang. Other issues that the sender must consider with written communication include barriers such as the receiver's cognitive and visual impairments. In addition, consider the developmental perspectives of the receiver because these influence the method of communication used.

Nonverbal communication describes all behaviors that convey messages without the use of words. This type of communication includes body movement, physical appearance, personal space, and touch. As a nurse be aware of body language, which includes posture, body position, gestures, eye contact, facial expression, and movement (Fig. 3-2). For clarity make sure that nonverbal communication is consistent with the spoken word. When assessing a patient's needs, assess the nonverbal messages received from him or her and validate them. For example, if you observe a patient wringing her hands and sighing often, ask, "You seem anxious today. Is there anything on your mind?" You avoid problems in language behavior through the consistent use of clear, mutually understood verbal terminology and nonverbal gestures. To avoid misinterpretation of nonverbal cues, be aware of any cultural

FIG 3-1 Communication is a two-way process.

FIG 3-2 An open, relaxed posture conveys interest.

norms or values (e.g., eye contact) that patients may have (see Skill 3-1).

Therapeutic communication is essential for excellent nursing practice. Nurses use communication skills in caring for patients by providing information and comfort, promoting understanding, clarifying misinformation, assisting in developing plans of care, and facilitating wellness through patient teaching. The nurse-patient relationship promotes a connection, which is an essential component of the healing process.

EVIDENCE-BASED PRACTICE

Effective therapeutic communication with patients across the life span is essential for successful nursing practice. Research identifies the following health outcomes as a result of effective therapeutic communication: empowerment, control of chronic disease, satisfaction with care, and improved quality of life (Rohrer et al., 2008). Nurse researchers and clinicians have developed creative modes of communicating with patients. For example, when interacting with patients with severe communication impairments, nurses can use augmentative and assistive communication (AAC). These include use of unaided AAC techniques (e.g., hands, face, and/or feet) and manual sign language, pantomime, gestures, and eye-blink systems. Aided AAC techniques include use of picture books, alphabet books, and pencil and paper systems (Finke et al., 2008). The nurse must initially determine the best mode of communication for a particular patient. The goal of any AAC technique is for patients with complex communication needs to effectively engage in interactions with nurses, family members, and other members of the health care team. Recommendations made from these studies underscore the need for nurses to improve and increase their efforts to communicate with these patients; they

need to be creative in their use of strategies. Nurses should receive adequate training in use of these AAC strategies and understand the implications of communication impairment. Research demonstrates the importance of being persistent in trying to communicate with such patients; allow for sufficient time for a patient to respond and pay close attention to nonverbal responses. In addition, it is essential to maintain a quiet environment. The use of these strategies can facilitate a successful nurse-patient interaction.

Managing patients with behavioral and/or cognitive impairments requires communication skills to assess and redirect patients and modify any negative behaviors. Effective communication is essential to the quality of life and well-being of patients (Boschart, 2009). Research shows that use of specific behavior-management strategies effectively reduces agitation and improves interactions with patients having difficulty with comprehension.

- Use role play and emphasize empathy.
- Use problem-free conversations and support strategies to demonstrate concern for patients.
- Frame brief interventions in a positive manner.
- Use video training programs in teaching communication strategies to nurses who interact with patients who have communication difficulties (Miller, 2008).
- Use therapeutic communication techniques to de-escalate a patient's anxiety or anger.

Communicating effectively with children with visual impairments and other disabilities poses a challenge for nurses (Parker et al., 2008). These children often lack access to powerful visual nonverbal cues such as facial expressions and gestures. To improve children's communication skills use:

- Microswitch interventions (supportive speech-output programs).
- Multicomponent partner training (tactile sign language, touch cues).
- Dual communication boards.
- Object symbols and adult-directed prompting and reinforcement.

This study provides evidence that children with impairments can develop functional communication skills if they are given intensive, consistent communication interventions and a mechanism for self-expression (Parker et al., 2008).

PATIENT-CENTERED CARE

Patient-centered care improves communication, promotes patient involvement in care, creates a positive relationship with health care providers, and results in improved adherence to treatment regimens. This strategy respects patients' beliefs and values about health and illness, including those of culturally diverse patients. In addition, patient-centered care includes patients and significant others in collaboration with health care providers to make decisions related to wellness and illness care. Benefits include improved satisfaction with care, self-efficacy and empowerment to manage care, and quality of life (Murphy, 2011; Robinson et al., 2008; Tucker et al., 2011).

The Quality and Safety Education for Nurses (QSEN) initiative includes specific quality and safety outcomes that are required of nurses to practice safely and effectively in complex health care systems (McKeon et al., 2009). The American Association of Colleges of Nursing (AACN) has recommended that students learn these patient-centered care competencies through teaching strategies such as unfolding case studies and simulation. Computer-based simulation is a recommended strategy to teach safe clinical practice. A study that examined the effectiveness of computer-based

simulation compared to traditional simulation in teaching patient-centered competencies for prelicensure nursing students found that students in both groups achieved similar competencies (McKeon et al., 2009).

Nurses face challenges when communicating with culturally and linguistically diverse patients. Effective communication between culturally diverse patients and nurses is essential to improving health outcomes. Furthermore, patient-centered care has been described as one approach to cultural competency education to guide health care providers to deliver respectful care that is responsive to patient preferences (Wilkerson et al., 2010). The following skills are necessary for using a patient-centered approach: the ability to elicit a patient's personal story, explore health beliefs and practices, and negotiate a health care management plan that is respectful of these preferences. In addition, it is also helpful to speak plainly; avoid mimicking a patient's accent or dialect. Understand that members of certain cultures use cultural phrases or slang common to their culture and this is not an indication they do not understand English.

When you communicate with patients of diverse cultures, an interpreter is sometimes necessary. A lack of attention to language barriers can lead to poor-quality communication and poor health outcomes (Bischoff and Hudelson, 2010). It is important to use trained medical interpreters rather than relying on bilingual colleagues or a patient's family or friends. The reliance on untrained interpreters has been associated with poor quality of health care and breaches of confidentiality. In the United States hospitals must follow requirements for providing culturally and linguistically appropriate health care to patients. When using an interpreter, address the patient and family directly; do not direct questions or comments to the interpreter. Take care to determine if the patient understood. Speak slowly in normal tones and avoid overly technical jargon or terms unique to a culture (Box 3-1). Adopting a flexible, respectful attitude that also communicates interest in the patient bridges any communication barriers that exist because of cultural differences between patient and caregiver.

Safety Guidelines

- 1 Listen to what and how a patient communicates, including content and verbal and nonverbal messages. Some patients express themselves clearly without difficulty. However, indirect and nonverbal cues communicate a patient's needs.

SKILL 3-1 Establishing the Nurse-Patient Relationship

A therapeutic nurse-patient relationship is the foundation of nursing care and involves using patient-centered therapeutic communication skills. Communication is essential in nursing since effective communication among patients, families, and health care providers is central to quality care (Majerovitz et al., 2009). The primary goal of therapeutic communication for the nurse is to promote wellness and personal growth in patients. Therapeutic communication empowers patients to make decisions but differs from social communication in that it is patient centered and goal directed with limited disclosure from the professional.

Social communication involves equal opportunity for personal disclosure, and both participants seek to have personal needs met (Keltner et al., 2011). Nurses do not share intimate details of their personal lives with patients. However, they use personal self-disclosure (e.g., outside interests, thoughts about local news, experience as a nurse) cautiously in selected situations. Personal

BOX 3-1 Special Approaches for Patients Who Speak Different Languages

- Use a caring tone of voice and facial expressions to help alleviate patients' fears and anxieties.
- Speak slowly and distinctly but not loudly.
- Use gestures, pictures, and role playing to help patients understand.
- Repeat a message in different ways if necessary.
- Be alert to and use words that a patient seems to understand and use them frequently.
- Keep messages simple and repeat them frequently.
- Avoid using medical terms that a patient may not understand.
- Use an appropriate language dictionary or have a medical interpreter or family member make flash cards to communicate key phrases.

From Giger J: *Transcultural nursing: assessment and interventions*, ed 6, St Louis, 2013, Mosby.

- 2 Know your attitudes toward the patient or situation. You need to be aware of your personal feelings to control how you communicate issues. Being unaware of personal feelings may lead to negative consequences in communication.
- 3 Control external factors in both the environmental setting (temperature of room, privacy issues) and the psychological setting (emotional state of the nurse and patient) that influence or hinder communication. When you are talking with a patient about his or her personal concerns, privacy is important. When teaching, try to have a family member/significant other present with whom to reinforce the content of the instruction. If a patient is experiencing subjective distress in the form of pain or anxiety, take measures to minimize these subjective experiences. Controlling noise level and interruptions is also important.
- 4 Establish and understand the purpose of interaction. This is an essential quality of effective communication. Without this quality communication is casual and superficial.
- 5 Guide the interaction, depending on the patient's condition and response. Patient needs remain the focus. For example, you establish that the purpose of the interaction is patient teaching; however, the patient just learned about the death of a loved one and expresses the need to talk about the death. You assist the patient by grieving first, remaining flexible and creative in the interaction.

self-disclosure is useful for the following goals: (1) to educate patients, (2) to build therapeutic alliances with patients, and (3) to encourage patients' independence (Fortinash and Holoday-Worret, 2008). For example, you share selected personal thoughts and life experiences with a patient to show that you understand what the patient is experiencing.

Skills essential to therapeutic communication include active listening, broad openings, humor, sharing perceptions, clarifying, focusing, informing, paraphrasing, reflecting, restating, summarizing, suggesting, using therapeutic silence, and using open-ended statements/questions. Most of these skills are defined with case illustrations identifying therapeutic and nontherapeutic examples of their use (Box 3-2). Paraphrasing is another skill that involves restating a patient's original message by transforming the message into your own words without losing the meaning. You achieve empathy in communication through the use of all the

BOX 3-2 Therapeutic Communication Techniques**Technique: Listening**

Definition: An active process of receiving information and examining one's reaction to messages received

Example: Consider the cultural practice of your patient, maintain appropriate eye contact, and be receptive to nonverbal communications

Therapeutic Value: Nonverbally communicates nurse's interest and acceptance to patient

Nontherapeutic Threat: Failure to listen, interrupting patient

Technique: Broad Openings

Definition: Encouraging patient to select topics for discussion

Example: "What are you thinking about?"

Therapeutic Value: Indicates acceptance by nurse and value of patient's initiative

Nontherapeutic Threat: Domination of interaction by nurse; rejecting responses

Technique: Restating

Definition: Repeating main thought that patient has expressed

Example: "You say that your mother left you when you were 5 years old."

Therapeutic Value: Indicates that nurse is listening and validates, reinforces, or calls attention to something important that has been said

Nontherapeutic Threat: Lack of validation of nurse's interpretation of message; being judgmental; reassuring; defending

Technique: Clarification

Definition: Attempting to improve the nurses' understanding of words, vague ideas, or the patient's unclear thoughts or asking patient to explain what he or she means

Example: "I'm not sure what you mean. Could you tell me again?"

Therapeutic Value: Helps to clarify patient's feelings, ideas, and perceptions and provide an explicit correlation between them and the patient's actions

Nontherapeutic Threat: Failure to probe; assumed understanding

Technique: Reflection

Definition: Directing back to patient ideas, feelings, questions, or content

Example: "You're feeling tense and anxious, and it's related to a conversation you had with your sister last night?"

Therapeutic Value: Validates nurse's understanding of what patient is saying and signifies empathy, interest, and respect for patient

Nontherapeutic Threat: Stereotyping patient's responses, inappropriate timing of reflections; inappropriate depth of feeling of reflections; inappropriate to the cultural experience and educational level of the patient

Technique: Humor

Definition: Discharging energy through comic enjoyment of the imperfect

Example: "This gives a whole new meaning to 'Just relax.'"

Therapeutic Value: Can promote insight by making conscious repressed material, resolving paradoxes, tempering aggression, and revealing new options; is a socially acceptable form of sublimation

Nontherapeutic Threat: Indiscriminate use; belittling patient; screen to avoid therapeutic intimacy

Technique: Informing

Definition: Demonstrating skills or giving information

Example: "I think it would be helpful for you to know more about how your medication works."

Therapeutic Value: Helpful in patient education about relevant aspects of patient's well-being and self-care

Nontherapeutic Threat: Giving advice

Technique: Focusing

Definition: Asking questions or making statements that help patient expand on a topic of importance

Example: "I think it would be helpful if we talk more about your relationship with your father."

Therapeutic Value: Allows patient to discuss central issues related to problem and keeps communication process goal directed

Nontherapeutic Threat: Allowing abstractions and generalizations; changing topics

Technique: Sharing Perceptions

Definition: Asking patient to verify nurse's understanding of what patient is thinking or feeling

Example: "You're smiling, but I sense that you're really very angry with me."

Therapeutic Value: Conveys nurse's understanding to patient and has potential for clearing up confusing communication

Nontherapeutic Threat: Challenging patient; accepting literal responses; reassuring; testing; defending

Technique: Theme Identification

Definition: Clarifying underlying issues or problems experienced by patient that emerge repeatedly during nurse-patient relationship

Example: "I've noticed that in all the relationships that you've described you've been hurt or rejected by the man. Do you think this is an underlying issue?"

Therapeutic Value: Allows nurse to best promote patient's exploration and understanding of important problems

Nontherapeutic Threat: Giving advice; reassuring; disapproving

Technique: Silence

Definition: Using silence or nonverbal communication for a therapeutic reason

Example: Sitting with patient and nonverbally communicating interest and involvement

Therapeutic Value: Allows patient time to think and gain insights, slows the pace of the interaction, and encourages patient to initiate conversation while conveying nurse's support, understanding, and acceptance

Nontherapeutic Threat: Questioning patient: asking for "why" responses; failing to break a nontherapeutic silence

Technique: Suggesting

Definition: Presenting alternative ideas for patient's consideration relative to problem solving

Example: "Have you thought about responding to your boss in a different way when he raises that issue with you? For example, you could ask him whether a specific problem has occurred."

Therapeutic Value: Increases patient's perceived options or choices.

Nontherapeutic Threat: Giving advice, inappropriate timing; being judgmental

aforementioned skills. Empathy is being sensitive and understanding of a patient's feelings and communicating this understanding to the patient. It differs from sympathy in that sympathy is nonobjective and noncritical.

Barriers to therapeutic communication include giving an opinion, offering false reassurance, being defensive, showing approval or disapproval, stereotyping, and asking, "Why?" The use of "why" questions causes increased defensiveness in patients and hinders communication. The therapeutic nurse-patient relationship is goal directed, with a patient moving toward productive modes of interpersonal functioning. Three overlapping phases characterize the nurse-patient relationship: orientation, working, and termination. The orientation phase involves learning about the patient and any initial concerns and needs. During orientation you clarify your role and that of other health care providers, establish rapport with the patient, collect information, establish goals, and clarify misunderstandings. When the orientation phase is successful and the patient is ready, work toward effective goal attainment begins with the working phase of the nurse-patient

relationship. The termination phase consists of evaluation and summary of progress toward prescribed goals. Prepare for termination generally at the beginning of a patient relationship. You must communicate effectively with patients throughout all three phases of the nurse-patient relationship.

Delegation and Collaboration

All health care providers must practice effective communication. The skill of establishing therapeutic communication cannot be delegated to nursing assistive personnel (NAP). The NAP observes and receives information from patients because of the length of time they are with patients. The nurse directs the NAP about:

- The proper way to interact verbally and nonverbally with select patients.
- Ways to arrange the environment to ensure privacy and confidentiality.
- Special considerations pertaining to communication with patients who are cognitively or sensorially impaired, older children, and anxious and potentially violent patients.

STEP

RATIONALE

ASSESSMENT

- 1 The first contact a nurse has with a patient occurs during the orientation phase. Address patient by name and introduce self and role on health care team ("Hello, my name is Sally Regan, and I am the registered nurse assigned to take care of you today. ...") Use clear, specific communication (verbal and nonverbal) to provide information and clarify concerns.
- 2 Assess the following behaviors: patient's needs, coping strategies, defenses, and adaptation styles.
- 3 Determine patient's need to communicate (e.g., constant use of call light, crying, patient who does not understand an illness or who has just been admitted).
- 4 Assess reason patient needs health care.
- 5 Assess factors about self and patient that normally influence communication: perceptions, values, and beliefs; emotions; sociocultural background; severity of illness; knowledge; age; verbal ability; roles and relationships; environmental setting; physical comfort or discomfort (see illustration).

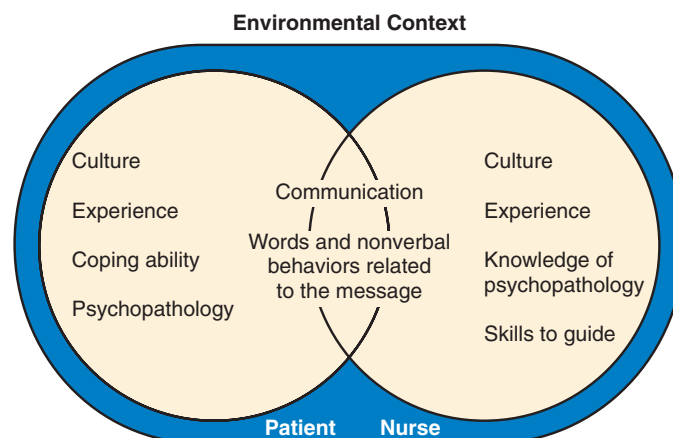

Congruent verbal and nonverbal communication expresses warmth and respect and helps to establish rapport. Clear, specific communication decreases confusion and anxiety and improves the quality of health care (O'Halloran et al., 2009).

Recurrent themes in patient's response help to identify problem areas related to health status (e.g., avoidance of questions, request for information, expression of a loss).

Patients in need of support, comfort, knowledge, or encouragement benefit from meaningful communication.

Nature of illness affects patient's coping ability and effectiveness in communicating needs and concerns.

Communication is a dynamic process influenced by interpersonal and intrapersonal processes. By assessing factors that influence communication, you can more accurately assess a patient's perception of health status (Rohrer et al., 2008).

STEP 5 Essential and influencing variables of the therapeutic communication environment. (Modified from Keltner N et al: Psychiatric nursing, ed 6, St Louis, 2011, Mosby.)

STEP

RATIONALE

- 6 Assess personal barriers to communicating with patient (e.g., bias toward patient's condition, anxiety from inexperience).
- 7 Assess patient's language and ability to speak. Does patient have difficulty finding words or associating ideas with accurate word symbols? Does patient have difficulty with expression of language and/or reception of messages? What is patient's primary language?

Barriers prevent you from conveying empathy and caring and obtaining relevant assessment information. Assessment determines need for special communication techniques (e.g., picture boards, aids such as a medical interpreter) (see illustration).

STEP 7 Communication tools for patient who cannot speak.

- 8 Assess patient's literacy level. Does he or she skip over uncommon or hard word, avoid asking questions, or have difficulty discussing concepts about illness? *Option:* use a standardized instrument such as the Rapid Estimate of Adult Literacy in Medicine (REALM) (Davis et al., 1993) or the Test of Functional Health Literacy in Adults (TOFHLA) (Parker et al., 1995).
- 9 Assess patient's ability to hear. Be sure that hearing aid is functional if worn. Be sure that patient hears and understands words (see Chapter 6).
- 10 Observe patient's pattern of communication and verbal or nonverbal behavior (e.g., gestures, tone of voice, eye contact).
- 11 Assess resources available in selecting communication methods:
 - a Review information in medical record and consider your past experience.
 - b Consult with family, health care provider, and other health care team members concerning patient's condition, problems, and impressions.
- 12 Before initiating the working phase of nurse-patient relationship, assess patient's readiness to work toward goal attainment.
- 13 Consider when patient is due to be discharged or transferred from health care agency.

Health literacy has a direct effect on health outcomes. Assessing patient's level of health literacy allows you to design more effective communication and teaching approaches.

Patients with hearing deficits require techniques to enhance hearing reception (e.g., speaking in normal tone, speaking so patient can see face).

Observation determines type of and manner of communication that you will use.

Relying totally on information from patient restricts the quality of interaction. Additional resources provide insight into best methods of communicating.

Collaboration with health care team members facilitates your response to patient based on integration of knowledge. Seek information from family after patient approval. Patient privacy must be maintained.

Patient's goals are identified and agreed on by effective communication skills such as restating and clarifying.

This allows you to anticipate the amount of time available to work with patient and when termination of relationship is to occur.

NURSING DIAGNOSES

- | | | |
|-----------------------|---------------------------------|--|
| • Anxiety | • Impaired social interaction | • Noncompliance |
| • Deficient knowledge | • Impaired verbal communication | • Readiness for enhanced decision making |
| • Fear | • Ineffective coping | |

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient expresses ideas, fears, and concerns clearly and openly with relief of anxiety. • Patient health care goals are identified and achieved. • Patient verbalizes understanding of information communicated by nurse. <p>2 Orientation phase</p> <p>a Prepare by providing a warm and accepting environment, establishing trust, formulating individualized patient goals, considering time allocation, formulating initial questions, and mentally preparing to keep one's mind clear of other concerns or distractions.</p> <p>b Prepare patient and environment physically: provide a quiet environment, maintain privacy, reduce distractions or interruptions, and take care of patient's physical needs (e.g., comfort or hygiene) before beginning discussion.</p> <p>3 Working phase</p> <p>a Use open-ended questions to identify strategies to develop a realistic plan to meet identified health goals of patients (e.g., "Tell me about your goals for this hospitalization/visit to the health care agency").</p> <p>4 Termination phase</p> <p>a Prepare by identifying methods of summarizing and synthesizing information pertinent for aftercare (e.g., "What are your plans for follow-up to maintain your health status?").</p>	<p>Once patients are able to talk directly about emotions, the focus is on coping more effectively with them (Keltner et al., 2011). Interaction remains patient focused. This provides a means to build trust and develop a knowledge base for patient to make decisions.</p> <p>Preparation is part of planned process that facilitates communication and interaction. Planning for orientation phase assists in identifying actual or potential problems, current health status, and experience. Without preparation, a risk exists of casual, nongoal-oriented communication. Taking care of basic needs promotes an environment for interaction and decreases patient distractions and interruptions.</p> <p>Open-ended questions promote goal attainment and avoid risk of misinterpretation.</p> <p>Effective communication by summarizing and synthesizing information reinforces behavior change.</p>
--	--

IMPLEMENTATION

<p>1 Orientation Phase: Establish the nurse-patient relationship.</p> <p>a Create a climate of warmth and acceptance. Be aware of nonverbal cues, both sent and received. Provide comfort and support to patient.</p> <p>b Use appropriate nonverbal behaviors (e.g., good eye contact, open relaxed position, sitting eye level with patient [see Fig. 3-2]).</p> <p>c Observe patient's nonverbal behaviors, including body language. If verbal behaviors do not match nonverbal behaviors, seek clarification from patient.</p> <p>d Explain purpose of interaction when information is to be shared.</p> <p>e Use active listening.</p> <p>f Identify patient's expectations in seeking health care.</p> <p>g Interview patient about health status, lifestyle, support systems, patterns of health and illness, and strengths and limitations.</p> <p>h Encourage patient to ask for clarification at any time during the communication.</p> <p>i Use therapeutic communication techniques when interacting with patient (refer to Box 3-2).</p> <p>2 Working Phase: Set mutual goals.</p> <p>a Use therapeutic communication skills such as restating, reflecting, and paraphrasing to identify and clarify strategies for attainment of mutually agreed-on goals.</p> <p>b Discuss and prioritize problem areas.</p>	<p>This facilitates open exchange without fear or anxiety.</p> <p>Appropriate nonverbal behaviors facilitate communication by providing a nonverbal message that shows interest in what patient has to say. Congruence between patient's verbal and nonverbal behaviors ensures that you receive the correct message.</p> <p>Information and explanation can decrease anxiety about the unknown. Active listening conveys interest in the patient's needs, concerns, and problems; conveys empathy. Identifying expectations conveys a level of interest in patient's needs. Interview facilitates a positive nurse-patient relationship and the development of trust, putting the patient at ease.</p> <p>This gives patient a sense of control and keeps channels of communication open. Techniques establish a greater understanding of messages sent and received.</p> <p>For communication between nurse and patient to be effective, both need to possess the skills and knowledge required for participation within the communicative interaction (Finke et al., 2008). A patient, nonjudgmental, supportive approach minimizes patient anxiety.</p>
--	---

STEP	RATIONALE
<p>c Provide information to patient and help him or her to express needs and feelings.</p> <p>d Use questions carefully and appropriately. Ask one question at a time and allow sufficient time to answer. Use direct questions. Use open-ended statements as much as possible such as, “Tell me about how you are feeling today.”</p>	<p>Patient is able to respond to help, develop workable solutions based on goals, and fully participate in a realistic plan for his or her well-being.</p> <p>This helps patient to express self and allows you to obtain thorough information about patient’s needs and concerns.</p>
<p>Clinical Decision Point <i>Avoid asking questions about information that may not yet have been disclosed to the patient (e.g., human immunodeficiency virus [HIV] status, diagnostic test results). Avoid asking “why” questions; this causes increased defensiveness in the patient and prevents communication.</i></p>	
<p>e Avoid communication barriers.</p> <p>3 Termination Phase: Communicate with the patient.</p> <p>a Use therapeutic communication skills to discuss discharge or termination issues and guide discussion related to specific patient changes in thoughts and behaviors.</p> <p>b Summarize with patient what you discussed during interaction, including goal achievement.</p>	<p>Barriers result in a message not being received, being distorted, or not being understood.</p> <p>Communication skills reinforce behaviors/skills learned during working phase of relationship.</p> <p>Signals the close of interaction and allows you and patient to depart with the same idea. Provides a sense of closure and mutual understanding.</p>

EVALUATION

<p>1 Observe patient’s verbal and nonverbal responses to your communication, noting his or her willingness to share information and concerns during orientation phase.</p>	<p>Verbal and nonverbal feedback reveals patient’s interest and willingness to communicate and reflects patient’s ability to form a therapeutic relationship.</p>
<p>2 Note your response to patient and patient’s response to you. Reflect on effectiveness of therapeutic techniques used in establishing rapport with patient.</p>	<p>Sensitivity to one’s ability in using therapeutic communication skills helps improve ability to adjust techniques when necessary.</p>
<p>3 During working phase evaluate patient’s ability to work toward identified goals. Elicit feedback (verbal and nonverbal) to determine success of goal attainment. Evaluate patient’s health status in relation to identified goals. Reevaluate and identify barriers if patient goals are not met.</p>	<p>Feedback is an essential step in evaluating new behaviors. Modifications are necessary if goals cannot be met.</p>
<p>4 During termination phase summarize and restate. Reinforce patient’s strengths, outline issues still requiring work, and develop an action plan.</p>	<p>Evaluates patient progress in terms of attainment of mutually agreed-on goals.</p>

Unexpected Outcomes

- 1 Patient verbally and nonverbally expresses feelings of anxiety, fear, anger, confusion, distrust, and helplessness. Patient often responds to internal and external factors and cues.
- 2 Feedback between nurse and patient reveals a lack of understanding and ineffective communication. Barriers to communication exist.
- 3 Nurse’s personal issues interfere with establishment of a therapeutic nurse-patient relationship.
- 4 Nurse is unable to acquire information about patient’s ideas, fears, and concerns. Communication techniques do not promote patient’s willingness to communicate openly. Trust is not established. Goals are not identified and therefore cannot be achieved.

Related Interventions

- Reassess patient’s level of anxiety, fear, and distrust. Attempt to determine the cause of anxiety or fear.
- Repeat message to patient at a later time.
- Determine influence affecting clear communication (e.g., cultural issues, literacy issues, physical limitations).
- Assess for and remove barriers to communication.
- Repeat message using another approach if possible.
- Consider cultural norms associated with eye contact, use of touch, personal space, and nonverbal behaviors.
- Avoid using medical terms that patient does not understand.
- Appropriately adjust communication style (e.g., be nonjudgmental, patient, and understanding).
- Use special approaches (gesture, pictures, role playing) for patients who have communication impairments.
- Use alternative communication techniques to promote patient’s willingness to communicate openly.
- Offer another professional with whom patient can talk to obtain necessary information.

Recording and Reporting

- Record in nurses' notes and electronic health record (EHR) the communication pertinent to patient's health, response to illness or therapies, and responses that demonstrate understanding or lack of understanding (include verbal and nonverbal cues).
- Report any relevant information obtained through patient's verbal and nonverbal behaviors to members of health care team.

Special Considerations

Teaching

- Use gestures, pictures, and role playing to help patient understand. Be alert to literacy status; determine if patient is able to access health information adequately. Be alert to words that patient seems to understand and use them frequently.
- Individualize patient teaching to meet patient needs. Always conduct teaching toward meeting patient's learning needs with consideration for his or her preferred methods for learning.

Pediatric

- Communicating with children requires an understanding of feelings and thought processes from the child's perspective (Hockenberry and Wilson, 2011).
- Use vocabulary that is familiar to the child, based on his or her level of understanding (age and developmental level). Try to be on same eye level as patient.

- Understand the child's cognitive, developmental, and functional level to select most appropriate communication techniques. Some age-appropriate communication techniques include storytelling and drawing (Hockenberry and Wilson, 2011).

Gerontologic

- Be aware of any cognitive or sensory impairment. Assess each patient individually and avoid stereotyping older adults who have cognitive or sensory impairments.
- It is important to understand the value of effective communication skills, history, and personality among older adults in terms of providing both human and therapeutic responses. Regression to earlier defenses is normal and adaptive with this population, particularly when facing illness.
- Make sure that older-adult patient with visual or hearing impairment uses assistive devices such as eyeglasses, large-print reading material, or hearing aids to assist in communication.

Home Care

- Identify primary family caregiver for patient and adapt techniques to assess level of understanding regarding his or her condition.
- Incorporate communication into patient's daily activities (e.g., bathing and dressing).

SKILL 3-2 Communicating with an Anxious Patient

Patients in the health care setting sometimes experience anxiety for a variety of reasons. A newly diagnosed illness, separation from loved ones, threat associated with diagnostic tests or surgical procedures, and expectations of life changes are just a few factors that cause anxiety. How successfully a patient copes with anxiety depends in part on previous experiences, the presence of other stressors, the significance of the event causing anxiety, and the availability of supportive resources. You can be a support to patients and help to decrease their anxiety through effective communication. Communication methods reviewed in this skill assist you in helping an anxious patient to clarify factors causing anxiety and cope more effectively. There are four stages of anxiety with corresponding behavioral manifestations: mild, moderate, severe, and panic (Box 3-3).

Delegation and Collaboration

The skill of communicating with an anxious patient cannot be delegated to nursing assistive personnel (NAP). The NAP may interact with anxious patients and must know how to respond and what to observe and report to the nurse. The nurse instructs the NAP about:

- The basic communication skills needed to interact verbally and nonverbally with anxious patients.
- The reason for a patient's anxiety.

BOX 3-3 Behavioral Manifestations of Anxiety: Stages of Anxiety

Mild Anxiety

- Increased auditory and visual perception
- Increased awareness of relationships
- Increased alertness
- Able to problem solve

Severe Anxiety

- Focus on fragmented details
- Headache, nausea, dizziness
- Unable to see connections between details
- Poor recall

Moderate Anxiety

- Selective inattention
- Decreased perceptual field
- Focus only on relevant information
- Muscle tension; diaphoresis

Panic State of Anxiety

- Does not notice surroundings
- Feeling of terror
- Unable to cope with any problem

STEP

RATIONALE

ASSESSMENT

- Provide a brief, simple introduction; introduce yourself and explain purpose of interaction.
- Assess for physical, behavioral, and verbal cues that indicate that patient is anxious such as dry mouth, sweaty palms, tone of voice, frequent use of call light, difficulty concentrating, wringing of hands, and statements such as, "I'm scared."

Anxiety limits amount of information patient can understand.

Anxiety interferes with usual manner of communication and thus interferes with patient's care and treatment. Extreme anxiety interferes with comprehension, attention, and problem-solving abilities.

STEP	RATIONALE
3 Assess for possible factors causing patient anxiety (e.g., hospitalization, unknown diagnosis, fatigue).	Understanding the source of anxiety assists in patient support and communication.
4 Assess factors influencing communication with patient (e.g., environment, timing, presence of others, values, experiences, need for personal space because of heightened anxiety).	Assessment helps to identify effective communication strategies.
5 Discuss with family members the possible causes of patient's anxiety.	Gathering information about patient from a family perspective is useful because family may provide new information or understanding of the situation (Keltner et al., 2011).

NURSING DIAGNOSES

- Anxiety
- Fear
- Impaired verbal communication
- Deficient knowledge
- Defensive coping
- Ineffective coping
- Decisional conflict
- Impaired social interaction

Related factors are individualized based on patient's condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient will sense less anxiety during interactions with nurse. • Patient is able to discuss area of concern. 	<p>Patient gains resources (e.g., use of deep-breathing exercises, guided imagery) to cope with stressor(s). Communication techniques ease anxiety and allow patient to focus on problem.</p>
--	---

Clinical Decision Point *First acknowledge and take care of anxious patient's physical and emotional discomfort but avoid dwelling on physical complaints. Focus on understanding patient, providing feedback and assisting in problem solving, and providing atmosphere of warmth and acceptance.*

2 Prepare for communication by considering the following: patient goals, time allocation, and resources.	Allows patient to establish rapport, achieve a sense of calm, and begin to analyze source of anxiety.
3 Recognize personal level of anxiety and consciously try to remain calm (breathe slowly and deeply, relax pelvic floor muscles). Be aware of nonverbal cues that indicate own anxiety (e.g., body language, posture, cadence of speech).	Your anxiety increases patient's anxiety.
4 Prepare a quiet, calm area, allowing ample personal space.	Decreasing stimuli has a calming effect. Invasion of personal space increases anxiety.

IMPLEMENTATION

1 Use appropriate nonverbal behaviors and active listening skills such as staying with patient at bedside and having a relaxed posture.	Nonverbal messages to patient express interest and help to alleviate anxiety.
2 Use appropriate verbal techniques that are clear and concise to respond to anxious patient. Use brief statements that acknowledge current state of feelings and provide direction to patient such as, "It seems to me that you're anxious" or "I notice that you seem anxious. Would you like to go to your room to rest?"	Appropriate techniques and statements provide reassurance and prevent further escalation of anxiety.
3 Help patient acquire alternative coping strategies such as progressive relaxation, slow deep-breathing exercises, and visual imagery (see Chapter 15).	Coping mechanisms provide foundation for effective communication so patient can explore causes of anxiety and steps to alleviate anxious feelings.
4 Provide necessary comfort measures.	Pain heightens patient's anxiety.

EVALUATION

1 Observe for continuing presence of physical signs and symptoms or behaviors reflecting anxiety.	Observation determines extent to which planned interaction relieved patient's anxiety.
2 Have patient discuss ways to cope with anxiety in the future and make decisions about own care.	This measures patient's ability to assume more health-promoting behavior.
3 Evaluate patient's ability to discuss factors causing anxiety.	This measures patient's ability to attend or focus on area of concern.

STEP

RATIONALE

Unexpected Outcomes

- 1 Physical signs and symptoms of anxiety continue. Your interaction has increased patient's anxiety; source of anxiety is not resolved.
- 2 Patient displays difficulty in decision making by avoiding your efforts at focusing discussion or is unable to discuss real concerns. Anxiety continues to prevent problem solving.
- 3 Anxiety continues to escalate.

Related Interventions

- Use refocusing or distraction skills such as relaxation or guided imagery to reduce anxiety (Fortinash and Holoday-Worret, 2008).
- Be clear and direct when communicating with patient to avoid misunderstanding.
- When used appropriately, touch helps control feelings of panic.
- Continue to use previous steps.
- Be very direct and clear when making requests. If patient needs to deal with stimulus causing anxiety, reintroduce when he or she is less anxious.
- Although touch is therapeutic, it requires individualized assessment of patient's anxiety level and need for personal space; some patients perceive this as threatening. When used appropriately, reassurance through human touch helps to control feelings of panic.
- As a last resort administer an antianxiety medication (per orders).

Recording and Reporting

- Record in nurses' notes and EHR cause of patient's anxiety and any exhibited signs and symptoms of behaviors.
- Report methods used to relieve anxiety and patient's response to ensure continuity of care between nurses.

Special Considerations**Teaching**

- Teaching patient to identify possible sources of anxiety such as illness, hospitalization, knowledge deficits, or other known stressors gives patient knowledge of anxiety and increases his or her sense of control.
- Remember that patients and their family members who are under stress often require repeated explanations.

Pediatric

- Children often demonstrate anxiety through physical and behavioral signs but are unable to express anxiety verbally. Some children express anxiety through restless behavior, physical complaints, or behavioral regression. Note any changes in child's behavior that occur during illness or hospitalization (Hockenberry and Wilson, 2011).

Gerontologic

- Anxiety is one of the most common symptoms seen in older adults. Patients often become ritualistic and intent on

performing activities a certain way. Anxiety develops as a result of a specific event or a general pattern of change (e.g., decline in health) (Meiner, 2011).

- Manage anxiety based on patient's presenting behaviors with consideration of any cognitive/physical impairment.
- Psychosocial factors such as anxiety and confusion, lack of mobility, and spatial organization of a long-term care facility are factors that decrease social contacts, thus hindering communication with peers and health care providers. This leads to further feelings of isolation, boredom, and increased anxiety.
- Older adults who are socially isolated have multiple medical problems and are more likely to have anxious and/or depressive symptoms. In addition, they are less likely to seek care for these symptoms.

Home Care

- Manage anxiety based on patient's presenting behaviors with a consideration of any cognitive/physical impairment.
- Anticipation of a home care visit increases a patient's anxiety and leads to exacerbation of symptoms. Therefore some patients avoid home care visits (Fortinash and Holoday-Worret, 2008).

SKILL 3-3 Communicating with an Angry Patient

Anger is the common underlying factor associated with potential for violence. Patients become angry for a variety of reasons. Anger is often directly related to a patient's experience with illness, or it is associated with problems that existed before the patient entered the health care setting. In the health care setting you have frequent contact with a patient and thus often become the target of his or her anger. It is important for you to understand that in many cases a patient's ability to express anger is important to recovery. For example, when a patient has experienced a significant loss, anger becomes a means to help cope with grief. Some patients express anger toward their nurses, but the anger often hides a specific problem or concern. For example, a patient diagnosed as having cancer voices displeasure with the nurse's care instead of expressing a fear of dying.

Dealing with angry patients is very stressful. Anger often represents rejection or disapproval of your care. Your efforts at satisfying an angry patient's needs can result in a failure to meet the priorities of other patients. Allow patients to express anger openly and do not feel threatened by their words. However, do not allow a patient's anger to threaten or compromise care. Skills for communicating with an angry or a potentially violent patient allow you to help the patient dealing with anger constructively and refocus emotional energy toward effective problem solving. De-escalation skills are useful techniques that you can use to manage a potentially violent patient; these skills range from using non-threatening verbal and nonverbal messages to safely disengaging and controlling the aggressor physically (Fortinash and Holoday-Worret, 2008).

Delegation and Collaboration

De-escalation is a skill that cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- The proper way to interact verbally and nonverbally with the angry patient.

- Their role as the nurse uses de-escalation techniques.
- Approaches that have been successful and unsuccessful in communicating with angry patients.

STEP **RATIONALE**

ASSESSMENT

<p>1 Observe for behaviors that indicate that the patient is angry (e.g., pacing, clenched fist, loud voice, throwing objects) and/or expressions that indicate anger (e.g., repeated questioning of nurse, not following requests, aggressive outbursts, threats).</p> <p>2 Assess factors that influence communication with the angry patient such as refusal to comply with treatment goals, use of sarcasm or hostile behavior, having a low frustration level, or being emotionally immature.</p> <p>3 Consider resources (e.g., health care team or family) available to assist in communicating with potentially violent patient.</p> <p>4 Assess for underlying medical conditions that may potentially lead to violent behavior.</p>	<p>Anger is a normal expression of frustration or response to feeling threatened. However, its expression often interferes with or blocks communication and interactions.</p> <p>Assessment allows you to accurately evaluate the situation or patient experiences that block or facilitate communication.</p> <p>This assists in clarifying cause and intervention required to deal with patient's anger.</p> <p>Patients with medical conditions such as traumatic brain injury, dementia, or drug/alcohol withdrawal may exhibit hostile, aggressive behaviors.</p>
---	--

Clinical Decision Point *With some violent behaviors (e.g., physical aggression) you may not be able to de-escalate the situation. When this potential exists, know whom to call for assistance (e.g., trained psychology technicians, security staff). Personal safety is paramount.*

NURSING DIAGNOSES

- | | | |
|---|--|---|
| <ul style="list-style-type: none"> • Anxiety • Defensive coping • Fear | <ul style="list-style-type: none"> • Impaired social interaction • Impaired verbal communication • Ineffective coping | <ul style="list-style-type: none"> • Risk for other-directed violence • Risk for self-directed violence |
|---|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient no longer exhibits verbal and nonverbal expressions of anger. <p>2 Prepare for interaction with an angry patient:</p> <p>a Pause to collect own thoughts, feelings, and reactions.</p> <p>b Determine what patient is saying.</p> <p>c Attempt a calm, firm, assertive approach. Try to talk in comfortable, reassuring voice.</p> <p>3 Prepare the environment to de-escalate a potentially violent patient:</p> <p>a Encourage other people, particularly those who provoke anger, to leave room or area.</p> <p>b Maintain adequate distance.</p> <p>c Maintain open exit. Position self closest to door to facilitate escape from a potentially violent situation. Do not block exit so patient feels that escape is unattainable.</p> <p>d When anger begins to disturb others, close door. This is particularly important when a patient becomes agitated.</p>	<p>De-escalation techniques successfully allow patient to express anger in a constructive way.</p> <p>Awareness and control of your reaction and responses facilitate more constructive interaction.</p> <p>Clarification of patient need or concern may help to de-escalate situation.</p> <p>Approach tends to lessen patient's agitation and anger.</p> <p>Potentially violent patient needs to be in an environment with decreased stimuli and have protection from injury to self or against others.</p> <p>Encourages patient's expression of anger rather than provokes it. Avoids pressuring patient; helps to prevent injury if anger becomes out of control.</p> <p>Prevents feeling of being trapped for both you and patient. Feeling trapped may cause a violent outburst. Safety of both parties is paramount.</p> <p>Agitation and anxiety can spread to others. Some hospital rooms are equipped with security windows and cameras to allow for observation of patients.</p>
--	--

Clinical Decision Point *Some patients are disruptive to one another, especially those who are hyperactive, intrusive, threatening, or exhibiting bizarre behaviors. For these patients, first try the least-restrictive measures before using more restrictive measures such as seclusion.*

STEP	RATIONALE
e Reduce disturbing factors in room (e.g., noise, drafts, inadequate lighting).	Reduces irritants that may heighten anger.
f Take care of patient's physical and emotional needs and discomforts (e.g., offer analgesic for pain).	Physical and emotional needs are often factors in patient's anger; sometimes patient is not aware of these needs.

IMPLEMENTATION

1 Responding to a potentially violent patient	
a Maintain nonthreatening verbal and nonverbal communication skills (e.g., use gestures that are slow and deliberate rather than sudden and abrupt).	Less chance of misinterpretation of message and less threatening. A relaxed atmosphere prevents further escalation. Creates climate of acceptance for patient.
b Use therapeutic silence and allow patient to vent feelings.	Often de-escalates anger. Anger expends emotional and physical energy; patient runs out of momentum and energy to maintain anger at high level.
c Answer questions as appropriate; if patient asks power-struggle type of question (challenging or confrontational type), redirect and set limits by giving clear, concise expectations. Inform patient of potential consequences without sounding threatening and follow through with consequences if patient does not change behaviors.	Setting limits on power-struggle questions provides structure and helps diffuse anger.
d If patient is making verbal threats to harm others, remain calm yet professional and continue to set limits on inappropriate behavior.	Angry patient loses ability to process information rationally and therefore may impulsively express anger through intimidation.

Clinical Decision Point *If imminent harm to another is present on discharge, notify proper authorities (e.g., nurse manager, security).*

e Maintain personal space and safety with patient who is making verbal threats of violence directed at others. Maintain nonthreatening position and nonverbal behavior, including body language, position, and cadence.	Avoiding sudden movements and loud tones prevents giving the appearance of an attack.
---	---

Clinical Decision Point *A potentially violent patient can be impulsive and explosive; therefore you need to keep personal safety skills in mind. In this case, avoid touch.*

f If patient appears to be calm and anger is defused, explore alternatives to situation or feelings of anger.	Processing with patient can prevent future explosive outbursts and teach patient effective ways of dealing with anger.
---	--

EVALUATION

1 Observe for continuing behaviors or verbal expressions of anger.	Indicates success of communication efforts.
2 Note patient's ability to answer questions and problem solve.	Determines whether anger has lessened so patient is able to focus on alternative coping skills.

Unexpected Outcomes

- 1 Patient continues to demonstrate nonverbal behaviors or verbal expression of anger or violence. You are unable to assist him or her in relieving source of anger or expressing anger openly without violent acts.

Related Interventions

- Reassess factors and remove or alter factors contributing to anger.
- Take charge with calm, firm directions. Give as-needed (prn) medications as ordered for agitation/escalating behaviors.
- Direct patient to a quiet area for a "time-out."
- Make sure that fellow staff members are available to assist if necessary.

Recording and Reporting

- Record in nurses' notes and EHR the cause of patient's anger (if determined), behaviors patient exhibits, de-escalation technique used, and patient's response to de-escalation efforts.
- Report technique used to de-escalate and patient's response to nurse in charge.

Special Considerations

Teaching

- Patients experiencing emotionally charged situations do not always comprehend instruction. Focus on understanding patient; providing feedback and assisting in problem solving; and providing an atmosphere of safety, warmth, and acceptance.

- Teaching patient to identify possible factors that contribute to angry outbursts such as inadequate coping skills, low frustration levels, illness, hospitalization, knowledge deficits, or other known stressors may give him or her a sense of control.
- Once anger has been de-escalated, teach patient new adaptive methods of coping with anger.

Pediatric

- Set limits for inappropriate behaviors exhibited by child such as a time-out. Apply such limits immediately because children tend to have less internal control over their own behaviors (Hockenberry and Wilson, 2011).

Gerontologic

- Patients who have cognitive impairments often exhibit tantrum-like behaviors in response to real or perceived frustration.

Use distraction techniques to remove cognitively impaired older-adult patient from disturbing stimuli or redirect patient to activity that is pleasurable (Meiner, 2011).

Home Care

- Personal safety for nurse against potentially violent patient or family member extends to all health care settings, including patient’s home. You may be in a potentially dangerous situation while giving care to patient at home because you are without support from other staff members.
- Be aware of physical surroundings of home, including possible exits.
- If de-escalation does not occur and you believe your safety is threatened, call for assistance or remove yourself from the situation.

SKILL 3-4 Communicating with a Depressed Patient

Depression is a state of feelings that is more than just sadness. It is a common psychiatric condition that affects a person’s ability to function in day-to-day activities. There are many symptoms of depression, the most common being apathy, feelings of sadness, fatigue, guilt, poor concentration, sleep disturbances, and suicidal thoughts. Depression results in both subjective and objective behaviors and patient reports of increased physical complaints (Box 3-4). Some patients report feeling anxious when depressed.

Objective signs include decrease in performance of activities of daily living (ADLs) and decreased time spent in social activities (altered social interaction).

Many patients in acute care settings suffering from either acute or chronic health conditions have symptoms of depression. Some patients have been formally diagnosed and treated with medications and/or psychotherapy; others may not have been diagnosed and therefore have not been treated. Use the nursing process to develop nursing interventions, expected outcomes, and evaluation of these outcomes for patients with depression. The intervention strategies emphasize use of therapeutic communication techniques.

BOX 3-4 Symptoms of Depression

Common Symptoms	Other Symptoms
• Apathy	• Fatigue
• Sadness	• Thoughts of death
• Sleep disturbances	• Decreased libido
• Hopelessness	• Feeling inadequate
• Helplessness	• Psychomotor agitation
• Worthlessness	• Verbal berating of self
• Guilt	• Spontaneous crying
• Anger	• Dependency, passiveness

From Keltner N et al: *Psychiatric nursing*, ed 6, St Louis, 2011, Mosby.

Delegation and Collaboration

The skill of communicating effectively with a depressed patient cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- The basic skills needed to interact verbally and nonverbally with the depressed patient.
- The possible causes and signs and symptoms of the patient’s depression.

STEP

RATIONALE

ASSESSMENT

- 1 Assess for physical, behavioral, and verbal cues that indicate that patient is depressed such as feelings of sadness, tearfulness, difficulty concentrating, increase in reports of physical complaints, and statements such as, “I’m sad/depressed.”
- 2 Assess for possible factors causing patient’s depression (e.g., acute or chronic illness, personal vulnerability, recent loss).
- 3 Assess factors influencing communication with patient (e.g., environment, timing, presence of others, values, experiences, poor concentration).
- 4 Discuss possible causes of patient’s depression with family members, including past history of the illness if necessary.

Depression interferes with usual manner of communication and thus with patient’s care and treatment. If depression is severe, it interferes with comprehension, attention, and problem-solving abilities.

Patient’s depressive state is sometimes unknown. Understanding the possible cause of depression assists in patient support and communication.

Understanding factors that influence communication helps you identify effective communication strategies.

Gathering information about patient from a family perspective is useful because family provides new information or understanding of the situation (Keltner et al., 2011).

STEP

Clinical Decision Point *First acknowledge and take care of depressed patient's physical and emotional discomfort but avoid dwelling on physical complaints. Focus on understanding patient, providing feedback, and assisting in problem solving.*

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Provide brief, simple introduction; introduce yourself and explain purpose of interaction.</p> <p>2 Accept patient as he or she is and focus on positive aspects of patient. Provide positive feedback.</p> <p>3 Be honest and empathic.</p> <p>4 Use appropriate nonverbal behaviors and active listening skills such as staying with patient at bedside.</p> <p>5 Use appropriate verbal techniques that are clear and concise when responding to patient. Use observational statements that acknowledge current state of feelings and provide direction to patient.</p> <p>6 Use open-ended questions such as, "Tell me about how you're feeling" or "You seem sad. Tell me about your sadness."</p> <p>7 Reward small decisions and independent actions. When necessary, make decisions that patients are not ready to make. Present situations that require no decision making.</p> <p>8 Respond to anger therapeutically; avoid becoming defensive or angry and encourage verbal expression of anger.</p> <p>9 Provide necessary comfort measures.</p> <p>10 Spend time with patient who is withdrawn.</p> <p>11 Ask patient about suicidal ideation and presence of a plan.</p> | <p>Symptoms associated with depression limit amount of information that patient can understand.</p> <p>Depressed patients often have low self-esteem. This approach helps to focus on their strengths.</p> <p>Honesty and empathy facilitate the development of trust.</p> <p>Nonverbal messages to patient express your interest and help to alleviate depressive symptoms.</p> <p>Appropriate techniques and statements provide reassurance to depressed patient. Expresses empathy.</p> <p>Encourages patient to continue talking, facilitating an in-depth discussion of symptoms.</p> <p>Depressed patients are often overly dependent and indecisive.</p> <p>Some depressed patients are angry; understand that anger is a symptom of their depression. Verbal expression often reduces tension.</p> <p>Depressed patients often have multiple somatic complaints; address and adequately treat the physical complaints (e.g., pain, nausea).</p> <p>This communicates patient's worth.</p> <p>Depressed patients are at increased risk for suicide. Other risk factors include general medical conditions, hopelessness, male gender, and increased age. The more developed the plan, the greater the risk of suicide (Keltner et al., 2011).</p> |
|--|--|

STEP

RATIONALE

EVALUATION

- 1 Observe for continuing presence of physical signs and symptoms or behaviors reflecting depression.
- 2 Have patient discuss ways to cope with depression in the future and make decisions about own care.
- 3 Evaluate patient's ability to discuss factors causing depression.

- Observation determines extent to which planned interaction relieved patient's depressive symptoms.
- Discussion measures patient's ability to assume more health-promoting behavior.
- Evaluation measures patient's ability to attend to or focus on area of concern.

Unexpected Outcomes

- 1 Depressive behaviors continue; interaction has been ineffective at relieving depressive symptoms.
- 2 Patient reports suicidal ideation with or without plan.

Related Interventions

- Continue to use therapeutic communication skills but try different techniques.
- Refer patient to mental health professional for consultation regarding use of pharmacologic agents and/or formal psychotherapy to treat depression.
- Refer patient to mental health professional for evaluation and possible admission to an inpatient psychiatric treatment facility.

Recording and Reporting

- Record in nurses' notes and EHR both objective and subjective behaviors (associated with depression) that patient is displaying and objective behaviors (associated with depression) observed by the nurse.
- Record and report methods used to improve these behaviors and patient's response.

Special Considerations

Teaching

- Teaching patient to identify possible sources of depression such as acute or chronic illness, personal vulnerability, ineffective coping, or other known stressors gives patient knowledge of depression and increases his or her sense of control over feelings of depression.
- Make teaching modifications with a consideration of impaired concentration and memory related to patient's depressed status (e.g., present a small amount of material at a time).

Pediatric

- Children often demonstrate symptoms of depression that differ from those of adults. They manifest depression through physical

(increased somatic complaints) and behavioral signs (poor school performance, social isolation) and are often unable to express depression verbally. Some children express depression through restless behavior or behavioral regression. It is important to note any changes in child's behavior that occur during illness or hospitalization (Hockenberry and Wilson, 2011).

Gerontologic

- Depression among older adults is a major health concern. It is important to differentiate between depression and any underlying medical illness in this population because the symptoms sometimes overlap. In addition, suicide risk is increased in older adults because this age-group experiences multiple losses such as loss of health status, independence, and social support system and financial losses (Keltner et al., 2011).

Home Care

- Depression is often present in home care settings. Educate family caregivers about how to identify symptoms. Manage depression based on patient's presenting behaviors with a consideration of any cognitive/physical impairment.

SKILL 3-5 Communicating with a Cognitively Impaired Patient

Nurses must communicate with patients who have complex physical and psychological issues. Patients with cognitive impairments pose a challenge for nurses because these patients may have limited ability to communicate. The act of communicating and expressing oneself is affected by a person's ability; consequently patients with cognitive impairments may have a disability that negatively affects communication (McGhee, 2011). Different types of cognitive impairments include acute and chronic. Acute cognitive impairment or delirium is largely reversible and may be caused by conditions such as infection, polypharmacy, and metabolic changes. Once the cause is identified and treated, the patient's mental status returns to a baseline condition. Chronic types of cognitive impairments include dementia (Alzheimer's disease, vascular dementia, frontal-temporal dementia), traumatic brain injury, and HIV-related cognitive dysfunction. These are irreversible, and the cognitive decline may be progressive.

Cognitive impairments accompanied by communication deficits often hinder a patient's ability to initiate conversation. Since it is time-consuming to interact with these patients, they may be deprived of human contact, which leads to depression, detachment, and isolation. The patient's inability to participate in self-care results in inadequate care and frustration by the health care staff. Patients with cognitive impairments may be at risk for physical status changes such as infection, falls and injury, and poor nutrition. A lack of quality nurse-patient interaction and communication barriers negatively affect patient outcomes. A patient-centered approach stresses the uniqueness of each patient and his or her individuality when assessing the patient's ability to communicate. Communication is essential to everyday life, and the nurse needs to be creative in the way he or she interacts with patients with cognitive impairments to ensure that the messages are sent and received.

Delegation and Collaboration

The skill of communicating effectively with a cognitively impaired patient cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- The proper communication skills needed to interact verbally and nonverbally with the cognitively impaired patient.
- The possible causes and signs and symptoms of the patient's cognitive impairment.

STEP

RATIONALE

ASSESSMENT

- 1 Assess for physical, behavioral, and verbal cues that indicate that a patient is cognitively impaired. Assess the orientation status of the patient (person, place, time) and perform a mini-mental examination (see Chapter 6).
- 2 Assess for possible factors causing patient's cognitive impairment (e.g., acute or chronic illness, fever, fluid and electrolyte imbalance, past history).
- 3 Assess factors influencing communication with patient (e.g., environment, timing, presence of others, values, experiences, prior sensory loss, poor concentration).
- 4 You may need to discuss possible causes of patient's cognitive impairment with family members or caregivers, including current illness, treatment regimen, and past medical history.

If the patient is unable to think, speak, or understand, communication strategies need to be adjusted to communicate effectively.

Patient's cognitive state is sometimes unknown to nurse. Understanding the possible cause of mental decline assists in patient support and communication.

Understanding factors that influence communication helps you to identify effective communication strategies.

Gathering information about patient from a family perspective is useful because family provides new information or understanding of the situation. It is important to establish patient's baseline mental status.

NURSING DIAGNOSES

- Acute confusion
- Decisional conflict
- Hopelessness
- Impaired social interaction
- Impaired verbal communication
- Ineffective coping
- Ineffective role performance
- Knowledge deficit

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient is able to communicate needs to nurse.
- 2 Prepare for communication by considering type of cognitive impairment, communication impairments, time allocation, and resources.
- 3 Be aware of your nonverbal cues that affect communication with the cognitively impaired patient (e.g., body language, posture, cadence of speech). Remain nonjudgmental.
- 4 Prepare environment physically by providing a quiet, calm area. Reduce distractions such as external noises.

Patient receives adequate resources to communicate effectively, given the limitations related to cognitive impairment.

Effective communication allows patient to establish rapport and have a quality nurse-patient interaction.

Frustration in communication with patients with cognitive impairment may negatively affect interaction with patient.

Decreasing stimuli has a calming effect. Ensuring that the environment is quiet and free from distractions enhances the communication experience.

IMPLEMENTATION

- 1 Approach patient from the front and face him or her when speaking.
- 2 Provide brief, simple introduction; introduce yourself and explain purpose of interaction.
- 3 Use appropriate nonverbal behaviors and active listening skills such as staying with patient at bedside or use of touch.
- 4 Use clear and concise verbal techniques to respond to patient. Use simple language and speak slowly; use short and simple sentences. Ask yes-or-no questions.
- 5 Ask one question at a time and allow time for response. Avoid rushing patient.
- 6 Repeat sentences using a steady voice and avoid being too quick to guess what the patient is trying to express.

This strategy ensures that patient both sees and hears you.

Symptoms associated with cognitive impairment limit amount of information that patient can understand.

Nonverbal messages to patient express your interest and convey empathy. Use of touch may help with concentration and reassurance.

Appropriate techniques and statements provide reassurance to cognitively impaired patient.

This gives patient time to process the information and respond.

Repetition allows time for patient to respond; it can be frustrating for patient if you misinterpret his or her message or pressure him or her to respond.

STEP

RATIONALE

- | | |
|--|--|
| <p>7 Use augmentative and assistive communication (AAC) devices to facilitate communication such as pictogram grid, talking mats, objects.</p> <p>8 Provide assistive devices such as eyeglasses or hearing aids to help with communication.</p> <p>9 Do not argue with patient or correct him or her if mistakes are made.</p> <p>10 Maintain meaningful interactions with patients and use creative modes of communication based on patient's comfort level and abilities.</p> | <p>Talking mats are communication aids that use picture symbols so the patient can place relevant images below a visual scale to indicate feelings (McGhee, 2011).</p> <p>Use of such devices facilitates clarity of communication experiences.</p> <p>Arguing can lead to increased frustration and agitation.</p> <p>Superficial, brief human contact may lead to sense of isolation and detachment.</p> |
|--|--|

EVALUATION

- | | |
|--|---|
| <p>1 Observe for clarity and understanding of messages sent and received.</p> <p>2 Observe verbal and nonverbal behaviors.</p> | <p>Observation determines extent to which cognitively impaired patient is able to express self.</p> <p>Observation reveals if patient is comfortable and needs have been met.</p> |
|--|---|

Unexpected Outcomes

- 1 Messages that are sent and received are not understood.
- 2 Patient becomes frustrated, and communication with nurse becomes more challenging.

Related Interventions

- Continue to use therapeutic communication skills when interacting with cognitively impaired patient. Be creative in using alternative strategies.
- Speak to patient as an adult and give time to process information. Use verbal and nonverbal methods to convey empathy with their frustration.
- Allow for periods of adequate rest; make frequent attempts to interact to minimize social isolation.

Recording and Reporting

- Record in nurses' notes and EHR both objective and subjective behaviors (associated with cognitive impairment) that patient is displaying and objective behaviors (associated with cognitive impairment) observed by the nurse.
- Record and report the methods used to communicate and patient's response.

Pediatric

- Children may exhibit cognitive impairments because of metabolic or neurologic conditions that may be acute or chronic in duration. Communication strategies with children should take into consideration their developmental level. Use pictures and drawings for patients who are unable to read.

Special Considerations

Teaching

- Teach patient to use various methods to communicate such as pictorial board or communication aids.
- Make teaching modifications with a consideration of impaired concentration and memory related to patient's cognitive status (e.g., present a small amount of material at a time; use simple and short phrases; repeat information as needed).

Gerontologic

- Many older adults have cognitive impairments. These impairments pose serious barriers to the reliability of the nurse's assessment of patients; therefore it is important to use effective verbal and nonverbal communication strategies. Poor communication can compromise care, leading to increased anxiety and frustration.

Home Care

- Manage care based on patient's presenting behaviors with a consideration of any cognitive/physical impairment. Include the family caregiver and friends in using effective communication strategies.

Critical Thinking Exercises

You are assigned to care for Mrs. Jones, an 84-year-old woman who was admitted to the hospital 2 days ago after falling at her son's home. She recently moved in with her son, her only child, following the sudden death of her husband. Her husband had been her primary caregiver since she was diagnosed with Alzheimer's disease 3 years ago. Neither her husband nor her son wanted to put her into a long-term care facility. She had emergency surgery to repair a fractured wrist. During shift report on a medical-surgical unit, the nurse tells you that the patient is withdrawn and confused. In addition, she has difficulty understanding verbal direction from the nursing staff.

- 1 Which steps are necessary to effectively communicate with a cognitively impaired patient?

When you approach the patient to perform an initial assessment, she is looking out the window and seems disoriented. She appears disheveled, and her lunch tray is untouched. You ask her if she needs assistance with ADLs such as bathing, dressing, and feeding, but you get a response that you cannot understand.

- 2 What should you do first to prepare to communicate with Mrs. Jones? Explain your choice(s).

You contact her son, who is her legal guardian; he tells you that he doesn't know his mother's baseline level of functioning because his father had been in denial about her mental decline and overall deterioration. The son does not know if she is capable of managing her own ADLs or needs assistance.

- 3 Describe strategies to use to determine Mrs. Jones' own sense of her ability to perform ADLs.

REVIEW QUESTIONS

- Which approach reflects an obstacle to effective nurse-patient communication?
 - Discussing fears about a patient with members of the health care team
 - Obtaining information about a critically ill patient from his or her family
 - Admitting a mistake to a patient's family
 - Avoiding issues that are uncomfortable for a patient
- The nurse is caring for a postoperative patient who is still having pain despite analgesia administration. Which statement by the nurse best reflects therapeutic communication?
 - "I think your doctor needs to know that you're still in pain."
 - "What do you want me to do about your pain problem?"
 - "When it comes to pain, your doctor tends to undermedicate his patients."
 - "Your pain will be a lot better in the morning."
- A patient recovering from a bilateral mastectomy for breast cancer tearfully tells the nurse that she is feeling depressed and worthless as a woman. Which communication phrase is not effective?
 - "Many women have body image concerns after undergoing this surgery."
 - "Tell me more about how you feel."
 - "Why do you feel depressed and worthless?"
 - "How long have you been feeling this way?"
- Which initial approach would be best when working with an anxious patient?
 - Tell the patient that everything he or she says will be kept private.
 - Ask the patient what he or she believes is causing his or her anxiety.
 - Watch the patient's behavior for the amount of anxiety being exhibited.
 - Explain what the patient can expect in terms that he or she can understand.
- A nurse is working with a potentially threatening patient. Which nursing intervention is most appropriate?
 - Speaking clearly and slightly louder so the patient does not need the nurse to repeat what was said.
 - Positioning himself or herself near the exit of the room to prevent being blocked by the patient.
 - Bringing in other team members so the patient knows there are others to help him or her gain control.
 - Asking the patient which comfort measures he or she uses when he or she becomes out of control.
- A visitor from another country became ill and required hospitalization. He is having difficulty getting the staff to understand his needs. Which approach by the nurse demonstrates the most cultural sensitivity?
 - Asking one of the patient's family members to help with the communication process
 - Using good eye contact while speaking clearly with easily understood words
 - Obtaining a medical interpreter to facilitate the communication process
 - Touching the patient more often while assessing him to make him feel that the nurse cares about him
- A patient is exhibiting signs and symptoms of anxiety. What should be the first step in establishing communication with him or her?
 - Providing good personal hygiene
 - Letting the patient make as many choices as possible
 - Being nonjudgmental and accepting of feelings
 - Exhibiting appropriate nonverbal behaviors and active listening skills

- A nurse is working with an older adult with a cognitive impairment who is having a tantrum and acting hostile toward other patients in the dayroom. Which approach by the nurse is most appropriate to handle this situation?
 - Asking three other staff members to help put the patient back to bed
 - Using the patient's favorite crackers to distract him from the other patients
 - Explaining to the patient how he will benefit by behaving better
 - Asking the family how they managed the tantrums while the patient was still living at home
- A patient recovering from a recent amputation of his foot because of diabetes has been very withdrawn and not sleeping or eating well. Which initial nursing intervention would be most effective to help him with his depression?
 - Suggesting the use of antidepressant medication to his health care provider
 - Spending time with the patient and telling him how lucky he is that he was able to keep most of his leg
 - Talking with physical therapy about how soon he can be fitted for a prosthesis
 - Encouraging the patient to talk about his feelings while allowing angry outbursts
- The nurse is preparing to provide patient education. Which question is most appropriate for the nurse to ask?
 - Are you ready to learn now?
 - Can you use a computer?
 - Is your family here to learn also?
 - How do you best learn?

 - Audio Glossary

KEY TERMS

Acuity systems	DAR	Incident report	SOAP
Case management	Documentation	Kardex	SOAPIE
Change-of-shift report	Documentation system	Objective data	Standardized care plan
Charting by exception (CBE)	Electronic health record	PIE	Subjective data
Critical/collaborative pathway	Flow sheet	Problem-oriented medical record (POMR)	Variance
	Focus charting	SBAR	
	Hand-off		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- List guidelines for effective communication and reporting.
- Describe measures to maintain confidentiality of patient information.
- Identify the purpose of the patient record.
- Describe the elements of a hand-off report and when it would be used.
- Discuss the role of computerization in documentation.
- Write a nurse's progress note using SOAP, SOAPIE, PIE, focus, and SBAR charting formats.
- Describe information found in a patient care profile and nursing Kardex.
- Accurately complete a nursing flow sheet.
- Explain guidelines used in documentation of home care and long-term care.
- Describe the role of critical pathways in multidisciplinary documentation.
- Complete an incident (adverse event) report accurately.

Nursing documentation is an essential and important component of health care delivery. Documentation is anything entered into a patient's electronic health record or written in a patient record. The Joint Commission's concern about communication errors in accredited health care organizations has led to continually updating goals to improve safety (TJC, 2012b). Nursing documentation ensures continuity of care, provides legal evidence, and evaluates patient outcomes. One of the challenges you will face is documenting quality patient care within the constraints imposed by regulations, limited resources, and finances. Your documentation provides a detailed account of a patient's plan of care, important assessment, and treatment, which must be an accurate and timely evaluation of information. Effective documentation ensures

continuity of care, maintains standards, and reduces errors. The quality of documentation depends on your ability to communicate effectively in both the written and spoken word. Furthermore, technology now offers new tools to improve documentation and patient care. You are held accountable for the accuracy of documentation that is in the patient record, and this information is confidential and needs to be protected.

Accreditation agencies such as The Joint Commission specify guidelines for documentation and require health care agencies to monitor and evaluate patient outcomes and appropriateness of care. This evaluation process occurs through an audit of information that is documented in patient records. The Joint Commission provides requirements for documentation in their standards (TJC, 2012a).

ELECTRONIC HEALTH RECORDS

Comprehensive computer systems in health care delivery have unlimited potential for improving the accuracy, efficiency, and quality of documentation. Researchers estimate that only 12% of health care agencies have a basic electronic record (Kutney-Lee and Kelly, 2011). However, the traditional paper medical record is no longer meeting the needs of today's health care industry. Key information such as patient allergies, current medications, and treatment complications may be lost from one episode of care (e.g., hospitalization or clinic visit) to the next visit, or they may be illegible, thus risking a patient's safety (Green and Thomas, 2008). The electronic health record (EHR) is a longitudinal electronic record of patient health information generated by one or more encounters in a care delivery setting (HIMSS, 2011). The EHR provides access to a patient's health record information at the time and place that clinicians need it. The EHR improves patient care quality by displaying clinical information that is patient centered where it is needed in a timely manner. It can provide better information access for patients and health care providers (Murphy, 2010). By 2014 the EHR should be implemented nationwide. Beginning in 2014, incentive payments from the Centers for Medicare and Medicaid Services will begin to diminish and there will be no incentive payments after 2015 for agencies that cannot demonstrate meaningful use of an EHR (Reimer, 2011).

Although EHRs are the wave of the future, many agencies have computerized medical record systems. Computerized documentation has features that potentially can improve documentation accuracy, timeliness and completeness of data entry, and communication among health care disciplines (Burnes-Bolton et al., 2008). In addition, computerized documentation systems are designed to reduce errors and provide standardized care plans or treatment protocols. Such a system relies on many data collection components, including flow sheets, medication records, and clinical care summaries. Software programs allow quick access to assessment data, and information automatically transfers to different reports. New technology allows for the use of pen-based or voice recognition programs.

The transition to computerized documentation presents both opportunities and challenges to nurses and nurse managers (Fig. 4-1). The Security Rule of HIPAA (1996) provides standards for the protection of electronic health information. The successful

FIG 4-1 Computerized documentation provides many benefits.

implementation of a computerized documentation system requires preparation, involvement, and commitment of the entire nursing staff. Awareness of legal risks and confidentiality issues are important challenges in the transition from paper to computerized systems. Numerous nursing and medical professional organizations have developed guidelines and strategies for safe computer charting (Box 4-1).

EVIDENCE-BASED PRACTICE

Computer-based health care records, informatics, and implementation of the electronic patient record all have major implications for the practice of nursing, the documentation of nursing care, improving patient safety, and evidence-based practice (Cherry, 2011, Watkins et al., 2009). Computer-based documentation systems are integral to improving and documenting quality nursing care. This type of system maintains a continual record of care planned and/or provided to a patient by nurses and other members of the health care team that can be used for research and assess quality of documentation and patient care (Saranto and Kinnunen, 2009). The nursing process is the foundation for all care of the patient. Documenting care within the patient care plan communicates the care provided, standardizes care, and helps nurses to perform care that is evidence based (Fogelberg-Dahm, 2008). Making sound decisions during implementation of computerized systems is the key to long-term success (Stone and Yoder, 2012).

BOX 4-1 Use of Electronic Health Record

- Sign on to the electronic health record (EHR) using only your password.
- Never share passwords and keep your password private.
- Review assessment data, problems identified (nursing diagnoses), goals and expected outcomes, and interventions and patient responses during contact with each patient before data entry.
- Follow procedures for entering information in all appropriate program functions.
- Review previously documented entries with those that you enter, noting if there is significant change in patient's status. Report changes to patient's health care provider.
- Do not leave information about a patient displayed on a monitor where others can see it. Keep a log that accounts for every copy of a computerized file that you have generated from the system.
- Follow agency confidentiality procedures for documenting sensitive material such as diagnosis of human immunodeficiency virus (HIV) infection.
- Know and implement agency protocol to correct documentation errors.
- Never create, change, or delete records unless your agency provides you with this authority.
- Software systems have a system for backup files. If you inadvertently delete part of the permanent record, follow agency policy. It is necessary to type an explanation into the computer file with the date, time, and your initials, and submit an explanation in writing to your manager.
- Save information as documentation is completed.
- Protect printouts from computerized records. Shredding printouts and logging in the number of copies generated by each caregiver minimize duplicate records and protect the confidentiality of patient information.
- Sign off when you leave the computer.

- Try to ensure that all computer modules are available and implemented in a timely manner.
- Be sure that the system can be modified to meet the needs of different nursing specialties (e.g., emergency department, labor and delivery).
- Choose a system that flows in a manner that is similar to the paper flow pathway previously used.
- Is the new system interoperable with any existing systems?
- Is there high quality training and support available before, during, and after implementation?
- Can the nurses and other users access the data seamlessly and without difficulty?

CONFIDENTIALITY

All members of the health care team are legally and ethically obligated to keep patient information confidential. Do not discuss a patient's examinations, observations, conversations, or treatments with other patients or staff not involved in the patient's care, unless the patient grants permission. Patient records and computer screens are accessed only by persons caring for the patient and must be kept out of view of anyone not caring for him or her. Sometimes patients request copies of their records, and they have a right to read them. One exemption to information access involves patients with mental illness. These patients can be denied access if it could cause personal harm to their physical or mental health. Agencies have specific policies for controlling the manner in which records are shared; usually they require patients to provide written permission for the release of medical information.

The Health Insurance Portability and Accountability Act of 1996 (HIPAA) protects patients' private health information. HIPAA governs all areas of health information management (e.g., reimbursement, coding, security, and patient records) (USDHHS, 1999). Previously the rule required written consent for disclosure of all patient information. Under new regulations, to eliminate barriers that delay access to care, providers are only to notify patients of their privacy policy and make a reasonable effort to obtain written acknowledgment of this notification. As a result of this act, patients have more control over their personal health care information and who has access to this information.

When you are a student in a clinical setting, confidentiality and compliance with HIPAA legislation are part of professional practice. You review the medical record only for information needed to provide safe, efficient care. For example, when you are assigned to provide complete care for a patient, you need to review the current medical record and plan of care. However, do not share information with other classmates or access the medical records of other patients on the specific clinical area. To further maintain confidentiality and protect patient privacy, do not have patient identifiers (e.g., room number, date of birth, medical record number, or other identifiable demographic information) on written materials used in your student clinical practice and do not photocopy, cut, or paste any patient information from the electronic record.

STANDARDS

Current Joint Commission standards require that all patients who are admitted to a health care agency have an assessment of physical, psychosocial, environmental, self-care, patient education, and discharge planning needs (TJC, 2012a). The Joint Commission standards require documentation to be within the context of

the nursing process, including evidence of patient and family teaching and discharge planning. Agency standards or policies often state the frequency of assessment; thus it is essential to know the standards of your health care organization.

The standards developed by The Joint Commission provide structure for health care organizations. Health care organizations are accountable to ensure adherence to documentation standards to protect the patient. Electronic records and information create complexities in information management and potential for error. The goal of information management is to support decision making and improve patient outcomes, therefore ensuring patient safety.

PATIENT-CENTERED CARE

The Joint Commission has recently released a roadmap of new standards that support care based on individual needs of the patient. Patient-centered care is care that is respectful to patient's values and beliefs. It includes culture, ethnicity, age, spiritual beliefs, spoken and written language, and patient literacy. It also identifies and addresses patient mobility and any precautions and safety risks of the patient (TJC, 2012a). Patient-centered care encourages active participation of a patient in all care decisions and questioning from patient and family. The patient role should no longer be passive but one of active, informed involvement that improves communication among patient, family, and the health care team. Effective communication that is patient centered increases patient safety (Carayon and Wood, 2009). Communication is individualized to a unique patient's needs gathered during admission to the hospital setting. Nurses continue to monitor for changes that may be needed in communication style across the patient's life span (TJC, 2012a).

MULTIDISCIPLINARY COMMUNICATION WITHIN THE HEALTH CARE TEAM

Patient care requires effective communication among the members of the health care team. Records and reports communicate specific information about a patient's health status and the interventions that all health care team members contribute toward improving his or her health. Multidisciplinary communication and documentation are necessary to provide more efficient and effective health care and improve patient outcomes.

A patient's record or chart is a confidential, permanent legal document containing information relevant to a patient's health care. Nurses and other health care providers record information about a patient's health care after each patient contact. The record is a continuing account of the patient's health status and needs, treatments delivered, results of diagnostic tests, and response to therapy.

Reports are oral, written, or audiotaped exchanges of information among caregivers (Fig. 4-2). Patient information may be received or reported verbally, by fax, or via paging system. Reports include information about a patient's clinical status, observations made about his or her behavior, data pertaining to diagnostic tests, and directions for changes in therapy. Common reports given by nurses include telephone reports, transfer reports, and adverse event reports (see *Procedural Guideline 4-3*).

Patient hand-off reports (see *Procedural Guideline 4-1*), a standardized approach to communication of patient information among caregivers, is being used by many health care organizations. A patient hand-off is not limited to nursing alone but can be interdisciplinary among all who provide care to the patient. Hand-off

FIG 4-2 Communication among members of the health care team.

must occur during shift change or any time the patient changes caregivers (TJC, 2012a; 2012b). They are to be used by nurses for relief coverage for breaks, for shift report, when patients transfer to different departments for studies, or for transfer to a different level of care within a hospital. Hand-off is also used across the health care continuum when patients leave one health system for another. Effective hand-off allows for face-to-face communication when available, which allows the person receiving care of the patient the opportunity to ask questions. During a hand-off communication process the patient and patient information are transferred to the next caregiver. Acceptance of patient care information and the associated caregiver responsibilities are achieved through effective communication that is complete and accurate. For example, during hand-off the sender of the patient information initially presents the patient name, room number, age, gender diagnosis, medical history, discharge planning, and confidential information. This is followed by patient vital signs and clinical assessments, changes in clinical condition, medication review, fluid balance, and patient safety risk assessment factors. The patient is an active participant in the hand-off process. Once hand-off is completed, the receiver of the information is given an opportunity to ask questions and confirm understanding. Incomplete or comprehensive information can negatively affect a patient's safety. A comprehensive hand-off not only is information sharing but also is the acceptance and effective transfer of all patient authority and responsibility (Joint Commission Center for Transforming Health-care, 2011; Runy, 2008).

When a nurse receives any information from a physician or health care provider by phone, he or she must ensure the accuracy and completeness of the information by writing it down and reading it back to the physician. When you accept a verbal order, telephone order, or critical test result, write down the order or critical test result as you hear it and then read it back to the individual who has given the order. By stating the information back, also called the *read-back*, to the individual giving the order or test result, you verify that the complete order or test result has been received and understood (NQF, 2011; TJC, 2011).

A nurse also communicates information through discussions or conferences among health care team members. For example, a discharge planning conference often involves members of all disciplines (i.e., nursing, medicine, social work, physical therapy, and dietary) who meet to discuss a patient's progress toward established discharge goals. A nurse needs to document this information in a patient's permanent record so all caregivers benefit from the information and plan the patient's care accordingly.

GUIDELINES FOR QUALITY DOCUMENTATION AND REPORTING

Quality documentation and reporting enhance efficient, safe, individualized patient care; you achieve this through the use of standard guidelines. Accurate documentation is one of the best defenses of legal claims associated with nursing care. Five common issues in malpractice caused by inadequate or incorrect documentation include (1) failing to document the correct time of events, (2) failing to record verbal orders or have them signed, (3) charting actions in advance to save time, (4) documenting incorrect data, and (5) failing to give a report or giving an incomplete report to an oncoming shift (Table 4-1).

To limit liability nursing documentation must clearly indicate that a nurse provided individualized, goal-directed nursing care to a patient based on the nursing assessment. The recorded information in a patient's record must describe exactly what happened to the patient. This is best achieved when you chart immediately after you have provided an intervention (Brown and King, 2008). Include all assessment findings, care plans, interventions, patient responses to interventions, and consultations/referrals in the medical record. Quality documentation and reporting must have the following characteristics: they must be factual, accurate, complete, current, and organized.

Factual

A record or report contains descriptive, objective information about what you see, hear, feel, and smell. An objective description is the result of direct observation and measurement such as "respiratory rate 20 and unlabored." Avoid terms such as *appears*, *seems*, or *apparently*, which are often subject to interpretation. For example, the description "the patient seems to be in pain" does not accurately communicate the facts to another caregiver. The phrase *seems* is not supported by any objective facts. Objective documentation needs to include your observations of patient behavior. For example, objective signs of pain include increased pulse rate, increased respiration, diaphoresis, or guarding a body part.

The only subjective data included in a record are what the patient actually verbalizes. Write subjective information with quotation marks, using the patient's exact words whenever possible. For example, you record, "Patients states, 'My stomach hurts.'" You also include complementary objective findings so the database is descriptive.

Accurate

The use of exact measurements in documentation establishes accuracy. For example, charting that an abdominal wound is "5 cm (2-inches) in length without redness, edema, or drainage" is more descriptive than "large wound healing well." It is essential to avoid unnecessary words and irrelevant details. For example, the fact that a patient is watching television is only necessary when this activity is significant to the patient's status and plan of care.

The Joint Commission requires health care organizations to standardize abbreviations, symbols, acronyms, and dose designations and establish a list of abbreviations that should never be used (TJC, 2012a). Use abbreviations carefully to avoid misinterpretation and minimize errors by spelling out confusing abbreviations. It is essential to know the abbreviation list of the agency in which you work and to use only the accepted abbreviations, symbols, and measures (e.g., metric) so all documentation is accurate and in compliance with standards. For example, the abbreviation for *every day (qd)* is **no longer used** (Box 4-2; see Chapter 20). If a treatment or medication is needed daily, the written order or

TABLE 4-1 Legal Guidelines for Recording

Guidelines	Rationale	Correct Action
Do not erase, apply correction fluid, or scratch out errors made while recording.	Charting becomes illegible: it appears as if you were attempting to hide information or deface record.	Draw single line through error, write word <i>error</i> above it, and sign your name or initials. Then record note correctly. Check agency policy.
Do not write retaliatory or critical comments about patient or care by other health care professionals.	Statements can be used as evidence for nonprofessional behavior or poor quality of care.	Enter only objective descriptions of patient's behavior; use quotations for patient's comments.
Need to add additional patient information.	New information is acquired. Forgot to chart during a shift.	If additional information is to be added to an existing entry, write the date and time of the new entry on the next available space and mark it as an addendum (date and time of prior note). Write the current date and time in the next available space and mark it as a late entry (date and time/shift missed).
Correct all errors promptly.	Errors in recording can lead to errors in treatment.	Avoid rushing to complete charting; be sure that information is accurate.
Record all facts.	Record must be accurate and reliable.	Be certain that entry is factual; do not speculate or guess.
Do not leave blank spaces in nurses' notes.	Another person can add incorrect information in space.	Chart consecutively, line by line; if space is left, draw line horizontally through it and sign your name at end.
Record all entries legibly and in black ink.	Illegible entries can be misinterpreted, causing errors and lawsuits; ink cannot be erased; black ink is more legible when records are photocopied or transferred to microfilm.	Never erase entries or use correction fluid and never use pencil.
If order is questioned, record that you sought clarification.	If you perform an order known to be incorrect, you are just as liable for prosecution as the health care provider.	Do not record "physician made error." Instead, chart that "Dr. Smith was called to clarify order for analgesic."
Chart only for yourself.	You are accountable for information that you enter into chart.	Never chart for someone else. Exception: If caregiver has left unit for day and calls with information that needs to be documented, include the name of the source of information in the entry and that the information was provided via telephone.
Avoid using generalized, empty phrases such as "status unchanged" or "had good day."	Specific information about patient's condition or case can be deleted accidentally if information is too generalized.	Use complete, concise descriptions of care.
Begin each entry with time and end with your signature and title.	This guideline ensures that correct sequence of events is recorded; signature documents who is accountable for care delivered.	Do not wait until end of shift to record important changes that occurred several hours earlier; be sure to sign each entry.
For computer documentation keep your password to yourself.	Maintains security and confidentiality.	Once logged on to the computer, do not leave the computer screen unattended.

BOX 4-2 Official "Do Not Use" Abbreviations

Do Not Use	Potential Problem	Use Instead
U, u (unit)	Mistaken for "0" (zero), the number "4" (four), or "cc"	Write "unit"
IU (International Unit)	Mistaken for IV (intravenous) or the number 10 (ten)	Write "International Unit"
Q.D., QD, q.d., qd (daily)	Mistaken for one another	Write "daily"
Q.O.D., QOD, q.o.d, qod (every other day)	Period after the Q mistaken for "I" and the "O" mistaken for "1"	Write "every other day"
Trailing zero (X.0 mg)	Decimal point is missed	Write X mg
Lack of leading zero (.X mg)		Write 0.X mg
MS	Can mean morphine sulfate or magnesium sulfate	Write "morphine sulfate"
M _{SO4} and MgSO ₄	Confused for one another	Write "magnesium sulfate"

TJC: Facts about the official "Do Not Use" list, available at http://www.jointcommission.org/facts_about_the_official/, accessed February 1, 2012.

care plan should write out the word “daily” or “every day.” The abbreviation *qd* (*every day*) can be misinterpreted to mean *O.D.* (*right eye*).

Correct spelling demonstrates a level of competency and attention to detail. Many terms are easy to misinterpret because they sound similar (e.g., dysphagia or dysphasia and dram or gram). Some spelling errors result in serious treatment errors (e.g., the names of certain medications such as digitoxin and digoxin or morphine and Numorphan are similar and you need to transcribe them carefully to ensure that a patient receives the correct medication).

The Joint Commission standards (2012a) require that “all entries in medical records be dated and a method is established to identify the authors of entries.” Therefore each entry in a patient’s record ends with the caregiver’s full name or initials and status. Sometimes you document interventions performed by another caregiver. For example, “Patient ambulated by Sue Smith, NA.” As a nursing student you need to enter full name, student nurse abbreviation (e.g., SN, NS), and educational institution such as “David Jones, SN (student nurse), CTCC (Central Texas Community College).”

Records need to reflect accountability during the time frame of the entry, which you accomplish best when you chart your own observations and actions. The signature holds that nurse accountable for information recorded. If information was inadvertently omitted from the record, it is acceptable for nurses to ask colleagues to chart information after they leave work. The entry needs to clearly show what was done and by whom (e.g., “At 11 AM Sam Turner, RN, called and reported that at 8 AM Demerol 100 mg IM was administered to patient for abdominal pain”). The nurse recording the information then signs this entry.

Complete

The information within a recorded entry or a report must be complete, containing appropriate and essential information. Criteria for thorough communication exist for certain health problems or nursing activities (Table 4-2). Document entries in a patient’s medical record and describe nursing care that you administer and the patient’s response. For example:

1915 Patient verbalizes sharp, throbbing pain localized along lateral side of right ankle, beginning approximately 15 minutes ago after twisting his foot on the stairs. Patient rates pain as 7 on a scale of 0 to 10. Pain increased to an 8 with movement, relieved to a 6 with elevation. Pedal pulses equal bilaterally. Right ankle circumference 1 cm larger than left. Ice applied. Percocet 2 tabs by mouth given for pain.

1945 Patient states pain somewhat relieved following application of ice and rates pain as 6 on a scale of 0 to 10. Health care provider notified for new analgesic order. Lee Turno, RN.

You record routine activities such as vital signs, daily hygiene, and ambulation on graphic records and flow sheets. Changes in functional ability or status require more detailed documentation. For example, your patient was unable to move from the bed to the chair without shortness of breath and now is no longer short of breath during this transfer. This change warrants more than simply recording incidence of ambulation on a flow sheet. Instead describe specifically how the patient responded during the transfer.

Current

Current documentation includes making timely entries in a patient’s record, which avoids omissions and delay in patient care (TJC, 2012a). To increase accuracy and decrease unnecessary duplication, many health care agencies locate medical records near

TABLE 4-2 Examples of Criteria for Reporting and Recording

Topic	Criteria To Report or Record
Assessment	
Subjective data	Description of episode/event in patient’s words in quotation marks Clarify onset, location, description of condition (severity; duration; frequency; precipitating, aggravating, and relieving factors)
Patient behavior (e.g., anxiety, confusion, hostility)	Onset, behaviors exhibited, precipitating factors
Objective data (e.g., rash, tenderness, breath sounds)	Onset, location, description of condition (severity; duration; frequency; precipitating, aggravating, and relieving factors)
Nursing Interventions and Evaluation	
Treatments (e.g., enema, bath, dressing change)	Time administered, equipment used (if appropriate), patient’s response (objective and subjective changes) compared to previous treatment (e.g., rated pain 2 on a scale of 0-10 during dressing change or “patient reported no abdominal cramping during enema”)
Medication administration	Immediately after administration document: time medication given, dose, route, any preliminary assessment (e.g., pain level, vital signs), patient response or effect of medication (e.g., 1200 “Pain reported at 7 (scale 0-10). Tylenol 500 mg given PO.” 1230: “Patient reports pain level 2 (scale 0-10) at 1330” or “Pruritus and hives developed over lower abdomen 1 hour after penicillin was given.”)
Patient teaching	Information presented; method of instruction (e.g., discussion, demonstration, videotape, booklet); patient response, including questions and evidence of understanding such as return demonstration or change in behavior
Discharge planning	Measurable patient goals or expected outcomes, progress toward goals, need for referrals

a patient’s bedside, which facilitate immediate documentation of care activities. Document the following activities or findings at the time of occurrence:

- Vital signs
- Pain assessment and evaluation
- Administration of medications and treatments
- Preparation for diagnostic tests or surgery
- Change in patient’s status and who was notified
- Treatment for a sudden change in patient’s status
- Patient response to intervention
- Admission, transfer, discharge, or death of a patient

Many health care agencies use military time, a 24-hour system that avoids misinterpretation of AM and PM times. The military clock ends with midnight at 2400 and begins 1 minute after midnight at 0001. For example, 1:00 PM is 1300 military time; 10:22 AM is 1022 military time. Fig. 4-3 compares military and civilian times.

Organized

You need to present written communication in logical order beginning with assessments, nursing interventions, and finally patient responses. Communication is more effective when it is clear, concise, and brief. Entries are more organized and clear if you make a list of what to include before beginning to record in the permanent legal record.

FIG 4-3 Military time clock. Instead of two 12-hour cycles, the military clock is one 24-hour time cycle (e.g., 3 PM is 1500 military time).

COMMON RECORD-KEEPING FORMS OR SCREENS

The patient chart or medical record contains evidence of a patient's health status. The chart includes a variety of forms or screens (as in the case of electronic records) to facilitate quick and comprehensive documentation. Use of these forms helps avoid duplication of information within the record.

Admission Nursing History Forms

A nurse completes a comprehensive nursing history form or screen to gather baseline assessment data when a patient is admitted to a nursing care unit. You use the admission data to form a plan of care and compare it to any changes in a patient's condition. The nursing history guides the admitting nurse through a complete assessment to identify relevant nursing diagnoses or problems for the patient's care plan. Each health care agency designs these forms or screens based on the standards of practice and philosophy of nursing care. Examples of information included in the nursing history are patient allergies, primary spoken/written language, advance directives, disabilities, and mobility/fall risk and medication reconciliation.

Flow Sheets and Graphic Records

Flow sheets and graphic records permit concise documentation of nursing information and patient data over time. They are especially useful for the documentation of routine observations or repeated specific measurements for a patient such as vital signs (see Chapter 6), intake and output, hygiene measures, medication administration (see Chapter 20), and pain assessment. Flow sheets use a format or system for entry of information, usually every 24 hours (Fig. 4-4). When documenting a significant change that you

recognize on a flow sheet, describe the change in the progress notes, including the patient's response to nursing interventions. For example, if a patient's blood pressure becomes dangerously low, record in the progress notes the blood pressure, relevant assessment such as pallor or dizziness, and any interventions to raise the blood pressure. Also include an evaluation of the interventions such as repeated blood pressures and relief of dizziness. Other health care providers such as nursing assistants may have the responsibility to document on nursing flow sheets or screens. Flow sheets and screens provide a quick, easy reference for the health care team members to assess a patient's status.

Patient Education Record

Patient teaching and education are essential nursing interventions. Many health care organizations have an education record that identifies a patient's knowledge base about his or her diagnosis, treatment, and medications. The goal of patient and family education is to promote health behavior and self-care by involving the patient and/or family in decisions, which improves health outcomes. Standards for patient education include assessment of needs, functional abilities, learning styles, and readiness to learn. You base patient education needs on the assessment and then teach patients about topics such as safe and effective use of medications, nutrition and dietary modifications, safe use of medical equipment, pain control, rehabilitative methods to promote and improve functional abilities, and self-care activities (TJC, 2012a). Hospitals provide educational materials for patients by handouts, many of which are accessed by the computer network in the hospital. When documenting on a patient teaching record, be specific about the information and/or skills taught, the patient's learning response, and information given to the patient.

Patient Care Summary or Kardex

Many health care agencies now have computerized systems that provide a concise set of information in the form of a patient care summary. This summary prints out for each patient during each shift. Data are updated automatically as new orders and nursing decisions enter the system.

In some health care settings a Kardex ("cardboard flip-over" file) kept at the nurses' station provides information for daily patient care needs. It has two parts: an activity and treatment section and a nursing care plan section. The updated information in both the patient summary and the Kardex eliminate the need for repeated referral to the chart for routine information throughout the day. The forms do not always become part of the permanent record. Information commonly found on the patient care summary or Kardex includes the following:

- Basic demographic data (e.g., age, religion)
- Primary medical diagnosis
- Current health care provider's orders (e.g., diet, activity, dressing changes)
- A nursing care plan
- Nursing orders or interventions (e.g., intake and output, comfort measures, teaching)
- Scheduled tests and procedures
- Safety precautions used in the patient's care
- Factors related to activities of daily living
- Nearest relative/guardian or person to contact in an emergency
- Emergency code status
- Allergies

Acuity Records

Many health care organizations use a patient acuity system as a method of determining the intensity of nursing care required for a group of patients. Acuity measurements for patients on a unit serve as a guide for determining staffing needs. An acuity recording system determines the hours of nursing care and number of staff required for a nursing unit.

Typically nurses enter acuity data into a computerized system in the morning. The administrative staff collects the acuity data electronically and use it to make appropriate staffing decisions. Acuity levels allow the nursing staff to compare patients with one another. For example, an acuity system might rate bathing patients from 1 to 5 (1 is totally dependent, 5 is independent); a patient returning from surgery who requires frequent monitoring and extensive care has an acuity level of 1. On the same continuum another patient awaiting discharge after a successful recovery from surgery has an acuity level of 5. Accurate acuity ratings justify the number and qualifications of staff needed to safely care for patients on a particular unit.

Standardized Care Plans

The trend among many health care organizations is to computerize care plans. These systems provide daily computer-generated care plans, which incorporate several nursing diagnoses or problems in a single care plan. These systems improve nursing documentation and facilitate high-quality care that is based on scientific evidence and proven experience (Fogelberg-Dahm, 2008). Standardized care plans are based on agency standards of nursing practice and are established guidelines used to care for patients with similar health problems. After completing a nursing assessment, you identify the patient's nursing diagnosis or health problem and select an appropriate standardized care plan for the patient medical record. You individualize it for each patient. Most standardized care plans allow for the addition of patient-specific outcomes and target dates for achieving these outcomes.

One advantage of standardized care plans is the establishment of evidence-based standards of care. By using standardized plans nurses learn to recognize the accepted requirements of care for patients. They also improve continuity of care among professional nurses. The Joint Commission supports the use of standardized care plans and no longer requires a written care plan for each patient.

One disadvantage of standardized care plans is an increased risk that the unique, individualized therapies needed by patients will go unrecognized. Standardized care plans do not replace your professional judgment and decision making. In addition, care plans need to be updated on a regular basis to ensure that content is current and appropriate.

Discharge Summaries

Discharge planning is a comprehensive process with emphasis placed on preparing a patient for discharge from a health care organization. Discharge planning, case management, and utilization review are all involved in patient care. A prospective payment system based on diagnosis-related groups (DRGs) encourages health care organizations to be more efficient and discharge a patient as soon as possible. Early hospital discharge improves hospital chances of full reimbursement. It is important to ensure that a patient's discharge results in desirable outcomes. You enhance discharge planning when you are responsive to changes in a patient's condition and involve the patient and family in the planning process (Bauer et al., 2009; Rose and Haugen, 2010). The discharge summary includes essential information for the patient, family, and health care organization (Box 4-3).

BOX 4-3 Discharge Summary Information

- Use clear, concise descriptions in patient's own language.
- Provide step-by-step description of how to perform a procedure (e.g., home medication administration). Reinforce explanation with printed instructions for the patient to take home.
- Identify precautions to follow when performing self-care or administering medications.
- Review any restrictions that may relate to activities of daily living (e.g., bathing, ambulating, and driving).
- Review signs and symptoms of complications to report to health care provider.
- List names and phone numbers of health care providers and community resources for the patient to contact.
- Identify any unresolved problem, including plans for follow-up and continuous treatment.
- List actual time of discharge, mode of transportation, and who accompanied patient.

Discharge planning begins at admission and becomes a more prominent part of care as a patient gets closer to discharge. There must be evidence of the involvement of the patient and family members in the discharge planning process so the patient and family have the necessary information and resources to return home (Bauer et al., 2009; Rose and Haugen, 2010). The Joint Commission (2012b) has standards for patient and family education necessary for effective discharge planning. When a patient is discharged from a health care organization, the members of the health care team prepare a discharge summary. It provides important information relating to the patient's ongoing health problems and need for health care after discharge. Discharge planning achieves specific outcomes that include identifying patients with ongoing health needs, collaborating with other health care professions to determine level of care, matching patients with appropriate referrals and resources, and streamlining the transition to the next level of care (Rose and Haugen, 2010). Include in the discharge summary the reason for hospitalization; significant findings; current status of the patient; and the teaching plan that is given to the patient or family, home care, rehabilitation, or long-term care facility (TJC, 2012a). Discharge summaries make the summary concise and instructive. They emphasize previous learning by the patient and family and care that needs to continue in any restorative care setting.

CHARTING SYSTEMS

A variety of documentation systems (computerized and written) exist for recording patient information and progress. The documentation system selected by nursing reflects the philosophy of the health care organization. The same documentation system is used throughout a specific agency, but there are several acceptable methods for recording health care data.

Narrative Documentation

A nurse enters narrative documentation for recording nursing care and activities that cannot be thoroughly explained on flow sheets or other standardized screens or forms. Narrative charting uses a storylike format to document specific information about a patient's conditions and nursing care, usually presented in chronologic order. Narrative charting is useful in emergency situations when the time and order of events are important. Organize a narrative in a clear, concise way (e.g., by using the nursing process to order

the data). In many settings methods such as focus or SBAR charting has replaced narrative charting.

Problem-Oriented Medical Records

A problem-oriented medical record (POMR) is a structured method of documenting narratives that emphasizes a patient's problems. This method organizes data using the nursing process, which facilitates communication about patient needs. Data are organized by problem or diagnosis. Ideally all members of the health care team contribute to the list of identified patient problems. This approach assists in coordinating an individualized plan of care with the following sections: database, problem list, care plan, and progress notes.

Patient Database

A database contains all available information pertaining to a patient. This section is the foundation for identifying patient problems and planning care. The database remains active and current for each patient and is revised as new data become available.

Problem List

You develop a patient's problem list after analyzing his or her assessment data. The problem list includes the patient's physiologic, psychological, sociocultural, spiritual, developmental, and environmental needs. Identify and list priority problems in chronologic order to serve as an organizing guide for the patient's care. Add new problems as they are identified during the ongoing nursing assessment. When a problem is resolved, you record the date and draw a line through the problem and its number.

Nursing Care Plan

All disciplines involved in a patient's care contribute to the development of a plan of care for a specific problem. For example, for a patient having a nutritional deficit, a nurse recommends feeding approaches, and a registered dietitian recommends types of dietary supplements. Care plan standards require that a plan of care be developed for all patients on admission to a health care organization (TJC, 2012a). Generally these plans include nursing diagnoses, expected outcomes, and interventions.

Progress Notes

Health care team members use progress notes to monitor and record the progress of a patient's problem (Box 4-4). Narrative notes, flow sheets, and discharge summaries are formats used to document patient progress (see Procedural Guideline 4-2).

SBAR Documentation. Structured communication provides a model for data about a patient's condition. SBAR is a technique that provides a framework for communication among members of the health care team such as physicians when there is a change in patient's condition. You apply this method to both written and verbal communication. SBAR standardizes communication and improves the effectiveness of information (Dunsford, 2009). When a patient's condition changes, use the following SBAR mnemonic:

- S:** Situation (Identify yourself, your unit, and the patient. State what is happening at the present time.)
- B:** Background (Give patient's diagnosis, reason for admission. Explain the circumstances leading up to the situation.) Have patient's chart available when reporting.
- A:** Assessment (Provide specific information [i.e., quantitative and qualitative data] as necessary. What do you think the problem is?)
- R:** Recommendation (Explain what you need. Be clear and specific. What would you do to correct the problem?) Read back any verbal or telephone orders received following your recommendation.

BOX 4-4 Formats for Recording Progress Notes**Narrative Note**

Describes patient data in a narrative paragraph

Example:

Patient states, “I’m dreading this surgery because last time I had a terrible reaction to the anesthesia and such terrible pain when they made me get out of bed.” Noted muscle tension and loud, agitated voice. Notified anesthesiologist, Dr. Martin, of patient’s prior experience. Discussed alternatives for anesthesia and pain-control options. Stressed importance of activity for circulation/healing. Encouraged to keep nurses informed of pain level/need for medication and that pain may be present but manageable.

SBAR (Acronym for Situation, Background, Assessment, and Recommendation)

SBAR is a system of structured communication used to share information about a patient’s condition.

Example:

S (Situation): Patient verbalized preoperative fears. Nurse noted muscle tension and loud, agitated voice.

B (Background): Patient fearful of surgery because of past experiences with anesthesia and pain.

A (Actions taken): Notified anesthesiologist, Dr. Martin, of patient’s prior experience. Discussed alternatives for anesthesia and pain-control options. Stressed importance of activity for circulation/healing. Encouraged to keep nurses informed of pain level/need for medication and that pain may be present but manageable.

R (Recommendation): Assess pain level at least every 4 hours after surgery. Provide nonpharmacologic pain-management techniques, and administer medication as needed.

SOAP (Acronym for Subjective Data, Objective Data, Assessment, and Plan)

Usually based on a numbered list of problems or nursing diagnoses

Example:

S (Subjective data) (the patient’s statements regarding the problem): Patient states, “I’m dreading this surgery because last time I had a terrible reaction to the anesthesia and such terrible pain when they made me get out of bed.”

O (Objective data) (observations that support or are related to subjective data): Noted muscle tension and loud, agitated voice.

A (Assessment/Analysis) (conclusions reached based on data): Fear related to pain/anesthesia.

P (Plan) (the plan for dealing with the situation): Notified anesthesiologist, Dr. Martin, of patient’s prior experience.

Discussed alternatives for anesthesia and pain-control options. Stressed importance of activity for circulation/healing. Encouraged to keep nurses informed of pain level/need for medication and that pain may be present but manageable.

PIE (Acronym for Problem, Intervention, and Evaluation)

Problem-oriented system in which progress notes are written based on a list of identified problems and detailed data may be entered by any member of the health care team

Example:

P (Problem): Patient states, “I’m dreading this surgery because last time I had a terrible reaction to the anesthesia and such terrible pain when they made me get out of bed.” Noted muscle tension and loud, agitated voice.

I (Intervention): Notified anesthesiologist, Dr. Martin, of patient’s prior experience. Discussed alternatives for anesthesia and pain-control options. Stressed importance of activity for circulation/healing. Encouraged to keep nurses informed of pain level/need for medication and that pain may be present but manageable.

E (Evaluation): Patient stated that she was “very relieved.” Stated that she would tell the nurses about pain.

Focus or DAR Charting (Acronym for Data, Action, and Response)

A way to organize progress notes to make them more clear and organized

Example:

D (Data): Patient states, “I’m dreading this surgery because last time I had a terrible reaction to the anesthesia and such terrible pain when they made me get out of bed.” Noted muscle tension and loud, agitated voice.

A (Nursing Action): Notified anesthesiologist, Dr. Martin, of patient’s prior experience. Discussed alternatives for anesthesia and pain-control options. Stressed importance of activity for circulation/healing. Encouraged to keep nurses informed of pain level/need for medication and that pain may be present but manageable.

R (Patient Response): Patient stated that she was “very relieved.” Stated understanding of the importance of informing the nurses about pain.

Note: Some agencies add *P (Plan)* and refer to this as *DARP* charting.

Example:

P (Plan): Assess pain level at least every 4 hours after surgery. Provide nonpharmacologic pain management techniques and administer medication as needed.

SBAR is a concrete approach for framing conversations, especially critical ones that require a nurse’s immediate attention and action. It allows for an easy and focused way to set expectations for what the team will communicate. SBAR promotes the provision of safe, efficient, timely, and patient-centered communication (Chaboyer et al., 2010; Day, 2010).

SBAR can also be used for multiple forms of communication. It can be used for a brief targeted report (e.g., as a preprocedure or postprocedure report) or as a change-of-shift report as shown here (Pope et al., 2008; Thomas et al., 2009).

S Situation (admission date, chief complaint and diagnosis)

B Background (medical history, allergies, code status, isolation, significant interventions, pain management, responses to interventions, report of abnormal studies, who was notified, any interventions, intravenous [IV] access)

A Assessment (review of systems: neurologic, respiratory, cardiac, gastrointestinal, genitourinary, musculoskeletal, peripheral vascular, skin, hematologic, endocrine, and psychosocial; vital signs; pain assessment and goals; blood sugar and sliding scale coverage; fall risk)

R Recommendations (patient’s daily goals, consultations, planned treatments, upcoming tests or surgery, discharge planning, and patient education)

SOAP Documentation. One way to structure narrative notes to document patient progress is the SOAP format. SOAP is a mnemonic for the following:

S: Subjective data (patient statements about the problem)

O: Objective data (data that are measured and observed or related to subjective data)

A: Assessment/Analysis (conclusions based on the subjective and objective data)

P: Plan (what the caregiver plans to do)

Some agencies add an *I* and *E* (i.e., SOAPIE). The *I* stands for *intervention*, and the *E* represents *evaluation*. The logic for SOAP (IE) notes is similar to that of the nursing process: collect data about a patient's problems, draw conclusions, and develop a plan of care. Number each SOAP note and title it according to the problem on the list.

PIE Documentation. The PIE note format of documentation is similar to that of SOAP charting in its problem-oriented nature. However, it differs from the SOAP method in that PIE charting has a nursing origin, whereas SOAP originated from a medical model. PIE is a mnemonic for the following:

P Problem or nursing diagnosis for the patient

I Interventions or actions taken

E Evaluation of the outcomes of nursing interventions

The PIE format simplifies documentation by combining the care plan and progress note into one record. The PIE format differs from that of SOAP because there are no assessment data in the narrative note. Assessment data are included in documentation on the flow sheets of each shift. You number or label the PIE notes according to a patient's problems. Resolved problems are dropped from daily documentation after your review. Continuing problems are documented daily.

Focus Charting. Another narrative format is focus charting or DAR (data, action, response). One distinction of focus charting is that it places less importance on patient problems and focuses on patient concerns such as a sign or symptom, a condition, a nursing diagnosis, a behavior, a significant event, or a change in condition. Each entry includes data (both subjective and objective), actions or nursing interventions, and patient response (e.g., evaluation of effectiveness). Nurses need to broaden their thinking to include any patient concerns, not just problem areas, and to apply critical thinking. Focus charting saves time because it is easy for caregivers to understand, is adaptable to most health care settings, and enables all caregivers to track a patient's condition and progress.

Source Records

In a source record a patient's chart is organized so each discipline (i.e., nursing, medicine, social work, and respiratory therapy) has a separate section in which to record data. The advantage of a source record is that it is easy for caregivers to locate the proper section of the record in which to make entries.

A disadvantage of the source record is that information about a specific problem may be distributed throughout the record. For example, the nurse describes the character of a patient's fractured femur pain and use of repositioning and narcotic analgesia in the nurses' notes and electronic health record (EHR). The health care provider notes in a separate section of the record the patient's bone healing and the plan for casting or surgery. The results of x-ray examinations that show bone healing are in the radiology results section of the record. The method makes it difficult to find chronological information about patient care or how the team is coordinating care to meet all of the patient's needs.

Charting by Exception

Charting by exception (CBE) is a system of documentation that aims to eliminate redundancy, makes documentation of routine care more concise, emphasizes abnormal findings, and identifies trends in clinical care. CBE is a shorthand method for documenting based on clearly defined standards of practice and

predetermined criteria for nursing assessments and interventions. This system involves completing a flow sheet that incorporates standard assessment and intervention criteria by placing a check mark in the appropriate standard box on the flow sheet to indicate normal findings and routine interventions. You write a narrative nurse's note *only* when there is an exception to the established standard or abnormal data are present. Assessments are standardized on forms so all health care providers evaluate and document findings consistently (Fig. 4-5).

The presumption with CBE is that the nurse assessed the patient and all standards are met unless otherwise documented. Changes in a patient's condition require thorough and precise descriptions of what happened, actions taken, and patient response to treatment. Legal risks in using CBE include difficulty in proving safe care if nurses are not disciplined in documenting exceptions.

Case Management Plan and Critical Pathways

Case management is a delivery of care model that coordinates patient services to provide high-quality patient care experiences that are cost effective and provide optimal patient outcomes (Hospital Case Management, 2010; Park and Huber, 2009). Collaboration and communication are promoted in a multidisciplinary approach using critical or collaborative pathways for a specific disease or condition that is summarized into a standardized care plan. Case management plans incorporate standardized documents that include short care plans for the problem, key interventions, and expected outcomes for patients with a specific disease or condition (Fig. 4-6). These pathways provide the ideal sequence and timing of interventions for all members of the health care team. Use of critical pathways provides a resource for caregivers to ensure that clinical care is given with transparent accountability (Earle-Foley, 2011). The goal of a critical pathway is to improve the quality of care, reduce risks, increase patient satisfaction, and improve outcomes (Marchisio and others, 2009).

Case management programs use multidisciplinary plans of care summarized into critical pathways, which include key interventions and expected outcomes within an established time frame (see Fig. 4-6). Critical pathways are evidence based, and the assessment and monitoring, interventions, and expected outcomes are based on research and/or clinical evidence from the literature or the practice standards of the health care agency.

Critical pathways state the goals and important treatment interventions based on best practice and patient expectations by documenting, monitoring, and evaluating variances and providing resources and outcomes. Variances are unexpected occurrences, unmet goals, and interventions not specified within the critical pathway time frame and reflect a positive or negative change. A positive variance occurs when a patient progresses more rapidly than the case management plan expected (e.g., use of a Foley catheter is discontinued a day early). A negative variance occurs when the activities on the critical pathway do not happen as predicted or outcomes are unmet (e.g., oxygen therapy is necessary for a new-onset breathing problem). Your responsibility is to document the variance and include causative factors, actions taken, patient response, and outcomes. Over time the recurrence of similar variances lead the health care team to revise a critical pathway, particularly if it affects quality of care or length of stay.

STANDARDIZED LANGUAGE

Standardized language enhances use of accurate nursing diagnoses, increases effective nursing interventions, and improves patient outcomes (Müller-Staub, 2009). Nursing care is more effective and

FIG 4-5 Charting by exception—assessment form. When standards in far left column are not met, a detailed note explaining findings must be entered. (Courtesy Barnes-Jewish Hospital, BJC Health System, St Louis, Mo.)

The screenshot displays a software interface for electronic documentation. At the top left, there is a box labeled 'Items' with the number '60'. Below this are several buttons: 'Quick pick list', 'All chief complaints', 'Chief complaint not listed', 'Constitutional symptoms', and 'Injury'. The main area is divided into three columns under the heading 'Body Organ Systems'. The first column lists systems: Cardiovascular (circled in red), Gastrointestinal, Genitourinary, Heent, and Hema/Lymp/Immunologic. The second column lists systems: Integumentary, Musculoskeletal, Neurologic/Psychiatric, and Respiratory. Below these are two lists of symptoms: '1-20' (Abdominal pain, Abrasion, Accidental ingestion, Ankle pain, Arm pain, Asthma (pediatric), Asthma attack, Back pain, Breast pain, Cellulitis, Cervical pain, Chest pain, Child crying, Closed head injury, Contusion, Cough, CVA, Diarrhea, Difficulty breathing, Dizziness) and '21-40' (Ear pain, Elbow pain, Fever, Fever in child, Foley cath replacement, Follow-up visit, Foot/toe pain, Foreign body, Fracture, G tube replacement, Gunshot wound, Hand pain, Headache, Hip pain, Increased urination, Insect bite, Knee pain, Laceration, Leg pain, Lower GU tract pain). On the right, there is a 'Chief Complaint(S)' section with four numbered entries, each with a text field, a 'Record' button, and a '5' or 'st' indicator. Below this is a 'Right Mouse (Record) to Erase' section with a list of symptoms (Motor vehicle accident, Nasal congestion, Pain, Pelvic pain, Rash, Recheck, Shortness of breath, Shoulder pain, Sore throat, Sprain, Suture removal, Toothache, Upper respiratory infection) and a 'Quick Find' button. At the bottom, there are buttons for 'Patient select screen' and 'Save/Document'.

FIG 4-6 Electronic Documentation. Nursing record. (Courtesy ER Choice, Irving, Tex.)

appropriate to patient needs when nurses use the same language to identify patient problems and plan patient outcomes. Several classification systems provide standardized language. The North American Nursing Diagnosis Association (NANDA) International (NANDA-I) (2012) has established standardized nursing diagnoses to describe patients' responses to health problems. The Nursing Interventions Classification (NIC) provides a label name, definition, and list of activities that a nurse performs to complete an intervention (Center for Nursing and Clinical Effectiveness, 2011a). Use of this standardized language in documentation may prove useful to communicate patient care needs more clearly.

Another standard form of language being used throughout health care is patient outcomes. The Nursing Outcomes Classification (NOC) provides an outcome label, a definition, and a list of interventions that can result in the outcome (Center for Nursing and Clinical Effectiveness, 2011b). The use of outcomes is essential when evaluating the achievement of patient care goals and the appropriateness of patient interventions.

Outcome statements require a target date for completion and evaluation of a patient's progress toward achievement at specific intervals. Evaluation of progress determines if the patient's problem or diagnosis is resolved or if you need to revise or extend the plan. You individualize each outcome for the particular patient using specific measurement criteria. Such a process promotes continuity of care across the continuum of a patient's care and centers on the patient's and family's ability to restore, maintain, or improve the patient's health. The implementation of NANDA-I, NIC, and NOC nursing diagnoses, interventions, and outcomes can lead to

higher quality of nursing diagnosis documentation, etiology-specific nursing interventions, and nursing-specific patient outcomes (Müller-Staub et al., 2008).

HOME CARE DOCUMENTATION

Home care continues to grow with shorter hospitalizations and increasing numbers of older adults requiring home care services. Medicare has specific guidelines for establishing eligibility for home care reimbursement. Skilled home nursing care is divided into six categories of practice: assessment, diagnosis, outcomes identification, planning, implementation, and evaluation of a care plan (Gorski, 2008). When you provide care in the home, documentation has different implications than in other areas of nursing. One primary difference is that the patient and family rather than the nurse witness the majority of care. In addition, documentation systems need to provide the entire health care team with the necessary information to work together effectively (Box 4-5). The documentation is both the quality control and the justification for reimbursement from Medicare, Medicaid, or private insurance companies. It is important to consistently document all of your services for reimbursement (e.g., direct skilled care, patient instructions, skilled observation, and evaluation visits) (TJC, 2012a).

Computerized patient records are evolving in the home care setting. The electronic health record will facilitate clarity, continuity of care, and comprehensiveness because of increased standardization of language (Gjevjon and Hellesø, 2010).

BOX 4-5 Home Care Forms for Documentation

The usual forms used to document home care include the following:

- Patient assessment
- Referral source information/intake form
- Discipline-specific care plans
- Physician or health care provider's plan of treatment
- Medication sheet
- Clinical progress notes
- Miscellaneous (conference notes, verbal order forms, telephone calls)
- Discharge summary
- Reports to third-party payers

LONG-TERM HEALTH CARE DOCUMENTATION

Increasing numbers of older adults and disabled people in the United States require care in long-term health care agencies. Nursing personnel face documentation challenges much different from those in the acute care setting. Adding EHR documentation will enhance communication among the health care providers,

along with improving patient safety and efficiency of delivery of care (Cherry et al., 2011). Changes in the Medicare program determine the standards and policies for reimbursement and documentation in long-term care. The federally mandated Long-Term Care Facility Resident Assessment Instrument provides standardized protocols for assessment and care planning and promotes quality improvement within and among agencies (Adams-Wendling et al., 2008). Documentation and coding of services will continue to impact reimbursement (Field and Gross, 2009).

Each resident in long-term care is assessed using the Long-Term Care Facility Resident Assessment Instrument mandated by the Omnibus Budget Reconciliation Act of 1989 (OBRA) and updated in 1998 (HCFA, 1998). A registered nurse is responsible for coordinating the plan of care. Documentation supports the assessment and planning process for patients using a multidisciplinary approach. Communication among health care providers, including nurses, social workers, recreational therapists, and dietitians, is essential in the documentation process. The fiscal support for long-term care residents depends on the justification of nursing care as demonstrated in sound documentation of the services rendered. The overall goal is a system of clinical documentation that identifies potential or actual problems and provides improved actions for each problem, which result in improved care for residents (Duda-Gardiner, 2010).

PROCEDURAL GUIDELINE 4-1 Giving a Hand-Off Report

In addition to written documentation, a nurse provides a change-of-shift report to the next nurse assuming responsibility for patient care. The purpose of the report is to provide continuity of care for the patient. *The Joint Commission 2012 National Patient Safety Goals* (2012b) for health care organizations standardize an approach to hand-off communication that includes opportunities to ask and respond to questions. Nurses give a hand-off report face-to-face, by audiotape recording, via telephone conversation, through a written report, in a computer format, or during “walking-planning” rounds at each patient’s bedside. It is important to have some type of guidelines for reporting to avoid repetitive, irrelevant, and speculative communication (Chaboyer et al., 2010; Robert Wood Johnson Foundation, 2009). It is essential to schedule an opportunity for oncoming nurses to ask questions for clarification after listening to the report to prevent omissions in care and ensure that appropriate interventions continue. Regardless of the form of the hand-off report, you must maintain confidentiality.

Delegation and Collaboration

The skill of giving a hand-off report cannot be delegated to nursing assistive personnel (NAP). Licensed practical nurses (LPNs) may report on patients for whom they care directly. The nurse directs the NAP about what to report to the nurse (e.g., increased pain, changes in vital signs) so there can be assessment, validation, and reporting of any changes in the hand-off report.

Equipment

- Worksheets, patient care summary or nursing Kardex, nursing care plan, critical pathway, or multidisciplinary treatment plan
- Tape recorder (according to agency policy)

Procedural Steps

- 1 Develop an organized format for delivering report that provides a description of patient needs and problems.
- 2 Gather information from documentation sources, NAP report, or other relevant documents.

Clinical Decision Point Report only relevant information to next shift to ensure staff’s timely responsiveness.

- 3 Prioritize information based on patient’s needs and problems.
- 4 For each patient include:
 - a *Background information:* Patient’s name, gender, age, current primary reason for hospitalization, and brief history. Also include any known allergies, emergency code status (i.e., do not resuscitate [DNR]) and special needs as related to any physical challenges (e.g., blind, hearing deficit, amputee).
 - b *Assessment data:* Provide objective observations and measurements made by the nurse during the shift. Describe patient’s condition and emphasize any recent changes. Include any relevant information reported by patient, family, or health care team members such as laboratory data and diagnostic test results.
 - c *Nursing diagnoses or patient problems:* State the nursing diagnoses or patient problem appropriate for patient. (Some agencies do not include nursing diagnoses in report.)
 - d *Interventions, outcomes, and evaluation:* (Steps can be combined in a report.)
 - (1) Describe therapies or treatments administered during shift and expected outcomes (e.g., medication changes, use of oxygen, referral visits). Specify how you

PROCEDURAL GUIDELINE 4-1 Giving a Hand-Off Report—cont'd

- implemented interventions uniquely for this patient. Report on evaluation by explaining patient's response and whether outcomes are met. Do not explain basic steps of a procedure.
- (2) Describe instructions or education given in the teaching plan and patient's/family's ability to demonstrate learning.
- e *Family information*: Report on family visitation or involvement, specifically as it influenced patient. Explain if you included family members in care procedures or instruction.
 - f *Discharge plan*: Review patient's progress toward discharge during each change-of-shift report. Discuss education progress, communication with referral agencies, and family preparation for discharge. This plan also identifies roles and responsibilities of the multidisciplinary team and their follow-up visits.
- g *Current priorities*: Clearly explain the priorities to which oncoming nurse must attend.
 - (1) Report significant clinical changes.
 - (2) Report on immediate treatment planned for any new admission.
 - (3) Explain status of activities for patients preparing for procedures and treatments.
 - (4) Describe current physical status of patients returning from diagnostic or operative procedures.
- 5 Ask staff from oncoming shift if they have any questions regarding information provided.
 - 6 If using a tape recorder, periodically evaluate for clarity, organization, rate of speaking, and volume level.

PROCEDURAL GUIDELINE 4-2 Documenting Nurses' Progress Notes

A variety of forms and formats communicate information about a patient's health status and care. Accurate documentation reflects the quality of care and provides evidence of each health care team member's accountability in giving care. The purpose of a patient's record is to provide information for communication, education, assessment, research, financial billing, auditing, and legal documentation (Table 4-3).

Because the nursing process directs a nurse's approach to patient care, documentation needs to reflect this process. Nurses record assessment data, changes in a patient's condition, nursing interventions, and an evaluation of the patient's progress toward established outcomes. Prompt documentation of this data increases accuracy and promotes effective communication to all members of the health care team.

Progress notes provide a format for documenting a patient's health status and progress. You can use a variety of formats when writing notes, including SBAR, SOAP, SOAPIE, PIE, and DAR. All caregivers need to be able to read the progress note and have a clear picture of the problem, level of care required, and results of interventions. The nurse caring for the patient is responsible for writing and signing each progress note, which includes full name and title.

Delegation and Collaboration

The skill of documenting nurse progress notes cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- What repetitive care activities to document on flow sheets (e.g., vital signs, intake and output [I&O], routine care).
- What to report to the nurse (e.g., increased pain, changes in vital signs) so he or she can reassess, validate, and document any changes in the progress note.

Equipment

- Progress note form (written or electronic)
- Black pen

Procedural Steps

- 1 Review assessment data, problems identified, goals and expected outcomes, nursing interventions, and patient response during contact with each patient and before documentation.
- 2 Document patient information in the narrative format chosen by the health care agency. Follow guidelines for charting to ensure quality documentation.
- 3 After each patient contact, identify information that needs to be documented. Consider:
 - a Abnormal findings.
 - b Changes in status.
 - c New problems identified.
- 4 Document in a timely fashion without leaving open spaces between notes and include date and time.
- 5 Using agency format, document in chronological order the following:
 - a Pertinent, factual, objective data
 - b Selected subjective data that validates or clarifies
 - c Nursing actions taken
 - d Patient responses to actions taken
 - e Additional plans needing to be implemented
 - f To whom information has been reported, including name and status
- 6 Sign progress note with full name or first initial and last name and status according to agency policy. Do not leave any open space between this note and the previously written note. Students are usually required to indicate their level of education and school affiliation.
- 7 Review previously documented entries with those that you enter, noting if there is significant change in the patient's status. Report any changes to the patient's health care provider.

TABLE 4-3 Purposes of Records

Purpose	Description
Communication	The record is a means for health care team members to communicate a patient's <i>needs</i> (e.g., individual therapies, patient education, discharge planning) and <i>progress</i> (e.g., response to therapies). Anyone reading the record should have a clear understanding of the plan of care.
Education	The record contains a variety of information, including medical and nursing diagnoses, signs and symptoms of disease, successful and unsuccessful therapies, diagnostic findings, and patient behaviors. Students of nursing, medicine, and other health-related disciplines use records as educational resources.
Assessment	Records provide data that nurses use to identify and support nursing diagnoses and plan proper interventions for care. Information from records adds to the nurse's own observations and assessment. Information in medical progress notes allows a nurse to anticipate the status of a patient and conduct an assessment that augments, validates, or confirms health care provider findings.
Research	Statistical data relating to the frequency of clinical disorders, complications, use of specific medical and nursing therapies, recovery from illness, and death can be gathered from patient records. Records describe characteristics of patient populations in a health care agency.
Financial billing	The medical record is a document that shows the extent to which hospitals should be reimbursed for services. For the agency to obtain full reimbursement, the record needs to show that all health care providers' orders were completed adequately and correctly, and it must reflect results of those orders.
Auditing and monitoring	A regular review of information in patient records gives a basis for evaluation of the quality and appropriateness of care provided in an agency. The Joint Commission (2012a) requires health care organizations to establish quality assessment and improvement programs to conduct objective, ongoing reviews of patient care. Review of records reveals information about the processes and outcomes of care.
Legal documentation	A medical record must be accurate because it is a legal document. In case of a lawsuit, the medical record, not the nursing care, is on trial. Nursing care may have been excellent; however, care not documented is care not done as far as a court of law is concerned.

PROCEDURAL GUIDELINE 4-3 Adverse Event/Incident Reporting

An incident or adverse event is any event not consistent with the routine operation of a health care unit or routine care of a patient. Examples include patient falls, needlestick injuries, medication errors, or a visitor becoming ill. The [National Quality Forum \(2011\)](#) identified a standardized list of preventable, serious adverse events that facilitate reporting of such events ([Table 4-4](#)). In 2011 the Institute of Medicine examined the safety of Health IT and its impact on patients ([IOM, 2011](#)). Included in this report was a recommendation that IT vendors should have a mandatory obligation to report adverse events, and users should voluntarily report these events. Completion of an occurrence report happens when there is actual or potential patient injury (near miss) that is not part of the patient record. Document in the patient's record an objective description of what you observed and follow-up actions taken without reference to the incident report/occurrence report. Reporting helps to identify high-risk trends in nursing care or daily unit operations that warrant correction. You complete the report even if an injury does not occur or is not apparent. The information from the reports helps nursing staff find solutions to prevent repeated incidents. The reports are an important part of the quality improvement program of a unit.

Adverse event/incident reports are important sources of data for enhancing understanding of underlying causes of events that, when analyzed, can improve patient safety ([ASHRM, 2008](#)).

Delegation and Collaboration

The skill of incident reporting cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report to the nurse any event such as a fall, incorrect treatment, or adverse reaction.
- Report to the nurse any pertinent information about the incident so an incident report can be completed.

Equipment

- Incident report/occurrence report form or screen
- Black pen

Procedural Steps

- 1 Use clinical reasoning skills to systematically and carefully determine what was involved in the incident. Either report the event as witnessed or determine from NAP what specifically occurred. Record the exact sequence of events involved, including time and type of incident; injury to patient, nurse, or other staff; and observation of factors that possibly contributed to the event (e.g., wet floor discovered in area of patient fall). Notify risk management per agency protocol.

Clinical Decision Point *Prepare the report on any questionable event. Do not avoid reporting because you believe that punitive actions will occur if reports are filed.*

- 2 Assess extent of any injury to patient or others, including patient's subjective report and objective physical examination findings.
- 3 If the adverse event involves an injury, take steps to restore individual's safety such as stabilizing patient's position after a fall and assessing for further injuries.
- 4 When patient sustains an injury, call the health care provider immediately.
- 5 When visitor or staff member sustains an injury, refer to emergency department or appropriate treatment setting.
- 6 Complete incident report form.

Clinical Decision Point *Document on report form as quickly as possible. The closer to the event, the more accurate the recording. (NOTE: This also necessitates that staff readily know where incident forms are kept and which forms to use for patients, visitors, and staff.)*

TABLE 4-4 Examples of Serious Reportable Events Occurring Within a Health Care Agency

- Surgery or other invasive procedure performed on the wrong patient
- Patient death or serious injury associated with use of restraints or bedrails
- Patient death or serious injury associated with use or function of a device in patient care in which device is used or functions other than intended
- Patient death or serious injury associated with a fall
- Patient death or serious injury associated with electrical shock
- Unintended retention of foreign object in a patient after surgery or invasive procedure
- Patient death or serious injury associated with elopement
- Patient death or serious injury associated with medication error
- Patient death or serious injury associated with unsafe administration of blood products
- Stage 3 or 4 pressure ulcer acquired after admission to a health care agency

Data from National Quality Forum: *Serious reportable events in health care: a consensus report-2011 update*, Washington, DC, 2011, National Quality Forum.

PROCEDURAL GUIDELINE 4-3 Adverse Event/Incident Reporting—cont'd

- a Record time of incident and describe exactly what occurred or was observed, using objective findings and observations. Use language that does not allow for subjective interpretation. Do not include personal opinions or feelings. Document victim's interpretation of incident by using quotes.
 - b Objectively describe patient's or staff member's condition when incident was discovered or observed.
 - c Describe measures taken by any caregivers at time of incident.
 - d Send completed report to designated department.
- 7 When patient is involved, document events of incident in patient's chart.
 - a Do not duplicate all information from report.
 - b Do not record that report was completed.
 - c Only enter objective description of what happened.
 - d Record any assessment and intervention activities initiated as a result of event.
 - 8 File the report properly with the risk management department or designated persons.

Critical Thinking Exercises

You and the nursing assistive personnel (NAP) are caring for a 55-year-old woman with type 2 diabetes who is scheduled for an appendectomy that evening. Elements of her care include monitoring vital signs every 2 hours, pain assessment, preoperative preparation, and glucose monitoring every 4 hours.

- 1 Noting the four elements of care listed, list the elements for which documentation may be delegated to NAP.
- 2 As you correctly noted, documentation of preoperative preparation cannot be delegated. Because the NAP will be providing other aspects of care, which information do you need to include in a report to the NAP about pain assessment, glucose monitoring, and preoperative preparation?
- 3 When you assess a patient's pain, it is important that you record your findings. Select the method of recording used in your agency and do a sample recording of the pain assessment.
- 4 The NAP reports to you that a patient's vital signs are 90/50, pulse 110, respirations 24. The patient states that he "feels dizzy and sweaty" after walking. Using the SBAR technique, how would you communicate this information to the physician or health care provider?
- 5 You have just completed preoperative teaching for a patient who is having surgery tomorrow for a total hip replacement. How would you document a patient's understanding of the information in a narrative note?

REVIEW QUESTIONS

- 1 When documenting information in a narrative note, the nurse should: (Select all that apply.)
 - 1 Document data immediately after care or treatment.
 - 2 Record information provided by another nurse.
 - 3 Begin each new entry with the date and time.
 - 4 Draw a single line through an error entry.
- 2 Military time is frequently used to document care. If oral hygiene was performed at 4:00 PM, what time would it be if documented according to military time?
 - 1 0400
 - 2 1400
 - 3 1600
 - 4 2400
- 3 There are multiple types of narrative charting. Which components would be found in focus charting?
 - 1 Data-Action-Response
 - 2 Problem-Intervention-Evaluation
 - 3 Subjective-Objective-Assessment-Plan
 - 4 Subjective-Evaluation-Assessment-Plan-Implementation-Evaluation
- 4 There are four purposes for charting by exception. Which statement best explains one of these purposes?
 - 1 To identify a change in a patient's condition
 - 2 To identify a change in a patient's medical orders
 - 3 To identify trends in clinical care
 - 4 To identify trends in resource utilization
- 5 Change-of-shift report or hand-off is an important component of care. Which standardized form of communication is used for exchanging patient information during handoff?
 - 1 SOAP documentation
 - 2 PIE Documentation
 - 3 SBAR documentation
 - 4 Focus charting
- 6 A patient with a complex medical condition and an unusual family situation has just been admitted to the nursing unit. What type of documentation is most appropriate for documenting this critical situation?
 - 1 SBAR documentation
 - 2 Charting by exception
 - 3 Focus charting
 - 4 PIE documentation

- 7 The nurse is documenting the care delivered to his patients. The best documentation would contain which of the following characteristics?
- 1 The majority of the documentation provides subjective data.
 - 2 The nurse's hunches are included in case a sudden change occurs in the patient's condition.
 - 3 The documentation contains only objective data.
 - 4 The documentation reflects individualized care based on assessment data.
- 8 During report the nurse refers to a critical pathway and notes that a positive variance has occurred with one of the patients. Which information provided by the nurse would support this statement?
- 1 A Foley catheter needed to be inserted because the patient couldn't void.
 - 2 A patient's fever dropped dramatically and sooner than expected.
 - 3 A patient had to be taken back to surgery.
 - 4 A patient's family has been visiting frequently.
- 9 Unexpected events occur in the health care arena. When would an incident report need to be completed?
- 1 When less than standard patient care has been provided
 - 2 To document an injury to a patient or visitor
 - 3 To identify potential risks in new treatments
 - 4 To identify when an adverse situation almost occurred in care
- 10 After receiving a narcotic for pain, the patient's respirations drop to a dangerous but stable level. Which documentation statement regarding the situation is best?
- 1 "Too much morphine was given; being monitored frequently and is stable; family at bedside and has been told of situation."
 - 2 "Incident report filed after patient received too much pain medication and had decreased respirations; is resting quietly; doctor notified."
 - 3 "Dilaudid 1 mg IV. RR8, BP 100/68, P 70 afterward; being monitored q15 min—see graphic for VS; MD notified."
 - 4 "Sleeping deeply and snoring after receiving narcotic IV; VS stable; nail beds pink, oxygen ready if needed; supervisor notified."

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify when it is appropriate to assess each vital sign.
- Accurately assess a patient's oral, rectal, axillary, tympanic membrane, and temporal artery temperatures.
- Correctly record vital signs.
- Describe factors that cause variations in body temperature, pulse, respirations, blood pressure, and oxygen saturation.
- Discuss factors in selecting temperature measurement sites.
- Accurately assess a patient's radial and apical pulses.
- Explain implications of a pulse deficit.
- Accurately assess a patient's respirations.
- Accurately measure a patient's blood pressure using techniques of auscultation and palpation.
- Discuss benefits and disadvantages of using an automatic blood pressure machine.
- Describe factors in selecting an extremity to measure blood pressure.
- Accurately assess a patient's oxygenation status using pulse oximetry.
- Identify ranges of acceptable vital sign values for infant, child, and adult.
- Appropriately delegate vital sign measurements to nursing assistive personnel.

Temperature, pulse, blood pressure, respirations and oxygen saturation are the most frequent measurements obtained by health care practitioners. These measurements indicate if the circulatory, pulmonary, neurological, and endocrine body systems are functioning normally. Because of their importance as indicators of the body's physiological status and response to physical, environmental, and psychological stressors, they are referred to as vital signs. Vital signs reveal sudden changes in a patient's condition, as well as changes that occur progressively over time. Any difference between a patient's normal baseline measurement and present vital signs may indicate the need for nursing therapies and necessary medical interventions.

Pain, a subjective symptom, is often referred to as a vital sign along with the other physiologic signs. Frequently pain is the symptom that leads patients to seek health care. For this reason assessment of a patient's pain status is critical to understanding his or her clinical status and progress. You will frequently perform assessment of a patient's level of comfort and pain with vital sign measurements (see Chapter 15).

Vital signs are included in a routine physical assessment (see Chapter 6). The nurse's findings aid in determining whether it is necessary to assess specific body systems more thoroughly. For example, during a routine vital sign measurement, the nurse notes an abnormal respiratory rate; he or she then auscultates lung sounds. Measurement of a single vital sign assesses a specific aspect of a patient's condition. For example, following administration of an antipyretic medication, a nurse measures the patient's temperature to evaluate the effects of a drug. Part of your clinical judgment involves deciding which vital sign to measure, when to obtain measurements, and the frequency of assessment (Box 5-1). Always obtain a baseline measurement of vital signs on first contact with a patient to provide a means for comparison with later vital sign measurements.

EVIDENCE-BASED PRACTICE

Automatic blood pressure machines are common in many agencies when frequent blood pressure assessment is necessary. When results of machines are compared to manual blood pressures obtained using a stethoscope and sphygmomanometer, the results are not

BOX 5-1 When to Take Vital Signs

- 1 On admission to a health care agency
- 2 In a hospital or care facility on a routine schedule according to a health care provider's order or standards of practice of agency
- 3 When assessing patient during home care visits
- 4 Before, during, and after a surgical or invasive diagnostic procedure
- 5 Before, during, and after the administration of medications or application of therapies that affect cardiovascular, respiratory, or temperature-control functions
- 6 Before, during, and after a transfusion of any type of blood products
- 7 Before, during, and after nursing interventions influencing a vital sign (e.g., before and after patient previously on bed rest ambulates, before and after patient performs range-of-motion exercises)
- 8 When patient reports specific symptoms of physical distress (e.g., feeling "funny" or "different")
- 9 When patient's general physical condition changes (e.g., loss of consciousness, increased intensity of pain)

the same (Heinemann et al., 2008). Both systolic and diastolic blood pressures are lower when measured electronically. The greatest difference occurs with diastolic values (Skirton et al., 2011).

It is important to limit use of automated blood pressure monitors to those that are independently validated and biannually calibrated. Calibrate blood pressure manometers (aneroid and automatic) twice each year against a mercury manometer and/or return to manufacturer for calibration and repair (Nelson et al., 2008). These units are quick and easy to use and provide a large digital display that gives a distinct reading.

- Use auscultatory devices to obtain blood pressure when a patient has cardiac dysrhythmias or unstable or low blood pressure (Skirton et al., 2011).
- Use electronic machines for screening blood pressures in normotensive patients.
- Use auscultatory devices to verify abnormal blood pressure measurements obtained with electronic machines, to manage hypertension, or following traumatic events (Skirton et al., 2011).

PATIENT-CENTERED CARE

Vital sign measurements require removing clothing or exposing areas considered inappropriate or offensive to patients from other cultures. You must be sensitive to each patient's need for privacy and observe cultural norms. When reporting findings, patients from cultures with paternalistic values rely on a male elder to receive information on their behalf.

- Provide privacy when performing apical pulse assessment, especially for traditional female patients and elders from Asian, Middle Eastern, Hispanic, and African cultures (Giger, 2013).
- Procedures that are normally noninvasive sometimes produce anxiety because of cultural variables of touch, privacy, and gender.
- Consult the health care provider and family decision maker regarding giving information to the patient about abnormal vital signs.
- Collectivistic cultures (e.g., Hispanics, Africans, and Asians) demonstrate their caring for ill members by protecting them from bad news about their health and well-being (Giger, 2013).

Safety Guidelines

- 1 A nurse caring for a patient is responsible for measuring vital signs. Nurses analyze vital signs to interpret their significance and make decisions about appropriate interventions.
- 2 Equipment must be clean, functional, properly calibrated, and appropriate for the patient's size, age, condition, and characteristics.
- 3 A nurse knows a patient's usual range of vital signs. His or her usual values may differ from the acceptable range for that age or physical state. They serve as a baseline for comparison with later findings; thus you detect changes in condition over time.
- 4 A nurse knows a patient's medical history, therapies, and prescribed medications. Some illnesses or treatments cause predictable vital sign changes. Most medications affect at least one of the vital signs.
- 5 Control or minimize environmental factors that affect vital signs. For example, assessing the patient's temperature in a warm, humid room may yield a value that is not a true indicator of the patient's condition.

- 6 Use an organized, systematic (step-by-step) approach when taking vital signs ensures accuracy of findings.
- 7 Based on the patient's condition, collaborate with the health care provider to decide the minimum frequency of vital sign assessment for each patient. Following surgery or treatment intervention, measure vital signs more frequently to detect complications. In a clinic or outpatient setting take vital signs before the health care provider examines the patient and after any invasive procedures. As a patient's physical condition worsens, it is important to monitor the vital signs as often as every 5 to 15 minutes. You are responsible for judging whether more frequent assessments are necessary.
- 8 Analyze the results of vital sign measurements and incorporate all the clinical findings about a patient in determining nursing diagnoses. Do not interpret vital signs in isolation. You need to know related physical signs or symptoms and be aware of the patient's ongoing health status.
- 9 Verify, communicate, and document significant changes in vital signs. Baseline measurements allow a nurse to identify changes in vital signs. When vital signs appear abnormal, it helps to have another nurse repeat the measurement. Inform the health care provider when vital signs become abnormal and report any changes to the nurse in charge.

SKILL 5-1 Measuring Body Temperature

NSO Vital Signs Module / Lessons 1 and 2

Body temperature is the difference between the amount of heat produced by body processes and the amount of heat lost to the external environment. The core temperature, or temperature of the deep body tissues, is under control of the hypothalamus and remains within a narrow range. Skin or body surface temperature rises and falls as the temperature of the surrounding environment changes, and it fluctuates dramatically.

The body tissues and cells function best within a relatively narrow temperature range, from 36° to 38° C (96.8° F to 100.4° F), but no single temperature is normal for all people. For healthy young adults the average oral temperature is 37° C (98.6° F). In clinical practice nurses learn the temperature range of individual patients. An acceptable temperature range for adults depends on age, gender, range of physical activity, hydration status, and state of health (Fig. 5-1).

Many factors affect body temperature, but physiologic and behavioral control mechanisms act to maintain a constant core

temperature. For example, the mechanism of peripheral vasodilation increases blood flow to the skin, which increases the amount of heat radiated to the environment. Control mechanisms have failed when heat produced by the body is not equal to heat lost to the environment. For example, patients without sweat gland function are unable to tolerate warm temperatures because they cannot adequately cool themselves. Fever occurs when heat loss mechanisms are unable to keep pace with excess heat production, resulting in an abnormal rise in body temperature. When an individual has a febrile condition (i.e., pyrexia), initiate temperature-control measures such as controlling environmental temperatures, removing external coverings, and administering ordered antipyretics to achieve better temperature control.

The purpose of measuring body temperature is to obtain a representative average temperature of core body tissues. Average usual temperature varies, depending on the measurement site used. Research findings from numerous studies are contradictory; however, it is generally accepted that rectal temperatures are usually 0.5° C (0.9° F) higher than oral temperatures. Axillary and tympanic temperatures are usually 0.5° C (0.9° F) lower than oral temperatures. Sites reflecting core temperature are more reliable indicators of body temperature than sites reflecting surface temperatures (Mazerolle et al., 2011) (Box 5-2).

To ensure accurate temperature readings you need to measure each site correctly. Use the same site when repeated measurements are necessary or when comparing temperature measurements over time. Each site has advantages and disadvantages (Box 5-3). You need to determine the safest and most accurate site for the patient.

Several types of thermometers are commonly available to measure body temperature (Box 5-4). The mercury-in-glass thermometer, once the standard device found in the clinical setting, is now prohibited because of the potential mercury hazards. However,

FIG 5-1 Ranges of normal temperature values and physiologic consequences of abnormal body temperature. (Modified from Thibodeau GA, Patton KT: Anatomy and physiology, ed 7, St Louis, 2010, Mosby.)

BOX 5-2 Core and Surface Temperature Measurement Sites

Core Site	Surface Site
<ul style="list-style-type: none"> • Rectum • Tympanic membrane • Temporal artery • Esophagus • Pulmonary artery • Urinary bladder 	<ul style="list-style-type: none"> • Skin • Oral cavity • Axilla

BOX 5-3 Advantages and Limitations of Select Temperature Measurement Sites**Oral****Advantages**

- Easily accessible—requires no position change
- Comfortable for patient
- Provides accurate surface temperature reading
- Reflects rapid change in core temperature
- Reliable route to measure temperature for intubated patients

Limitations

- Causes delay in measurement if patient recently ingested hot/cold fluids or foods, chewed gum, or smoked
- Not used with patients who have had oral surgery or facial trauma or are unable to position in mouth, shaking chills, or history of seizures
- Not used with infants; small children; or confused, unconscious, or uncooperative patients
- Risk for body fluid exposure

Tympanic Membrane**Advantages**

- Easily accessible site
- Obtained without disturbing, waking, or repositioning patient
- Used for patients with tachypnea without affecting breathing
- Provides accurate core reading because eardrum is close to hypothalamus; sensitive to core temperature changes
- Very rapid measurement (2 to 5 seconds)
- Unaffected by oral intake of food or fluids or smoking
- Used in newborns to reduce infant handling and heat loss

Limitations

- More variability of measurement than with other core temperature devices
- Requires removal of hearing aids before measurement
- Requires disposable sensor cover with only one size available
- Readings possibly distorted with otitis media and cerumen impaction
- Not used with patients who have had surgery of the ear or tympanic membrane
- Does not accurately measure core temperature changes during and after exercise
- Affected by ambient temperature devices such as incubators, radiant warmers, and facial fans
- Anatomy of ear canal makes it difficult to correctly position in neonates, infants, and children younger than 3 years of age
- Inaccuracies reported because of incorrect positioning of handheld unit

Rectal**Advantages**

- Argued to be reliable when oral temperature cannot be obtained

Limitations

- Lags behind core temperature during rapid temperature changes
- Not used for patients with diarrhea or those who have had rectal surgery, rectal disorders, bleeding tendencies, or neutropenia

- Requires positioning and is often source of patient embarrassment and anxiety
- Risk for body fluid exposure
- Requires lubrication
- Not used for routine vital signs in newborns
- Readings influenced by impacted stool

Axilla**Advantages**

- Safe and inexpensive
- Used with newborns and unconscious patients

Limitations

- Long measurement time
- Requires continuous positioning
- Measurement lags behind core temperature during rapid temperature changes
- Not recommended for detecting fever in infants and young children
- Requires exposure of thorax, which can result in temperature loss, especially in newborns
- Affected by exposure to the environment, including time it takes to place thermometer
- Underestimates core temperature

Skin**Advantages**

- Inexpensive
- Provides continuous reading
- Safe and noninvasive
- Used for neonates

Limitations

- Measurement lags behind other sites during temperature changes, especially during hyperthermia
- Impaired adhesion from diaphoresis or sweat
- Affected by environmental temperature
- Cannot be used for patients with allergy to adhesive

Temporal Artery**Advantages**

- Easy to access without position change
- Very rapid measurement
- Comfortable with no risk of injury to patient or nurse
- Eliminates need to disrobe or unbundle
- Can be used for premature infants, newborns, and children
- Reflects rapid change in core temperature
- Sensor cover not required

Limitations

- Inaccurate with head covering or hair on forehead
- Affected by skin moisture such as diaphoresis or sweating

mercury-in-glass thermometers are sometimes found in patients' homes.

Delegation and Collaboration

The skill of temperature measurement can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP by:

- Communicating the appropriate route, device, and frequency of temperature measurement.
- Explaining any precautions needed in positioning the patient for rectal temperature measurement.
- Reviewing the usual temperature values and significant changes to report to the nurse.

BOX 5-4 Types of Thermometers

Electronic Thermometer (Fig. 5-2)

- Thermometer is a rechargeable battery-powered display unit with a thin wire cord and a temperature-processing probe covered by a disposable cover.
- Within 1 minute after placement, the thermometer displays a digital temperature reading.
- Separate probes are available for oral and axillary temperature measurement (blue tip) and rectal temperature measurement (red tip).

Tympanic Thermometer

- The probe consists of an otoscope-like speculum with an infrared sensor tip that detects heat radiated from the tympanic membrane of the ear (Fig. 5-3).
- Within seconds after placing in the ear canal and depressing the scan button, a digital reading appears on the display unit. A sound signals when the peak temperature has been measured.

Temporal Artery Thermometer

- An infrared scanner is swept across the forehead. If the patient is diaphoretic, also scan just behind the ear (Fig. 5-4).
- Within seconds after scanning, a digital reading appears on the display unit.

Chemical Dot Single-Use or Reusable Thermometer

- Thermometer consists of thin strips of plastic with a temperature sensor at one end and chemically impregnated dots formulated to change color at different temperatures (Fig. 5-5).
- Chemical dots on the thermometer change color to reflect temperature reading, usually within 60 seconds.
- It is useful for screening temperatures, especially in infants, during invasive procedures, for a patient on protective isolation, and in orally intubated critical care clients.
- It is not appropriate for monitoring fever in acutely ill clients or monitoring temperature therapies.
- It can be used at axillary or rectal site if covered by a plastic sheath with a placement time of 3 minutes.

FIG 5-2 Electronic thermometer with disposable plastic probe cover. (Photo courtesy Welch Allyn.)

FIG 5-4 A temporal artery thermometer measures the heat from blood flowing through the superficial temporal artery. (Photo courtesy Exergen.)

FIG 5-3 Tympanic membrane thermometer with disposable plastic probe cover. (Copyright © Covidien. All rights reserved.)

FIG 5-5 Chemical dot, disposable, single-use thermometer.

Equipment

- Thermometer (selected based on site used; see Box 5-3)
- Soft tissue or wipe
- Alcohol swab
- Water-soluble lubricant (for rectal measurements only)

- Pen and vital sign flow sheet, record form, or electronic health record (EHR)
- Clean gloves (optional), plastic thermometer sleeve, disposable probe or sensor cover
- Towel

STEP

RATIONALE

ASSESSMENT

<p>1 Determine need to measure patient's body temperature:</p> <p>a Note patient's risks for temperature alterations:</p> <ul style="list-style-type: none"> • Expected or diagnosed infection • Open wounds or burns • White blood cell count below 5000/mm³ or above 12,000/mm³ • Immunosuppressive drug therapy • Injury to hypothalamus • Exposure to temperature extremes • Blood product infusion • Hypothermia or hyperthermia therapy • Postoperative status <p>b Assess for signs and symptoms that accompany temperature alteration:</p> <ul style="list-style-type: none"> • <i>Hyperthermia</i>: Decreased skin turgor, dry mucous membranes; tachycardia; hypotension; decreased venous filling; concentrated urine • <i>Heatstroke</i>: Hot, dry skin; tachycardia; hypotension; excessive thirst; muscle cramps; visual disturbances; confusion or delirium • <i>Hypothermia</i>: Pale skin; skin cool or cold to touch; bradycardia and dysrhythmias; uncontrollable shivering; reduced level of consciousness; shallow respirations <p>c Assess for factors that normally influence temperature:</p> <ul style="list-style-type: none"> • Age 	<p>Certain conditions place patients at risk for temperature alterations and require more frequent temperature measurement and nursing assessment.</p> <p>Physical signs and symptoms alert you to alterations in body temperature.</p> <p>Allows nurse to accurately assess for presence and significance of temperature alteration.</p> <p>Older adults have a narrower range of temperature than younger adults.</p>
<p>Clinical Decision Point <i>No single temperature is normal for all people. A temperature within an acceptable range in an adult may reflect a fever in an older adult. Undeveloped temperature-control mechanisms in infants and children cause temperature to rise and fall rapidly (Davie and Amoore, 2010).</i></p>	
<ul style="list-style-type: none"> • Exercise • Hormones • Stress • Environmental temperature • Medications • Daily fluctuations <p>2 Determine appropriate measurement site and device for patient (see Box 5-3). Use disposable thermometer for patient on isolation precautions.</p> <p>3 Determine previous baseline temperature and measurement site (if available) from patient's record.</p> <p>4 Assess patient's knowledge of procedure.</p>	<p>Muscle activity increases metabolism, which increases heat production and raises temperature (Davie and Amoore, 2010). Women have wider temperature fluctuations than men because of menstrual cycle hormonal changes, because body temperature varies during menopause, and because women have thicker layer of subcutaneous fat (Davie and Amoore, 2010).</p> <p>Stress elevates temperature.</p> <p>Infants and older adults are more sensitive to environmental temperature changes.</p> <p>Some drugs impair or promote sweating, vasoconstriction, or vasodilation or interfere with ability of hypothalamus to regulate temperature.</p> <p>Body temperature normally changes 0.5° to 1° C (0.9° to 1.8° F) during a 24-hour period. Temperature is lowest during early morning. Most patients have maximum temperature elevation between 5 PM and 7 PM; temperature falls gradually during night.</p> <p>Determines if patient's status contraindicates selection of a specific method or site.</p> <p>Allows nurse to assess for change in condition. Provides comparison with future temperature measurements.</p> <p>Encourages cooperation; minimizes risks and anxiety. Identifies teaching needs.</p>

STEP

RATIONALE

NURSING DIAGNOSES

- | | | |
|---|--|--|
| <ul style="list-style-type: none"> • Hyperthermia • Hypothermia | <ul style="list-style-type: none"> • Ineffective thermoregulation | <ul style="list-style-type: none"> • Risk for imbalanced body temperature |
|---|--|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Body temperature is within acceptable range for patient's age-group. • Body temperature returns to baseline range following therapies for abnormal temperature. <p>2 Explain to patient the way you will measure temperature and importance of maintaining proper position until reading is complete.</p> <p>3 Collect and bring appropriate supplies to the patient's bedside.</p> <p>4 Verify that patient has not had anything to eat or drink and not has chewed gum or smoked within the past 15 minutes of having oral temperature measured (Davie and Amooore, 2010).</p> | <p>Thermoregulation is maintained.</p> <p>Environmental factors that alter temperature are controlled.</p> <p>Promotes patient cooperation and increases compliance. Patients are often curious about their temperatures and should be cautioned against prematurely removing thermometer to read results.</p> <p>Ensures an organized approach for body temperature measurement</p> <p>Oral food and fluids, smoking, and gum can alter temperature measurement.</p> |
|---|---|

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Perform hand hygiene.</p> <p>2 Assist patient to comfortable position that provides easy access to temperature measurement site.</p> <p>3 Obtain temperature reading.</p> <p>a Assess oral temperature (electronic):</p> <p>(1) <i>Optional:</i> Apply clean gloves when there are respiratory secretions or facial or mouth wound drainage.</p> <p>(2) Remove thermometer pack from charging unit. Attach oral thermometer probe stem (blue tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure on ejection button.</p> <p>(3) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place (see illustration).</p> | <p>Reduces transmission of microorganisms.</p> <p>Ensures patient's comfort and accuracy of temperature reading.</p> <p>An oral probe cover is removable without physical contact.</p> <p>Charging provides battery power. Ejection button releases plastic cover from probe stem.</p> <p>Soft plastic cover will not break in patient's mouth and prevents transmission of microorganisms between patients.</p> |
|---|--|

STEP 3a(3) Nurse inserts electronic thermometer probe stem into probe cover. Cover snaps in place.

STEP

RATIONALE

- (4) Ask patient to open mouth; gently place thermometer probe under tongue in posterior sublingual pocket lateral to center of lower jaw (see illustration).

Heat from superficial blood vessels in sublingual pocket produces temperature reading. With electronic thermometer temperatures in right and left posterior sublingual pocket are significantly higher than in area under front of tongue.

STEP 3a(4) Probe under tongue in posterior sublingual pocket.

- (5) Ask patient to hold thermometer probe with lips closed.
 (6) Leave thermometer probe in place until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from under patient's tongue.
 (7) Push ejection button on thermometer probe stem to discard plastic probe cover into appropriate receptacle.
 (8) If wearing gloves, remove and dispose in appropriate receptacle and perform hand hygiene.
 (9) Return thermometer probe stem to storage position of thermometer unit.

Maintains proper position of thermometer during recording.
 Probe must stay in place until signal occurs to ensure accurate reading.

Reduces transmission of microorganisms.

Reduces transmission of microorganisms.

Protects probe stem from damage. Returning thermometer probe stem automatically causes digital reading to disappear.

b Assess rectal temperature (electronic):

- (1) Draw curtain around bed and/or close room door. Assist patient to side-lying or Sims' position with upper leg flexed. Move aside bed linen to expose only anal area. Keep patient's upper body and lower extremities covered with sheet or blanket.
 (2) Perform hand hygiene and apply clean gloves. Cleanse anal region when feces and/or secretions are present. Remove soiled gloves and reapply clean gloves.
 (3) Remove thermometer pack from charging unit. Attach rectal thermometer probe stem (red tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure on ejection button.
 (4) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place.
 (5) Using a single use package, squeeze a liberal amount of lubricant on tissue. Dip probe cover of thermometer, blunt end, into lubricant, covering 2.5 to 3.5 cm (1 to 1½ inches) for adult.
 (6) With nondominant hand separate patient's buttocks to expose anus. Ask patient to breathe slowly and relax.
 (7) Gently insert thermometer into anus in direction of umbilicus 3.5 cm (1½ inches) for adult. Do not force thermometer.
 (8) If you feel resistance during insertion, withdraw immediately. Never force thermometer.

Maintains patient's privacy, minimizes embarrassment, and promotes comfort.

Maintains standard precautions when exposed to items soiled with body fluids (e.g., feces).

Ejection button releases plastic cover from probe stem.

Soft plastic probe cover prevents transmission of microorganisms between patients.

Lubrication minimizes trauma to rectal mucosa during insertion. Tissue avoids contamination of remaining lubricant in container.

Fully exposes anus for thermometer insertion. Relaxes anal sphincter for easier thermometer insertion.

Ensures adequate exposure against blood vessels in rectal wall.

Prevents trauma to mucosa.

STEP

RATIONALE

Clinical Decision Point *If you cannot adequately insert thermometer into rectum or resistance is felt during insertion, remove thermometer and consider alternative method for obtaining temperature.*

- | | |
|--|---|
| <p>(9) Once positioned, hold thermometer probe in place until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from anus (see illustration).</p> | <p>Probe must stay in place until signal occurs to ensure accurate reading.</p> |
|--|---|

STEP 3b(9) Probe inserted into anus.

- | | |
|---|--|
| <p>(10) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle. Wipe probe stem with alcohol swab, paying particular attention to ridges where probe stem connects to probe.</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>(11) Return thermometer stem to storage position of recording unit.</p> | <p>Protects probe stem from damage. Returning thermometer stem automatically causes digital reading to disappear.</p> |
| <p>(12) Wipe patient's anal area with soft tissue to remove lubricant or feces and discard tissue. Assist patient in assuming a comfortable position.</p> | <p>Provides for comfort and hygiene.</p> |
| <p>(13) Remove and dispose of gloves in appropriate receptacle. Perform hand hygiene.</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>c Assess axillary temperature (electronic):</p> | |
| <p>(1) Draw curtain around bed and/or close room door. Assist patient to supine or sitting position. Move clothing or gown away from shoulder and arm.</p> | <p>Maintains patient's privacy, minimizes embarrassment, and promotes comfort. Exposes axilla for correct thermometer probe placement.</p> |
| <p>(2) Remove thermometer pack from charging unit. Attach oral thermometer probe stem (blue tip) to thermometer unit. Grasp top of thermometer probe stem, being careful not to apply pressure on ejection button.</p> | <p>Charging provides battery power. Ejection button releases plastic cover from probe stem.</p> |
| <p>(3) Slide disposable plastic probe cover over thermometer stem until cover locks in place.</p> | <p>Soft plastic probe cover prevents transmission of microorganisms between patients.</p> |

STEP

RATIONALE

- (4) Raise patient's arm away from torso. Inspect for skin lesions and excessive perspiration; if needed, dry axilla. Insert thermometer probe into center of axilla (see illustration), lower arm over probe, and place arm across patient's chest.

Maintains proper position of thermometer against blood vessels in axilla.

STEP 3c(4) Place thermometer probe in axilla.

Clinical Decision Point Do not use axilla if skin lesions are present because local temperature is sometimes altered and area may be painful to touch.

- (5) Once thermometer probe is positioned, hold it in place until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from axilla.
- (6) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle.
- (7) Return thermometer stem to storage position of recording unit.
- (8) Assist patient in assuming comfortable position, replacing linen or gown.
- (9) Perform hand hygiene.

Thermometer probe must stay in place until signal occurs to ensure accurate reading.

Reduces transmission of microorganisms.

Returning thermometer stem to storage position automatically causes digital reading to disappear. Protects stem from damage. Restores comfort and sense of well-being.

Reduces transmission of microorganisms.

d Assess tympanic membrane temperature:

- (1) Assist patient in assuming comfortable position with head turned toward side, away from you. If patient has been lying on one side, use upper ear. Obtain temperature from patient's right ear if you are right-handed. Obtain temperature from patient's left ear if you are left-handed.
- (2) Note if there is an obvious presence of cerumen (earwax) in patient's ear canal.
- (3) Remove thermometer handheld unit from charging base, being careful not to apply pressure to ejection button.
- (4) Slide disposable speculum cover over the otoscope-like lens tip until it locks in place. Be careful not to touch lens cover.
- (5) Insert speculum into ear canal following manufacturer instructions for tympanic probe positioning:

Ensures comfort and facilitates exposure of auditory canal for accurate temperature measurement.

Heat trapped in ear facing down causes false-high temperature reading

The less acute the angle of approach, the better the probe seal.

Cerumen impedes the lens cover of speculum. Switch to other ear or select alternative measurement site.

Charging base provides battery power. Removal of handheld unit from base prepares it to measure temperature. Ejection button releases plastic probe cover from thermometer tip.

Soft plastic probe cover prevents transmission of microorganisms between patients. Lens cover should not have dust, fingerprints, or cerumen obstructing optical pathway.

Correct positioning of probe with respect to ear canal allows maximal exposure of tympanic membrane.

STEP

RATIONALE

- (a) Pull ear pinna backward, up, and out for an adult (see illustration). For children less than 3 years of age, pull pinna down and back, point covered probe toward midpoint between eyebrow and sideburns. For children older than 3 years, pull pinna up and back (Hockenberry and Wilson, 2011).

The ear tug straightens the external auditory canal, allowing maximum exposure of tympanic membrane and therefore correctly positioning speculum.

STEP 3d(5)(a) Tympanic membrane thermometer with probe cover placed in patient's ear.

- (b) Move thermometer in a figure-eight pattern.
- (c) Fit speculum tip snug in canal, pointing toward the nose.
- (6) Once positioned, press scan button on handheld unit. Leave speculum in place until audible signal indicates completion and patient's temperature appears on digital display.
- (7) Carefully remove speculum from auditory meatus. Push ejection button on handheld unit to discard speculum cover into appropriate receptacle.
- (8) If temperature is abnormal or second reading is necessary, replace probe cover and wait 2 minutes before repeating in same ear or repeat measurement in other ear. Consider an alternative temperature site or instrument.
- (9) Return handheld unit to thermometer base.
- (10) Help patient assume a comfortable position.
- (11) Perform hand hygiene.

Some manufacturers recommend movement of speculum tip in a figure-eight pattern that allows sensor to detect maximum tympanic membrane heat radiation.

Gentle pressure seals ear canal from ambient air temperature, which alters readings as much as 2.8° C (5° F).

Pressing scan button causes detection of infrared energy. The speculum tip must stay in place until signal occurs to ensure accurate reading.

Reduces transmission of microorganisms. Automatically causes digital reading to disappear.

Lens cover must be free of cerumen to maintain optical path. Time allows ear canal to regain usual temperature.

Protects sensor tip from damage.

Restores comfort and sense of well-being.

Reduces transmission of microorganisms.

e Assess temporal artery temperature:

- (1) Ensure that forehead is dry; dry with a towel if needed.
 - (2) Place sensor firmly on patient's forehead.
 - (3) Press red scan button with your thumb. Slowly slide thermometer straight across forehead while keeping sensor flat and firmly on skin (see Fig. 5-4).
 - (4) If patient is diaphoretic, keeping scan button depressed, lift sensor after sweeping forehead and touch sensor on neck just behind the earlobe. Peak temperature occurs when clicking sound during scanning stops. Release scan button.
 - (5) Gently clean sensor with alcohol swab and perform hand hygiene.
- 4** Inform patient of temperature reading and record measurement.
- 5** Return thermometer to charger.

Moisture interferes with thermometer sensor.

Flush contact avoids measurement of ambient temperature.

Thermometer continuously scans for highest temperature when scan button is depressed.

Sensor is cooled by diaphoresis, resulting in an inaccurate temperature. Area behind earlobe is less affected by diaphoresis.

Prevents transmission of microorganisms.

Promotes participation in care and understanding of health status.

Maintains battery charge of thermometer unit.

STEP

RATIONALE

EVALUATION

- 1 If you are assessing temperature for the first time, establish it as baseline if it is within acceptable range.
- 2 Compare temperature reading with patient's previous baseline and acceptable temperature range for patient's age-group.
- 3 If patient has fever, take temperature approximately 30 minutes after administering antipyretics and every 4 hours until temperature stabilizes.

Unexpected Outcomes

- 1 Patient has temperature 1° C (1.8° F) or more above usual range.
- 2 Patient has temperature 1° C (1.8° F) or more below usual range.
- 3 Unable to obtain temperature.

Recording and Reporting

- Record temperature and route on vital sign flow sheet, nurses' notes, or electronic health record (EHR).
- Report abnormal findings to nurse in charge or health care provider.

Special Considerations

Teaching

- Identify patient's ability to initiate preventive health measures and recognize alteration in body temperature. Educate patients and family members about measures to prevent body temperature alterations.
- Educate patients about risk factors for hypothermia and frostbite: fatigue; malnutrition; hypoxemia; cold, wet clothing; alcohol intoxication.
- Educate patients about risk factors for heatstroke: strenuous exercise in hot, humid weather; tight-fitting clothing in hot environments; exercising in poorly ventilated areas; sudden exposures to hot climates; poor fluid intake before, during, and after exercise.
- Educate patients regarding importance of taking and continuing antibiotics as directed until course of treatment for infection is completed.

Used to compare future temperature measurements.

Body temperature fluctuates within narrow range; comparison reveals presence of abnormality. Improper placement or movement of thermometer can cause inaccuracies. Second measurement confirms initial findings of abnormal body temperature.

Determines if temperature begins to fall in response to therapy.

Related Interventions

- Initiate measures to lower body temperature:
 - Cool room environment (Thompson and Kagan, 2010).
 - Reduce external covering on patient's body to promote heat loss but do not induce shivering (Thompson and Kagan, 2010).
 - Keep clothing and bed linen dry.
 - Apply hypothermia blanket as ordered (see Chapter 40).
 - Limit physical activity and sources of emotional stress.
 - Administer antipyretics as ordered.
 - Increase fluid intake to at least 3 L daily (unless contraindicated).
 - Initiate measures to stimulate appetite and provide nutrients to meet increased energy needs.
 - Prevent or control spread of infection.
 - Provide wound care (see Chapter 38).
 - Perform pulmonary hygiene (see Chapter 24).
 - Promote adequate urinary elimination (see Chapter 33).
- Initiate measures to raise body temperature:
 - Apply warm blankets and, unless contraindicated, offer warm liquids.
 - Apply hyperthermia blankets if ordered (see Chapter 40).
 - Remove wet clothing or linen.
- Reassess correct placement of temperature probe or sensor.
- Choose alternative temperature measurement site.
- Obtain alternative temperature measurement device.

Pediatric

- Infants and young children may lose more heat to the environment because of their increased body surface area/volume ratios.
- Critically ill children sometimes have cool skin but a high core temperature because of poor perfusion to the skin.
- Use axillary temperatures for screening purposes only; axillary temperature cannot be relied on to detect fever in infants and young children (Lim et al., 2008).
- Children may assume prone position for rectal temperature measurement.
- With children who cry or become restless, it is best to take temperature as the last vital sign.

Gerontologic

- The temperature of older adults is at the lower end of the acceptable temperature range: 36° C (96.8° F).
- Temperatures considered within normal range often reflect a fever in an older adult.
- Adults without teeth or older adults with poor muscle control may be unable to close their mouth tightly enough to obtain accurate oral temperature readings.
- Older adults are very sensitive to environmental temperature changes because their thermoregulatory systems are not as efficient (Ebersole et al., 2008).

- Oral temperature measurement is more reliable in older adults because cerumen tends to be drier and cilia become stiff, contributing to buildup of cerumen impaction, which interferes with accurate tympanic temperature measurement (Lu et al., 2009).
- A decrease in sweat gland reactivity in the older adult results in a higher threshold for sweating at high temperatures, which can lead to hyperthermia.
- With aging a loss of subcutaneous fat reduces the insulating capacity of the skin.
- Older adults are at high risk for hypothermia because of diminished sensation to cold, abnormal vasoconstrictor responses, and impaired shivering.

Home Care

- Assess temperature and ventilation of patient's environment to determine existence of any environmental conditions that influence patient's temperature.
- In the home some patients continue to use mercury-in-glass thermometers. Assess safe storage of these thermometers to protect from breakage and mercury spills. Educate patient and family caregiver on proper use of the thermometer, mercury hazards, and proper disposal of any mercury-containing devices. Suggest alternative temperature measurement devices for home use.

SKILL 5-2 Assessing Radial Pulse

NSO Vital Signs Module / Lesson 3

 Video Clip

The ejection of blood from the heart distends the walls of the aorta. Because of the force of the blood exiting the heart, aortic distention creates a pulse wave that travels rapidly toward the extremities. When the pulse wave reaches a peripheral artery, you can feel it by palpating the artery lightly against underlying bone or muscle. The pulse is the palpable bounding of the blood flow. The number of pulsing sensations occurring in 1 minute is the pulse rate.

Assessing the patient's peripheral pulse sites offers valuable data for determining the integrity of the cardiovascular system. An abnormally slow, rapid, or irregular pulse indicates the inability of the heart to deliver adequate blood to the body; a pulse deficit may be present (see [Procedural Guideline 5-1](#)). The strength or amplitude of a pulse reflects the volume of blood ejected against the arterial wall with each heart contraction. If the volume decreases, the pulse often becomes weak and difficult to palpate. In contrast, a full bounding pulse is an indication of increased volume.

The integrity of peripheral pulses indicates the status of blood perfusion to the area distributed by the pulse ([Table 5-1](#)). For example, assessment of the right femoral pulse determines whether

blood flow to the right leg is adequate. If a peripheral pulse distal to an injured or treated area of an extremity feels weak on palpation, the volume of blood reaching tissues below the affected area may be inadequate, and surgical intervention may be necessary.

You can assess any artery for pulse rate, but the radial and carotid arteries are commonly used because they are easy to palpate ([Fig. 5-6](#)). When a patient's condition suddenly worsens, the carotid site is recommended for finding a pulse quickly. Assessment of other peripheral pulse sites such as the brachial or femoral artery is unnecessary when routinely obtaining vital signs. Other peripheral pulses are assessed when a complete physical (see [Chapter 6](#)) is conducted or when the radial artery is not available for assessment because of surgery, trauma, or impaired blood flow.

Delegation and Collaboration

The skill of radial pulse measurement can be delegated to nursing assistive personnel (NAP) if the patient's condition is stable. The skill cannot be delegated when the patient's condition is unstable

TABLE 5-1 Pulse Sites

Site	Location	Rationale for Selection
Temporal	Over temporal bone of head, above and lateral to the eyebrow	Easily accessible site to assess pulse in children
Carotid	Along medial edge of sternocleidomastoid muscle in neck	Easily accessible site to assess character of peripheral pulse; used during physiologic shock or cardiac arrest when other sites are not palpable
Apical	Fourth to fifth intercostal space at left midclavicular line	Site used to auscultate apical pulse
Brachial	Groove between biceps and triceps muscles at antecubital fossa	Site used to auscultate upper-extremity blood pressure; assesses status of circulation to lower arm
Radial	Radial or thumb side of forearm at wrist	Common site to assess character of peripheral pulse; assesses status of circulation to hand
Ulnar	Ulnar side of forearm at the wrist	Site used to assess status of circulation to ulnar side of hand; used to perform Allen's test
Femoral	Below inguinal ligament, midway between symphysis pubis and anterior superior iliac spine	Site used to assess character of pulse during physiologic shock or cardiac arrest when other pulses are not palpable; assesses status of circulation to the leg
Popliteal	Behind knee in popliteal fossa	Site used to auscultate lower-extremity blood pressure; assesses status of circulation to lower leg
Posterior tibial	Inner side of each ankle, below medial malleolus	Site used to assess status of circulation to the foot
Dorsalis pedis	Along top of foot between extension tendons of great and first toe	Site used to assess status of circulation to the foot

FIG 5-6 Palpating the radial pulse.

since the patient is at high risk for acute or serious cardiac problems or when the nurse is evaluating a response to a treatment or medication. The nurse instructs the NAP by:

- Communicating the appropriate site for pulse rate; frequency of measurement; and factors related to the patient history such as risk for abnormally slow, rapid, or irregular pulse.
- Reviewing patient's usual pulse rate and significant changes to report to the nurse.
- Reviewing the specific abnormalities to report to the nurse for further assessment.

Equipment

- Wristwatch with second hand or digital display
- Pen and vital sign flow sheet or electronic health record (EHR)

STEP

RATIONALE

ASSESSMENT

- Determine need to assess radial pulse:
 - Assess for any risk factors for pulse alterations:
 - A history of heart disease
 - Cardiac dysrhythmia
 - Onset of sudden chest pain or acute pain from any site
 - Invasive cardiovascular diagnostic tests
 - Surgery
 - Sudden infusion of large volume of intravenous (IV) fluid
 - Internal or external hemorrhage
 - Administration of medications that alter cardiac function
 - Assess for signs and symptoms of altered cardiac function such as presence of dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations, edema of dependent body parts, cyanosis, or pallor of skin (see [Chapter 6](#)).
 - Assess for signs and symptoms of peripheral vascular disease such as pale, cool extremities; thin, shiny skin with decreased hair growth; thickened nails.
 - Assess for factors that influence radial pulse rate and rhythm: age, exercise, position changes, fluid balance, medications, temperature, sympathetic stimulation (e.g., caffeine or nicotine).
- Determine patient's previous baseline pulse rate (if available) from patient's record.

Certain conditions place patients at risk for pulse alterations. A history of peripheral vascular disease often alters pulse rate and quality.

Physical signs and symptoms often indicate alteration in cardiac function, which affects radial pulse rate and rhythm.

Physical signs and symptoms indicate alteration in local arterial blood flow.

Can anticipate factors that alter pulse, ensuring accurate interpretation.

Dysrhythmics, cardiotonics, antihypertensives, vasodilators, and vasoconstrictors affect pulse rate and rhythm.

Allows you to assess for change in condition. Provides comparison with future pulse measurements.

NURSING DIAGNOSES

- Activity intolerance
- Decreased cardiac output
- Deficient fluid volume
- Ineffective peripheral tissue perfusion

Related factors are individualized based on patient's condition and needs.

PLANNING

- Expected outcomes following completion of procedure:
 - Radial pulse is palpable, within usual range for patient's age.
 - Rhythm is regular.
 - Radial pulse is strong, firm, and elastic.
- Explain to patient that you will assess radial pulse rate (HR). Encourage patient to relax as much as possible. If he or she has been active, wait 5 to 10 minutes before assessing pulse. If patient has been smoking or ingesting caffeine, wait 15 minutes before assessing pulse.
- Collect appropriate equipment and bring to patient's bedside

Usual range for adults is 60 to 100 beats/min.

Cardiac status is stable.

Radial artery is patent.

Anxiety, activity, caffeine, and smoking elevate heart rate.

Assessing radial pulse rate at rest allows for objective comparison of values.

Ensures an organized approach for assessing a radial pulse.

STEP

RATIONALE

IMPLEMENTATION

- 1 Perform hand hygiene.
- 2 If necessary, draw curtain around bed and/or close door.
- 3 Assist patient with assuming a supine or sitting position.
- 4 If patient is supine, place his or her forearm straight alongside or across lower chest or upper abdomen with wrist extended straight (see illustration A). If sitting, bend patient's elbow 90 degrees and support lower arm on chair or on nurse's arm. Place tips of first two or middle three fingers of hand over groove along radial or thumb side of patient's inner wrist (see illustration B). Slightly extend or flex wrist with palm down until you note strongest pulse.

Reduces transmission of microorganisms.
 Maintains privacy and minimizes embarrassment.
 Provides easy access to pulse sites.
 Fingertips are most sensitive parts of hand to palpate arterial pulsation. Nurse's thumb has pulsation that interferes with accuracy. Relaxed position of lower arm and extension of wrist permit full exposure of artery to palpation.

STEP 4 A, Pulse check with patient's forearm at side with wrist extended. B, Hand placement for pulse check.

- 5 Lightly compress against radius, obliterate pulse initially, and relax pressure so pulse becomes easily palpable.
- 6 Determine strength of pulse. Note whether thrust of vessel against fingertips is bounding (4+); full increased, strong (3+); expected (2+); barely palpable, diminished (1+); or absent, not palpable (0).
- 7 After palpating a regular pulse, look at watch second hand and begin to count rate. Count the first beat after the second hand hits the number on the dial; count as one, then two, and so on.
- 8 If pulse is regular, count rate for 30 seconds and multiply total by 2.
- 9 If pulse is irregular, count rate for a full 60 seconds. Assess frequency and pattern of irregularity.
- 10 When pulse is irregular, compare radial pulses bilaterally.

Pulse assessment is more accurate when using moderate pressure. Too much pressure occludes pulse and impairs blood flow. Strength reflects volume of blood ejected against arterial wall with each heart contraction. Accurate description of strength improves communication among nurses and other health care providers.
 Rate is determined accurately only after pulse has been palpated. Timing begins with zero. Count of one is first beat palpated after timing begins.

A 30-second count is accurate for rapid, slow, or regular pulse rates.

Inefficient contraction of heart fails to transmit pulse wave, resulting in irregular pulse. Longer time ensures accurate count. A marked difference between pulses indicates that arterial flow is compromised to one extremity and nurse needs to take action.

Clinical Decision Point If pulse is irregular, assess for pulse deficit (see *Procedural Guideline 5-1*), which may indicate alterations in heart function.

- 11 Assist patient return to comfortable position.
- 12 Discuss findings with patient as needed.
- 13 Perform hand hygiene.

Promotes comfort and sense of well-being.
 Promotes participation in care and understanding of health status.
 Reduces transmission of microorganisms.

STEP

RATIONALE

EVALUATION

- 1 If assessing pulse for first time, establish radial pulse as baseline if it is within acceptable range.
- 2 Compare pulse rate and character with patient's previous baseline and acceptable range for patient's age.

Used to compare future pulse assessments.

Allows nurse to assess for change in patient's condition and presence of cardiac alteration.

Unexpected Outcomes

- 1 Patient has weak, thready, or difficult-to-palpate radial pulse.
- 2 An adult patient's pulse rate is more than 100 beats/min (tachycardia).
- 3 An adult patient's pulse rate is less than 60 beats/min (bradycardia).
- 4 Patient has an irregular pulse.

Related Interventions

- Assess both radial pulses and compare findings.
- Observe for symptoms associated with ineffective tissue perfusion, including pallor and cool skin distal to weak pulse.
- Assess for swelling in surrounding tissues or any encumbrance (e.g., dressing or cast) that may impede blood flow.
- Obtain Doppler or ultrasound stethoscope to detect low-velocity blood flow (see Chapter 6).
- Have another nurse assess pulse.
- Identify related data, including fever, pain, fear or anxiety, recent exercise, low blood pressure, blood loss, or inadequate oxygenation.
- Observe for signs and symptoms associated with abnormal cardiac function, including dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations, edema of body parts, cyanosis, or pallor of the skin.
- Auscultate the apical pulse (see Skill 5-3).
- Confer with health care provider and be prepared to order/obtain an electrocardiogram.
- Auscultate apical pulse (see Skill 5-3).
- Assess for pulse deficit (see Procedural Guideline 5-1).

Recording and Reporting

- Record pulse rate and assessment site on vital sign flow sheet, nurses' notes, or EHR.
- Document measurement of pulse rate after administration of specific therapies in nurses' notes and EHR.
- Report abnormal findings to nurse in charge or health care provider.

Special Considerations

Teaching

- Patients taking certain prescribed cardiotoxic or antidysrhythmic medications need to learn to assess their own pulse rates to detect side effects of medications. Patients undergoing cardiac rehabilitation need to learn to assess their own pulse rates to determine their response to exercise.
- Teach patients taking heart medications or starting a prescribed exercise regimen how to monitor carotid pulse rate.

Pediatric

- Radial artery is difficult to assess in an infant. Apical, femoral, or brachial pulse is best site for assessing pediatric heart rate and rhythm until 2 years of age.

- Children often have a sinus dysrhythmia, which is an irregular heartbeat that speeds up with inspiration and slows down with expiration.

- Breath holding in a child affects pulse rate.

Gerontologic

- Older adults have a reduced heart rate with exercise because of a decreased responsiveness to catecholamines.
- It takes longer for the heart rate to rise in the older adult to meet sudden increased demands that result from stress, illness, or excitement. Once elevated, the pulse rate of an older adult takes longer to return to normal resting rate (Ebersole et al., 2008).
- Peripheral vascular disease is more common among older adults, making radial pulse assessment difficult.

Home Care

- Patients taking certain prescribed cardiac medications should learn to assess their own pulse rates to detect side effects of medications.

SKILL 5-3 Assessing Apical Pulse

NSO Vital Signs Module / Lesson 3

The apical pulse is the most reliable noninvasive way to assess cardiac function. The apical pulse rate is the assessment of the number and quality of apical sounds in 1 minute. Each apical pulse is the combination of two sounds, S_1 and S_2 . S_1 is the sound of the tricuspid and mitral valves closing at the end of ventricular filling, just before systolic contraction begins. S_2 is the sound of the pulmonic and aortic valves closing at the end of the systolic contraction.

You use a stethoscope to auscultate sound waves of the apical pulse (Fig. 5-7). The stethoscope is a closed cylinder that amplifies sound waves as they reach the surface of the body. The five major parts of the stethoscope are the earpieces, binaurals, tubing, bell, and diaphragm.

The plastic or rubber earpieces should fit snugly and comfortably in your ears. Binaurals should be angled and strong enough so the earpieces stay firmly in place without causing discomfort. The

FIG 5-7 Acoustic stethoscope.

earpieces follow the contour of the ear canal, pointing toward the face when the stethoscope is in place.

The polyvinyl tubing should be flexible and 30 to 45 cm (12 to 18 inches) in length; longer tubing decreases sound transmission. Stethoscopes can have one or two tubes. At the end of the tubing is the chest piece, consisting of a bell and diaphragm that you rotate into position, depending on which part you choose to use. To test, lightly tap to determine which side is functioning. Some stethoscopes have one chest piece that combines features of the bell and diaphragm. When you apply light pressure, the chest piece is a bell, whereas exerting more pressure converts the bell into a diaphragm.

The diaphragm is the larger, circular, flat-surfaced portion of the chest piece. It transmits high-pitched sounds created by high-velocity movement of air and blood. Position the diaphragm to make a tight seal against the patient's skin. Exert enough pressure to complete the seal, leaving a temporary red ring on the patient's skin after you remove the diaphragm.

The bell is the cone-shaped portion of the chest piece, usually surrounded by a rubber ring to avoid chilling the patient during placement. It transmits low-pitched sounds created by the low-velocity movement of blood. Hold the bell lightly against the skin for sound amplification.

Delegation and Collaboration

The skill of apical pulse measurement can be delegated to nursing assistive personnel (NAP) if the patient is stable and not at high risk for acute or serious cardiac problems. Often you measure the apical pulse when you suspect an irregularity in the radial pulse or when a patient's condition requires a more accurate assessment. In this situation pulse assessment cannot be delegated to NAP. When measurement of apical pulse is a routine practice, the nurse instructs the NAP by:

- Communicating the frequency of measurement and factors related to the patient history such as risk for abnormally slow, rapid, or irregular pulse.
- Reviewing patient's usual pulse values and the need to report any abnormalities in rate or rhythm to the nurse.

Equipment

- Stethoscope
- Wristwatch with second hand or digital display
- Pen and vital sign flow sheet or electronic health record (EHR)
- Alcohol swab

STEP

Patient's voice interferes with nurse's ability to hear sound when measuring apical pulse. Assessing apical pulse rate at rest allows for objective comparison of values.</p>
<p>3 Collect and bring appropriate supplies to the patient's bedside.</p>	<p>Ensures an organized approach for assessing radial pulse.</p>

STEP

RATIONALE

IMPLEMENTATION

- 1 Perform hand hygiene.
- 2 If necessary, draw curtain around bed and/or close door.
- 3 Assist patient to supine or sitting position. Move aside bed linen and gown to expose sternum and left side of chest.
- 4 Locate anatomic landmarks to identify point of maximal impulse (PMI), also called apical *impulse* (see [Chapter 6](#)). The heart is located behind and to left of sternum with base at top and apex at bottom. Find angle of Louis just below suprasternal notch between sternal body and manubrium; it feels like a bony prominence (see illustration A). Slip fingers down each side of angle to find second intercostal space (ICS) (see illustration B). Carefully move fingers down left side of sternum to fifth ICS and laterally to left midclavicular line (MCL) (see illustration C). A light tap felt within area 1 to 2.5 cm ($\frac{1}{2}$ to 1 inch) of PMI is reflected from apex of heart (see illustration D).

Reduces transmission of microorganisms.
 Maintains privacy and minimizes embarrassment.
 Exposes portion of chest wall for selection of auscultatory site.

Use of anatomic landmarks allows correct placement of stethoscope over apex of heart. This position enhances ability to hear heart sounds clearly. If unable to palpate PMI, reposition patient on left side. In the presence of serious heart disease, you may locate PMI to the left of the MCL or at the sixth ICS.

STEP 4 A, Nurse locates sternal notch. B, Nurse locates second intercostal space. C, Nurse locates fifth intercostal space. D, Nurse locates point of maximal impulse at fifth intercostal space at left midclavicular line.

- 5 Place diaphragm of stethoscope in palm of hand for 5 to 10 seconds.

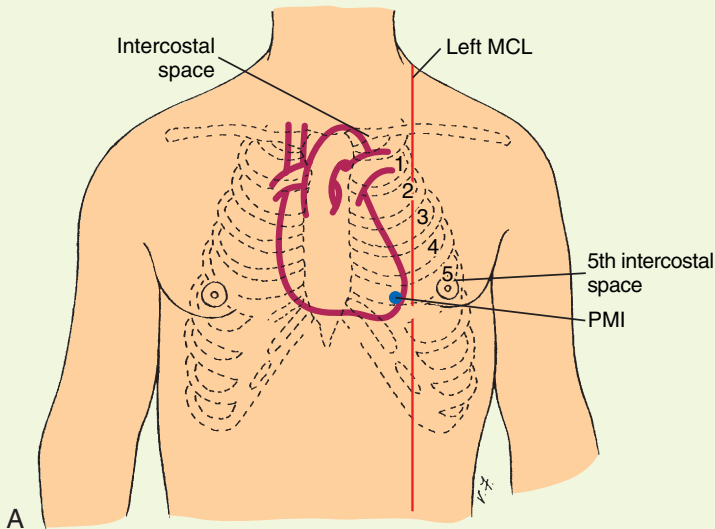

Warming of metal or plastic diaphragm prevents patient from being startled and promotes comfort.

STEP

RATIONALE

- 6 Place diaphragm of stethoscope over PMI at fifth ICS, at left MCL, and auscultate for normal S_1 and S_2 heart sounds (heard as “lub-dub”) (see illustrations).

Allow stethoscope tubing to extend straight without kinks that would distort sound transmission. Normal sounds S_1 and S_2 are high pitched and best heard with diaphragm.

STEP 6 A, Location of point of maximal impulse (PMI) in adult. B, Listening to PMI in an adult.

- 7 When you hear S_1 and S_2 with regularity, use second hand of watch and begin to count rate: when sweep hand hits number on dial; start counting with zero, then one, two, and so on.
- 8 If apical rate is regular, count for 30 seconds and multiply by 2.
- 9 If HR is irregular or patient is receiving cardiovascular medication, count for a full 1 minute (60 seconds).
- 10 Note regularity of any dysrhythmia (S_1 and S_2 occurring early or late after previous sequence of sounds) (e.g., every third or every fourth beat is skipped).
- 11 Replace patient's gown and bed linen; help him or her return to comfortable position.

Apical rate is determined accurately only after you are able to auscultate sounds clearly. Timing begins with zero. Count of one is first sound auscultated after timing begins.

You can assess regular apical rate within 30 seconds.

Irregular rate is more accurately assessed when measured over longer interval.

Regular occurrence of dysrhythmia within 1 minute indicates inefficient contraction of heart and potential alteration in cardiac output.

Restores comfort and promotes sense of well-being.

Clinical Decision Point *If apical rate is abnormal or irregular, repeat measurement or have another nurse conduct measurement. Original measurement may be incorrect. Second measurement confirms initial findings of an abnormal HR.*

- 12 Discuss findings with patient as needed.
- 13 Perform hand hygiene.
- 14 Clean earpieces and diaphragm of stethoscope with alcohol swab routinely after each use.

Promotes participation in care and understanding of health status.

Reduces transmission of microorganisms.

Stethoscopes are frequently contaminated with microorganisms.

Regular disinfection can control nosocomial infections.

EVALUATION

- 1 If assessing pulse for first time, establish apical rate as baseline if it is within an acceptable range.
- 2 Compare apical rate and character with patient's previous baseline and acceptable range of HR for patient's age.

Used to compare future pulse assessments.

Allows nurse to assess for change in patient's condition and for presence of cardiac alteration.

Unexpected Outcomes

- 1 An adult patient's apical pulse is greater than 100 beats/min (tachycardia).
- 2 Patient's apical pulse is less than 60 beats/min (bradycardia).
- 3 Patient's apical rhythm is irregular.

Related Interventions

- Identify related data, including fever, pain, fear or anxiety, recent exercise, low blood pressure, blood loss, or inadequate oxygenation.
- Observe for signs and symptoms associated with abnormal cardiac function, including dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations, edema of body parts, cyanosis, or dizziness.
- Assess for factors that decrease HR such as digoxin and antiarrhythmic drugs.
- Observe for signs and symptoms associated with abnormal cardiac function, including dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations, edema of body parts, cyanosis, or dizziness.
- Have another nurse assess apical pulse.
- Report findings to nurse in charge and/or health care provider. It may be necessary to withhold prescribed medications that alter HR until health care provider can evaluate need to alter dosage.
- Assess for pulse deficit (see [Procedural Guideline 5-1](#)).
- Report findings to nurse in charge and/or health care provider, who may order an electrocardiogram to detect cardiac conduction alteration.

Recording and Reporting

- Record apical pulse rate and rhythm on vital sign flow sheet, nurses' notes, or EHR.
- Document measurement of apical pulse rate after administration of specific therapies in appropriate area in EHR as per agency policy.
- If apical pulse not found at fifth ICS and left MCL, document location of PMI.
- Report abnormal findings to nurse in charge or health care provider.

Special Considerations**Teaching**

- Teach caregivers of patients taking prescribed cardiotoxic or antidysrhythmic medications how to assess apical pulse rates to detect side effects of medications.

Pediatric

- The PMI of an infant is usually located at the third to fourth ICS near the left sternal border.

- In infants and children younger than 2 years, an apical pulse is more reliable and is counted for 1 full minute because of possible irregularities in rhythm.
- Breath holding in an infant or child affects apical pulse rate.

Gerontologic

- The PMI is often difficult to palpate in some older adults because the anterior-posterior diameter of the chest increases with age and the heart becomes repositioned because of left ventricular enlargement.
- When assessing older adult women with sagging breast tissue, gently lift the breast tissue and place the stethoscope at the fifth ICS or the lower edge of the breast.
- Heart sounds are sometimes muffled or difficult to hear in older adults because of an increase in air space in the lungs.
- The older adult has a decreased HR at rest ([Ebersole et al., 2008](#)).

Home Care

- Assess home environment to determine which room affords a quiet environment for auscultation of apical rate.

PROCEDURAL GUIDELINE 5-1 Assessing Apical-Radial Pulse Deficit

The difference between pulses assessed from two different sites, or a pulse deficit, provides information about heart and blood vessel function. When a pulse deficit is assessed between the apical and radial pulses, the volume of blood ejected from the heart may be inadequate to meet the circulatory needs of the tissues, and intervention may be required. To assess for a pulse deficit, the nurse and a second health care provider assess a peripheral pulse rate and the apical pulse rate simultaneously and compare the measurements.

Delegation and Collaboration

The skill of assessing an apical-radial pulse deficit cannot be delegated to nursing assistive personnel (NAP) while the nurse assesses the apical pulse. Collaboration between the nurse and a second health provider is required.

Equipment

- Stethoscope
- Watch with second hand or digital display

PROCEDURAL GUIDELINE 5-1 Assessing Apical-Radial Pulse—cont'd

- Pen and vital sign flow sheet or electronic health record (EHR)
- Alcohol swab

Procedural Steps

- 1 Determine need to assess for pulse deficit. Irregular heart rate and signs and symptoms such as dyspnea, fatigue, chest pain, and palpitations may indicate abnormal cardiac function.
- 2 Perform hand hygiene.
- 3 Collect and bring appropriate supplies to the patient's bedside and draw curtain around bed and/or close door.
- 4 Explain to the patient that two people will be assessing heart function at the same time.
- 5 Assist patient to supine or sitting position. Move aside bed linen and gown to expose sternum and left side of chest.
- 6 Locate apical and radial pulse sites. Nurse auscultates apical pulse (see Skill 5-3) while second provider palpates radial pulse (see Skill 5-2).
- 7 Nurse begins pulse count by calling out loud when to begin counting pulses.
- 8 Each nurse completes a 60-second pulse count simultaneously. The count ends when the nurse states "stop." Sixty seconds is required when a discrepancy between pulse sites is expected or when the rhythm is irregular.
- 9 If the pulse count differs by more than 2, a pulse deficit exists. The pulse deficit reflects the number of ineffective cardiac contractions in 1 minute.
- 10 If a pulse deficit is noted, assess for other signs and symptoms of decreased cardiac output (see Chapter 6).
- 11 Discuss findings with patient as needed.
- 12 Perform hand hygiene.
- 13 Record apical pulse, radial pulse, and pulse deficit in nurses' notes and EHR. Inform the nurse in charge or health care provider of presence of a pulse deficit.

SKILL 5-4 Assessing Respirations

NSO Vital Signs Module / Lesson 4

Respiration is the exchange of oxygen (O₂) and carbon dioxide (CO₂) between cells of the body and the atmosphere. Three processes of respiration are: ventilation, mechanical movement of gases into and out of the lungs; diffusion, movement of oxygen and carbon dioxide between the alveoli and the red blood cells; and perfusion, distribution of red blood cells to and from the pulmonary capillaries. You assess ventilation by observing the rate, depth, and rhythm of respiratory movements. Accurate assessment of respiration depends on recognizing normal thoracic and abdominal movements. Normal breathing is both active and passive. On inspiration the diaphragm contracts, and the abdominal organs move down to increase the size of the chest cavity. At the same time the ribs and sternum lift outward to promote lung expansion. On expiration the diaphragm relaxes upward, and the ribs and sternum return to their relaxed position (Fig. 5-8). During quiet breathing the chest wall gently rises and falls. The body uses more energy during inspiration than during expiration. Expiration is an active process only during exercise, voluntary hyperventilation, and certain disease states.

Delegation and Collaboration

The skill of counting respirations can be delegated to nursing assistive personnel (NAP) unless the patient is considered unstable (i.e., complaints of dyspnea). The nurse instructs the NAP by:

- Communicating the frequency of measurement and factors related to patient history or risk for increased or decreased respiratory rate or irregular respirations.

Video Clip

- Reviewing any unusual respiratory values and significant changes to report to the nurse.

Equipment

- Wristwatch with second hand or digital display
- Pen and vital sign flow sheet or electronic health record (EHR)

FIG 5-8 Diaphragmatic and chest wall movement during inspiration and expiration.

STEP

RATIONALE

ASSESSMENT

<p>1 Determine need to assess patient's respirations:</p> <p>a Assess for risk factors of respiratory alterations:</p> <ul style="list-style-type: none"> • Fever • Pain and anxiety • Diseases of chest wall or muscles • Constrictive chest or abdominal dressings • Presence of abdominal incisions • Gastric distention • Chronic pulmonary disease (emphysema, bronchitis, asthma) • Traumatic injury to chest wall with or without collapse of underlying lung tissue • Presence of a chest tube • Respiratory infection (pneumonia, acute bronchitis) • Pulmonary edema and emboli • Head injury with damage to brainstem • Anemia <p>b Assess for signs and symptoms of respiratory alterations such as the following:</p> <ul style="list-style-type: none"> • Bluish or cyanotic appearance of nail beds, lips, mucous membranes, and skin • Restlessness, irritability, confusion, reduced level of consciousness • Pain during inspiration • Labored or difficult breathing • Orthopnea • Use of accessory muscles • Adventitious breath sounds (see Chapter 6) • Inability to breathe spontaneously • Thick, frothy, blood-tinged, or copious sputum production <p>c Assess for factors that influence the character of respirations:</p> <ul style="list-style-type: none"> • Exercise • Anxiety • Acute pain • Smoking • Medications • Body position • Neurologic injury • Hemoglobin function 	<p>Certain conditions place patient at risk for ventilatory alterations detected by changes in respiratory rate, depth, and rhythm.</p> <p>Physical signs and symptoms indicate alterations in respiratory status.</p> <p>Allows you to anticipate factors that influence respirations, ensuring a more accurate interpretation. Respirations increase in rate and depth to meet need for additional oxygen and rid body of carbon dioxide. Anxiety causes increase in respiration rate and depth because of sympathetic nervous system stimulation. Pain alters rate and rhythm of respirations; breathing becomes shallow. Patient inhibits or splints chest wall movement when pain is in area of chest or abdomen. Chronic smoking changes pulmonary airways, resulting in an increased respiratory rate at rest when not smoking. Narcotic analgesics, general anesthetics, and sedative hypnotics depress rate and depth; amphetamines and cocaine increase rate and depth; bronchodilators cause dilation of airways, which ultimately slows respiratory rate. Standing or sitting erect promotes full ventilatory movement and lung expansion; stooped or slumped posture impairs ventilatory movement; lying flat prevents full chest expansion. Damage to the brainstem impairs the respiratory center and inhibits rate and rhythm. Decreased hemoglobin levels lower amount of oxygen carried in blood, which results in increased respiratory rate to increase oxygen delivery. An increase in altitude lowers amount of saturated hemoglobin, which increases respiratory rate and depth.</p>
---	---

STEP	RATIONALE
<p>2 Assess pertinent laboratory values:</p> <p>a <i>Arterial blood gases (ABGs)</i>: Normal ranges (values vary slightly among agencies):</p> <ul style="list-style-type: none"> pH, 7.35 to 7.45 PaCO₂, 35 to 45 mm Hg HCO₃, 22 to 28 mEq/L PaO₂, 80 to 100 mm Hg SaO₂, 95% to 100% <p>b <i>Pulse oximetry (SpO₂)</i>: Normal SpO₂ ≥ 95%-100%; 90% is a red flag; anything less indicates hypoxemia (Valdez-Lowe et al., 2009) (see Procedural Guideline 5-3)</p> <p>c <i>Complete blood count (CBC)</i>: Normal CBC for adults (values vary within agencies):</p> <ul style="list-style-type: none"> Hemoglobin: 14 to 18 g/100 mL, males; 12 to 16 g/100 mL, females Hematocrit: 42% to 52%, males; 37% to 47%, females Red blood cell count: 4.7 to 6.1 million/mm³, males; 4.2 to 5.4 million/mm³, females 	<p>ABG values measure arterial blood pH, partial pressure of oxygen and carbon dioxide, and arterial oxygen saturation, which reflect patient's oxygenation status.</p> <p>SpO₂ less than 85% is often accompanied by changes in respiratory rate, depth, and rhythm.</p> <p>CBC measures red blood cell count; volume of red blood cells; and concentration of hemoglobin, which reflects patient's capacity to carry oxygen.</p>
<p>3 Determine previous baseline respiratory rate (if available) from patient's record.</p>	<p>Assesses for change in condition. Provides comparison with future respiratory measurements.</p>

NURSING DIAGNOSES

- Activity intolerance
- Impaired gas exchange
- Ineffective airway clearance
- Impaired spontaneous ventilation
- Ineffective breathing pattern

Related factors are individualized based on patient's condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> Respiratory rate is within acceptable range. Respirations are regular and of normal depth. 	<p>Adults average 12 to 20 breaths/min. Respiratory status is stable.</p>
<p>2 If patient has been active, wait 5 to 10 minutes before assessing respirations.</p>	<p>Exercise increases respiratory rate and depth. Assessing respirations while patient is at rest allows for objective comparison of values.</p>
<p>3 Assess respirations after pulse measurement in adult.</p>	<p>Inconspicuous assessment of respirations immediately after pulse assessment prevents patient from consciously or unintentionally altering rate and depth of breathing.</p>
<p>4 Be sure that patient is in comfortable position, preferably sitting or lying with the head of the bed elevated 45 to 60 degrees.</p>	<p>Sitting erect promotes full ventilatory movement. Position of discomfort causes patient to breathe more rapidly.</p>

Clinical Decision Point Assess patients with difficulty breathing (dyspnea) such as those with heart failure or abdominal ascites or in late stages of pregnancy in the position of greatest comfort. Repositioning may increase the work of breathing, which increases respiratory rate.

IMPLEMENTATION

<p>1 Draw curtain around bed and/or close door. Perform hand hygiene.</p>	<p>Maintains privacy. Prevents transmission of microorganisms.</p>
<p>2 Be sure that patient's chest is visible. If necessary, move bed linen or gown.</p>	<p>Ensures clear view of chest wall and abdominal movements.</p>
<p>3 Place patient's arm in relaxed position across abdomen or lower chest or place your hand directly over patient's upper abdomen.</p>	<p>A similar position used during pulse assessment allows respiratory rate assessment to be inconspicuous. Patient's or nurse's hand rises and falls during respiratory cycle.</p>
<p>4 Observe complete respiratory cycle (one inspiration and one expiration).</p>	<p>Rate is accurately determined only after nurse has viewed respiratory cycle.</p>
<p>5 After observing cycle, look at second hand of watch and begin to count rate: when sweep hand hits number on dial, begin time frame, counting one with first full respiratory cycle.</p>	<p>Timing begins with count of one. Respirations occur more slowly than pulse; thus timing does not begin with zero.</p>

STEP	RATIONALE
6 If rhythm is regular, count number of respirations in 30 seconds and multiply by 2. If rhythm is irregular, less than 12, or greater than 20, count for 1 full minute.	Respiratory rate is equivalent to number of respirations per minute. Suspected irregularities require assessment for at least 1 minute (Box 5-5).
7 Note depth of respirations by observing degree of chest wall movement while counting rate. In addition, assess depth by palpating chest wall excursion or auscultating posterior thorax after you have counted rate (see Chapter 6). Describe depth as shallow, normal, or deep.	Character of ventilatory movement reveals specific disease states restricting volume of air from moving into and out of lungs.
8 Note rhythm of ventilatory cycle. Normal breathing is regular and uninterrupted. Do not confuse sighing with abnormal rhythm.	Character of ventilations reveals specific types of alterations. Periodically people unconsciously take single deep breaths or sighs to expand small airways prone to collapse.

Clinical Decision Point Any irregular respiratory pattern or periods of apnea (cessation of respiration for several seconds) are symptoms of underlying disease in the adult, and you need to report this to the health care provider or nurse in charge. Further assessment and immediate intervention are often necessary.

9 Replace bed linen and patient's gown.	Restores comfort and promotes sense of well-being.
10 Perform hand hygiene.	Reduces transmission of microorganisms.
11 Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.

EVALUATION

1 If assessing respirations for first time, establish rate, rhythm, and depth as baseline if within acceptable range.	Used to compare future respiratory assessment.
2 Compare respirations with patient's previous baseline and usual rate, rhythm, and depth.	Allows nurse to assess for changes in patient's condition and presence of respiratory alterations.
3 Correlate respiratory rate, depth, and rhythm with data obtained from pulse oximetry and ABG measurements if available.	Evaluation of ventilation, perfusion, and diffusion are interrelated.

BOX 5-5 Alterations in Breathing Pattern

Alteration	Description
Apnea	Respirations cease for several seconds. Persistent cessation results in respiratory arrest.
Biot's respiration	Irregular respirations vary in depth and are interrupted by periods of apnea.
Bradypnea	Rate of breathing is regular but abnormally slow (fewer than 12 breaths/min).
Cheyne-Stokes respiration	Respiratory rate and depth are irregular, characterized by alternating periods of apnea and hyperventilation. Respiratory cycle begins with slow, shallow breaths that gradually increase to abnormal rate and depth. The pattern reverses; breathing slows and becomes shallow, climaxing in apnea before respiration resumes.
Hyperpnea	Respirations are increased in depth; occurs normally during exercise.
Hyperventilation	Rate and depth of respirations increase. Hypocarbica, an abnormally low level of carbon dioxide in the blood, may occur.
Hypoventilation	Respiratory rate is abnormally low; depth of ventilation may be depressed. Hypercarbica, an abnormally elevated level of carbon dioxide in the blood, may occur.
Kussmaul's respiration	Respirations are abnormally rapid and deep but regular; common in diabetic ketoacidosis.
Tachypnea	Rate of breathing is regular but abnormally rapid (more than 20 breaths/min).

Unexpected Outcomes

- 1 Patient's respiratory rate is below 12 breaths/minute (bradypnea) or above 20 breaths/minute (tachypnea). Breathing pattern is sometimes irregular (see Box 5-5). Depth of respirations is increased or decreased. Patient complains of feeling short of breath.
- 2 Patient demonstrates Kussmaul's, Cheyne-Stokes, or Biot's respirations (see Box 5-5).

Related Interventions

- Assess for related factors, including obstructed airway, abnormal breath sounds, productive cough, restlessness, anxiety, and confusion (see Chapter 6).
- Assist patient to supported sitting position (semi- or high-Fowler's) unless contraindicated.
- Provide oxygen as ordered (see Chapter 23).
- Assess for environmental factors that influence patient's respiratory rate such as secondhand smoke, poor ventilation, or gas fumes.
- Notify health care provider or nurse in charge if alteration continues.
- Notify health care provider for additional evaluation and possible medical intervention.

Recording and Reporting

- Record respiratory rate on vital sign flow sheet, nurses' notes, or EHR.
- Record abnormal depth and rhythm in appropriate area in nurses' notes and EHR.
- Document measurement of respiratory rate after administration of specific therapies in nurses' notes and EHR.
- Record type and amount of oxygen therapy, if used, in nurses' notes and EHR.
- Report abnormal findings to nurse in charge or health care provider.

Special Considerations

Teaching

- Patients who demonstrate decreased ventilation often benefit from learning deep breathing and coughing exercises.
- Instruct family caregiver to contact home care nurse or health care provider if unusual fluctuations in respiratory rate occur.

Pediatric

- Assess respiratory rates before other vital signs or assessments if you are able to view movement of chest wall or abdomen. This allows assessment of rate and rhythm before child becomes anxious because of stranger anxiety or fear of other assessment procedures.
- Average respiratory rate (breaths per minute) for newborns is 30 to 60; infant (6 months to 1 year) is 30; toddler (2 years) is

25 to 32; and child from 3 to 12 years is 20 (Hockenberry and Wilson, 2011).

- Children up to age 7 breathe abdominally; thus respirations are observed by abdominal movement.
- An irregular respiratory rate and short apneic spells are normal for newborns.
- Nurses can simply observe infant or young child while chest and abdomen are exposed.
- Use cardiorespiratory monitors for infants or newborns that are at risk for respiratory compromise or sustained apnea.

Gerontologic

- Aging causes ossification of costal cartilage and downward slant of ribs, resulting in more rigid rib cage, which reduces chest wall expansion. Kyphosis and scoliosis, frequent in older adults, may also restrict chest expansion.
- Depth of respirations tends to decrease with aging.
- Change in lung function with aging results in respiratory rates generally higher in older adults, with a range of 16 to 25 breaths/min.
- Some older adults depend more on accessory abdominal muscles during respiration than weakened thoracic muscles.

Home Care

- Assess for environmental factors in the home that influence patient's respiratory rate such as secondhand smoke, poor ventilation, or gas fumes.

SKILL 5-5 Assessing Arterial Blood Pressure

NSO Vital Signs Module / Lesson 5

Blood pressure (BP) is the force exerted by blood against the vessel walls. The peak pressure occurs when the ventricular contraction of the heart, or systole, forces blood under high pressure into the aorta. When the ventricles relax, the blood remaining in the arteries exerts a minimal or diastolic pressure. Diastolic pressure is the minimal pressure exerted against the arterial wall at all times.

The standard unit for measuring blood pressure is millimeters of mercury (mm Hg). The most common technique of measuring blood pressure is auscultation with a sphygmomanometer and stethoscope. As the sphygmomanometer cuff is deflated, the five different sounds heard over an artery are called *Korotkoff phases*.

The sound in each phase has unique characteristics (Fig. 5-9). Blood pressure is recorded with the systolic reading (first Korotkoff sound) before the diastolic (beginning of the fifth Korotkoff sound). The difference between systolic and diastolic pressure is the pulse pressure. For a blood pressure of 120/80, the pulse pressure is 40.

Hypertension

Hypertension is a major factor underlying death from heart attack and stroke in the United States and Canada. The Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (NHBPEP, 2003) has set criteria for determining categories of hypertension (Table 5-2). Prehypertension is a designation for patients at high risk for developing hypertension.

FIG 5-9 The sounds auscultated during blood pressure measurement can be differentiated into five Korotkoff phases. In this example the blood pressure is 140/90 mm Hg.

In these patients early intervention by adoption of healthy lifestyles reduces the risk of or prevents hypertension. Hypertension is defined as systolic blood pressure (SBP) of 140 mm Hg or greater, diastolic blood pressure (DBP) of 90 mm Hg or greater, or taking antihypertensive medication (NHBPEP, 2003). The diagnosis of hypertension in adults requires the average of two or more readings taken at each of two or more visits after an initial screening.

One blood pressure recording revealing a high systolic or diastolic blood pressure does not qualify as a diagnosis of hypertension. However, if you assess a high reading (e.g., 150/90 mm Hg), encourage the patient to return for another checkup within 2 months (Table 5-3).

Hypotension

Hypotension occurs when the systolic blood pressure falls to 90 mm Hg or below. Although some adults normally have a low blood pressure, for most people a low blood pressure is an abnormal finding associated with illness (e.g., hemorrhage or myocardial infarction). Orthostatic hypotension, also referred to as *postural hypotension*, occurs when a normotensive person develops symptoms (e.g., light-headedness or dizziness) and low blood pressure when rising to an upright position. In severe cases loss of consciousness may occur. Orthostatic changes in vital signs are effective indicators of blood volume depletion. Some medications cause orthostatic hypotension, especially in young patients and older adults.

Blood Pressure Equipment

You measure arterial blood pressure either directly (invasively) or indirectly (noninvasively). The direct method requires electronic monitoring equipment and the insertion of a thin catheter into an artery. The risks of invasive blood pressure monitoring require use in an intensive care setting.

TABLE 5-2 Classification of Blood Pressure for Adults Ages 18 Years and Older*

Category	Systolic (mm Hg)	and/or	Diastolic (mm Hg)
Normal	<120	and	<80
Prehypertension	120-139	or	80-89
Stage 1	140-159	or	90-99
Stage 2	≥160	or	≥100

From National High Blood Pressure Education Program; National Heart, Lung, and Blood Institute; National Institutes of Health: The seventh report of the Joint National Committee on Prevention, Detection, Evaluation and Treatment of High Blood Pressure, *JAMA* 289(19):2560, 2003.

*Based on the average of two or more readings taken at each of two or more visits after an initial screening. Patient is not taking antihypertensive drugs and not acutely ill. When systolic and diastolic blood pressures fall into different categories, the higher category should be selected to classify the individual's blood pressure status. For example, 160/92 mm Hg should be classified as stage 2 hypertension.

TABLE 5-3 Recommendations for Blood Pressure Follow-up

Initial Blood Pressure	Follow-up Recommended*
Normal	Recheck in 2 years.
Prehypertension	Recheck in 1 year.†
Stage 1 hypertension	Confirm within 2 months.†
Stage 2 hypertension	Evaluate or refer to source of care within 1 month. For those with higher pressure (e.g., >180/110 mm Hg), evaluate and treat immediately or within 1 week, depending on clinical situation and complications.

*Modify follow-up scheduling according to reliable information about past blood pressure measurements, other cardiovascular risk factors, or target organ damage.

†Provide advice about lifestyle modifications.

The more common noninvasive method requires use of the sphygmomanometer and stethoscope. A sphygmomanometer includes a pressure manometer, an occlusive cloth or disposable vinyl cuff that encloses an inflatable rubber bladder, and a pressure bulb with a release valve that inflates the bladder. The aneroid pressure manometer has a glass-enclosed circular gauge containing a needle that registers millimeter calibrations. Before using the aneroid manometer, make sure that the needle is pointing to zero. The release valve of the sphygmomanometer that holds the pressure constant must be clean and freely movable in either direction.

Cloth or disposable vinyl compression cuffs contain an inflatable bladder and come in several different sizes. The size selected is proportional to the circumference of the limb that you are assessing. Ideally the width of the cuff should be 40% of the circumference (or 20% wider than the diameter) of the midpoint of the limb on which the cuff is to be used (Fig. 5-10). The bladder enclosed within the cuff should encircle at least 80% of the upper arm (NHBPEP, 2003). Many adults require a large adult cuff. A regular-size cuff holds a bladder in the width of 12 to 13 cm (4.8 to 5.2 inches) and the length of 22 to 23 cm (8.5 to 9 inches). An improperly fitting cuff produces inaccurate blood pressure measurements (Box 5-6).

Electronic or automatic blood pressure machines consist of an electronic sensor positioned inside a blood pressure cuff attached

BOX 5-6 Common Mistakes in Blood Pressure Assessment

Error	Effect
Bladder or cuff too wide	False low reading
Bladder or cuff too narrow or too short	False-high reading
Cuff wrapped too loosely or unevenly	False-high reading
Deflating cuff too slowly	False-high diastolic reading
Deflating cuff too quickly	False-low systolic and false-high diastolic reading
Arm below heart level	False-high reading
Arm above heart level	False-low reading
Arm not supported	False-high reading
Stethoscope that fits poorly or impairment of examiner's hearing, causing sounds to be muffled	False-low systolic and false-high diastolic reading
Stethoscope applied too firmly against antecubital fossa	False-low diastolic reading
Inflating too slowly	False-high diastolic reading
Repeating assessments too quickly	False-high systolic reading
Inaccurate inflation level	False-low systolic reading
Multiple examiners using different Korotkoff sounds for diastolic readings	False-high systolic and false-low diastolic reading

BOX 5-7 Advantages and Limitations of Assessing Blood Pressure Electronically**Advantages**

- Ease of use
- Efficient when frequent repeated measurements are indicated
- Stethoscope not required
- Allows blood pressure to be recorded more frequently, as often as every 15 seconds with accuracy

Limitations

- Expensive
- Requires source of electricity
- Requires space to position machine
- Sensitive to outside motion interference and cannot be used in patients with seizures, tremors, or shivers or patients unable to cooperate
- Not accurate for patients with irregular heart rate or hypotension or in conditions with reduced blood flow (e.g., hypothermia)
- Accuracy standards for electronic blood pressure machine manufacturers are voluntary
- Vulnerable to error among older adults and obese patients (Heinemann et al., 2008).

to an electronic processor (see [Procedural Guideline 5-2](#)). Electronic devices have limitations but are useful when frequent measurements are necessary ([Box 5-7](#)).

Delegation and Collaboration

The skill of blood pressure measurement can be delegated to nursing assistive personnel (NAP) unless the patient is considered unstable (i.e., hypotensive). The nurse instructs the NAP by:

- Explaining the appropriate limb for measurement, blood pressure cuff size, and equipment (manual or electronic) to be used.
- Communicating the frequency of measurement and factors related to the patient's history such as risk for orthostatic hypotension.
- Reviewing the patient's usual blood pressure values and significant changes or abnormalities to report to the nurse.

Equipment

- Aneroid sphygmomanometer
- Cloth or disposable vinyl pressure cuff of appropriate size for patient's extremity
- Stethoscope
- Alcohol swab
- Pen and vital sign flow sheet or electronic health record (EHR)

FIG 5-10 Guidelines for proper blood pressure cuff size. Cuff width equals 20% more than upper arm diameter or 40% of circumference around upper arm and two thirds of upper arm length.

STEP

RATIONALE

ASSESSMENT

1 Determine need to assess patient's blood pressure:**a** Assess risk factors for blood pressure alterations:

- History of cardiovascular disease
- Renal disease
- Diabetes mellitus
- Circulatory shock (hypovolemic, septic, cardiogenic, or neurogenic)
- Acute or chronic pain
- Rapid intravenous (IV) infusion of fluids or blood products
- Increased intracranial pressure
- Postoperative status
- Toxemia of pregnancy

b Assess for signs and symptoms of blood pressure alterations. In patients at risk for high blood pressure (HBP), assess for headache (usually occipital), flushing of face, nosebleed, and fatigue in older adults. Hypotension is associated with dizziness; mental confusion; restlessness; pale, dusky, or cyanotic skin and mucous membranes; cool, mottled skin over extremities.**c** Assess for factors that influence blood pressure:

- Age
- Gender
- Daily (diurnal) variation
- Position
- Exercise
- Weight
- Sympathetic stimulation
- Medications
- Smoking
- Ethnicity

2 Determine best site for blood pressure assessment. Avoid applying cuff to extremity when IV fluids are infusing, an arteriovenous shunt or fistula is present, or breast or axillary surgery has been performed on that side. In addition, avoid applying cuff to extremity that has been traumatized or diseased or requires a cast or bulky bandage. Use lower extremities when brachial arteries are inaccessible.

Certain conditions place patients at risk for blood pressure alteration.

Physical signs and symptoms indicate alterations in blood pressure. Hypertension is often asymptomatic until pressure is very high.

Allows you to anticipate factors that influence respirations, ensuring a more accurate interpretation.

Acceptable values for blood pressure vary throughout life (see Pediatric and Gerontologic Considerations).

During and after menopause women often have higher blood pressures than men of same age.

Blood pressure varies throughout day; pressure is highest during the day between 10:00 AM and 6:00 PM and lowest in early morning.

Blood pressure falls as person moves from lying to sitting or standing position; normally postural variations are minimal.

Increases in oxygen demand by the body for activity increase blood pressure.

Obesity is an independent predictor of hypertension.

Pain, anxiety, or fear stimulates the sympathetic nervous system, causing blood pressure to rise.

Antihypertensives, diuretics, beta-adrenergic blockers, vasodilators, calcium channel blockers, angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), and antidysrhythmics lower blood pressure; opioids and general anesthetics also cause a drop in blood pressure.

Smoking results in vasoconstriction, a narrowing of blood vessels.

Blood pressure rises acutely and returns to baseline approximately 15 minutes after stopping smoking (NHBPEP, 2003).

Incidence of hypertension is higher in African Americans than in European Americans. African Americans tend to develop more severe hypertension at an earlier age and have twice the risk for the complications of hypertension (i.e., stroke and heart attack). Hypertension-related deaths are also higher among African Americans.

Inappropriate site selection may result in poor amplification of sounds, causing inaccurate readings. Application of pressure from inflated bladder temporarily impairs blood flow and can further compromise circulation in extremity that already has impaired blood flow.

STEP	RATIONALE
3 Determine previous baseline blood pressure and site (if available) from patient's record. Determine any report of latex allergy.	Assesses for change in condition. Provides comparison with future blood pressure measurements. If patient has latex allergy, verify that stethoscope and blood pressure cuff are latex free.
4 Assess patient's knowledge of procedure.	Encourages cooperation, minimizes risks and anxiety. Identifies teaching needs.

NURSING DIAGNOSES

- Decreased cardiac output
- Deficient fluid volume
- Excess fluid volume
- Ineffective tissue perfusion

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcome following completion of procedure: <ul style="list-style-type: none"> • Blood pressure is within acceptable range for patient's age. 	Cardiovascular status is stable.
2 Explain to patient that you will assess blood pressure. Have him or her rest at least 5 minutes before measuring lying or sitting blood pressure and 1 minute before measuring standing. Ask patient not to speak while you are measuring blood pressure.	Reduces anxiety that falsely elevates readings. Exercise causes false elevations in blood pressure. Talking to a patient during blood pressure assessment increases readings 10% to 40% (NHBPEP, 2003).
3 Be sure that patient has not exercised, ingested caffeine, or smoked for 30 minutes before assessment of blood pressure.	Smoking increases blood pressure immediately and lasts up to 15 minutes. The effects of coffee or caffeine increase blood pressure up to 3 hours (NHBPEP, 2003).
4 Have patient assume sitting or lying position. Be sure that room is warm, quiet, and relaxing.	Maintains patient's comfort during measurement. Patient's perceptions that the physical or interpersonal environment is stressful affect blood pressure.
5 Select appropriate cuff size (see Fig. 5-10) and ensure that other equipment is in the patient's room.	Use of improper-size cuff causes false-low or false-high reading (see Box 5-6).
6 Perform hand hygiene.	Reduces transmission of microorganisms.

IMPLEMENTATION

1 Assess blood pressure by auscultation: <ul style="list-style-type: none"> a Upper extremity: With patient sitting or lying, position his or her forearm at heart level with palm turned up (see illustration). If sitting, instruct patient to keep feet flat on floor without legs crossed. If supine, patient should not have legs crossed. 	If arm is extended and not supported, patient will perform isometric exercise that can increase diastolic pressure. Placement of arm above level of heart causes false-low reading, 2 mm Hg for each inch above heart level.
Lower extremity: With patient prone, position patient so knee is slightly flexed.	Leg crossing can falsely increase blood pressure.

STEP 1a Patient's forearm supported on bed.

STEP

- b** Expose extremity (arm or leg) fully by removing constricting clothing.
- c** Palpate brachial artery (arm, see illustration A) or popliteal artery (leg, see illustration B). With cuff fully deflated, apply bladder of cuff above artery by centering arrows marked on cuff over artery (see illustration C). If cuff does not have any center arrows, estimate center of bladder and place this center over artery. Position cuff 2.5 cm (1 inch) above site of pulsation (antecubital or popliteal space). With cuff fully deflated, wrap it evenly and snugly around upper arm (see illustration D).
- d** Position manometer gauge vertically at eye level. You should be no farther than 1 meter (approximately 1 yard) away.
- e** Measure blood pressure.

RATIONALE

Ensures proper cuff application. Do not place blood pressure cuff over clothing.

Popliteal artery is just below patient's thigh, behind knee. Placing bladder directly over artery ensures that you apply proper pressure during inflation. Loose-fitting cuff causes false-high readings.

Looking up or down at scale can result in distorted readings.

A

B

C

D

STEP 1c A, Palpating brachial artery. B, Blood pressure cuff applied around thigh. C, Aligning blood pressure cuff arrow with brachial artery. D, Blood pressure cuff wrapped around upper arm.

STEP	RATIONALE
(1) Two-step method:	
(a) Relocate brachial pulse. Palpate artery distal to cuff with fingertips of nondominant hand while inflating cuff rapidly to a pressure 30 mm Hg above point at which pulse disappears. Slowly deflate cuff and note point when pulse reappears. Deflate cuff fully and wait 30 seconds.	Estimating prevents false-low readings. Determine maximal inflation point for accurate reading by palpation. If unable to palpate artery because of weakened pulse, use an ultrasonic stethoscope (see Chapter 6). Completely deflating cuff prevents venous congestion and false-high readings.
(b) Place stethoscope earpieces in ears and be sure that sounds are clear, not muffled.	Ensure that each earpiece follows angle of ear canal to facilitate hearing.
(c) Relocate brachial artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing.	Proper stethoscope placement ensures best sound reception. Stethoscope improperly positioned causes muffled sounds that often result in false-low systolic and false-high diastolic readings. The bell provides better sound reproduction, whereas the diaphragm is easier to secure with fingers and covers a larger area.
(d) Close valve of pressure bulb clockwise until tight. Quickly inflate cuff to 30 mm Hg above patient's estimated systolic pressure.	Tightening valve prevents air leak during inflation. Rapid inflation ensures accurate measurement of systolic pressure.
(e) Slowly release pressure bulb valve and allow manometer needle to fall at rate of 2 to 3 mm Hg/second.	Too-rapid or too-slow a decline causes inaccurate readings.
(f) Note point on manometer when you hear first clear sound. The sound will slowly increase in intensity.	First Korotkoff sound reflects systolic blood pressure.
(g) Continue to deflate cuff gradually, noting point at which sound disappears in adults. Note pressure to nearest 2 mm Hg. Listen for 20 to 30 mm Hg after last sound and allow remaining air to escape quickly.	Beginning of fifth Korotkoff sound is indication of diastolic pressure in adults (NHBPEP, 2003). Fourth Korotkoff sound involves distinct muffling of sounds and is indication of diastolic pressure in children.
(2) One-step method:	
(a) Place stethoscope earpieces in ears and be sure that sounds are clear, not muffled.	Earpieces should follow angle of ear canal to facilitate hearing.
(b) Relocate brachial artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing.	Proper stethoscope placement ensures optimal sound reception. Stethoscope improperly positioned causes muffled sounds that often result in false-low systolic and false-high diastolic readings. Bell provides better sound reproduction, whereas diaphragm is easier to secure with fingers and covers larger area.
(c) Close valve of pressure bulb clockwise until tight. Quickly inflate cuff to 30 mm Hg above patient's usual systolic pressure.	Tightening valve prevents air leak during inflation. Inflation above systolic level ensures accurate measurement of systolic pressure.
(d) Slowly release pressure bulb valve and allow manometer needle to fall at rate of 2 to 3 mm Hg/second. Note point on manometer when you hear first clear sound. Sound will slowly increase in intensity.	Too-rapid or too-slow a decline in mercury level causes inaccurate readings. First Korotkoff sound reflects systolic pressure.
(e) Continue to deflate cuff gradually, noting point at which sound disappears in adults. Note pressure to nearest 2 mm Hg. Listen for 10 to 20 mm Hg after last sound and allow remaining air to escape quickly.	Beginning of fifth Korotkoff sound is indication of diastolic pressure in adults (NHBPEP, 2003). Fourth Korotkoff sound involves distinct muffling of sounds and is indication of diastolic pressure in children (NHBPEP, 2003).
(f) The Joint National Committee (NHBPEP, 2003) recommends the average of two sets of blood pressure measurements 2 minutes apart. Use second set of blood pressure measurements as patient's baseline.	Two sets of blood pressure measurements help to prevent false-positive readings based on patient's sympathetic response (alert reaction). Averaging minimizes effect of anxiety, which often causes first reading to be higher than subsequent measures (NHBPEP, 2003).
(g) Remove cuff from patient's arm unless you need to repeat measurement.	Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of patient's arm.
(h) If this is first assessment of patient, repeat procedure on other arm.	Comparison of blood pressure in both arms detects circulatory problems. (Normal difference of 5 to 10 mm Hg exists between arms.)
(i) Help patient return to comfortable position and cover upper arm if previously clothed.	Restores comfort and provides sense of well-being.
(j) Discuss findings with patient as needed.	Promotes participation in care and understanding of health status. Makes patient accountable for follow-up assessment. Systolic blood pressure in leg is 10 to 40 mm Hg higher than arm but diastolic blood pressure is same.

STEP	RATIONALE
(k) Perform hand hygiene. Clean earpieces and diaphragm of stethoscope with alcohol swab as needed.	Reduces transmission of microorganisms. Controls transmission of microorganisms when nurses share stethoscope.
2 Assess systolic blood pressure by palpation: a Follow Steps 1a through 1d of auscultation method. b Locate and then continually palpate brachial, radial, or popliteal artery with fingertips of one hand. Inflate cuff to a pressure 30 mm Hg above point at which you can no longer palpate pulse.	Ensures accurate detection of true systolic pressure once pressure valve is released.

Clinical Decision Point *If unable to palpate artery because of weakened pulse, use a Doppler ultrasonic stethoscope (Fig. 5-11).*

FIG 5-11 Doppler ultrasonic stethoscope over brachial artery to measure blood pressure.

c Slowly release valve and deflate cuff, allowing manometer needle to fall at rate of 2 mm Hg/second. Note point on manometer when pulse is again palpable.	Too-rapid or too-slow a decline results in inaccurate readings. Palpation helps identify systolic pressure only.
d Deflate cuff rapidly and completely. Remove cuff from patient's extremity unless you need to repeat measurement.	Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of extremity.
e Help patient return to comfortable position and cover extremity if previously clothed.	Restores comfort and promotes sense of well-being.
f Discuss findings with patient as needed.	Promotes participation in care and understanding of health status.
g Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 If assessing blood pressure for the first time, establish baseline blood pressure if it is within acceptable range.	Used to compare future blood pressure measurements.
2 Compare blood pressure reading with patient's previous baseline and usual blood pressure for patient's age.	Allows nurse to assess for change in condition. Provides comparison with future blood pressure measurements.

Unexpected Outcomes

- 1 Patient's blood pressure is above acceptable range.

- 2 Patient's blood pressure is not sufficient for adequate perfusion and oxygenation of tissues.

- 3 Unable to obtain blood pressure reading.

- 4 Patient experiences orthostatic hypotension.

Related Interventions

- Repeat measurement in other extremity and compare findings.
- Verify correct selection and placement of blood pressure cuff.
- Have another nurse repeat measurement in 1 to 2 minutes.
- Observe for related symptoms that are not apparent unless blood pressure is extremely high, including headache, facial flushing, nosebleed, and fatigue in older patient.
- Report blood pressure to nurse in charge or health care provider to initiate appropriate evaluation and treatment.
- Administer antihypertensive medications as ordered.

- Compare blood pressure value to baseline.
- Position patient in supine position to enhance circulation and restrict activity that decreases blood pressure further.
- Repeat measurement with sphygmomanometer. Electronic blood pressure devices are less accurate in low-flow conditions.
- Assess for signs and symptoms associated with hypotension, including tachycardia; weak, thready pulse; weakness; dizziness; confusion; and cool, pale, dusky, or cyanotic skin.
- Assess for factors that contribute to a low blood pressure, including hemorrhage, dilation of blood vessels resulting from hyperthermia, anesthesia, or medication side effects.
- Report blood pressure to nurse in charge or health care provider to initiate appropriate evaluation and treatment.
- Increase rate of IV infusion or administer vasoconstriction drugs if ordered.

- Determine that no immediate crisis is present by obtaining pulse and respiratory rate.
- Assess for signs and symptoms of decreased cardiac output; if present, notify nurse in charge or health care provider immediately.
- Use alternative sites or procedures to obtain blood pressure; use Doppler ultrasonic instrument (see [Chapter 6](#)); palpate systolic blood pressure.

- Maintain patient safety.
- Return patient to safe position in bed or chair.

Recording and Reporting

- Record blood pressure and site assessed on vital sign flow sheet, nurses' notes, and EHR.
- Document measurement of blood pressure after administration of specific therapies in nurses' notes and EHR.
- Record any signs or symptoms of blood pressure alterations in nurses' notes and EHR.
- Report abnormal findings to nurse in charge or health care provider.

Special Considerations

Teaching

- Educate patient about risks for hypertension. Persons with family history of hypertension, premature heart disease, lipidemia, or renal disease are at significant risk. Obesity, cigarette smoking, heavy alcohol consumption, high blood cholesterol and triglyceride levels, and continued exposure to stress from psychosocial and environmental conditions are factors linked to hypertension (NHBPEP, 2003).
- Primary prevention of hypertension includes lifestyle modifications (e.g., lose weight, exercise daily, reduce sodium and saturated fat intake, and maintain adequate intake of dietary

potassium and calcium). Cigarette smoking is a significant risk factor; thus encourage patients to avoid tobacco in any form (NHBPEP, 2003).

- Instruct primary caregiver to take blood pressure at same time each day and after patient has had a brief rest. Take blood pressure sitting or lying down; use same position and arm each time you take pressure.
- Instruct primary caregiver that, if the blood pressure is difficult to hear, it is probably caused by one of the following: cuff too loose, not large enough, or too narrow; stethoscope not over arterial pulse; cuff deflated too quickly or too slowly; or cuff not pumped high enough for systolic readings.

Pediatric

- Blood pressure measurement is not a routine part of assessment in children younger than 3 years.
- Blood pressure measurement can frighten children. Prepare child for squeezing feeling of inflated blood pressure cuff by comparing sensation to elastic band on finger or a tight hug on the arm.
- Obtain blood pressure in child before performing anxiety-producing tests or procedures.

- Korotkoff sounds are difficult to hear in children because of low frequency and amplitude. Using the bell of a pediatric stethoscope is often helpful.

Gerontologic

- Older adults, especially frail older adults, have lost upper-arm mass, requiring special attention to selection of blood pressure cuff size.
- Skin of older adults is more fragile and susceptible to cuff pressure when measurements are frequent. More frequent assessment of skin under cuff or rotation of measurement sites is recommended.
- Older adults have an increase in systolic pressure related to decreased vessel elasticity.
- Older adults often experience a fall in blood pressure after eating.

- Instruct older adults to change position slowly and wait after each change to avoid postural hypotension and prevent injuries.

Home Care

- Assess home noise level to determine the room that provides the quietest environment for assessing blood pressure.
- Instruct patient in the importance of an appropriate-size blood pressure cuff for home use.
- Assess family's financial ability to afford a sphygmomanometer for performing blood pressure evaluations on a regular basis. Recommend electronic devices or aneroid sphygmomanometers that have proven to be accurate according to standard testing and appropriate-size cuffs. Finger blood pressure monitors are inaccurate (NHBPEP, 2003).

PROCEDURAL GUIDELINE 5-2 Assessing Blood Pressure Electronically

NSO Vital Signs Module / Lesson 5

Many different styles of electronic blood pressure machines are available to determine blood pressure automatically (Fig. 5-12). Electronic machines rely on an electronic sensor to detect the vibrations caused by the rush of blood through an artery. Although electronic blood pressure machines are fast, you must consider their advantages and limitations. The devices are used when frequent assessment is required such as in critically ill or potentially unstable patients, during or after invasive procedures, or when therapies require frequent monitoring. Verify an assessment of an abnormal blood pressure by an electronic machine with a sphygmomanometer and stethoscope.

FIG 5-12 Noninvasive electronic blood pressure machine. (Photo courtesy Welch Allyn.)

Delegation and Collaboration

The skill of blood pressure measurement using an electronic blood pressure machine can be delegated to nursing assistive personnel (NAP) unless the patient is considered unstable (i.e., hypotensive). The nurse instructs the NAP by:

- Communicating the frequency and extremity for measurement.
- Reviewing how to select appropriate-size blood pressure cuff for designated extremity and appropriate cuff for the machine.
- Reviewing patient's usual blood pressure and report significant changes or abnormalities to the nurse.

Equipment

- Electronic blood pressure machine
- Source of electricity
- Blood pressure cuff of appropriate size as recommended by manufacturer
- Pen and vital sign flow sheet or electronic health record (EHR).

Procedural Steps

- 1 Determine appropriateness of using electronic blood pressure measurement. Patients with irregular heart rate, peripheral vascular disease, seizures, tremors, and shivering are not candidates for this device.
- 2 Determine best site for cuff placement.
- 3 Collect and bring appropriate equipment to patient's bedside.
- 4 Perform hand hygiene. Assist patient to comfortable position, either lying or sitting. Plug in and place device near patient, ensuring that connector hose between cuff and machine reaches.
- 5 Locate on/off switch and turn on machine to enable device to self-test computer systems.
- 6 Select appropriate cuff size for patient extremity (Table 5-4) and appropriate cuff for machine. Electronic blood pressure cuff and machine must be matched by manufacturer and are not interchangeable.
- 7 Expose extremity by removing constricting clothing to ensure proper cuff application. Do not place blood pressure cuff over clothing.
- 8 Prepare blood pressure cuff by manually squeezing all the air out of the cuff and connecting it to connector hose.

Continued

PROCEDURAL GUIDELINE 5-2 Assessing Blood Pressure Electronically—cont'd

TABLE 5-4 Proper Blood Pressure Cuff Size for Electronic Monitor*

Cuff Size	Limb Circumference (cm)
Small adult	17-25
Adult	23-33
Large adult	31-40
Thigh	38-50

*A 12- to 24-foot cord is required for adult blood pressure monitoring.

**STEP 9** Aligning blood pressure cuff arrow with brachial artery.

- 9 Wrap flattened cuff snugly around extremity, verifying that only one finger can fit between cuff and patient's skin. Make sure that "artery" arrow marked on outside of cuff is placed correctly (see illustration).
- 10 Verify that connector hose between cuff and machine is not kinked. Kinking prevents proper inflation and deflation of cuff.
- 11 Following manufacturer directions, set frequency control for automatic or manual and press the start button. The first blood pressure measurement pumps cuff to a peak pressure of about 180 mm Hg. After this pressure is reached, the machine begins a deflation sequence that determines the blood pressure. The first reading determines peak pressure inflation for additional measurements.
- 12 When deflation is complete, digital display provides most recent values and flash time in minutes that has elapsed since the measurement occurred (see illustration).

**STEP 12** Digital electronic blood pressure display. (Image courtesy Welch Allyn.)

Clinical Decision Point If unable to obtain blood pressure with electronic device, verify machine connections (e.g., plugged into working electrical outlet, hose-cuff connections tight, machine on, correct cuff). Repeat electronic blood pressure; if unable to obtain, use auscultatory technique (see Skill 5-5).

- 13 Set frequency of measurements and upper and lower alarm limits for systolic, diastolic, and mean blood pressure readings. Intervals between measurements can be set from 1 to 90 minutes. The nurse determines frequency and alarm limits based on patient's acceptable range of blood pressure, nursing judgment, and health care provider order.
- 14 Obtain additional readings at any time by pressing the start button. Pressing the cancel button immediately deflates the cuff.
- 15 If frequent measurements are required, the cuff may be left in place. Remove it at least every 2 hours to assess underlying skin integrity and if possible alternate measurement sites. Patients with abnormal bleeding tendencies are at risk for microvascular rupture from repeated inflations. When patient no longer requires frequent blood pressure monitoring, remove and clean cuff according to agency policy to reduce transmission of microorganisms.
- 16 Discuss findings with patient. Perform hand hygiene.
- 17 Compare electronic blood pressure readings with auscultatory measurements to verify accuracy of electronic device.
- 18 Record blood pressure and site assessed on vital sign flow sheet, EHR, or nurses' notes; record any signs or symptoms of blood pressure alterations in narrative form in EHR and nurses' notes; report abnormal findings to nurse in charge or health care provider.

PROCEDURAL GUIDELINE 5-3 Measuring Oxygen Saturation (Pulse Oximetry)

NSO Airway Management Module / Lesson 2

Pulse oximetry is the noninvasive measurement of arterial blood oxygen saturation, the percent to which hemoglobin is filled with oxygen. A pulse oximeter is a probe with a light-emitting diode (LED) connected by cable to an oximeter. The LED emits light wavelengths that are absorbed differently by the oxygenated and deoxygenated hemoglobin molecules. The more hemoglobin saturated by oxygen, the higher the oxygen saturation. Normally SpO₂ is greater than 95%.

The measurement of oxygen saturation is simple, painless, and has few of the risks associated with more invasive measurements of oxygen saturation such as arterial blood gas sampling. A vascular, pulsatile area is needed to detect the change in the transmitted light when making measurements with a digit or earlobe probe. Conditions that decrease arterial blood flow such as peripheral vascular disease, hypothermia, pharmacologic vasoconstrictors, hypotension, or peripheral edema affect accurate determination of oxygen saturation in these areas. For patients with decreased peripheral perfusion, you can apply a forehead sensor. Factors that affect light transmission such as outside light sources or patient motion also affect the measurement of oxygen saturation. Carbon monoxide in the blood, jaundice, and intravascular dyes can influence the light reflected from hemoglobin molecules.

In adults you can apply reusable and disposable oximeter probes to the earlobe, finger, toe, bridge of the nose, or forehead (Box 5-8). Pulse oximetry is indicated in patients who have an unstable oxygen status or are at risk for impaired gas exchange.

Delegation and Collaboration

The skill of oxygen saturation measurement can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP by:

- Communicating specific factors related to the patient that can falsely lower oxygen saturation.
- Informing NAP about appropriate sensor site and probe.
- Notifying frequency of oxygen saturation measurements for specific patient.
- Instructing to notify nurse immediately of any reading lower than SpO₂ of 95% or value for specific patient.
- Instructing to refrain from using pulse oximetry to obtain heart rate because oximeter will not detect an irregular pulse.

Equipment

- Oximeter
- Oximeter probe appropriate for patient and recommended by oximeter manufacturer
- Acetone or nail polish remover if needed
- Pen and vital sign flow sheet or electronic health record (EHR)

Procedural Steps

- 1 Determine need to measure patient's oxygen saturation. Assess risk factors for decreased oxygen saturation (e.g., acute or chronic compromised respiratory problems, change in oxygen therapy, chest wall injury, recovery from anesthesia).

BOX 5-8 Characteristics of Pulse Oximeter Sensor Probes and Sites

Digit Probe

- Easy to apply, conforms to various sizes

Earlobe Probe

- Clip-on smaller and lighter, although more positional than digit probe
- Yields strong correlation with oxygen saturation
- Greater accuracy at lower saturations suggested in research
- Good when uncontrollable or rhythmic movements (e.g., hand tremors during exercise) are present
- Vascular bed least affected by decreased blood flow

Forehead Sensor

- Greater accuracy during decreased perfusion suggested in research
- Reliable for patients on vasoactive medications
- Detects desaturation quicker than other sites
- Does not require a pulsatile vascular bed
- Good when uncontrollable or rhythmic movements (e.g., hand tremors) are present
- Requires headband to secure sensor

Disposable Sensor Pad

- Can be applied to a variety of sites: earlobe of adult, nose bridge, palm or sole of infant
- Less restrictive for continuous oxygen saturation monitoring
- Expensive
- Contains latex
- Possible that skin under adhesive becomes moist and harbors pathogens
- Available in variety of sizes; pad can be matched to infant weight

- 2 Assess for signs and symptoms of alterations in oxygen saturation (e.g., altered respiratory rate, depth, or rhythm; adventitious breath sounds [see Chapter 6]; cyanotic nails, lips, mucous membranes, or skin; restlessness; difficulty breathing).
- 3 Assess for factors that influence measurement of SpO₂ (e.g., oxygen therapy; respiratory therapy such as postural drainage and percussion; hemoglobin level; hypotension; temperature; nail polish [Cicek et al., 2010], and medications such as bronchodilators).
- 4 Review patient's medical record for health care provider's order or consult agency procedure manual for standard of care for measurement of SpO₂.
- 5 Determine previous baseline SpO₂ (if available) from patient's record.
- 6 Determine most appropriate patient-specific site (e.g., finger, earlobe, bridge of nose, forehead) for sensor probe placement by measuring capillary refill (see Chapter 6). If capillary refill is less than 2 seconds, select alternative site.
 - a Site must have adequate local circulation and be free of moisture.

Continued

PROCEDURAL GUIDELINE 5-3 Measuring Oxygen Saturation (Pulse Oximetry)—cont'd

- b A finger free of polish or acrylic nail is preferred (Cicek et al., 2011).
 - c If patient has tremors or is likely to move, use earlobe or forehead.
 - d If the patient finger is too large for the clip on probe, as may be the case with obesity or edema, the clip-on probe may not fit properly (Mininni, 2009); obtain a disposable (tape-on) probe.
- 7 Bring equipment to the bedside and perform hand hygiene.
 - 8 Position patient comfortably. Instruct him or her to breathe normally.
 - 9 Attach sensor to monitoring site (see illustration). If using finger, remove fingernail polish from digit with acetone or polish remover. Instruct patient that clip-on probe will feel like a clothespin on the finger but will not hurt.

STEP 9 Oximeter sensor attached to finger.

Clinical Decision Point Do not attach probe to finger, ear, or bridge of nose if area is edematous or skin integrity is compromised. Do not use earlobe and bridge of nose sensors for infants and toddlers because of skin fragility. Do not attach sensor to fingers that are hypothermic. Select ear or bridge of nose if adult patient has a history of peripheral vascular disease. Do not use disposable adhesive sensors if patient has a latex allergy. Do not place sensor on same extremity as electronic blood pressure cuff because blood flow to finger will be temporarily interrupted when cuff inflates and cause inaccurate reading that can trigger alarms (Skirton et al., 2011).

- 10 Once sensor is in place, turn on oximeter by activating power. Observe pulse waveform/intensity display and audible beep. Correlate oximeter pulse rate with patient's radial pulse.
- 11 Leave sensor in place 10 to 30 seconds or until oximeter readout reaches constant value and pulse display reaches full strength during each cardiac cycle. Inform patient that oximeter alarm will sound if sensor falls off or patient moves it. Read SpO₂ on digital display.
- 12 If you plan to monitor oxygen saturation continuously, verify SpO₂ alarm limits preset by manufacturer at a low of 85% and a high of 100%. Determine limits for SpO₂ and pulse rate as indicated by patient's condition. Verify that alarms are on. Assess skin integrity under sensor probe every 2 hours; relocate sensor at least every 4 hours and more frequently if skin integrity is altered or tissue perfusion compromised.
- 13 If you plan intermittent or spot-checking of SpO₂, remove probe and turn oximeter power off. Cleanse sensor and store sensor in appropriate location.
- 14 Discuss findings with patient. Perform hand hygiene.
- 15 Compare SpO₂ with patient's previous baseline and acceptable SpO₂.
- 16 Record SpO₂ on vital sign flow sheet, EHR, or nurses' notes; indicate type and amount of oxygen therapy used by patient during assessment; record any signs or symptoms of alterations in oxygen saturation in narrative form in nurses' notes and EHR; report abnormal findings to nurse in charge or health care provider.

Critical Thinking Exercises

You are assigned to Mr. Augsten, a 56-year-old university professor. He is admitted from the trauma unit following a motorcycle-automobile accident. Mr. Augsten has a fractured left humerus and pelvis. Although he was wearing a helmet, he suffered a concussion. When doing your admissions assessment you note a cast on his left arm and an intravenous (IV) line in his right antecubital fossa. He received IV narcotics in the emergency department and is very sleepy. He awakens only to touch.

- 1 Which admission vital signs can you assign to the nursing assistive personnel (NAP)? Which directions do you provide the NAP regarding obtaining routine vital signs for this patient?
- 2 The NAP reports that the blood pressure for Mr. Augsten is 94/60 mm Hg. You note that the emergency department nurse recorded a blood pressure of 140/86 mm Hg. Which interventions should you consider at this time? What might explain the differences in blood pressure values?
- 3 The nurse directed the NAP to report a respiratory rate of 16 or less. The NAP documents a respiratory rate of 12 in the vital sign flow sheet but does not report the rate to you until you inquire. She states

that Mr. Augsten was speaking with her so it was not important to bother the nurse. What is your response to the NAP? Explain the significance of the respiratory rate.

- 4 You direct the NAP to repeat Mr. Augsten's blood pressure and respiratory rate in 30 minutes. In a half hour the NAP reports a blood pressure in the right arm of 160/100 and a respiratory rate of 20. She also notes that Mr. Augsten was sleeping quietly. What is your response?

REVIEW QUESTIONS

- 1 The nurse is assessing the axillary temperature of a confused patient with a fever. Which actions by the nurse will best help provide an accurate measurement? (Select all that apply.)
 - 1 Drying the axilla before placing the thermometer probe
 - 2 Holding the thermometer probe in place
 - 3 Placing the patient in a supine position
 - 4 Checking that the patient has not had anything to eat or drink recently

- 2 After checking the tympanic temperature two consecutive times in an 82-year-old patient, the nurse finds the reading to be several degrees lower than expected. What is the most appropriate nursing action at this time?
- 1 Obtain a different thermometer
 - 2 Observe for the presence of cerumen
 - 3 Document the temperature assessed
 - 4 Record the average between the two readings
- 3 A patient with abdominal ascites is having his respiratory rate assessed. Which is the best action to obtain the respiratory assessment for this patient?
- 1 The patient is assessed while flat, supine, and quiet.
 - 2 The patient's head is elevated based on his desire.
 - 3 The nurse tells the patient when to begin breathing for the assessment.
 - 4 The nurse holds the patient's wrist while counting respirations.
- 4 The nurse is preparing to assess a patient's blood pressure. Which statement by the nurse will help promote an accurate reading?
- 1 "Just relax while I put the cuff on your arm."
 - 2 "This is painless and will take just a minute."
 - 3 "The cuff can go over your thin silk sleeve."
 - 4 "Please uncross your legs while I do this."
- 5 Place in correct order the following sequencing steps for two-step blood pressure measurement using the brachial artery.
- a Relocate brachial artery and inflate blood pressure cuff.
 - b Palpate brachial artery.
 - c Obtain proper sized cuff.
 - d Apply deflated cuff above brachial artery.
 - e Apply bell of stethoscope over artery.
 - f Release pressure in cuff.
 - g Record first and last sounds.
- 1 c, d, b, e, a, f, g,
 - 2 c, b, a, d, e, g, f,
 - 3 c, b, d, a, e, f, g,
 - 4 b, c, d, a, e, g, f
- 6 Electronic blood pressure monitoring cannot be used on certain patients. Which of these patients can have an electronic blood pressure monitor?
- 1 The patient with constant extremity tremors
 - 2 The patient with diabetes mellitus
 - 3 The feverish patient who is shivering
 - 4 The patient with an irregular heart rate
- 7 Mr. Marquis is 87 years old and is admitted to your medical unit for pneumonia of 4 days' duration. His temperature is 37.2° C (99° F). The NAP questions why his temperature is so low for a person with an active infection. Your best response is:
- 1 His body has compensated for the infection by increasing heart rate.
 - 2 He probably had an antipyretic in the assisted-living facility where he lived.
 - 3 He took a cool shower before he was admitted.
 - 4 The baseline temperature of older adults is lower because of loss of subcutaneous fat.
- 8 You are checking the vital signs of a 75-year-old patient. The radial pulse is irregular, and about every fourth beat is different. The patient offers no complaints. What is your next action?
- 1 Report the findings to the health care provider immediately.
 - 2 Obtain a blood pressure.
 - 3 Obtain an apical heart rate.
 - 4 Notify the nurse in charge.
- 9 Which of the following nursing interventions is/are correct when determining a pulse deficit? (Select all that apply.)
- 1 Counting for 30 seconds and multiplying by 2
 - 2 Starting to count after the peripheral first beat is heard
 - 3 Using a peripheral artery and apical pulse
 - 4 Counting simultaneously with another health care provider
- 10 Which of the following blood pressures would classify as prehypertension? (Select all that apply.)
- 1 118/78
 - 2 126/82
 - 3 130/80
 - 4 132/94

KEY TERMS

Atrophy	Costovertebral angle (CVA)	Erythema	Orthostatic hypotension
Auscultation	tenderness	Friction rub	Pallor
Bruit	Crackles	Inspection	Palpation
Cardiomegaly	Cyanosis	Intercostal space	Percussion
Cerumen	Dorsum	Nares	
Conjunctiva	Edema	Olfaction	

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss the purposes of physical assessment.
- Describe the techniques used with each assessment skill.
- Describe proper positioning for a patient during each phase of the examination.
- Describe how to conduct a physical examination on patients from diverse cultures.
- List techniques to promote a patient's physical and psychological comfort during an examination.
- Make environmental preparations before an assessment.
- Identify data to collect from the nursing history before an examination.
- Discuss normal physical findings for patients across the life span.
- Discuss ways to incorporate health promotion and health teaching into an assessment.
- Identify self-screening assessments commonly performed by patients.
- Use physical assessment techniques and skills during routine nursing care.
- Document assessment findings on appropriate forms.
- Communicate abnormal findings to appropriate personnel.

Nurses perform systematic physical assessments on a regular basis in nearly every health care setting. In acute care settings you will perform more comprehensive assessments when patients are admitted to agencies and brief physical assessments at the beginning of each shift to identify changes in a patient's status for comparison with the previous assessment. A routine physical assessment takes 10 to 15 minutes

and reveals information that supplements a patient's database. In nursing homes and home care settings, you will complete similar assessments weekly, monthly, or more frequently when a patient's health status changes. Ongoing, objective, and comprehensive assessments promote continuity in health care.

Nurses are often the first to detect changes in patients' conditions. For this reason the ability to think critically and

interpret patient behaviors and physiologic changes are essential. The skills of physical assessment are powerful tools for detecting both subtle and obvious changes in a patient's health.

EVIDENCE-BASED PRACTICE

The American Cancer Society estimates that 68,130 cases of melanoma were diagnosed in 2010. The highly malignant cancer occurs slightly more often in men than women (ACS, 2011a). There are several risk factors for melanoma, including fair skin that freckles or burns easily, red or blond hair, blue or green eyes, long term treatment with ultraviolet light, and a first-degree relative having melanoma.

The ACS (2011a) recommends that people engage in regular skin self-examination (SSE). Women who have positive body image and older women are more likely to perform skin SSE (Chait et al., 2009). According to the U.S. Preventive Services Task Force, evidence showing that there is a benefit to whole body screening as a way to effectively reduce morbidity and mortality from melanoma is lacking (Wolff, 2009). The National Guideline Clearinghouse suggests that full-body screening may benefit people who have a high risk (Marret et al., 2007). Further study is needed to know whether the accuracy and cost of skin cancer screening warrant recommending it for the general public.

- Instruct patients to conduct a complete monthly SSE, noting moles, blemishes, and birthmarks. Instruct to inspect all skin surfaces.
- Perform the examination after a bath or shower, including a head to toe check.
- Use a well-lit room and mirrors for the exam. Have a partner help, increasing the chance that the self-examination is thorough.
- Instruct patient to report to their health care provider any change in size or color of moles, or skin lesions or a sore that does not heal, start to bleed, ooze, or feel different (swollen, hard, lumpy, itchy, or tender to the touch).
- Use supportive communication (Glantz et al., 2010, Mujumdar et al., 2009) to inform patients of ways to prevent skin cancer by avoiding overexposure to the sun.
- Use sunscreen and lip balms (needed most between the hours of 10 AM and 4 PM).
- Use sun protection of 30 SPF or higher and use on hazy days. Use at least one ounce to cover the average adult. Reapply every 2 hours.
- Wear a hat with a 2- to 3-inch brim. Avoid straw hats that do not offer much protection.
- Wear a shirt. Dark fabric protects more effectively than light fabric, and tightly woven fabric is preferred.
- Dry clothes protect more than wet clothes.
- Use wraparound sunglasses. These should have labels that indicate at least 99% UV protection.
- Do not use tanning beds and sunlamps.
- Seek shade, especially in the middle of the day. Test the strength of the sun. If your shadow is shorter than you, the rays of the sun are the strongest.

PATIENT-CENTERED CARE

An admission assessment involves a detailed review of a patient's condition and includes a nursing history and behavioral and physical examination. The health history comprises an interview with patients to gather subjective data about their current state of health and any presenting conditions. Conduct a patient-centered

TABLE 6-1 Development of Individualized Nursing Diagnoses

Assessment Method	Findings	Patterns	Nursing Diagnosis
Inspection of skin	Skin along sacral area is intact. There is a 3-cm area of redness around coccyx; skin blanches on palpation. No skin lesions are observed.	There is pressure area around coccyx.	Risk for impaired skin integrity
Palpation of skin	Skin is moist from diaphoresis. There is tenderness to palpation at sacral area. Skin turgor is elastic.	Skin moisture promotes maceration.	
Historical data	Patient suffered fractured left leg. Patient is immobilized because of left leg traction.	Continued pressure is exerted over sacrum.	

interview to learn about problems from the patient's perspective. Have patients explain their symptoms by allowing them to offer details. Use open-ended questions and be sure the patients have exhausted their descriptions. For example, as a patient is describing a symptom, you can say "go on" to encourage more information sharing.

A physical assessment includes a head-to-toe review of each body system, which offers objective information about a patient. A patient's condition and response affect the extent of an examination. After gathering data, you group significant findings into patterns of data (clusters) that reveal actual or potential nursing diagnoses (Table 6-1). Each abnormal finding directs you to gather additional data. Initial assessment and examination provide a baseline for a patient's functional status and serve as a comparison for future assessment findings. In addition, the information is useful in selecting the best nursing measures to manage a patient's health problems.

The physical assessment is an ideal time to offer individualized patient teaching and to encourage promotion of health practices such as breast (Box 6-1) and genital (Box 6-2) self-examination. A patient should understand any symptoms he or she presents with as well as symptoms to look for in detecting problems. For example, educate patients about the American Cancer Society (ACS) (2012a and 2012b) guidelines for early detection of breast and genital cancers. Integrate health promotion and education into physical assessment activities. There are "teachable moments" when you can share findings and educate patients about health promotion.

Respect patients' cultural diversity and beliefs when completing a physical assessment. It is important to remember that cultural differences influence a patient's behavior. Consider the patient's health beliefs, use of alternative therapies, nutritional habits, relationships with family, and comfort with your physical closeness during the history and examination. Be culturally aware and avoid stereotyping on the basis of culture, race, sexual preference, or age. There is a difference between cultural and physical characteristics.

BOX 6-1 Breast Self-Examination

According to the [American Cancer Society \(ACS\) \(2012\)](#), screening refers to tests and exams used to find a disease, like cancer, in people who do not have any symptoms. Breast self-examination (BSE) is optional for women starting in their 20s ([ACS, 2012](#)). Women should be told about the benefits and limitations of BSE and report any breast changes to their health professional right away.

Research has shown that BSE plays a small role in finding breast cancer compared with finding a breast lump by chance or simply being aware of what is normal for each woman. Some women feel very comfortable doing BSE regularly (usually monthly after their period), which involves a systematic step-by-step approach to examining the look and feel of their breasts. Other women are more comfortable simply looking and feeling their breasts in a less systematic approach, such as while showering or getting dressed or doing an occasional thorough exam ([ACS, 2012](#)).

A regular breast self-examination (BSE) should be done monthly so a woman becomes familiar with the usual appearance and feel of her breast. Familiarity makes it easier to notice any changes in the breast from 1 month to another. Early discovery of a change from what is “normal” is the main idea behind BSE.

For women who menstruate, the best time to do BSE is 2 or 3 days after a period ends, when the breasts are least likely to be tender or swollen. For women who no longer menstruate, pick a day such as the first day of the month to remind yourself to do BSE.

Procedure

- 1 Stand before a mirror. Inspect both breasts for anything unusual such as skin redness; any discharge from the nipples; puckering, dimpling, or scaling of the skin.

- 2 Watching closely in the mirror, clasp hands behind your head and bring elbows forward. Note how chest muscles tighten.

- 3 Next press hands firmly on hips and bow slightly toward the mirror as you pull your shoulders and elbows forward.

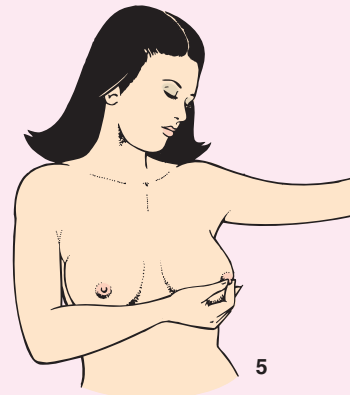

The next part of the examination may be done in the shower. Gliding fingers over soapy skin makes it easier to appreciate the texture underneath.

- 4 Raise your left arm. Use three or four fingers of your right hand to explore your left breast firmly, carefully, and thoroughly. Beginning at the outer edge, press the flat part of your fingers in small circles, moving the circles slowly around the breast. Gradually work toward the nipple. Be sure to cover the entire breast. Pay special attention to the area between the breast and the armpit itself. Feel for any unusual lump or mass under the skin.

- 5 Gently squeeze the nipple and look for discharge. Repeat the examination on your right breast.

BOX 6-1 Breast Self-Examination—cont'd

- 6 Lie flat on your back, left arm over your head, and a pillow or folded towel under your left shoulder. This position flattens the breast and makes it easier to examine. Use the same circular motion described earlier. Repeat on your right breast.

Call your health care provider if you find a lump or other abnormality.

6

From American Cancer Society: Learn about cancer, American Cancer Society recommendations for early breast cancer detection, <http://www.cancer.org/Cancer/BreastCancer/DetailedGuide/breast-cancer-detection>, accessed May 19, 2012; Seidel HM et al: *Mosby's guide to physical examination*, ed 7, St Louis, 2011, Mosby.

BSE, Breast self-examination.

BOX 6-2 Genital Self-Examination

All men 15 years and older should perform this examination monthly. Perform the examination during or after a warm bath or shower when the scrotal sac is relaxed. Call your health care provider if you find a lump or any other abnormality.

Penile Examination

- 1 Stand naked in front of a mirror and hold the penis in your hand and examine the head. Pull back the foreskin if uncircumcised.
- 2 Inspect and palpate the entire head of the penis in a clockwise motion, looking carefully for any bumps, sores, or blisters.
- 3 Look for any bumpy warts.
- 4 Look at the opening at the end of the penis for discharge.
- 5 Look along the entire shaft of the penis for the same signs.
- 6 Separate pubic hair at the base of the penis and carefully examine the skin underneath.

**Testicular Examination**

- 1 Look for swelling or lumps in the skin of the scrotum while looking in the mirror.
- 2 Use both hands, placing the index and middle fingers under the testicles and the thumb on top.
- 3 Gently roll the testicle, feeling for hard lumps; smooth, rounded bumps; or thickening.
- 4 Find the epididymis (feels like a small “bump” on the upper or middle outer side of the testis).
- 5 Feel for small, pea-size lumps on the front and side of the testicle. The lumps are usually painless and are abnormal.

From Seidel HM et al: *Mosby's guide to physical examination*, ed 7, St Louis, 2011, Mosby.

Your recognition of cultural diversity helps to respect a patient's uniqueness and provide a higher-quality care. Improved patient outcomes can result from recognition and respect for cultural diversity (Cherry and Stuart, 2011).

- Learn to use open-ended questions to identify sociocultural and religious values that influence health/illness beliefs and practices.

- Communicate respect through proper use of distance, attention, eye contact, tone, and loudness of voice.
- Use a professional interpreter familiar with a patient's culture and language.
- Allow time for responses.
- Observe verbal and nonverbal language and communication patterns of patients.

- Work with the established family hierarchy as identified by a patient.
- Learn words that are offensive to the culture. For example, some Southeast Asian groups do not use words such as vagina, penis, and breasts because they find them offensive.
- Obtain information about health risks common to a cultural group. Certain diseases are prevalent in some groups. For example, malaria is prevalent among Africans and Asians, and parasitic worms are prevalent among migrants from the Third World.
- Integrate knowledge of cultural differences in growth and development, physical characteristics, and norms in interpreting assessment data.
- Biologic/racial characteristics influence physical traits such as skin and mucosal color, hair texture/color, and height and weight.
- Develop awareness of healing modalities such as cupping, coining, and pinching used by some cultures, especially Asians, which may leave the skin discolored or scratched.
- It is not unusual for patients from ethnocultural groups to ask for a family member to be present during an examination to interpret for them or provide moral support.
- Use gender-congruent health care providers to perform a physical assessment.
- Ask permission before you touch a patient.
- Drape a patient thoroughly and use the bedside screen or curtains.

Safety Guidelines

- 1 Prioritize an assessment based on a patient's presenting signs and symptoms or health care needs. For example, when a patient develops sudden shortness of breath, first assess the lungs and thorax. If a patient is acutely ill, you may choose to assess only the involved body systems. Use judgment to ensure that an examination is relevant and inclusive.
- 2 Organize an examination. Compare both sides of the body for symmetry. If a patient becomes fatigued, offer rest periods. Perform painful or intrusive procedures near the end of an examination.
- 3 Use a head-to-toe approach following the sequence of inspection, palpation, percussion, and auscultation (except during abdominal assessment). This sequence facilitates an effective assessment.
- 4 Encourage a patient's active participation. Patients usually know about their physical condition. Often a patient can let you know when certain findings are normal or when there have been changes.
- 5 Always identify a patient using at least two identifiers other than the room number. For example, use the patient's name and date of birth, comparing them with the identification band or medical record (*The Joint Commission [TJC], 2012*). In long-term care settings, identification bands are not used; however, pictures are available for identification. **CAUTION:** Patients with sensory impairments or altered level of consciousness (LOC) may answer to a name other than their own.
- 6 Follow standard precautions for infection control. During an assessment you may have contact with body fluids and discharge. Always wear clean gloves when there are breaks in the skin, lesions, or wounds or when having contact with mucous membranes. In some circumstances you will need to wear a gown.
- 7 Consider the possibility of latex allergy. The incidence of serious allergic reaction to latex has increased dramatically (*Seidel et al., 2011*).
- 8 Record quick notes to facilitate accurate documentation. Inform a patient that you will be recording the data.
- 9 Record a summary of the assessment using appropriate medical terminology and in the sequence that findings are gathered. Use commonly accepted medical abbreviations to keep notes concise. Be thorough and descriptive, especially for abnormal findings.

ASSESSMENT TECHNIQUES

Use assessment techniques during each patient contact, including activities such as bathing, administering medications, other therapies, or while talking with a patient. This practice will help you learn to become more observant and better able to identify changes quickly.

Inspection, palpation, percussion, auscultation, and olfaction are the five basic assessment techniques. Each skill allows you to collect a broad range of physical data about patients. Nurses need experience to recognize normal variations among patients and ranges of normal for an individual. Remember, cultural diversity is one factor that influences both normal variations and potential alterations that you may find during an assessment. It is important to take the time needed to carefully assess each body part. Hurrying causes you to overlook significant signs and make incorrect conclusions about a patient's condition.

Inspection is the visual examination of body parts or areas. An experienced nurse learns to make multiple observations almost simultaneously while becoming very perceptive of any abnormalities. The secret is to always pay attention to patients. Watch all movements and look carefully at the body part that you are inspecting. It is important to recognize normal physical characteristics of patients of all ages before trying to distinguish abnormal findings.

Inspection requires good lighting and full exposure of body parts. Inspect each area for size, shape, color, symmetry, position, and the presence of abnormalities. If possible inspect each area compared with the same area on the opposite side of the body. When necessary, use additional light such as a penlight to inspect body cavities such as the mouth and throat. *Do not hurry. Pay attention to detail.* Verify and clarify all abnormalities with subjective patient data. In other words, ask the patient for further information about each abnormality or change such as whether the change is recent.

Palpation uses the sense of touch. Through palpation the hands make delicate and sensitive measurements of specific physical signs. Palpation detects resistance, resilience, roughness, texture, temperature, and mobility. You often use palpation with or after visual inspection. You often use different parts of the hand to detect specific characteristics. For example, the dorsum (back) of the hand is sensitive to temperature variations. The pads of the fingertips detect subtle changes in texture, shape, size, consistency, and pulsation of body parts. The palm of the hand is especially sensitive to vibration. You measure position, consistency, and turgor by lightly grasping a body part with the fingertips.

Help a patient relax and assume a comfortable position because muscle tension during palpation impairs the ability to palpate correctly. Asking a patient to take slow, deep breaths enhances muscle relaxation. Palpate tender areas last because they could cause a patient to become tense and impede the assessment. Ask a patient to point out areas that are more sensitive and note any nonverbal

signs of discomfort. Patients appreciate clean, warm hands; short fingernails; and a gentle approach. Palpation is either light or deep and is controlled by the amount of pressure applied with the fingers or hand. Light palpation precedes deep palpation. Consider a patient's condition, the area being palpated, and the reason for using palpation. For example, when a patient is admitted to the emergency department after an automobile accident, consider the factors surrounding the patient's injury and inspect the chest wall carefully before performing any palpation around the area of the ribs.

For light palpation apply pressure slowly, gently, and deliberately, depressing approximately 1 cm (1/2 inch) (Fig. 6-1, A). Check tender areas further, using light intermittent pressure. After light palpation you may use deeper palpation to examine the condition of organs (Fig. 6-1, B). Depress the area that you are examining by approximately 2 cm (1 inch). Caution is the rule. Bimanual palpation involves one hand placed over the other while applying pressure. The upper hand exerts downward pressure as the other hand feels the subtle characteristics of underlying organs and masses. Seek the assistance of a qualified instructor before attempting deep palpation.

Percussion involves tapping the body with the fingertips to vibrate underlying tissues and organs. The vibration travels through body tissues, and the character of the resulting sound reflects the

density of underlying tissue. The denser the tissue, the quieter the sound is. By knowing various densities of organs and body parts, you learn how to locate organs or masses, map their edges, and determine their size. An abnormal sound suggests a mass or substance such as air or fluid in a body cavity. The skill of percussion is used more often by advanced practice nurses (APNs) than by nurses in daily practice at the bedside.

The most commonly used percussion technique is the indirect technique. You perform the indirect technique by placing the middle finger of your nondominant hand firmly against the body surface. With palm and fingers remaining off the skin, the tip of the middle finger of the dominant hand strikes the base of the distal joint of the finger (Fig. 6-2). Use a quick, sharp stroke, keeping the forearm stationary. Relax the wrist to deliver the proper blow. Once the finger has struck, the wrist snaps back. If the blow is not sharp, if the hand is held loosely, or if the palm rests on the body surface, the sound is softened; and you will not detect the presence of underlying structures. A light, quick blow produces the clearest sounds. Table 6-2 describes the five different percussion sounds.

Auscultation is listening with a stethoscope to sounds produced by the body. To auscultate correctly, listen in a quiet environment for both the presence of sound and its characteristics. To be successful in auscultation, you must first recognize normal sounds from each body structure, including the passage of blood through an

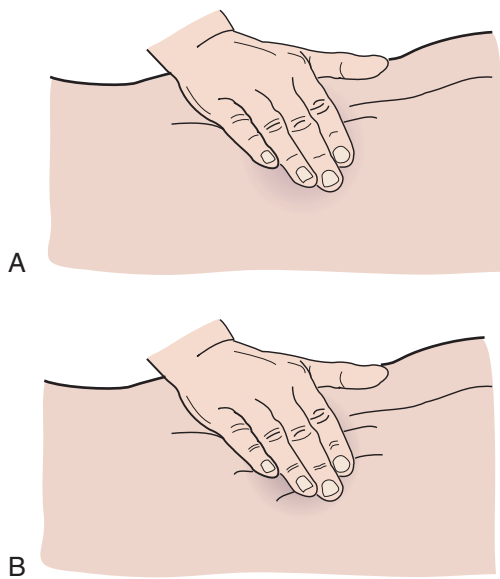

FIG 6-1 A, During light palpation gentle pressure against underlying skin and tissues can be used to detect areas of irregularity and tenderness. B, During deep palpation depress tissue to assess condition of underlying organs.

FIG 6-2 Percussion of abdomen. (From Seidel HM et al: Mosby's guide to physical examination, ed 6, St Louis, 2006, Mosby.)

Sound	Intensity	Pitch	Duration	Quality	Common Location
Tympany	Loud	High	Moderate	Drumlike	Gastric air bubble, puffed-out cheek
Resonant	Loud	Low	Long	Hollow	Healthy lung
Hyperresonant	Very loud	Low	Longer than resonance	Booming	Emphysematous lung
Dull	Soft to moderate	Moderate to High	Moderate	Thudlike	Over liver
Flat	Soft	High	Short	Very dull	Over muscle

artery, heart sounds, and movement of air through the lungs. These sounds vary according to the location in which they can be most easily heard. Likewise you become familiar with areas that normally do not emit sounds. Practice listening to many normal sounds so you can recognize abnormal sounds when they arise.

To auscultate you need good hearing acuity, a good stethoscope, and knowledge of how to use the stethoscope properly (Box 6-3).

BOX 6-3 Using a Stethoscope

- 1 Place earpieces in both ears with tips of earpieces turned toward the face. *Lightly* blow against the diaphragm (flat side of chest piece). Now place the earpieces in both ears with the tips turned toward the back of the head and again blow against the diaphragm. Compare comfort in the ears and amplification of sounds with earpieces in both directions. Earpieces pointing toward the face should fit snugly and comfortably.
- 2 If the stethoscope has both a diaphragm (flat side) and a bell (bowl shaped with a rubber ring), put earpieces in ears and lightly blow against the diaphragm. The chest piece can be turned to allow sound to be carried through either side (bell or diaphragm) of the chest piece. If sound is faint, lightly blow into the bell. Then turn the chest piece and blow again against both the diaphragm and the bell. The diaphragm is used for higher-pitched heart sounds, bowel sounds, and lung sounds. The bell is used for lower-pitched heart sounds and vascular sounds.
- 3 With earpieces in place and using the diaphragm, move the diaphragm lightly over the hair on your arm. The bristling sound mimics a sound heard in the lungs. When listening for significant sounds, hold the diaphragm still and firmly make a tight seal against the skin to eliminate extraneous sounds.
- 4 Place the diaphragm over the front of your chest directly on your skin and listen to your own breathing, comparing the bell and the diaphragm. Repeat the process while listening to your own heartbeat. Ask someone to speak in a conversational tone and note how the speech detracts from hearing clearly. When using a stethoscope, both you and the patient should remain quiet.
- 5 With the earpieces in your ears, gently tap the tubing. Note that it generates extraneous sounds. When listening to a patient, maintain a position that allows the tubing to extend straight and hang free. Movement may allow it to rub or bump objects, creating extraneous sounds. Kinked tubing muffles sounds.
- 6 Care of a stethoscope: Remove earpieces regularly and clean or remove cerumen (earwax). Keep the bell and diaphragm free of dust, lint, and body oils. Keep the tubing away from your body oils. Avoid draping the stethoscope around the neck next to the skin. To clean, wipe the entire stethoscope (e.g., diaphragm, tubing) with alcohol or soapy water. Be sure to dry all parts thoroughly. Follow manufacturer recommendations.
- 7 Infection control: Harmful bacteria, even antibiotic-resistant microorganisms, can be transferred from patient to patient when using portable equipment such as stethoscopes (Uneke et al., 2010). Follow agency infection control guidelines, especially contact precautions, to decrease this risk. Clean a stethoscope (diaphragm/bell) with a disinfectant before reuse on another patient. Using a disinfectant such as isopropyl alcohol (with or without chlorhexidine), benzalkonium, and sodium hypochlorite is effective in reducing the number of bacterial colonies. Earpieces of stethoscopes are also sources of transferable bacteria when you inadvertently touch your ears and then care for a patient. Potential pathogens could contaminate earpieces. Using hand hygiene before and after patient contact decreases the risk of transmitting microorganisms from your ear to your patient (Uneke et al., 2010).

Nurses with hearing disorders may purchase stethoscopes with greater sound amplification and may need to ask colleagues to verify some findings through auscultation. It is essential to place the stethoscope directly on a patient's skin because clothing obscures and changes sound. Through auscultation the nurse notes that there are four characteristics of sound:

- **Frequency:** Number of sound wave cycles generated per second by a vibrating object. The higher the frequency, the higher the pitch of a sound and vice versa.
- **Loudness:** Amplitude of a sound wave. Auscultated sounds are described as loud or soft.
- **Quality:** Sounds of similar frequency and loudness from different sources. Terms such as *blowing* or *gurgling* describe quality of sound.
- **Duration:** Length of time that sound vibrations last. Duration of sound is short, medium, or long. Layers of soft tissue dampen the duration of sounds from deep internal organs.

A nurse cannot be successful at auscultation without knowing how to use a stethoscope properly. Chapter 5 describes the parts of the acoustic stethoscope and use of the bell and diaphragm.

Olfaction uses the sense of smell to detect abnormalities that go unrecognized by any other means. Some alterations in body function and certain bacteria create characteristic odors (Table 6-3).

TABLE 6-3 Assessment of Characteristic Odors

Odor	Site or Source	Potential Causes
Alcohol	Oral cavity	Ingestion of alcohol; diabetes mellitus
Ammonia	Urine	Urinary tract infection, renal failure
Body odor	Skin, particularly in areas where body parts rub together (e.g., under arms, beneath breasts, perineal area)	Poor hygiene, excess perspiration (hyperhidrosis), foul-smelling perspiration (bromhidrosis)
	Wound site	Wound abscess; infection
	Vomitus	Abdominal irritation, contaminated food
Feces	Rectal area	Bowel obstruction
	Vomitus/oral cavity (fecal odor)	Fecal incontinence; fistula
Fetid, sweet odor	Tracheostomy or mucus secretions	Infection of bronchial tree (<i>Pseudomonas</i> bacteria)
Foul-smelling stools in infants	Stool	Malabsorption syndrome
Halitosis	Oral cavity	Poor dental or oral hygiene, gum disease; sinus infection
Musty odor	Casted body part	Infection inside cast
Stale urine	Skin	Uremic acidosis
Sweet, fruity ketones	Oral cavity	Diabetic acidosis
Sweet, heavy, thick odor	Draining wound	<i>Pseudomonas</i> (bacterial) infection

PREPARATION FOR ASSESSMENT

Preparation of the environment, equipment, and patient facilitates a smooth assessment. Provide patients privacy to promote their comfort and the efficiency of an examination. In a health care agency, close the door and pull privacy curtains. In the home examine the patient in the bedroom. A comfortable environment includes a warm, comfortable temperature; a loose-fitting gown or pajamas for a patient; adequate direct lighting; control of outside noises; and precautions to prevent interruptions by visitors or other health care personnel. If possible, place the bed or examination table at waist level so you can assess a patient easily. During an examination you must protect a patient from falls and injury and return the bed to a safe height at the completion of the assessment (TJC, 2012).

Preparing the Patient

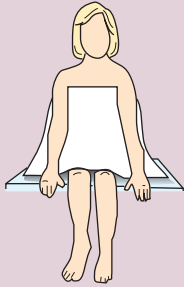

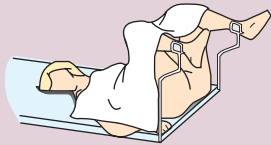

Prepare patients both physically and psychologically for accurate assessments. A tense, anxious patient may have difficulty understanding, following directions, or cooperating with your instructions. To prepare a patient:

- 1 Provide comfort by allowing the opportunity to empty the bowel or bladder (a good time to collect needed specimens).
- 2 Provide privacy.
- 3 Minimize a patient's anxiety and fear by conveying an open, receptive, and professional approach. Using simple

terms, thoroughly explain what will be done, what the patient should expect to feel, and how he or she can cooperate. Even if a patient appears unresponsive, it is still important to explain your actions.

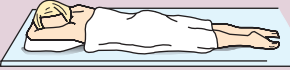

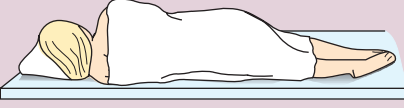

- 4 Provide access to body parts while draping areas that are not being examined.
- 5 Reduce distractions. Turn down volume or turn off radio or television.
- 6 Eliminate drafts, control room temperature, and provide warm blankets.
- 7 Help patients assume positions during assessments so body parts are accessible and patients stay comfortable (Table 6-4). A patient's ability to assume positions depends on physical strength and limitations. Some positions are uncomfortable or embarrassing; keep a patient in position no longer than is necessary.
- 8 Pace assessment according to an individual's physical and emotional tolerance.
- 9 Use a relaxed tone of voice and facial expressions to put a patient at ease.
- 10 Encourage a patient to ask questions and report discomfort felt during the examination.
- 11 Have a third person of patient's gender in the room during assessment of genitalia. This prevents a patient from accusing you of behaving in an unethical manner.
- 12 At conclusion of an assessment, ask the patient if there are any concerns or questions.

TABLE 6-4 Positions for Physical Assessment

Position	Areas Assessed	Rationale	Limitations
	Head and neck, back, posterior thorax and lungs, anterior thorax and lungs, breasts, axillae, heart, vital signs, upper extremities	Sitting upright provides full expansion of lungs and better visualization of symmetry of upper body parts.	Physically weakened or developmentally disabled patient is sometimes unable to sit. Use supine position with head of bed elevated instead.
	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen, extremities, pulses	This is most normally relaxed position. It provides easy access to pulse sites.	If patient becomes short of breath easily, raise head of bed.
	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen	Position is for abdominal assessment because it promotes relaxation of abdominal muscles.	Patients with painful disorders are more comfortable with knees flexed.
	Female genitalia and genital tract	This position provides maximal exposure of genitalia and facilitates insertion of vaginal speculum.	Lithotomy position is embarrassing and uncomfortable; thus examiner minimizes time that patient spends in it. Keep patient well draped. Patients with arthritis or other joint deformities may be unable to tolerate the position.

Continued

TABLE 6-4 Positions for Physical Assessment—cont'd

Position	Areas Assessed	Rationale	Limitations
Sims' 	Rectum and vagina	Flexion of hip and knee improves exposure of rectal and genitourinary areas.	Joint deformities hinder patient's ability to bend hip and knee.
Prone 	Musculoskeletal system	This position is for assessing extension of hip joint, skin, and buttocks.	Patients with respiratory difficulties do not tolerate this position well.
Lateral recumbent 	Heart	This position aids in detecting murmurs.	Patients with respiratory difficulties do not tolerate this position well.
Knee-chest 	Rectum	This position provides maximal exposure of rectal area.	This position is embarrassing and uncomfortable. Patients with arthritis or other joint deformities may be unable to assume it.

PHYSICAL ASSESSMENT OF VARIOUS AGE-GROUPS

Children and Adolescents

- 1 Routine assessments of children focus on health promotion and illness prevention, particularly for care of well children with competent parenting and no serious health problems (Hockenberry and Wilson, 2011). Focus on growth and development, sensory screening, dental examination, and behavioral assessment.
- 2 Children who are chronically ill, disabled, in foster care, or foreign-born adopted may require additional assessments because of unique health needs.
- 3 When obtaining histories of infants and children, gather all or part of the information from parents or guardians.
- 4 Children who are chronically ill, disabled, in foster care, or adopted from a foreign country may require additional assessment because of their unique health risks.
- 5 Parents may think that the examiner is testing or judging them. Offer support during examination and do not pass judgment.
- 6 Call children by their preferred name and address parents as "Mr. and Mrs. Brown" rather than by first names.
- 7 Open-ended questions often allow parents to share more information and describe more of the child's problems.
- 8 Older children and adolescents respond best when treated as adults and individuals and often can provide details about their health history and severity of symptoms.

- 9 An adolescent has a right to confidentiality. After talking with parents about historical information, arrange to be alone with the adolescent to speak privately and perform the examination.

Older Adults

- 1 Do not assume that aging is always accompanied by illness or disability. Older adults are able to adapt to change and maintain functional independence (Touhy and Jett, 2010).
- 2 A thorough assessment of an older adult provides critical information that can be used to maximize independence (Cress, 2012).
- 3 Provide adequate space for an examination, particularly if a patient uses a mobility aid.
- 4 Plan the history and examination, taking into account an older adult's energy level, physical limitations, pace, and adaptability. You may need more than one session to complete the assessment (Touhy and Jett, 2010).
- 5 Measure performance under the most favorable conditions. Take advantage of natural opportunities for assessment (e.g., during bathing, grooming, mealtime) (Touhy and Jett, 2010).
- 6 Sequence an examination to keep position changes to a minimum. Be efficient throughout the examination to limit patient movement.
- 7 Be sure that an examination of an older adult includes review of mental status.

SKILL 6-1 General Survey

The general survey begins a review of a patient's primary health problems, and it includes assessment of vital signs, height and weight, general behavior, and appearance. It provides information about characteristics of an illness, a patient's hygiene, skin

condition and body image, emotional state, recent changes in weight, and developmental status. The survey reveals important information about a patient's behavior that influences how you communicate instructions and continue an assessment.

Delegation and Collaboration

The skill of completing the general survey cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Measure the patient's height and weight.
- Obtain vital signs (not the initial set, but subsequent measurements if patient is stable).
- Monitor oral intake and urinary output.
- Report a patient's subjective signs and symptoms to the nurse.

Equipment

- Stethoscope
- Sphygmomanometer and cuff
- Thermometer
- Digital watch or wristwatch with second hand
- Tape measure
- Clean gloves (use nonlatex if necessary)
- Tongue blade
- Appropriate electronic record or documentation form

|---|---|
| <p>1 Note if patient has had any acute distress: difficulty breathing, pain, anxiety. If such signs are present, defer general survey until later and focus immediately on affected body system.</p> <p>2 Review graphic sheet for previous vital signs and consider factors or conditions that may alter values (see Chapter 5).</p> <p>3 Determine patient's primary language. If you identify a need for an interpreter, determine the availability of a professional interpreter. It is best to have an interpreter of the same gender who is older and mature. Have the interpreter translate verbatim if possible.</p> <p>4 After reviewing history, confirm primary reason patient has sought health care.</p> <p>5 Identify patient's normal height, weight, and body mass index. If a sudden gain or loss in weight has occurred, determine amount of weight change and period of time in which it occurred. Assess if patient has recently been dieting or following an exercise program. Use growth chart for children under 18 years of age.</p> <p>6 Review patient's past fluid intake and output (I&O) records.</p> <p>7 Identify patient's general perceptions about personal health.</p> <p>8 Assess for evidence of latex allergy, which may include contact dermatitis or systemic reactions. Ask if patient has risk factors such as food allergies (papaya, avocado, banana, peach, kiwi, or tomato); has high latex exposure (housekeepers, food handlers, health care worker); or must avoid products containing latex (rubber bands, adhesive tape, certain paints or carpets).</p> | <p>Signs establish priorities regarding which part of the examination to conduct first.</p> <p>Provides baseline and historical data about patient's vital signs.</p> <p>Facilitates patient understanding and promotes accuracy of information provided by patient.</p> <p>Keeps assessment focused on patient to ensure that his or her expectations are addressed.</p> <p>Generally a body mass index of 25 to 29.9 for men and women is overweight, whereas 30 and over is obese (Seidel et al., 2011). Fluid retention is one factor that must be ruled out. A person's weight can fluctuate daily because of fluid loss or retention (1 L of water weighs 1 kg [2.2 pounds]).</p> <p>Fluid and electrolyte balance affects health and function in all body systems. Intake includes all liquids taken orally, by feeding tube, and parenterally. Liquid output includes urine, diarrhea stool, vomitus, drainage from fistulas and gastric suction, and drainage from postsurgical tubes such as chest tubes or Jackson-Pratt drains.</p> <p>Assessment of patient's general appearance coupled with patient's own perceptions may reveal specific problem areas.</p> <p>Gloves are worn during certain aspects of the assessment. Repeated exposure to latex may result in more serious reactions, including asthma, itching, and anaphylaxis (Ball and Bindler, 2010; Seidel et al., 2011).</p> |
|---|---|

NURSING DIAGNOSES

- | | | |
|---|---|---|
| <ul style="list-style-type: none"> • Anxiety • Bathing self-care deficit • Deficient fluid volume • Excess fluid volume • Fear | <ul style="list-style-type: none"> • Imbalanced nutrition: less than body requirements or more than body requirements • Impaired physical mobility • Impaired skin integrity | <ul style="list-style-type: none"> • Ineffective breathing pattern • Ineffective peripheral tissue perfusion • Latex allergy response • Pain (acute, chronic) |
|---|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient demonstrates alert, cooperative behavior without evidence of physical or emotional distress during assessment. • Patient provides appropriate subjective data related to physical condition. | <p>You use a calm and confident approach during assessment. Patient has no abnormal findings.</p> <p>Patient is able to cooperate with assessment.</p> |
|--|--|

STEP	RATIONALE
2 <i>Prepare patient:</i> Tell patient that you will be doing a routine process to check for areas of concern. Ask patient to tell you if any area that you examine hurts when touched.	Understanding promotes patient's cooperation. Pain is an important finding during assessment.
3 Perform hand hygiene. Assemble necessary equipment. Position patient initially, either sitting or lying supine with head of bed elevated.	Prevents transmission of microorganisms. Promotes efficiency of exam.
IMPLEMENTATION	
1 Throughout assessment note patient's verbal and nonverbal behaviors. Determine patient's level of consciousness (LOC) and orientation by observing and talking to him or her (Box 6-4).	Behaviors may reflect specific physical abnormalities. Dementia and LOC influence ability to cooperate.
2 Obtain temperature, pulse, respirations, and blood pressure unless taken within last 3 hours or if a serious potential change is noted (e.g., change in LOC or difficulty breathing) (see Chapter 5). Inform patient of vital signs.	Vital signs provide important information regarding physiologic changes in relation to oxygenation and circulation.
3 Note the patient's gender and race, and ask their age. Note patient's external physical features.	Gender influences type of examination performed and manner in which you make assessments. Different physical characteristics and predisposition to illnesses are related to gender and race.
4 If uncertain whether patient understands a question, rephrase or ask a similar question.	Inappropriate response from a patient may be caused by language barriers or deterioration of mental status, preoccupation with illness, or decreased hearing acuity.
5 If patient's responses are inappropriate, ask short, to-the-point questions regarding information patient should know, for example: "Tell me your name." "What is the name of this place?" "Tell me where you live." "What day is this?" "What month is this?" or "What season of the year is this?"	Measures patient's orientation to person, place, and time. You may note this in documentation as "Oriented × 3." If disoriented in any way, include subjective and/or objective data rather than just documenting "disoriented."
6 If patient is unable to respond to questions of orientation, offer simple commands, for example, "Squeeze my fingers" or "Move your toes."	LOC exists along a continuum, ranging from full responsiveness, to inability to consciously initiate meaningful behaviors, to unresponsiveness to stimuli.
7 Assess affect and mood: Note if verbal expressions match nonverbal behavior and if appropriate to situation.	Reflects patient's mental and emotional status, consciousness, and feelings.
8 Watch patient interact with spouse or partner, older-adult child, or caregiver. Be alert for indications of fear, hesitancy to report health status, or willingness to let caregiver control assessment interview. Does partner or caregiver have a history of violence, alcoholism, or drug abuse? Is the person unemployed, ill, or frustrated with caring for a patient? Note if patient has any obvious physical injuries.	Suspect abuse in patients who have suffered obvious physical injury or neglect, show signs of malnutrition, or have ecchymoses (bruises) on the extremities or trunk. Health care providers are often the first to identify evidence of abuse because patients may not be able to tell family or friends. Partners or caregivers may have history of abusive or addictive behaviors.

BOX 6-4 Characteristics of Dementia**Cognition**

- Memory impaired: trouble recalling recent conversations, events, and appointments
- Frequently misplaces objects

Speech/Language

- Struggles to find words
- Conversation possibly incoherent

Activity

- Unchanged from usual behavior
- Difficulty performing tasks that require many steps

Mood and Affect

- Depressed
- Apathetic
- Uninterested

Delusions/Hallucinations

- Can be some delusions
- No hallucinations

STEP

RATIONALE

Clinical Decision Point Be discreet in how you conduct the interview. Ask direct questions about abuse in private. It is often necessary to delay assessment to a later time when the partner or caregiver is not present. Asking a partner or caregiver to leave during an assessment creates an awkward situation, but inquiring about possible abuse in front of an abuser puts a patient at risk for further abuse. Patients are more likely to reveal any problems when the suspected abuser is absent from the room.

- 9 Observe for signs of abuse:
- a **Child:** Blood on underclothing, pain in genital area, difficulty sitting or walking, pain on urination, vaginal or penile discharge, itching or unusual color in genital area, physical injury inconsistent with parent's or caregiver's account of how injury occurred.
 - Indicates child sexual abuse (Hockenberry and Wilson, 2011; Seidel et al., 2011). Suggests child physical abuse.
 - b **Female patient:** Injury or trauma inconsistent with reported cause or obvious injuries to head, face, neck, breasts, abdomen, and genitalia (e.g., black eyes, abrasions, bruises/welts, broken nose, lacerations, broken teeth, strangulation marks, burns, human bites, orbital fractures, fractured skull).
 - Suggests domestic abuse (Hegarty et al., 2008; Seidel et al., 2011). These signs also apply to male patient being abused by female partner.
 - c **Older adult:** Injury or trauma inconsistent with reported cause, injuries in unusual locations (e.g., neck or genitalia), pattern injuries (left when an object with which a person is struck leaves an imprint), parallel injuries (e.g., bilateral ecchymosis on the upper arms suggesting that patient was held and shaken), burns (shaped like a cigarette, iron, rope), fractures, poor hygiene, and poor nutrition.
 - Indicates elder abuse/neglect (Seidel et al., 2011; Touhy and Jett, 2010). Prolonged interval between injury and time patient sought medical care also indicates older adult abuse or neglect.

Clinical Decision Point A pattern of findings indicating abuse usually mandates a report to a social service center (refer to state guidelines). Obtain immediate consultation with health care provider, social worker, and other support staff to facilitate placement in a safer environment.

- 10 Assess posture and position, noting alignment of shoulders and hips while patient stands and/or sits. Observe whether patient is slumped, erect, or has a bent posture (see illustration). Assess body movements. Are they purposeful? Are there tremors of the extremities? Are any body parts immobile? Are movements coordinated or uncoordinated?
- Reveals musculoskeletal problem, mood, or presence of pain.
 - May indicate neurologic or muscular problem or emotional stress (see Skill 6-7).

STEP 10 Observe patient's position and posture.

- 11 Assess speech. Is it understandable and moderately paced? Is there an association with patient's thoughts?
- Alterations reflect neurologic impairment, injury or impairment of mouth, improperly fitting dentures, differences in dialect or language, and some mental illnesses.
- 12 Observe hygiene and grooming for presence or absence of makeup, type of clothes (hospital or personal), and cleanliness. Hair, teeth, and nails are good places to assess for hygiene status.
- Grooming may reflect activity level before examination, resources available to purchase grooming supplies, patient's mood, and self-care practices. It may also reflect culture, lifestyle, economic status, and personal preferences.
 - a Observe color, distribution, quantity, thickness, texture, and lubrication of hair.
 - Changes in hair may reflect hormonal changes, changes from aging, poor nutrition, or use of certain hair-care products.

STEP	RATIONALE
<ul style="list-style-type: none"> b Inspect condition of nails (hands and feet). Note color, length, symmetry, cleanliness, and shape. Nails are normally transparent, smooth, and well rounded, with smooth, intact cuticle. c Assess presence or absence of body odor. 	<p>Changes indicate inadequate nutrition or grooming practices, nervous habits, or systemic diseases.</p> <p>Body odor may result from physical exercise, deficient hygiene, or physical or mental abnormalities. Inadequate oral hygiene or unhealthy teeth cause bad breath.</p>
<p>13 Inspect exposed areas of skin and ask if patient has noted any changes, including:</p> <ul style="list-style-type: none"> a Pruritus, oozing, bleeding b Appearance of a mole (nevus), bump, or nodule; change in sensation; itchiness, tenderness, or pain c Petechiae (pinpoint-size red or purple spots on skin caused by small hemorrhages in the skin layers) 	<p>Determines presence of abnormalities and cancerous lesions. Melanoma is an aggressive form of skin cancer; detection and prompt treatment are critical (Box 6-5).</p> <p>Itching could result from dry skin. Oozing could indicate infection, and bleeding may indicate a blood disorder.</p> <p>These are key indicators that a lesion may be cancerous.</p>
<p>14 Inspect skin surfaces. Compare color of symmetric body parts, including areas unexposed to sun. Look for any patches or areas of skin color variation.</p>	<p>Petechiae may indicate serious blood clotting disorder, drug reaction, or liver disease.</p> <p>Changes in color can indicate pathologic alterations (Table 6-5).</p>

BOX 6-5 Malignant Melanoma Mnemonics

The ABCDE Rule of Melanoma

Here is a simple way to remember the characteristics that should alert you to the possibility of malignant melanoma.

- A Asymmetry of lesion: One side different than the other
- B Borders: Irregular (uneven, lumpy edges)
- C Color: Blue/black or variegated; pigmentation not uniform; variations/multiple colors (tan, black) with areas of pink, white, gray, blue, or red
- D Diameter greater than 6 mm
- E Evolving: Change in size, shape, color; itching or bleeding

Malignant melanoma. (From Zitelli B, Davis H: *Atlas of pediatric physical diagnosis*, ed 5, St Louis, 2007, Mosby.)

From American Academy of Dermatology (AAD): *How to examine your skin*, Washington, DC, 2011, AAD; and American Cancer Society (ACS): *Can melanoma be prevented*, Atlanta, 2011a, The Society.

TABLE 6-5 Skin Color Variations

Color	Condition	Cause	Assessment Location
Bluish (cyanosis)	Related to hypoxia (late sign of decreased oxygen levels)	Heart or lung disease, cold environment	Nail beds, lips, base of tongue, skin (severe cases)
Pallor (decrease in color)	Reduced amount of oxyhemoglobin	Anemia Shock	Face, conjunctivae, nail beds, palms of hands
	Reduced visibility of oxyhemoglobin resulting from decreased blood flow		Skin, nail beds, conjunctivae, lips
Loss of pigmentation	Vitiligo	Congenital autoimmune condition causing lack of pigment	Patchy areas on skin over face, hands, arms
Yellow-orange (jaundice)	Increased deposit of bilirubin in tissues	Liver disease, destruction of red blood cells	Sclerae, mucous membranes, skin
Red (erythema)	Increased visibility of oxyhemoglobin caused by dilation or increased blood flow	Fever, direct trauma, blushing, alcohol intake	Face, area of trauma, and areas at risk for pressure such as sacrum, shoulders, elbows, and heels
Tan-brown	Increased amount of melanin	Suntan, pregnancy	Areas exposed to sun: face, arms; areolae, nipples

STEP

RATIONALE

Clinical Decision Point Be alert for basal cell carcinomas such as an open sore that does not heal, a shiny nodule, a pink or reddish growth, or scarlike area. These are often seen in sun-exposed areas and frequently occur in sun-damaged skin.

- 15 Carefully inspect color of face, oral mucosa, lips, conjunctiva, sclera, palms of hands, and nail beds. Abnormalities are easier to identify in areas of body where melanin production is lowest.

Clinical Decision Point When assessing the skin of a patient with bandages, cast, restraints, or other restrictive devices, note report of pain or tingling and areas of pallor, decreased temperature, decreased movement, and impaired sensation, which may indicate impaired circulation. Immediate release of pressure from the restrictive device may be necessary.

- 16 Use ungloved fingertips to palpate skin surfaces to feel texture and moisture of intact skin. Changes in texture may be the first indication of skin rashes in dark-skinned patients. Hydration, body temperature, and environment may affect the skin. Older adults are prone to xerosis, presenting as dry, scaly skin (Touhy and Jett, 2010). Localized texture changes result from trauma, surgical wounds, or lesions.
- a Stroke skin surfaces lightly with fingertips to detect texture of surface of skin. Note whether skin is smooth or rough, thick or thin, or tight or supple and if localized areas of hardness or lesions are present. Allows detection of localized areas of hardness and/or tenderness within subcutaneous skin layers.
- b Palpate any areas that appear irregular in texture. Skin on dorsum of hand is thin, which allows detection of subtle temperature changes. Cool skin temperature often indicates decreased blood flow. A stage I pressure ulcer may cause warmth and erythema (redness) of an area. Environmental temperature and anxiety may also affect skin temperature.
- c Using dorsum (back) of hand, palpate for temperature of skin surfaces. Compare symmetric body parts. Compare upper and lower body parts. Note distinct temperature difference and localized areas of warmth.

Clinical Decision Point In patients who receive routine injections (e.g., insulin, heparin), localized areas of hardness may be palpated over injection sites. Develop a plan to rotate injection sites systematically. Site rotation prevents local skin changes from repeated injections (Lewis et al., 2011).

- 17 Apply clean gloves. Inspect character of any secretions; note color, odor, amount, and consistency (e.g., thin and watery, thick and oily). Remove gloves. Description of secretions helps to indicate type of lesion, presence of infection, or wound healing.
- 18 Assess skin turgor by grasping fold of skin on sternum, forearm, or abdomen with fingertips. Release skinfold and note ease and speed with which skin returns to place (see illustration). With reduced turgor skin remains suspended or “tented” for a few seconds before slowly returning to place, indicating decreased elasticity and possible dehydration. With altered turgor, provide measures for prevention of pressure ulcers (see Chapter 18).

STEP 18 Checking skin turgor.

- 19 Assess condition of skin for pressure areas, paying particular attention to regions at risk for pressure (e.g., sacrum, greater trochanter, heels, occipital area, clavicles). If you see areas of redness, place fingertip over area, apply gentle pressure, and release. Look at skin color. Normal reactive hyperemia (redness) is a visible effect of localized vasodilation, the normal response of the body to lack of blood flow to underlying tissue. Affected area of skin normally blanches with fingertip pressure. If area does not blanch, suspect tissue injury.

STEP

RATIONALE

Clinical Decision Point *With evidence of normal reactive hyperemia, reposition patient and develop a turning schedule if he or she is dependent (see Chapter 18).*

- 20** When you detect a lesion, use adequate lighting to inspect color, location, texture, size, shape, and type (Box 6-6). Also note grouping (e.g., clustered or linear) and distribution (e.g., localized or generalized).
- a** Use gloves if lesion is moist or draining. Gently palpate any lesion to determine mobility, contour (e.g., flat, raised, or depressed), and consistency (e.g., soft or hard).
 - b** Note if patient reports tenderness with or without palpation.
 - c** Measure size of lesion (height, width, depth) with a centimeter ruler.
- 21** Remove gloves. Discard used supplies and gloves in proper receptacle. Assist patient to comfortable position. Perform hand hygiene.

Observation of skin lesions allows for accurate description and identification.

Gentle palpation prevents rupture of underlying cysts. Gloves reduce transmission of microorganisms.

Tenderness may indicate inflammation or pressure on body part. Provides for a baseline to assess changes in lesion over time.

Prevents transmission of infections.

BOX 6-6 Types of Skin Lesions

Macule: Flat, nonpalpable change in skin color; smaller than 1 cm (0.4 inch) (e.g., freckle, petechia)

Vesicle: Circumscribed elevation of skin filled with serous fluid; smaller than 0.5 cm (0.2 inch) (e.g., herpes simplex, chickenpox)

Papule: Palpable, circumscribed, solid elevation in skin; smaller than 0.5 cm (0.2 inch) (e.g., elevated nevus)

Ulcer: Deep loss of skin surface that may extend to dermis and frequently bleeds and scars; varies in size (e.g., venous stasis ulcer)

Tumor: Solid mass that may extend deep through subcutaneous tissue; larger than 1 to 2 cm (0.4 to 0.8 inch) (e.g., epithelioma)

Atrophy: Thinning of skin with loss of normal skin furrow with skin appearing shiny and translucent; varies in size (e.g., arterial insufficiency)

STEP

RATIONALE

BOX 6-6 Types of Skin Lesions—cont'd

Pustule: Circumscribed elevation of skin similar to vesicle but filled with pus; varies in size (e.g., acne, staphylococcal infection)

Wheal: Irregularly shaped, elevated area or superficial localized edema; varies in size (e.g., hive, mosquito bite)

Nodule: Elevated solid mass, deeper and firmer than papul; 0.5 to 2 cm (0.2 to 0.8 inch) (e.g., wart)

**EVALUATION**

- 1 Observe throughout assessment for evidence of physical or emotional distress, which may alter assessment data.
- 2 Compare assessment findings with previous observations.
- 3 Ask patient if there is information about physical condition that you have not discussed.

Interaction during assessment reveals emotional problems. Maneuvers used during physical examination reveal presence of physical problems. Determines if change has occurred. Some patients think that they are bothering you by asking questions unless the opportunity for questions is provided.

Unexpected Outcomes

- 1 Patient demonstrates acute distress (e.g., shortness of breath, acute pain, severe anxiety).
- 2 Patient has abnormal skin condition (e.g., dry texture, reduced turgor, lesions, or erythema).
- 3 Patient is unwilling or unable to provide adequate information relating to identified concerns.

Related Interventions

- Respond immediately to identified need (e.g., repositioning, oxygen, or medication as appropriate).
- Obtain vital signs.
- Notify health care provider.
- Identify contributing factors and prevent continued irritation or damage as appropriate (see [Chapter 18](#)).
- Seek information from family members if present.
- Review patient's record for baseline data.

Recording and Reporting

- Record patient's vital signs on vital sign flow sheet.
- Record description of alterations in patient's general appearance.
- Describe patient's behaviors using objective terminology. Include patient's self-report of signs and symptoms.
- Report abnormalities and acute symptoms to nurse in charge or health care provider.

Special Considerations**Teaching**

- During general survey inform patient about normal range of vital signs for age and physical condition and normal weight for height and body frame.
- If patient is on established diet, discuss any problems that he or she has preparing a diet or selecting food. The best form of weight reduction is to achieve gradual weight loss by increasing

exercise and decreasing caloric intake. Refer to clinical dietitian for specific information.

Pediatric

- Measurement of physical growth is a key element in evaluation of a child's health status. These physical growth parameters include height, length, weight, skinfold thickness, and arm and head circumference (Hockenberry and Wilson, 2011). Use growth charts specific to child's age and condition.
- Weigh infants nude. Weigh children in light underclothes or gown.
- A child's interactions with parents provide valuable information regarding the child's behavior.

Gerontologic

- An older adult's presenting signs and symptoms are sometimes deceiving. An older adult has a diminished physiologic reserve that sometimes masks the usual, or "classic," signs and symptoms of a disease. In older adults signs and symptoms are often blunted or atypical (Touhy and Jett, 2010).
- Common skin changes with aging include dryness, thinning, decreased elasticity, and prominent small blood vessels. Common lesions include seborrheic keratosis (pigmented raised, warty lesion); cherry angioma (bright, ruby-red round papules);

cutaneous tags (soft pinkish-tan to light-brown pedunculated lesions); and solar lentiginos (gray-brown, irregular macular lesions on sun-exposed areas) (Seidel et al., 2011).

- Inspection of the feet is critically important in the presence of impaired circulation, impaired vision, and diabetes mellitus. Common foot conditions include ulceration, fungal infection, corns, calluses, bunions, plantar warts, and hammer toe.

Home Care

- In the home the focus may be on the patient's ability to perform basic self-care tasks. Be sure that the home assessment builds on all health concerns identified in other settings.
- The home health nurse takes a small portable scale to monitor weight changes.

Long-Term Care

- The minimum data set (MDS) is a tool that includes a comprehensive assessment of residents in the long-term care setting. It provides an ongoing comprehensive assessment of each resident, emphasizing functional ability and both a physical and a psychosocial profile. Only a registered nurse (RN) can function as the assessment coordinator (Cress, 2012). All members of the interdisciplinary team make contributions.

SKILL 6-2 Head and Neck Assessment

Examination of the head and neck includes assessment of the head, eyes, ears, nose, mouth, and sinuses. Assessment of the head and neck uses inspection, palpation, and auscultation, with inspection and palpation often used simultaneously.

Delegation and Collaboration

The skill of assessing the head and neck cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Observe for nasal discharge and nasal bleeding.
- Report any findings found during routine care (e.g., oral care, bathing) to the nurse for further assessment.

Equipment

- Stethoscope
- Clean gloves (use nonlatex if necessary)
- Tongue blade
- Pen light

STEP

RATIONALE

ASSESSMENT

- 1 Assess for history of headache, dizziness, pain, or stiffness.
- 2 Determine if the patient has a history of eye disease, diabetes mellitus, or hypertension.
- 3 Ask if patient has experienced blurred vision, flashing lights, halos around lights or a reduced visual field.
- 4 Ask if patient has experienced ear pain, itching, discharge, vertigo, tinnitus (ringing in the ears), or change in hearing.
- 5 Review patient's occupational history.
- 6 Ask if patient has a history of allergies, nasal discharge, epistaxis (nosebleeds), or postnasal drip.
- 7 Determine if patient smokes or chews tobacco.

Headaches and dizziness are signs of stress, a symptom of another underlying problem such as high blood pressure, or a result of injury.

Common conditions predispose patients to visual alterations requiring health care provider referral.

These common symptoms indicate visual problems.

These signs and symptoms indicate infection or hearing loss.

Patient's occupation can create a risk of injury, potential for eye fatigue, or prolonged noise exposure.

History is useful in determining source of nasal and sinus drainage.

Tobacco users have greater risk for mouth and throat cancer (ACS, 2012b.)

NURSING DIAGNOSES

- Deficient knowledge
- Impaired oral mucous membranes
- Ineffective health maintenance
- Risk for injury

Related factors are individualized based on patient's condition or needs.

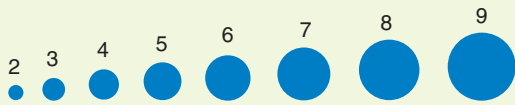

STEP

RATIONALE

PLANNING

- | | |
|--|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient recognizes warning signs and symptoms of eye, ear, sinus, and mouth disease. • Patient takes appropriate safety precautions for occupational injury related to the head and neck. • Patient exhibits good visual acuity, normal hearing, moist and intact oral mucosa, and head and neck without masses or lesions. <p>2 Prepare patient. Tell him or her that you will be completing a routine examination of the head and neck to check for areas of concerns.</p> <p>3 Anticipate teaching topics so that during the exam, you can instruct patient on common symptoms of eye, ear, sinus, and mouth problems, and occupational health safety.</p> <p>4 Perform hand hygiene. Assemble necessary equipment.</p> | <p>No abnormalities identified.</p> <p>Awareness of warning signs improves adherence with reporting problems to healthcare provider.</p> <p>Awareness of safety precautions improves adherence to healthful behaviors.</p> <p>Patient has no abnormal findings.</p> <p>Understanding promotes patient's cooperation.</p> <p>Enables you to incorporate teaching during examination.</p> <p>Prevents transmission of microorganisms. Promotes efficiency of exam.</p> |
|--|--|

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Position patient sitting upright if possible.</p> <p>2 Inspect the head.
Note head position and facial features. Look for symmetry.</p> <p>3 Assess the eyes:</p> <p>a Inspect position of eyes, color, condition of conjunctiva, and movement.</p> <p>b Assess patient's near vision (ability to read newspaper or magazines) and far vision (ability to follow movement, read clock, watch television, or read signs at a distance).</p> <p>c Inspect pupils for size, shape, and equality (see illustration).</p> | <p>Provides for more thorough examination of head and neck structures.</p> <p>Head tilting to one side may indicate hearing or visual loss. Neurologic disorders such as paralysis often affect facial symmetry.</p> <p>Asymmetric positioning may reflect trauma or tumor growth. Differences in color are sometimes congenital; changes in color of conjunctiva may be the result of local infection or symptomatic of another abnormality (e.g., pale conjunctiva is associated with anemia).</p> <p>A patient with visual acuity or visual field loss indicates need for supporting self-care measures (e.g., feeding, bathing, hygiene, dressing) and teaching.</p> <p>Normal pupils are round, regular, and equal in size and shape.</p> |
|---|--|
- 

STEP 3c Pupil sizes in millimeters.
- | | |
|---|---|
| <p>d Test pupillary reflexes. To test reaction to light, dim room lights. If you cannot dim lights, cup hand over eye to temporarily shield the light. As patient looks straight ahead, move penlight from side of patient's face and direct light on pupil. Observe pupillary response of both eyes, noting briskness and equality of reflex (see illustrations A and B).</p> | <p>Darkened room normally ensures brisk response of pupils to light. Pupil that is illuminated constricts. Pupil in other eye should constrict equally (consensual light reflex).</p> |
|---|---|

STEP

RATIONALE

STEP 3d A, Holding penlight to side of patient's face. B, Illumination of pupil causes pupillary constriction.

- (1) Test for accommodation by asking patient to focus on a distant object, which dilates the pupil. Then have the patient shift to a near object about 7 to 8 cm (3 inches) from the nose and observe for pupil constriction and convergence of the eyes. **NOTE:** You can also ask patient to follow an object (e.g., finger, pen) with eyes from far to near point.
- 4 Assess hearing. Note patient's response to questions and presence/use of a hearing aid. If you suspect a patient has hearing loss, ask him or her to repeat random words that you state. Use one- or two-syllable words. Repeat, gradually increasing voice intensity until patient correctly repeats the words.

Absence of constriction, convergence or an asymmetric response requires further ophthalmologic assessment (Seidel et al., 2011).

Patients normally hear 3 to 6 sounds clearly when whispered (Seidel et al., 2011). For patient with obvious hearing impairment, speak clearly and concisely, stand so patient can see your face, stand toward patient's good ear, use a low pitch, and avoid yelling.

Clinical Decision Point If hearing deficit is present, have a qualified nurse inspect patient's ears because impaired hearing may be the result of impacted cerumen, external otitis, or swelling in ear canal because of allergic reactions to materials in hearing aids.

- 5 Inspect nose externally for shape, skin color, alignment, drainage, and presence of deformity or inflammation. Note color of mucosa and any lesions, discharge, swelling, or presence of bleeding. If drainage appears infectious, consult with health care provider about obtaining a specimen.
- 6 In patients with a nasogastric (NG), nasointestinal (NI), or nasotracheal tube, inspect nares for excoriation, inflammation, or discharge. Using a penlight, look up into each naris. Stabilize tube as needed.
- 7 Inspect sinuses by palpating gently over frontal and maxillary areas. Use thumbs to apply pressure up and under the eyebrows to assess frontal sinuses. Use thumbs to apply pressure over maxillary sinuses, about 1 inch below eyes.
- 8 Assess the mouth:
 - a Apply clean gloves. Inspect the lips for color, texture, hydration, and lesions. Have females remove their lipstick.
 - b Inspect the teeth, and note position and alignment. Note the color of teeth and presence of dental caries, tartar, and extraction sites.
 - c Inspect the mucosa and gums. Determine if patient wears dentures or retainers and if they are comfortable. Remove dentures to visualize and palpate gums. Use a tongue blade to lightly depress the tongue and inspect the oral cavity with a penlight (see illustration). Inspect the oral mucosa, tongue, teeth, and gums for color, hydration, texture, and obvious lesions.
 - d If oral lesions are present, palpate gently with a gloved hand for tenderness, size, and consistency.

Character of discharge and inflammation indicates allergy or infection. Perforation and erosion of septum and puffiness and/or increased vascularity of mucosa indicate habitual drug use.

Swallowing or coughing reflex causes movement of tubes against nares, and pressure against tissues and mucosa can result in tissue erosion.

Infection, allergy, or drug use sometimes causes tenderness.

Normal lips are pink, moist, symmetrical, and smooth.

Reveals quality of hygiene and discoloring effects of cola, coffee, and tobacco, Teeth are normally smooth, white, and shiny.

Dentures and retainers can cause chronic irritation. Normal mucosa is glistening, pink, smooth and moist. Precancerous lesions can go unnoticed and progress rapidly.

Cancerous lesions tend to be hard and non-tender.

STEP

RATIONALE

STEP 8c Inspect mouth.

9 Inspect and palpate the neck.

- a Ask patient if there is a history of neck pain or difficulty moving the neck.
- b Neck muscles: Inspect neck for bilateral symmetry of muscles. Ask patient to flex and hyperextend neck and turn head side to side.
- c Lymph nodes.
 - (1) With patient's chin raised and head tilted slightly, inspect area where lymph nodes are distributed and compare both sides (see illustration).

Assesses function of all neck structures, including neck muscles; lymph nodes; thyroid glands; and trachea.

May indicate muscle strain, head injury, local nerve injury, or swollen lymph nodes.

Detects muscle weakness, strain, and range of motion (ROM).

Lymph nodes are sometimes enlarged from infection or various diseases such as cancer.

STEP 9c(1) Palpable lymph nodes of head and neck. (From Seidel HM et al: *Mosby's guide to physical examination*, ed 7, St Louis, 2011, Mosby.)

- (2) To examine lymph nodes, have patient relax with neck flexed slightly forward. To palpate, face or stand to side of patient and use pads of middle three fingers of hand (see illustration). Palpate gently in a rotary motion for superficial lymph nodes.

This position relaxes tissues and muscles.

STEP

RATIONALE

STEP 9c(2) Palpation of cervical lymph nodes.

- | | |
|--|---|
| <p>(3) Note if lymph nodes are large, fixed, inflamed, or tender.</p> <p>10 Remove gloves. Discard used supplies and gloves in proper receptacle. Assist patient to comfortable position. Perform hand hygiene.</p> | <p>Large, fixed, inflamed, or tender lymph nodes indicate local infection, systemic disease, or neoplasm.</p> <p>Reduces transmission of infection.</p> |
|--|---|

EVALUATION

- | | |
|--|---|
| <p>1 Compare assessment findings with previous observations.</p> <p>2 Ask patient to describe common symptoms of eye, ear, sinus, or mouth disease.</p> <p>3 Ask patient to list occupational safety precautions.</p> | <p>Identifies changes in patient's condition.</p> <p>Measures patient's ability to recognize abnormalities.</p> <p>Knowledge allows patient to take safety precautions.</p> |
|--|---|

Unexpected Outcomes

- 1 Patient has yellow nasal discharge, sneezing, and complaint of sinus pain.
- 2 Patient complains of severe headache and dizziness when standing.
- 3 Patient has mouth sore that bleeds easily, a lump or thickening in the cheek, or a white or red patch in the mucosa.
- 4 Patient is unable to describe common symptoms of eye, ear, sinus, and mouth problems, and occupational health safety factors.

Related Interventions

- Reposition into semi-Fowler's or other comfortable position to relieve sinus pain.
- Monitor temperature for fever.
- Notify health care provider if these are new findings.
- Respond immediately by obtaining vital signs, especially blood pressure.
- Return patient to bed in position of comfort to minimize dizziness and relieve headache.
- Identify contributing factors (e.g., stress, pain, or elevated blood pressure).
- Notify health care provider.
- Notify health care provider.
- Reinstruction is necessary.

Recording and Reporting

- Record all findings, including any abnormal findings such as hearing or visual loss, pain and its location, current infection, and character of drainage in nurses' notes, electronic health record (EHR), or flow sheet.
- Report any unexpected findings or changes to charge nurse or health care provider.

Special Considerations

Teaching

- Explain the common visual changes associated with aging, including reduced acuity (presbyopia), loss of or a reduction in peripheral vision, reduced tearing, and sensitivity to glare or bright lights. Inform patients when to seek help from an eye-care professional.

- Teach the visually impaired patient and family how to adjust room arrangements at home to promote safer ambulation. Self-help aids are available to assist patient with functioning independently with daily activities.

Pediatric

- Some infants resist eye examination by closing eyes. Using distraction encourages eye opening (Hockenberry and Wilson, 2011).
- Headaches in children are usually caused by loss of sleep, poor nutrition, eye fatigue, and allergies. Children as young as 3 years of age can develop severe migraine headaches, but the

symptoms are vague and difficult to diagnose (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults commonly have loss of peripheral vision caused by changes in the lens.
- Instruct patients older than age 65 to have regular hearing checks.
- Measuring visual acuity helps determine level of assistance that patient requires with daily living activities and ability of patient to safely ambulate and function independently within home.

SKILL 6-3 Thorax and Lung Assessment

Assessment of the thorax and lungs requires review of the ventilatory and respiratory functions of the lungs. It is a critical part of assessment because alterations can be life-threatening. Changes in respiration can occur quickly as a result of immobility, infection, and fluid overload. Use data from all body systems to determine the nature of pulmonary alterations. You will use inspection, palpation, and auscultation during the examination.

Before assessing the thorax and lungs, know the landmarks of the chest (Fig. 6-3, A-C). These landmarks help you identify findings and use assessment skills correctly. A patient’s nipples, angle of Louis at the sternum, suprasternal notch, costal angle, clavicles, and vertebrae are key landmarks. Keep a mental image of the location of the lobes of the lung and the position of each rib (Fig. 6-4, A-C).

Locating the position of each rib is critical to visualizing the lobe of the lung being assessed. To begin, locate the angle of Louis by palpating the “speed bump” at the manubriosternal junction, where the second rib connects with the sternum. The angle is often

visible and palpable. Count the ribs and intercostal spaces (between the ribs) from this point. The number of each intercostal space corresponds with that of the rib just above it. The spinous process of the third thoracic vertebra and the fourth, fifth, and sixth ribs help to locate the lung lobes laterally. The lower lobes project laterally and anteriorly (Fig. 6-4, B). Posteriorly the tip or inferior margin of the scapula lies approximately at the level of the seventh rib (Fig. 6-4, C).

During the examination, you will use auscultation to listen to breath sounds using a stethoscope. You can hear these sounds best when the person breathes deeply through the mouth. Adventitious sounds (abnormal sounds) result from air passing through fluid, mucus, or narrowed airways or from an inflammation between the pleural linings. The four types of adventitious sounds include crackles, rhonchi, wheezes, and pleural friction rubs (Table 6-6). Note the location and characteristics of the sounds, diminished breath sounds, or the absence of breath sounds. Determine where in the respiratory cycle the abnormal sounds are heard.

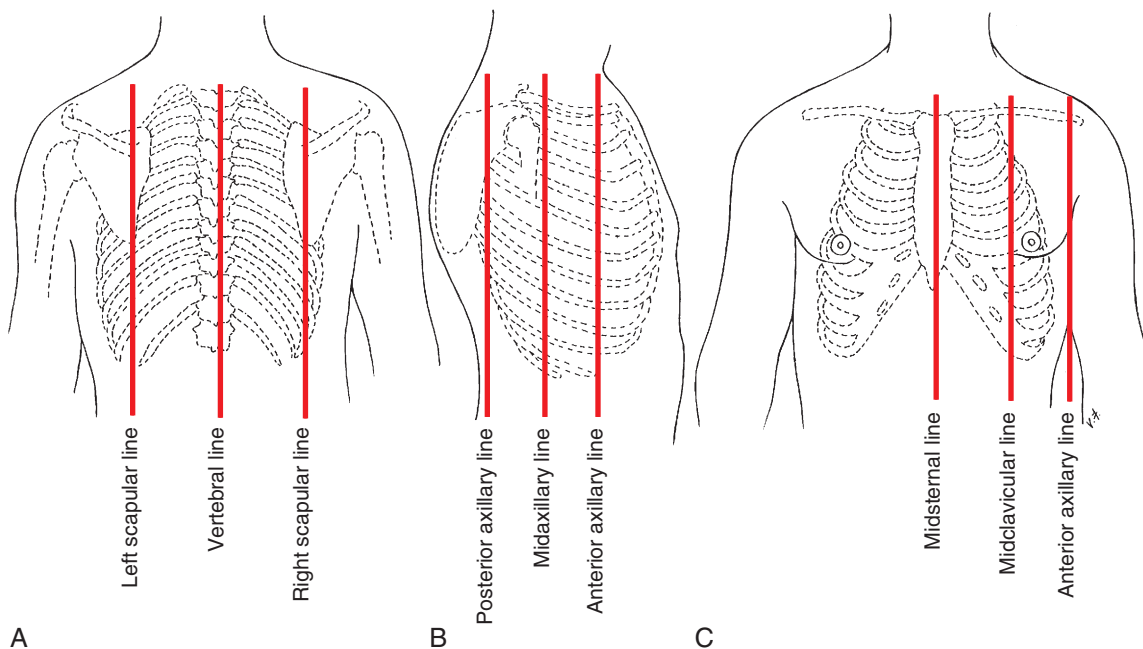

FIG 6-3 Anatomic landmarks and order of progression for examination of thorax. **A**, Posterior thorax. **B**, Anterior thorax. **C**, Lateral thorax.

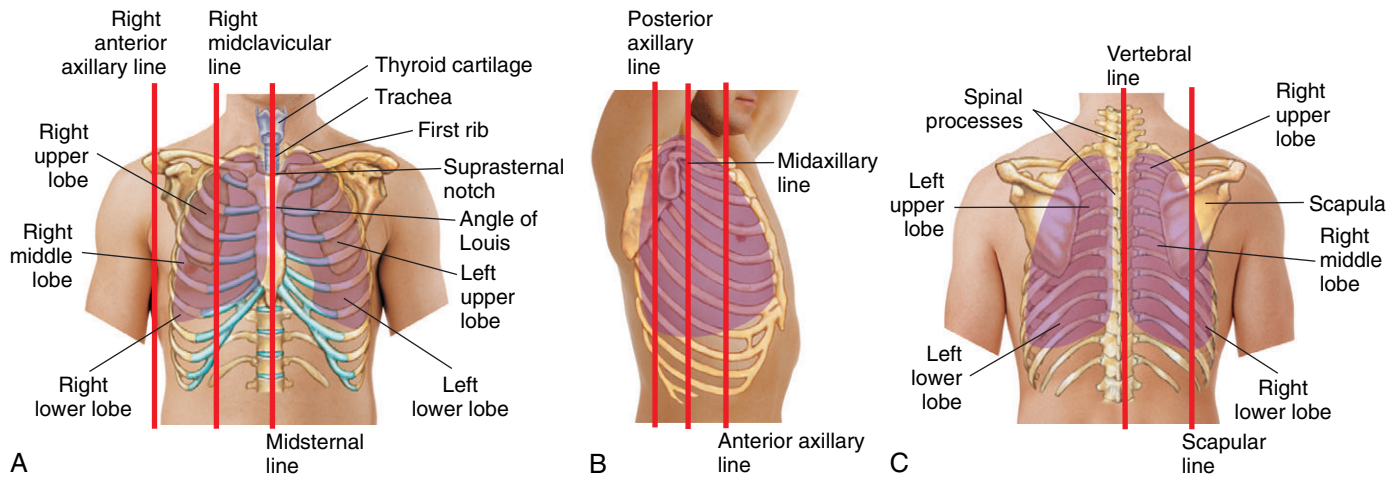

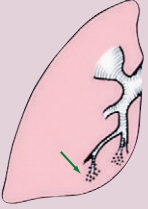

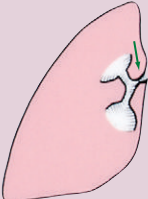

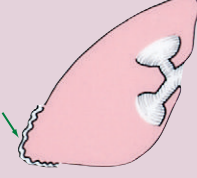

FIG 6-4 Position of lung lobes in relation to anatomical landmarks. **A**, Anterior position. **B**, Lateral position. **C**, Posterior position. (From Seidel HM, et al: *Mosby's guide to physical examination*, ed 7, St Louis, 2007, Mosby.)

TABLE 6-6 Adventitious Breath Sounds

Sound	Site Auscultated	Cause	Character
Crackles (formerly called rales) 	Most common in dependent lobes: right and left lung bases	Random, sudden reinflation of groups of alveoli; also related to increase in fluid in small airways	Fine, short, interrupted crackling sounds heard during end of inspiration, expiration, or both; may or may not change with coughing; sound like crushing cellophane Medium crackles: lower, moister sounds heard during middle of inspiration; not cleared with coughing Coarse crackles: loud bubbly sounds heard during inspiration; not cleared with coughing
Rhonchi (sonorous wheeze) 	Heard primarily over trachea and bronchi; if loud enough, can be heard over most lung fields	Fluid or mucus in larger airways causing turbulence; muscular spasm	Loud, low-pitched, continuous sounds heard more during expiration; sometimes cleared by coughing Sound like blowing air through fluid with a straw
Wheezes (sibilant wheeze) 	Heard over all lung fields but more distinct over posterior lung fields	High-velocity airflow through severely narrowed or obstructed bronchus	High-pitched, musical sounds such as a squeak heard continuously during inspiration or expiration; usually louder on expiration Do not clear with coughing
Pleural friction rub 	Heard over anterior lateral lung field (if patient is sitting upright)	Inflamed pleura, parietal pleura rubbing against visceral pleura	Has grating quality heard best during inspiration; does not clear with coughing; heard loudest over lower lateral anterior surface

Data from Seidel HM et al: *Mosby's guide to physical examination*, ed 7, St Louis, 2011, Mosby.

Delegation and Collaboration

The skill of assessing the lungs and thorax cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Measure the patient's respirations after vital signs confirm patient is stable.
- Report respiratory distress, difficulty breathing, and changes in rate and depth.

- Keep head of bed elevated for a patient who has respiratory difficulties.

Equipment

- Stethoscope

STEP

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <p>1 Assess history of tobacco or marijuana use, including type of tobacco, duration (number of years), and amount in pack-years. Pack-years equal number of years smoking times the number of packs per day (e.g., 4 years \times $\frac{1}{2}$ pack per day equals 2 pack-years). If patient has quit, determine the length of time since smoking stopped.</p> <p>2 Ask if patient experiences any of the following: <i>persistent cough</i> (productive or nonproductive), sputum production, <i>blood-streaked sputum</i>, <i>chest pain</i>, shortness of breath, orthopnea, dyspnea during exertion, activity intolerance, or <i>recurrent attacks of pneumonia or bronchitis</i>.</p> <p>3 Determine if patient works in environment containing pollutants (e.g., asbestos, arsenic, coal dust, or chemical irritants) or requiring exposure to radiation. Does patient have exposure to secondhand cigarette smoke?</p> <p>4 Review history for known or suspected human immunodeficiency virus (HIV) infection, substance abuse, low income, residence or employment in nursing home or shelter, homelessness, recent imprisonment, being a family member of patient with tuberculosis (TB), and immigration to the United States from a country where TB is prevalent (Furlow, 2010).</p> <p>5 Ask if patient has history of persistent cough, hemoptysis (bloody sputum), unexplained weight loss, fatigue, night sweats, and/or fever.</p> <p>6 Does patient have history of chronic hoarseness?</p> <p>7 Assess for history of allergies to pollen, dust, or other airborne irritants and to any foods, drugs, or chemical substances.</p> <p>8 Review family history for cancer, TB, allergies, or chronic obstructive pulmonary disease (COPD).</p> | <p>Smoking is a major cause of lung cancer, heart disease, and chronic lung disease (emphysema and chronic bronchitis). Risk factors for lung cancer include history of smoking for over 20 years, exposure to environmental pollution, and secondhand smoke (ACS, 2012b).</p> <p>Symptoms of respiratory alterations help to localize objective physical findings. (Warning signals for lung cancer are in italics.)</p> <p>Patients with chronic respiratory disease, particularly asthma, have symptoms aggravated by change in temperature and humidity, irritating fumes or smoke, emotional stress, and physical exertion.</p> <p>These are known risk factors for exposure to and/or development of TB.</p> <p>These are signs and symptoms for both TB and HIV infection.</p> <p>Hoarseness indicates laryngeal disorder or abuse of cocaine or opioids (sniffing).</p> <p>Allergic response is associated with wheezing on auscultation, dyspnea, cyanosis, and diaphoresis.</p> <p>Familial history places patient at risk for lung disease.</p> |

|--|--|

STEP

RATIONALE

IMPLEMENTATION

1 Position and prepare patient for examination:

- a Position patient sitting upright. For bedridden patient elevate head of bed 45 to 90 degrees. If unable to tolerate sitting, use the supine and side-lying positions.
- b Remove gown or drape first from posterior chest, keeping front of chest and legs covered. As examination progresses, remove gown from area being examined.
- c Explain all steps of procedure, encouraging patient to relax and breathe normally through the mouth.

2 Posterior thorax:

- a If possible, stand behind patient. Inspect thorax for shape and symmetry. Note any deformities, position of spine, slope of ribs, or symmetric expansion during inspiration. Note the anteroposterior diameter.

Promotes full lung expansion during examination. Patients with chronic respiratory disease may need to sit up throughout the examination because of shortness of breath. May require assistance of another caregiver to position unresponsive patients.

Avoids unnecessary exposure and provides full visibility of thorax. Allows direct placement of diaphragm or bell on patient's skin, which enhances clarity of sounds.

Anxiety alters respiratory function. Breathing through the mouth decreases extraneous sounds from air passing through the nose.

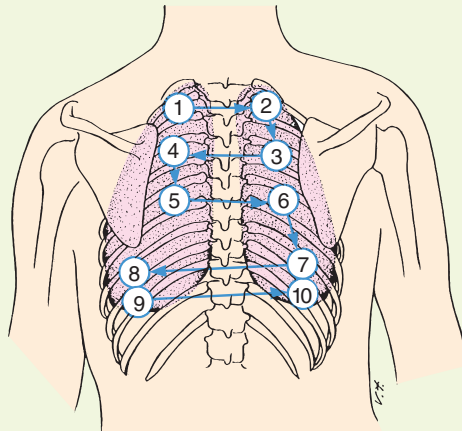

Allows for identification of impairment in chest expansion and any symptoms of respiratory distress. Normal chest contour is symmetrical. In a child, the shape of chest is almost circular, with anteroposterior (AP) diameter in 1:1 ratio. In an adult the AP is one third to one half of the side-to-side diameter. Chronic lung disease causes ribs to be more horizontal and increases AP diameter, resulting in a "barrel chest." Patients with breathing problems assume postures that improve ventilation.

Clinical Decision Point When a patient holds the chest wall during breathing, this indicates localized chest pain. Assess the nature of pain, including onset, severity, precipitating factors, quality, region, and radiation.

- b Determine the rate and rhythm of breathing (see Chapter 5). Examine the thorax as a whole. Have patient relax.
- c Systematically palpate the thoracic muscles and skeleton for lumps, masses, pulsations, and unusual movement (see illustration). If the patient voices pain or tenderness, avoid deep palpation. If there is a suspicious mass, palpate lightly for shape, size, and qualities of a lesion (see Skill 6-1). Do not palpate painful areas deeply.

This is a good time to count respirations, with patient relaxed and unaware of inspection. Awareness could alter respirations.

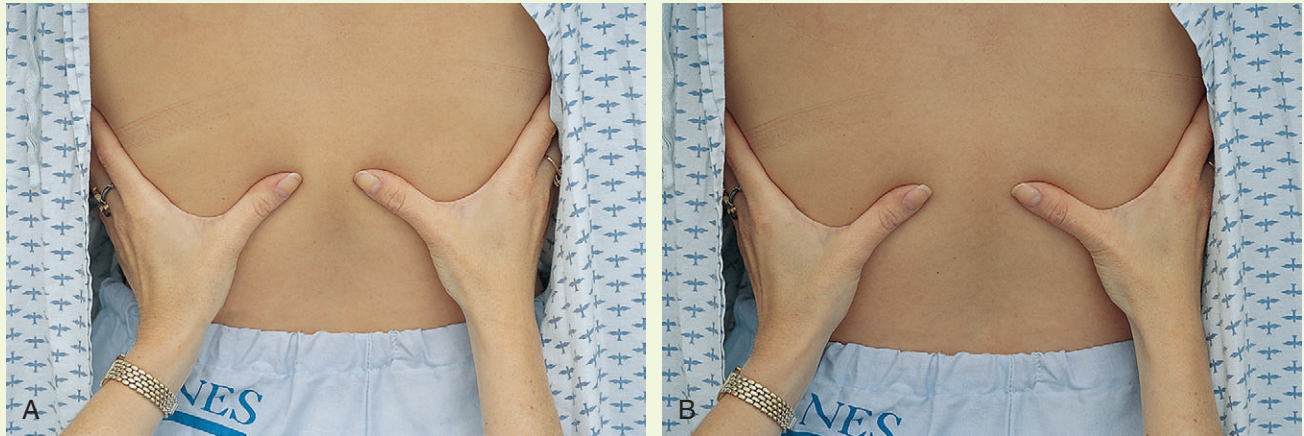

Palpation assesses further characteristics and confirms or supplements findings from inspection. Localized swelling or tenderness indicates trauma to ribs or underlying cartilage. A fractured rib fragment could be displaced.

STEP 2c Pattern for assessment of posterior thorax.

STEP

- d** Assess chest excursion by standing behind patient and placing thumbs along spinal processes at tenth rib, with palms lightly contacting posterolateral surfaces (see illustration A). Keep thumbs about 5 cm (2 inches) apart, with thumbs pointing toward spine and fingers pointing laterally. Press hands toward patient's spine to form small skinfold between thumbs. After exhalation patient takes deep breath. Note movement of thumbs (see illustration B) and symmetry of chest wall movement. Normally symmetric separation of thumbs occurs during chest excursion 3 to 5 cm (1½ to 2 inches).

STEP 2d A, Position of hands for palpation of posterior thorax excursion. B, As patient inhales, movement of chest excursion separates nurse's thumbs.

RATIONALE

Palpation of chest excursion assesses depth of patient's breathing. This technique is good measure to evaluate patient's ability to perform deep-breathing exercises (see Chapter 36). Limited movement on one side indicates that patient is voluntarily splinting during ventilation because of pain. Avoid allowing hands to slide over the skin, which gives a false measure of excursion.

- e** Auscultate breath sounds. Instruct patient to take slow, deep breaths with mouth slightly open. Place diaphragm of stethoscope firmly on skin, over the posterior chest wall and the intercostal spaces (see illustration). Have the patient fold arms in front of the chest and keep the head bent forward. Listen to an entire inspiration and expiration at each stethoscope position (see pattern in Step 2c.) If sounds are faint, as in obese patients, ask the person to breathe harder and faster temporarily. Systematically compare breath sounds over right and left sides, listening for normal and adventitious sounds.

Assesses movement of air through tracheobronchial tree (Table 6-7). Recognition of normal airflow sounds allows detection of sounds caused by mucus or airway obstruction. Characterize sounds by length of inspiratory and expiratory phases.

STEP 2e Use of diaphragm of stethoscope to auscultate breath sounds. (From Seidel HM et al: Mosby's guide to physical examination, ed 6, St Louis, 2006, Mosby.)

STEP

RATIONALE

- f** If you auscultate adventitious sounds, have patient cough. Listen again with stethoscope to determine if sound has cleared with coughing. See [Table 6-7](#) for a description of adventitious breath sounds.
- 3** Lateral thorax:
- a** Instruct patient to raise arms and inspect chest wall for same characteristics as reviewed for posterior chest.
- b** Extend palpation and auscultation of posterior thorax to lateral sides of chest, except for excursion measurement (see illustration).
- 4** Anterior thorax:
- a** Inspect accessory muscles of breathing: sternocleidomastoid, trapezius, and abdominal muscles, noting effort to breathe.
- b** Inspect width or spread of costal angle made by costal margins and tip of sternum. Angle is usually larger than 90 degrees between margins.
- c** Observe patient's breathing pattern, observing symmetry and degree of chest wall and abdominal movement. Respiratory rate and rhythm are more often assessed on anterior chest wall.
- d** Palpate anterior thoracic muscles and ribs for lumps, masses, tenderness, or unusual movement, following a systematic pattern across and down (see illustration).

Coughing may clear adventitious sounds. Rhonchi often are eliminated or altered by coughing. Crackles and wheezes are not.

Improves access to lateral thoracic structures.

Locates abnormalities in lateral lung fields.

Extent to which accessory muscles are used reveals degree of effort to breathe. The accessory muscles move little with normal passive breathing. Patients who require great effort and rely on these muscles may produce a grunting sound.

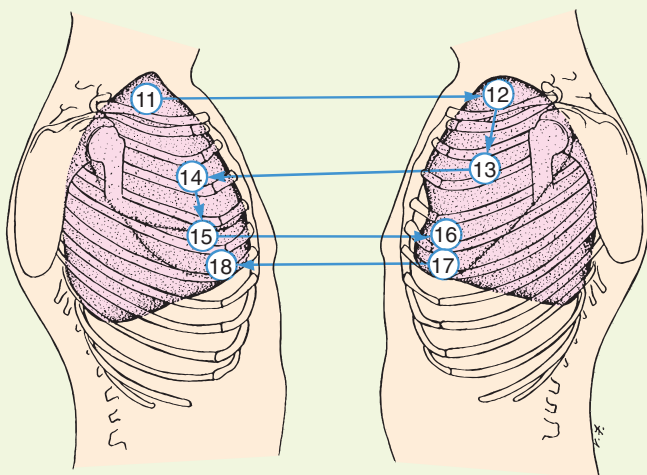

Indicates congenital, acquired, or traumatic alterations that may influence patient's chest expansion.

Assesses patient's effort to breathe: symmetric, passive movement indicates no respiratory distress. Male patient's breathing is diaphragmatic, while female's is more costal.

Localized swelling or tenderness indicates trauma to underlying ribs or cartilage.

TABLE 6-7 Normal Breath Sounds

Type	Description	Location	Origin
Bronchial	Loud and high-pitched sounds with hollow quality Expiration lasts longer than inspiration (3:2 ratio).	Best heard over trachea	Created by air moving through trachea close to chest wall
Bronchovesicular	Medium-pitched and blowing sounds of medium intensity Inspiratory phase equal to expiratory phase	Best heard posteriorly between scapulae and anteriorly over bronchioles lateral to sternum at first and second intercostal spaces	Created by air moving through large airways
Vesicular	Soft, breezy, and low-pitched sounds Inspiratory phase 3 times longer than expiratory phase	Best heard over periphery of lung (except over scapula)	Created by air moving through smaller airways

STEP 3b Pattern for assessment of lateral thorax.

STEP 4d Pattern for assessment of anterior chest.

STEP

RATIONALE

- | | |
|--|--|
| <ul style="list-style-type: none"> e Palpate anterior chest excursion. Place hands over each lateral rib cage, with thumbs approximately 5 cm (2 inches) apart and angled along each costal margin. As patient inhales deeply, thumbs should symmetrically move apart 3 to 5 cm (1½ to 2 inches), with each side expanding equally. f With patient sitting, auscultate anterior thorax. Begin above clavicles; move across and then down as during palpation. Compare right and left sides. Give special attention to lower lobes, where mucus commonly gathers. | <p>Assesses depth of patient's breathing and ability to perform deep-breathing exercises. Certain abnormalities are evident if expansion is not symmetric.</p> |
| <p>5 Clean and store stethoscope. Perform hand hygiene.</p> | <p>A systematic pattern of assessment comparing sides helps to identify abnormal sounds.</p> <p>Reduces transmission of infection.</p> |

EVALUATION

- | | |
|---|--|
| <p>1 Compare respiratory findings with assessment characteristics for thorax and lungs.</p> | <p>Determines presence of abnormalities.</p> |
| <p>2 Have patient identify factors leading to lung disease.</p> | <p>Demonstrates learning.</p> |

Unexpected Outcomes

- 1 Patient has copious mucus production; audible inspiratory wheezing; or congested cough with thick mucus.
- 2 Respirations are rapid or slow and irregular (see Chapter 5), and bulging of intercostal spaces is present.
- 3 Chest excursion is reduced. Depth of breathing is reduced by pain, postural deformity, or fatigue.
- 4 Patient is unfamiliar with risks for lung disease.

Related Interventions

- Help patient cough by splinting chest; teach to inhale slowly through nose, exhale, and cough; encourage expectoration of mucus.
- Auscultate breath sounds before and after cough to evaluate cough effectiveness.
- Auscultate lungs for adventitious sounds.
- Encourage increased oral intake (if permitted).
- If unable to clear airway by coughing, suctioning may be indicated (see Chapter 25).
- Monitor vital signs.
- Notify health care provider.
- Position patient more upright if appropriate.
- Auscultate lungs for adventitious sounds.
- Notify health care provider.
- Reposition patient more comfortably.
- Administer analgesic if appropriate.
- Education is necessary.

Recording and Reporting

- Record patient's respiratory rate and character; breath sounds, including type, location, and presence on inspiration, expiration, or both; changes noted after coughing; and other physical assessment findings in nurses' notes, EHR, or flow sheet.
- Report abnormalities immediately to nurse in charge or health care provider.

Special Considerations

Teaching

- Educate patients about risks of cigarette smoking. Smoking accounts for at least 30% of all cancer deaths and 80% of lung cancer deaths (ACS, 2012b). Individuals who stop smoking have the potential to live longer than those who continue to smoke. The probability of these individuals dying from lung cancer or other related causes continues to decline with further abstinence.
- Explain to patients that exposure to radiation, arsenic, and asbestos from occupational, medical, and environmental sources; air pollution; history of TB, and secondhand smoke contribute significantly to lung cancer (ACS, 2012b).
- Discuss with patients the warning signs of lung cancer such as a persistent cough, sputum streaked with blood, chest pains, and recurrent attacks of pneumonia or bronchitis.

Pediatric

- In children observe for use of accessory muscles, which indicate respiratory distress. Retractions may involve intercostal,

suprasternal, supraclavicular, or sternal muscles (Hockenberry and Wilson, 2011).

- Use the bell of the stethoscope to auscultate lung sounds in children. Breath sounds are louder in children because of their thin chest walls.
- Children younger than 7 years of age normally exhibit noticeable abdominal or diaphragmatic movement. Older children and adults exhibit more costal or thoracic movement.
- Head bobbing and nasal flaring in infants are signs of significant respiratory distress (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults have a costal angle (anteriorly) of slightly less than 90 degrees. The AP diameter sometimes increases from kyphosis.
- In older adults chest expansion is reduced because of calcification of rib cartilage and partial contraction of inspiratory muscles.
- Individuals with chronic or immunosuppressing conditions, including asthma, should receive the pneumococcal vaccine before age 64. Individuals who received the vaccine before age 65 should receive another dose at age 65 or 5 years after the previous dose. Those who receive the vaccine at or after age 65 should receive only a single dose. There is no indication to revaccinate (CDC, 2010).

SKILL 6-4 Cardiovascular Assessment

A patient who presents with signs or symptoms of heart (cardiac) problems such as chest pain may be suffering a life-threatening condition requiring immediate attention. In this situation you act quickly and perform the portions of the examination that are absolutely necessary. Conduct a more thorough assessment when the patient is more stable. This will reveal baseline heart function and any risks for heart disease. Patients tend to seek information about heart disease because it remains a leading cause of death in the United States. The heart, neck vessels, and peripheral circulation are assessed together because the systems work in unison.

Your assessment can determine the integrity of the circulatory system. Inadequate tissue perfusion results in an inadequate delivery of oxygen and nutrients to cells, a condition called *ischemia*. This is caused by constriction of vessels or occlusion (blockage) from clot formation. The effects of ischemia depend on the duration of the problem and the metabolic needs of the tissues. Ischemia results in pain. If lack of oxygen to tissues is unrelieved, tissue necrosis (death) occurs. An embolus is a blood clot that breaks loose and travels through the circulation. If the clot obstructs circulation to the lungs or brain, it can be life threatening.

You begin assessment of the heart after examining the lungs because the patient is already in a suitable position with the chest

exposed. Assessment then proceeds to the neck vessels and ends with evaluating peripheral circulation. The skills of inspection, palpation, auscultation, and percussion are used during the examination.

Delegation and Collaboration

The skill of completing a comprehensive cardiovascular assessment cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Count peripheral pulses after vital signs confirm patient is stable.
- Recognize skin temperature and color changes of affected extremities and report any changes to the nurse.
- Recognize changes in peripheral pulses and report any changes to the nurse.

Equipment

- Stethoscope
- Doppler stethoscope (optional)
- Conducting gel (if a Doppler stethoscope is used)
- Gloves

STEP

RATIONALE

ASSESSMENT

1 Assess patient for history of smoking, alcohol intake, caffeine intake (e.g., coffee, tea, soft drinks, energy drinks, and chocolate), and use of “recreational” drugs. Determine exercise habits and dietary patterns and intake.	These contribute to risk factors for cardiovascular disease. In addition, caffeine and alcohol cause tachycardia. Insufficient exercise and intake of fatty and salty foods increase risk for cardiovascular disease.
2 Determine if patient is taking medications for cardiovascular function (e.g., antiarrhythmics, antihypertensives, beta-blockers, antianginals) and if patient knows their purpose, dosage, and side effects.	Allows you to assess patient’s adherence to and understanding of drug therapies. Medications for cardiovascular function cannot be taken intermittently.
3 Ask if patient has experienced dyspnea, chest pain or discomfort, palpitations, excess fatigue, cough, leg pain or cramps, edema of the feet, cyanosis, fainting, and orthopnea. Ask if symptoms occur at rest or during exercise.	These are the cardinal symptoms of heart disease. Cardiovascular function is sometimes adequate during rest but not during exercise.
4 If patient reports chest pain, determine onset (sudden or gradual), precipitating factors, quality, region, severity, and if it radiates. Anginal pain is usually a deep pressure or ache that is substernal and diffuse, radiating to one or both arms, neck, or jaw.	Symptoms reveal acute coronary syndrome (ACS) or coronary artery disease (CAD).
5 Assess family history for heart disease, diabetes mellitus, high cholesterol and/or lipid levels, hypertension, stroke, or rheumatic heart disease.	Family history of these conditions increases risk for heart and vascular disease.
6 Ask patient about a history of any preexisting heart conditions (e.g., heart failure, congenital heart disease, CAD, dysrhythmias, or murmurs), heart surgery, or vascular disease (e.g., hypertension, phlebitis, varicose veins).	Knowledge reveals patient’s level of understanding of condition. A preexisting condition influences which examination techniques to use and the expected findings.
7 Determine if patient experiences leg cramps; numbness or tingling in extremities; sensation of cold hands or feet; pain in legs; or swelling or cyanosis of feet, ankles, or hand.	These are signs and symptoms of vascular disease.
8 If patient experiences leg pain or cramping in lower extremities, ask if it is relieved by walking or standing for long periods or if it occurs during sleep.	Relationship of symptoms to exercise clarifies if problem is vascular or musculoskeletal. Pain caused by vascular condition tends to increase with activity. Musculoskeletal pain is usually not relieved when exercise ends.
9 Ask women if they wear tight-fitting underwear or hosiery and sit or lie in bed with legs crossed.	Tight hosiery around lower extremities and crossing legs can impair venous return, promoting clot formation.

STEP

RATIONALE

NURSING DIAGNOSES

- Activity intolerance
- Decreased cardiac output
- Deficient knowledge
- Ineffective peripheral tissue perfusion
- Pain (acute, chronic)
- Risk for peripheral neurovascular dysfunction

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Heart rate is 60 to 100 beats/min (adolescent through adult), without extra sounds or murmurs. • Point of maximal impulse (PMI) is palpable at fifth intercostal space at left midclavicular line in children older than 7 years of age and adults. • Patient describes changes in own behavior that could improve cardiovascular function. • Patient describes schedule, dosage, purpose, and benefits of medications being taken for cardiovascular function. • Blood pressure is within normal limits for patient (see Chapter 5). • Carotid pulse is localized, strong, elastic, and equal bilaterally. No change occurs during inspiration or expiration; without carotid bruit. • Jugular veins distend when patient lies supine and flatten when patient is in sitting position. • Peripheral pulses are equal and strong (2+); extremities are warm and pink, with capillary refill less than 2 seconds. There is no dependent edema. Peripheral hair growth is symmetric and evenly distributed, and the skin is free of lesions. <p>2 Anticipate teaching topics so that during the exam, you can instruct patient on risks for heart and vascular disease.</p> <p>3 Perform hand hygiene. Prepare necessary supplies.</p> | <p>Indicates normal rate and sinus rhythm.</p> <p>Indicates normal heart position.</p> <p>Information may improve patient's health behavior habits.</p> <p>Information related to health benefits may improve adherence to therapy.</p> <p>This is one indicator of normal cardiovascular function.</p> <p>This indicates a patent vessel.</p> <p>Venous pressure is normal.</p> <p>Peripheral circulation is intact.</p> <p>Allows you to incorporate teaching during examination.</p> <p>Reduces transmission of infection. Promotes efficient examination.</p> |
|--|---|

IMPLEMENTATION

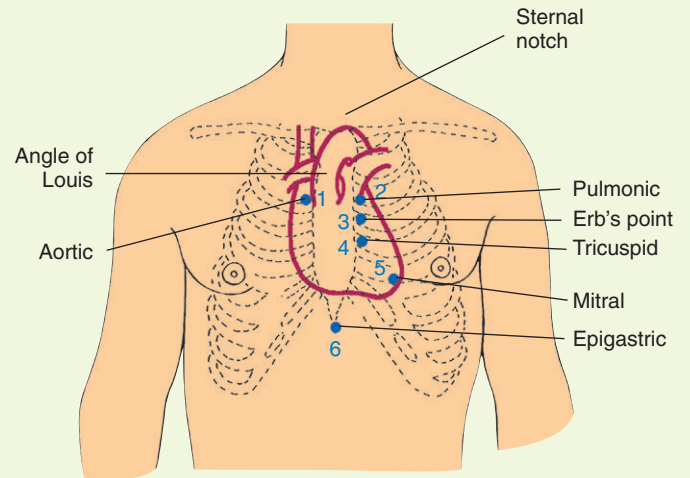

- | | |
|--|---|
| <p>1 Help patient be as relaxed and comfortable as possible.</p> <p>2 Have patient assume semi-Fowler's or supine position.</p> <p>3 Explain procedure. Avoid facial gestures reflecting concern.</p> <p>4 Be sure that room is quiet.</p> <p>5 Assess the heart:</p> <p>a Form a mental image of the exact location of the heart (see illustration). The base of the heart is the upper portion, and the apex is the bottom tip. The surface of the right ventricle constitutes most of the anterior surface of the heart.</p> <p>b Find the angle of Louis, felt as a ridge in the sternum approximately 5 cm (2 inches) below the suprasternal notch (between the sternal body and the manubrium). Slip fingers down each side of angle to feel adjacent ribs. The intercostal spaces are just below each rib.</p> <p>c Find the following anatomic landmarks (see illustration):</p> | <p>An anxious or uncomfortable patient can have mild tachycardia, which alters findings.</p> <p>Provides adequate visibility and access to left thorax and mediastinum. Patient with heart disease often experiences shortness of breath while lying flat.</p> <p>Patients with previously normal cardiac history may become anxious if you show concern.</p> <p>Subtle, low-pitched heart sounds are difficult to hear.</p> <p>Visualization improves ability to assess findings accurately and determines possible source of abnormalities.</p> <p>Provides you with landmarks to locate and assess heart sounds.</p> <p>Familiarity with landmarks allows you to describe findings more clearly and ultimately may improve assessment.</p> |
|--|---|

STEP

STEP 5a Anatomic position of heart.

RATIONALE

STEP 5c Anatomic sites for assessment of cardiac function.

- (1) The aortic area is at the second intercostal space, right of patient's sternum, close to the sternal border (1).
- (2) The pulmonic area is at the second intercostal space, left of patient's sternum, close to the sternal border (2).
- (3) The second pulmonic area is found by moving down the left side of the sternum to the third intercostal space, close to the sternal border (3), also referred to as *Erb's point*.
- (4) The tricuspid area (4) is located at the fourth left intercostal space along the sternum, close to the sternal border.
- (5) The mitral area is found by moving fingers laterally to patient's left to locate fifth intercostal space at left midclavicular line (5).
- (6) The epigastric area (6) is at the inferior tip of the sternum.

- d** Stand to patient's right to inspect and palpate the precordium with patient supine. Note any visible pulsations and more exaggerated lifts. Closely inspect the area of the apex. Palpate for pulsations (placing proximal half of four fingers together and then alternating with ball of hand at all anatomic landmarks).

Listening to the heart sounds from too far away from the sternal border decreases the ability to hear them clearly.

Reveals size and symmetry of the heart. The apical impulse may be visible at the midclavicular line in the fifth intercostal space. The apical impulse (PMI) may become visible only when the patient sits up, bringing the heart closer to the anterior wall. Obesity obscures the ability to visualize the PMI. There should be no pulsations or vibrations. A thrill is a continuous palpable sensation, such as the purring of a cat. A thrust is the upward lift felt when palpating the chest wall.

STEP

- e Locate the PMI by palpating with fingertips along the fifth intercostal space in midclavicular line (see illustration). Note a light, brief pulsation in an area 1 to 2 cm ($\frac{1}{2}$ to 1 inch) in diameter at the apex.

RATIONALE

In the presence of serious heart disease, the PMI is located to the left of the midclavicular line related to the enlarged left ventricle. In chronic lung disease the PMI may be to the right of the midclavicular line as a result of right ventricular enlargement.

STEP 5e Palpation of point of maximal impulse. (From Seidel HM et al: Mosby's guide to physical examination, ed 7, St Louis, 2011, Mosby.)

Clinical Decision Point Presence of a palpable thrill is not normal and indicates a disruption of blood flow caused by a defect in closure of a heart valve or atrial septal defect. Report to health care provider.

Clinical Decision Point A stronger than expected impulse is a heave or lift, which indicates increased cardiac output or left ventricular hypertrophy. Report to health care provider.

- f If palpating PMI is difficult, turn patient onto left side.
- g Inspect epigastric area and palpate abdominal aorta. Note you should feel a localized strong beat.
- h Auscultate heart sounds.
 - (1) Have patient sit up and lean slightly forward; then have him or her lie supine; and end the examination with patient in a left lateral recumbent position (see illustration A to C). In a female patient it may be necessary to lift the left breast to hear heart sounds more effectively.

Maneuver moves the heart closer to the chest wall.

Rules out reduced blood flow or diffuse pulse, which indicates an abnormality.

Different positions help to clarify type of sounds heard. Sitting position is best to hear high-pitched murmurs (if present). Supine is a common position to hear all sounds. Left lateral recumbent is the best position to hear low-pitched sounds.

STEP

RATIONALE

STEP 5h(1) Patient positions for auscultation of heart sounds. **A**, Sitting. **B**, Supine. **C**, Left lateral. (From Seidel HM et al: Mosby's guide to physical examination, ed 7, St Louis, 2011, Mosby.)

- | | |
|---|---|
| <p>(2) While auscultating sounds at each anatomic landmark, ask patient not to speak but to breathe comfortably. Begin with the diaphragm of the stethoscope; alternate with the bell. Use very light pressure for the bell. Inch the stethoscope along; avoid jumping from one area to another. Do not try to hear all heart sounds at once.</p> | <p>Auscultation requires you to isolate each heart sound at all auscultation sites, especially in patients with soft heart sounds.</p> |
| <p>(3) Begin at the apex or PMI; move systematically to the aortic area, pulmonic area, Erb's point, tricuspid area, and mitral area (see illustration in Step 5c). (NOTE: Some examiners use reverse sequence.) S_1 is loudest at the apex and is simultaneous with the carotid pulse. NOTE: a helpful mnemonic for remembering heart sound locations: A Pig Eats Too Much (Aortic, Pulmonic, Erb's point, Tricuspid, Mitral).</p> | <p>At normal slow rates S_1 is high pitched and dull in quality and sounds like a "lub." This sound precedes the systolic phase of heart contraction.</p> |
| <p>(4) Listen for S_2 at each site. This sound is loudest at the aortic area. Heart sounds vary by pitch, loudness, and duration, depending on the auscultatory site (Table 6-8).</p> | <p>Normal sounds S_1 and S_2 are high pitched and best heard with the diaphragm. S_2 precedes the diastolic phase and sounds like "dub."</p> |
| <p>(5) After both sounds are heard clearly as "lub-dub," count each combination of S_1 and S_2 as one heartbeat. Count the number of beats for 1 minute.</p> | <p>Determines apical pulse rate.</p> |

STEP

RATIONALE

- (6) Assess heart rhythm by noting the time between S_1 and S_2 (systole) and then the time between S_2 and the next S_1 (diastole). Listen to the full cycle at each auscultation area. Note regular intervals between each sequence of beats. There should be a distinct pause between S_1 and S_2 .
- (7) When the heart rate is irregular, compare apical and radial pulses (Table 6-9). Auscultate the apical pulse and then immediately palpate the radial pulse. A colleague can assess the radial pulse while assess the apical pulse.
- i Auscultate for extra heart sounds at each site. Note pitch, loudness, duration, timing, location on chest wall, and where it is heard in cardiac cycle.
- (1) Use the stethoscope bell and listen for low-pitched extra heart sounds such as S_3 and S_4 gallops, clicks, and rubs. S_3 , or a ventricular gallop, occurs just after S_2 at the end of ventricular diastole. It sounds like “lub-dub-ee” or “Ken-tuc-ky.” S_4 , or an atrial gallop, occurs just before S_1 or ventricular systole. It sounds like “dee-lub-dub” or “Ten-nes-see.”
- (2) With patient leaning forward or lying on the left side, listen for friction rubs as “squeaky” or rubbing sounds.
- Failure of heart to beat at regular intervals is a dysrhythmia, which interferes with the ability of the heart to pump effectively.
- Determines if a pulse deficit (radial pulse is slower than apical) exists. Deficit indicates that ineffective contractions of the heart fail to send pulse waves to the periphery.
- Abnormal sounds include murmurs. Characteristics of murmurs help to identify contributing factors.
- Premature rush of blood into a ventricle that is stiff or dilated or an atrial contraction pushing against a ventricle that is not accepting blood causes gallops.
- Rubs result from lungs or inflamed visceral and parietal layers of the pericardium of the heart rubbing against one another.

TABLE 6-8 Heart Sounds According to Auscultatory Area

	Aortic	Pulmonic	Second Pulmonic	Mitral	Tricuspid
Pitch	$S_1 < S_2$	$S_1 < S_2$	$S_1 < S_2$	$S_1 > S_2$	$S_1 = S_2$
Loudness	$S_1 < S_2$	$S_1 < S_2$	$S_1 < S_2^*$	$S_1 > S_2^\dagger$	$S_1 > S_2$
Duration	$S_1 > S_2$	$S_1 > S_2$	$S_1 > S_2$	$S_1 > S_2$	$S_1 > S_2$

Modified from Seidel HM et al: *Mosby's guide to physical examination*, ed 7, St Louis, 2011, Mosby.

* S_1 is relatively louder in second pulmonic area than in aortic area.

† S_1 may be louder in mitral area than in tricuspid area.

TABLE 6-9 Abnormalities in Rates and Rhythms

Type	Findings	Description
Atrial fibrillation	Rapid, random contractions of atria cause irregular ventricular beats >100 beats/min and atrial beats at 200-350 beats/min	Atria discharge very rapidly, with some impulses not reaching ventricles. This condition occurs in rheumatic heart disease and mitral stenosis. It causes reduced cardiac output.
Sinus arrhythmia	Pulse rate changes during respiration, increasing at peak of inspiration and decreasing during expiration.	Blood is momentarily trapped in lungs during inspiration, causing a fall in stroke volume of heart.
Sinus bradycardia	Pulse rhythm is regular, but rate is <60 beats/min.	Sinoatrial node fires less frequently. This is common in well-conditioned athletes and with use of antiarrhythmic medications.
Sinus tachycardia	Pulse rhythm is regular, but rate is accelerated to >100 beats/min.	Exercise, emotional stress, and caffeine or alcohol ingestion are common factors that cause increased firing of sinoatrial node.
Premature ventricular contraction	Premature beat occurs before regularly expected heart contraction. Underlying rhythm can be any rate.	Ventricle contracts prematurely because of electrical impulse bypassing normal conduction pathway. It may occur so early that it is difficult to detect as second beat. It may be followed by a pause.

STEP

RATIONALE

- j** Auscultate for heart murmurs over each of the auscultation sites.
- (1) When you detect a murmur, listen carefully to note where you hear it best. Note the intensity of the murmur.
 - (2) Note if the murmur is low, medium, or high in pitch, using the bell for low-pitched sounds.
- 6** Assess neck vessels:
- a** To assess carotid arteries: have patient remain in sitting position.
 - b** Inspect neck on both sides for obvious arterial pulsations. Sometimes a pulse wave can be seen.
 - c** Palpate each carotid artery separately with index and middle fingers around medial edge of sternocleidomastoid muscle. Ask patient to raise chin slightly, keeping the head straight (see illustration) or slightly away from artery. Note rate and rhythm, strength, and elasticity of artery. Also note if pulse changes as patient inhales and exhales.

Murmurs are sustained swishing or blowing sounds heard at the beginning, middle, or end of systole or diastole. Increased blood flow through a normal valve, forward flow through a stenotic valve or into a dilated vessel or chamber, or backward flow through a valve that fails to close causes murmurs.

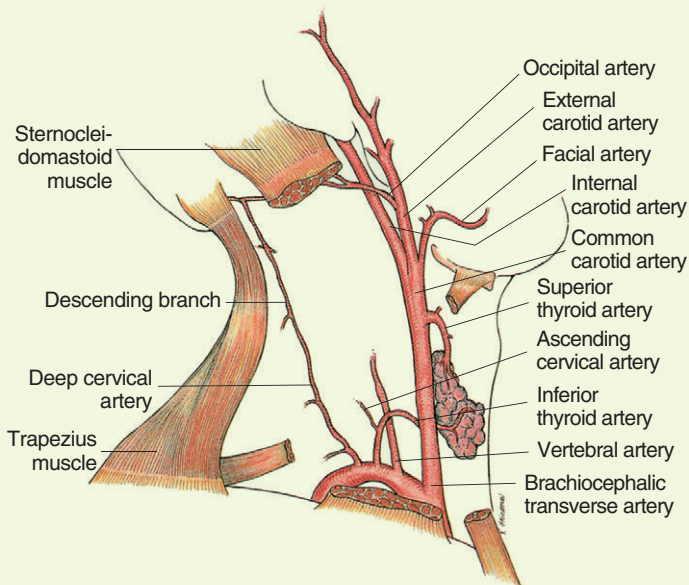

Intensity is related to rate of blood flow through the heart or the amount of blood regurgitated.

Pitch depends on velocity of blood flow through the valves.

Allows easier mobility of neck to expose artery for inspection and palpation.

Carotids are the only sites to assess quality of pulse wave (see illustration). Experience is required to evaluate wave in relation to events of cardiac cycle.

If both arteries were occluded simultaneously, patient could lose consciousness from reduced circulation to the brain. Turning the head improves access to artery. A change indicates a sinus arrhythmia.

STEP 6b Anatomic position of carotid artery.

STEP 6c Palpate each carotid artery separately.

Clinical Decision Point Do not palpate or massage the carotid artery vigorously. Stimulation of carotid sinus causes a reflex drop in heart rate and blood pressure.

- d** Place bell of stethoscope over each carotid artery, auscultating for blowing sound (bruit) (see illustration). Ask patient to hold a breath for a few heartbeats so respiratory sounds do not interfere with auscultation (Seidel et al., 2011).

Narrowing of the lumen of the carotid artery by arteriosclerotic plaques causes disturbance in blood flow. Blood passing through narrowed section creates turbulence and emits blowing or swishing sound. Normally you do not hear a bruit.

STEP

RATIONALE

- e To assess jugular venous pressure (JVP), have patient assume a supine position. Raise the head of the bed 45 degrees, avoiding neck hyperextension or flexion. Locate the highest point along the internal jugular vein where a pulsation can be seen (good lighting helps). Locate the sternal angle with a centimeter ruler and measure the vertical distance between the sternal angle and the meniscus of the internal jugular vein (see illustration).

Normal veins are flat when patient is sitting, and pulsations become evident as you lower patient's head. A height of pulsation greater than 2.5 cm (1 inch) indicates fluid overload or right-sided heart failure.

STEP 6d Auscultation for carotid artery bruit. (From Seidel HM et al: Mosby's guide to physical examination, ed 7, St Louis, 2011, Mosby.)

STEP 6e Position for assessment of jugular vein distention. (From Seidel HM et al: Mosby's guide to physical examination, ed 7, St Louis, 2011, Mosby.)

7 Peripheral vascular assessment:

- a Inspect lower extremities for changes in color and condition of skin (Table 6-10). Note skin and nail texture, hair distribution, venous patterns, edema, and scars or ulcers. Compare skin color with patient lying and standing.
- b Palpate edematous areas, noting mobility, consistency, and tenderness.
- c Assess for pitting edema by pressing area firmly with one finger for 5 seconds and releasing. Depth of indentation determines severity (see illustration).
 - 2 mm: 1+ edema
 - 4 mm: 2+ edema
 - 6 mm: 3+ edema
 - 8 mm: 4+ edema

Changes may reflect impaired peripheral circulation.

Assists in determining extent of edema.

Unilateral edema of affected leg is the most common physical finding of deep vein thrombosis (DVT), although symptoms are similar to other conditions, making diagnosis difficult (Carter, 2010).

Use a tape measure to measure the circumference of the extremity.

Measuring circumference establishes a baseline for future comparison.

TABLE 6-10 Signs of Venous and Arterial Insufficiency

Assessment Criterion	Venous	Arterial
Pain	Aching; increases in evening and with dependent position	Burning, throbbing, cramping; increases with exercise
Paresthesia	None	Numbness, tingling, decreased sensation
Temperature	Normal to touch	Cool to touch
Color	Normal or cyanotic	Pale; worsened by elevation of extremity; dusky red when extremity is lowered
Capillary refill	Not applicable	>2 seconds
Pulse	Present	Decreased or absent
Skin changes	Brown pigmentation around ankles	Thin, shiny skin; decreased hair growth; thickened nails
Ulcerations	Shallow ulcers around ankles (chronic venous stasis); edema apparent	Deep, well defined at site of trauma or tips of toes

STEP

RATIONALE

STEP 7c Assessing for pitting edema. (From Seidel HM et al: Mosby's guide to physical examination, ed 7, St Louis, 2011, Mosby.)

- d Check capillary refill by grasping patient's fingernail or toenail and noting color of nail bed. Apply gentle, firm pressure to nail bed. Release quickly, watching for color change. Circulation is restored and normally returns to pink color in less than 2 seconds.
- e Ask if patient experiences pain or tenderness and gently palpate for heat, firmness, or localized swelling of the calf muscle, which are signs of phlebitis or DVT.

Capillary refill is measured in seconds; less than 2 seconds is brisk, whereas greater than 4 seconds is sluggish. Cold environmental temperature with vasoconstriction and vascular disease can delay refill. Local pressure from a cast or bandage also slows refill. Patients who have been immobilized for at least 3 days and who have bone or joint disease, lengthy surgery, surgical correction of joint or bone, heart failure, shock, varicose veins, or pain are at risk for impaired tissue perfusion (Carter, 2010).

Clinical Decision Point Homans' sign (pain in calf on dorsiflexion of foot) is no longer considered a reliable indicator for the presence or absence of DVT (Carter, 2010; Seidel et al., 2011) and should not be considered a reliable test. Trauma to a vein or muscle, reduced mobility, and increased blood clotting are reliable risk factors. If calf is swollen, tender, or red, notify patient's health care provider for further assessment and evaluation. If there is a strong suspicion of DVT, testing for Homans' sign is contraindicated. If a clot is present, it may become dislodged from its original site during this test. This could result in a pulmonary embolism.

- f Palpate peripheral arteries.
 - (1) Start at the most distal part of each extremity. Palpate each peripheral artery for equality, comparing side to side; elasticity of vessel wall (depress and release artery, noting ease with which it springs back to shape); and strength of pulse (force of blood against arterial wall) using the following rating scale (Seidel et al., 2011):
 - 0 Absent, not palpable
 - 1+ Diminished, pulse barely palpable, weak and thready, and easy to obliterate
 - 2+ Normal pulse, easy to palpate
 - 3+ Full, easy to palpate, increases
 - 4+ Strong, bounding against fingertips, and cannot be obliterated
 - (2) Palpate radial pulse by lightly placing tips of first and second fingers in groove formed along radial side of forearm, lateral to flexor tendon of wrist (see illustration).
 - (3) Palpate ulnar pulse by placing fingertips along ulnar side of forearm (see illustration).
 - (4) Palpate brachial pulse by locating groove between biceps and triceps muscles above elbow at antecubital fossa (see illustration). Place tips of first two fingers in muscle groove.
 - (5) Have patient lie supine with feet relaxed and palpate dorsalis pedis pulse. Gently place fingertips between great and first toe; slowly move fingers along groove between extensor tendons of great and first toe until pulse is palpable (see illustration).
 - (6) Palpate posterior tibial pulse by having patient relax and extend feet slightly. Place fingertips behind and below medial malleolus (ankle bone) (see illustration).

Comparison of both arteries allows you to determine any localized obstruction or disturbance in blood flow. Pulses should be symmetric side to side. If asymmetry is noted, look for other factors related to impaired circulation.

Pulse is relatively superficial and should not require deep palpation.

Palpated when arterial insufficiency to hand is expected or when you assess for radial occlusion (e.g., during arterial blood gas sampling) which may affect circulation to hand (see Chapter 43).

Artery runs along medial side of extended arm, requiring moderate palpation. If difficult to palpate, hyperextend arm to bring pulse site closer to the surface.

Artery lies superficially and does not require deep palpation. Pulse may be congenitally absent.

Artery is easily palpable with foot relaxed.

STEP

- (7) Palpate popliteal pulse by having patient slightly flex knee with foot resting on table or bed. Instruct patient to keep leg muscles relaxed. Palpate deeply into popliteal fossa with fingers of both hands placed just lateral to midline. Patient may also lie prone to achieve exposure of artery (see illustration).

RATIONALE

Flexion of knee and muscle relaxation improve accessibility of artery. Popliteal pulse is one of the more difficult pulses to palpate.

STEP 7f(2) Palpation of radial pulse.

STEP 7f(5) Palpation of dorsalis pedis pulses.

STEP 7f(3) Palpation of ulnar pulse.

STEP 7f(6) Palpation of posterior tibial pulse.

STEP 7f(4) Palpation of brachial pulse.

STEP 7f(7) Palpation of popliteal pulse with patient prone.

STEP

- (8) Apply clean gloves. With patient supine, palpate femoral pulse by placing first two fingers over inguinal area below inguinal ligament, midway between pubic symphysis and anterosuperior iliac spine (see illustration).
- 9 If pulses are difficult to palpate or are not palpable, use a Doppler instrument over the pulse site:
- (1) Apply conducting gel to patient's skin over pulse site or onto transducer tip of probe. Turn Doppler on.
 - (2) Gently apply ultrasound probe to skin, changing Doppler angle until pulsation is audible. Adjust volume as needed (see illustration). Wipe off gel from patient and Doppler.
- 8 Remove gloves and discard used supplies and gloves in proper receptacle. Assist patient to comfortable position. Perform hand hygiene.

RATIONALE

Supine position prevents flexion in groin area, which interferes with artery access.

Doppler amplifies sounds, allowing you to hear low-velocity blood flow through peripheral arteries.

Reduces transmission of infection.

STEP 7f(8) Palpation of femoral pulse.

STEP 7g(2) Use of Doppler to assess brachial pulse.

EVALUATION

- | | |
|--|---|
| 1 Compare findings with normal assessment characteristics of heart and vascular system. | Determines presence of abnormalities. |
| 2 If heart sounds are not audible or pulses are not palpable, ask another nurse to confirm assessment. | Validates abnormal assessment findings. |
| 3 Ask patient to describe behaviors that increase risk for heart and vascular disease. | Demonstrates learning. |
| 4 Compare pulses and capillary refill bilaterally with previous assessment. | Demonstrates change from baseline measures. |

Unexpected Outcomes

- 1 Abnormal findings that differ from previous assessments require you to **notify the health care provider**. These include:
- Pulsations, vibrations, or both are palpable. These are the result of valvular problem, murmur, or both.
 - PMI is to the left of midclavicular line, which is the result of cardiomegaly.
 - Extra heart sounds S_3 or S_4 are auscultated. Extra sounds indicate atrial or ventricular gallop.
 - Murmur is auscultated. Impaired blood flow through heart indicates need for immediate medical attention. Some murmurs are benign.
 - JVP is elevated. This is a sign of right-sided heart failure or fluid overload.

Related Interventions

- Prepare to obtain or assist with electrocardiogram (ECG).

Unexpected Outcomes

- 2 Heart rate is irregular, with rate less than 60 beats/min or more than 100 beats/min.
- 3 Pulse deficit is noted. There is risk for inadequate cardiac output.
- 4 Patient is unable to explain risks for heart or vascular disease.
- 5 Previously palpable dorsalis pedis pulses are diminished or absent, indicating circulatory compromise.
- 6 Patient's lower extremities have pale, cool, thin, and shiny skin, with reduced hair growth and thickened nails, indicating chronic arterial insufficiency.

Related Interventions

- Check blood pressure. If low, dysrhythmia is contributing to inadequate cardiac output.
- Observe for sensations or reports of dizziness or feeling “faint.”
- Prepare to obtain ECG.
- Obtain vital signs.
- Additional education is needed.
- Elevate extremity.
- Instruct patient in proper foot care.
- Refer to podiatrist for nail trimming.
- Inspect feet for signs of impaired skin integrity.

Recording and Reporting

- Document quality (clear or muffled), intensity (weak or pounding), rate, and rhythm (regular, regularly irregular, or irregularly irregular) of heart sounds and peripheral pulses on nurses' notes, EHR, or flow sheet.
- Document additional cardiac findings, jugular venous pressure, and condition of extremities in nurses' notes, EHR, or flow sheet.
- Document activity level and subjective data related to fatigue, shortness of breath, and chest pain.
- Report immediately to health care provider any irregularities in heart function and indications of impaired arterial blood flow.
- Report to health care provider changes in peripheral circulation, which may indicate circulatory compromise, which may result in permanent nerve damage or tissue death if untreated.

Special Considerations

Teaching

- Explain risk factors for heart disease: high dietary intake of saturated fat or cholesterol, lack of regular aerobic exercise, smoking, excess weight, stressful lifestyle, hypertension, and family history of heart disease.
- Refer patient (if appropriate) to resources available for controlling or reducing risks (e.g., nutrition counseling, exercise class, and stress-reduction programs).
- Encourage patient to discuss with health care provider the need for periodic C-reactive protein (CRP) testing. CRP levels assess a patient's cardiovascular disease risk.

- Help patient to find resources to assist in quitting smoking because this lowers the risk for coronary heart disease and coronary vascular disease (ACS, 2011b). Nicotine in cigarette smoke causes vasoconstriction.
- Patients who are at risk benefit from taking a daily low dose of aspirin. Consult health care provider before starting therapy.

Pediatric

- PMI is at fourth intercostal space at left midclavicular line in children younger than 7 years of age (Hockenberry and Wilson, 2011).
- Capillary refill in infants is usually less than 1 second.
- It is not uncommon for children to have third heart sounds (S₃). Sinus arrhythmia occurs normally in many infants and children (Hockenberry and Wilson, 2011).
- Children have louder, higher-pitched heart sounds because of their thin chest walls.

Gerontologic

- PMI may be difficult to find in an older adult because antero-posterior diameter of the chest deepens.
- Accidental massage of the carotid sinus during palpation of the carotid artery is a particular problem for older adults, causing a sudden drop in heart rate from vagal nerve stimulation.
- Older adults with hypertension benefit from regular monitoring of blood pressure (daily, weekly, or monthly). Home monitoring kits are available. Teach patient how to use them correctly.

SKILL 6-5 Abdominal Assessment

Abdominal assessment is complex because of the multiple organs located within and near the abdominal cavity. This area of the body is associated with many health complaints; and many people are embarrassed by bowel or bladder dysfunction, reproductive problems, or urinary elimination problems. Abdominal pain is one of the most common symptoms that patients report when seeking medical care. It can be caused by alterations in organs such as the stomach, gallbladder, or intestines; or the pain may be the result of spinal or muscular injury. An accurate assessment requires matching the patient's history with a careful assessment of the location of physical symptoms (Table 6-11).

To perform an effective abdominal assessment you need to know the location and function of the underlying structures involved, including the lower pelvis, kidneys, rectum, genitalia, liver, gallbladder, stomach, spleen, appendix, pancreas, intestines, and reproductive organs (Fig. 6-5). An abdominal assessment is routine after abdominal surgery, for any patient who has undergone invasive diagnostic tests of the gastrointestinal (GI) tract, and for patients with abnormalities affecting GI function (see Chapter 44). The order of an abdominal assessment differs from that of other assessments. You begin with inspection and follow with auscultation. It is important to auscultate before palpation and percussion

because these maneuvers alter the frequency and character of bowel sounds.

Delegation and Collaboration

The skill of abdominal assessment cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report the development of abdominal pain and changes in the patient's bowel habits or dietary intake to the nurse.

Equipment

- Stethoscope
- Tape measure
- Examination light
- Water-based marking pen
- Drapes

TABLE 6-11 Common Causes of Abdominal Pain

Condition	Physical Alteration	Physical Signs and Symptoms
Appendicitis	Obstruction of appendix associated with inflammation, perforation, and peritonitis Patient often lies on back or side with knees flexed to decrease pain	Sharp pain directly over the irritated peritoneum 2-12 hours after onset. Often pain localizes in right lower quadrant (McBurney's point) between anterior iliac crest and umbilicus. Associated with rebound tenderness. Accompanied by anorexia, nausea, and vomiting.
Celiac disease	Damage to small intestine mucosa from ingestion of barley, rye, oats, and wheat	Foul-smelling diarrhea, abdominal distention, and symptoms of malnutrition may be present.
Cholecystitis	Obstruction of cystic duct causing inflammation or distention of the gallbladder	<i>Murphy's sign</i> : Apply gentle pressure below right subcostal arch and liver margin. Sharp pain and increased respiratory rate occur when patient takes a deep breath (Seidel et al, 2011).
Constipation	Disruption in normal bowel pattern, which may occur with opioid use or inadequate fiber and fluid intake	Generalized discomfort accompanied by distention and palpation of a hard mass in the left lower quadrant. Nausea and vomiting may begin after several days.
Crohn's disease	Chronic inflammatory lesion of the ileum	Steady colicky pain in the right lower quadrant, with cramping, tenderness, flatulence, nausea, fever, and diarrhea. Often associated with bloody stools, weight loss, weakness, and fatigue. A tender mass of thickened intestine may be palpated in right lower quadrant.
Gastroenteritis	Inflammation of the stomach and intestinal tract	Generalized abdominal discomfort accompanied by anorexia, nausea, vomiting, diarrhea, abdominal cramping.
Pancreatitis	Inflammation of the pancreas associated with alcoholism, drug reaction, and gallbladder disease	Steady severe epigastric pain close to umbilicus radiates to back. Associated with abdominal rigidity and vomiting. Pain is unrelieved by vomiting, worsens by lying supine.
Paralytic ileus	Obstruction of the small bowel that occurs after abdominal surgery, from abdominal radiation, or from use of anticholinergic medications	Generalized severe abdominal distention, nausea, and vomiting. Decreased/absent bowel sounds.
Peptic ulcers (gastric and duodenal)	Damage of gastrointestinal (GI) mucosa at any area of the GI tract. May be caused by bacterial infection (<i>Helicobacter pylori</i>) or nonsteroidal antiinflammatory drugs (NSAIDs) Thought to be unrelated to stress Aggravated by smoking and excessive alcohol use	<i>Gastric ulcer</i> : Dull epigastric pain, localized midline. Early satiety; not usually relieved by food or antacids. <i>Duodenal ulcer</i> : Pain is episodic, lasting 30 minutes to 2 hours. It is located midline in epigastric region, may radiate around costal border to back; described as aching, burning, or gnawing. Typically occurs 1-3 hours after meals and at night (12 midnight to 3 AM). Often relieved by food/antacid. <i>Both (dyspepsia syndrome)</i> : Complaints of fullness, epigastric discomfort, vague feeling of nausea, abdominal distention, and bloating; anorexia; weight loss.

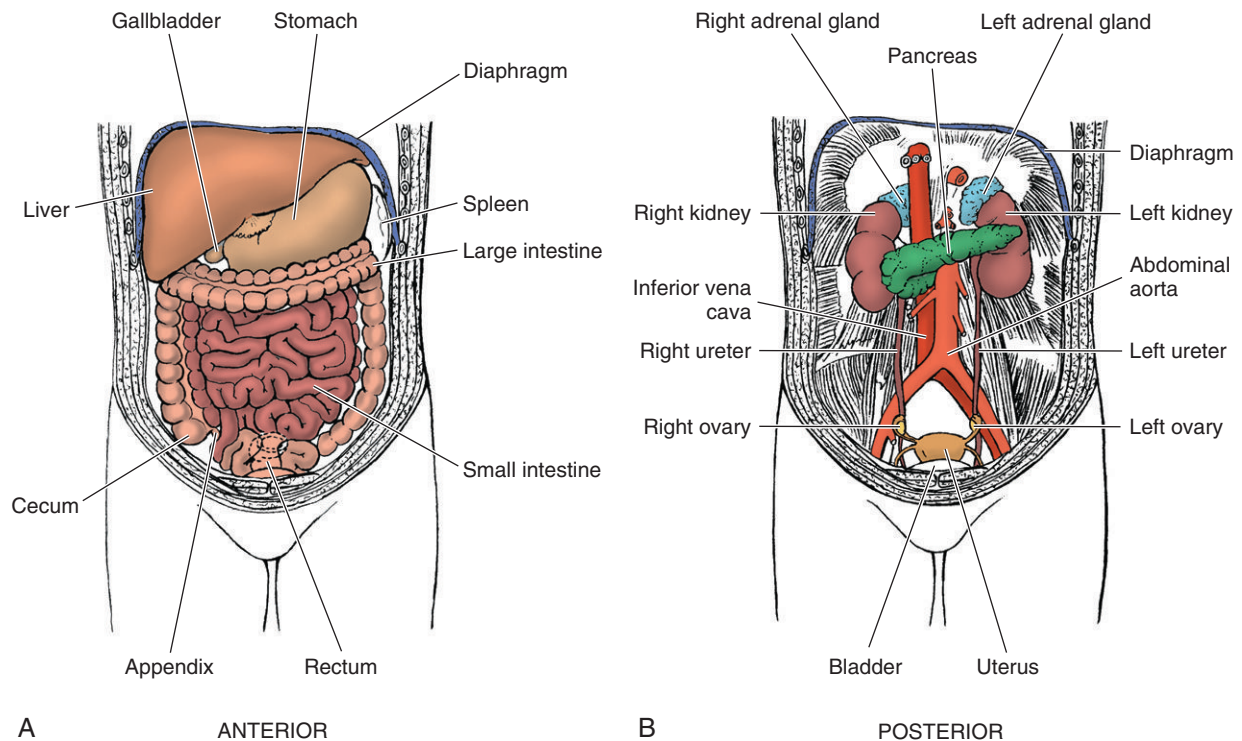

FIG 6-5 Location of organs in abdomen. **A**, Anterior. **B**, Posterior. (Modified from Mosby's expert 10 minute physical examinations, ed 2, St Louis, 2005, Mosby.)

STEP

RATIONALE

ASSESSMENT

- 1 If patient has abdominal or low back pain, assess the character of pain in detail (location, onset, frequency, precipitating factors, aggravating factors, type of pain, severity, course).
 - 2 Carefully observe patient's movement and position such as lying still with knees drawn up, moving restlessly to find a comfortable position, or lying on one side or sitting with knees drawn up to chest.
 - 3 Assess patient's normal bowel habits: frequency of stools; character of stools; recent changes in character of stools; measures used to promote elimination such as laxatives, enemas, and dietary intake; and eating and drinking habits.
 - 4 Determine if patient has had abdominal surgery, trauma, or diagnostic tests of the GI tract.
 - 5 Assess if patient has had recent weight changes or intolerance to diet (nausea, vomiting, cramping, especially in past 24 hours).
 - 6 Assess for difficulty in swallowing, belching, flatulence, bloody emesis (hematemesis), black or tarry stools (melena), heartburn, diarrhea, or constipation.
 - 7 Determine if patient takes antiinflammatory medications (e.g., aspirin, steroids, and nonsteroidal antiinflammatory drugs [NSAIDs]), or antibiotics.
 - 8 Review family history of cancer, kidney disease, alcoholism, hypertension, or heart disease.
- Knowing pattern of characteristics of pain helps determine its source.
- Positions assumed by patient reveal nature and source of pain (e.g., peritonitis, kidney stone, appendicitis). Patients with peritonitis lie still because movement aggravates the pain. The supine position worsens acute pancreatitis pain; a flexed knee, curved-back position brings relief. Patients with appendicitis lie on side or back with knees flexed in an attempt to decrease muscle strain on the abdominal wall.
- Data compared with information from physical assessment may help identify cause and nature of elimination problems.
- Surgery or trauma to the abdomen may result in altered position of underlying organs. Diagnostic tests may change character of stool.
- Changes may indicate alterations in upper GI tract (e.g., stomach or gallbladder) or lower colon.
- Indicative of GI alterations.
- These medications may cause GI upset or bleeding.
- Information may reveal risk for significant abdominal alterations. Chronic alcohol ingestion causes GI and liver problems.

STEP

RATIONALE

9 Review patient's history for health care occupation, hemodialysis, intravenous drug use, household or sexual contact with hepatitis B virus (HBV) carrier, sexually active heterosexual person (more than one sex partner in previous 6 months), sexually active homosexual or bisexual man, international traveler in area of high HBV prevalence.

These are risk factors for HBV exposure. Abdominal findings for hepatitis include jaundice, hepatomegaly, anorexia, abdominal and gastric discomfort, tea-colored urine, and clay-colored stools (Lewis et al., 2011).

NURSING DIAGNOSES

- | | | |
|---|---|--|
| <ul style="list-style-type: none"> • Constipation • Deficient knowledge • Diarrhea | <ul style="list-style-type: none"> • Imbalanced nutrition: less than body requirements • Nausea | <ul style="list-style-type: none"> • Imbalanced nutrition: more than body requirements • Ineffective health maintenance • Pain (acute, chronic) |
|---|---|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Abdomen is soft and symmetric, with smooth and even contour. No mass, distention, or tenderness is palpable. There are no forceful visible pulsations.
 - Bowel sounds are active and audible in all four quadrants.
 - No costovertebral angle (CVA) tenderness is present.
 - Patient denies discomfort or worsening of existing discomfort following examination.
 - Patient is able to list warning signs of colorectal cancer.
- 2 Anticipate teaching topics so that during the exam, you can instruct patient about warning signs of colorectal cancer.
- 3 Perform hand hygiene. Prepare necessary supplies.

These are normal abdominal assessment findings.

Indicates normal peristaltic activity.

Indicates no inflammation of kidney.

Proper examination procedures have been implemented.

Demonstrates learning.

Allows you to incorporate instruction during physical assessment.

Reduces risk of transmission of infection. Ensures efficiency during examination.

IMPLEMENTATION

- 1 Prepare patient for abdominal assessment:
 - a Ask if patient needs to empty bladder or defecate.
 - b Keep upper chest and legs draped.
 - c Be sure that room is warm.
 - d Have patient lie supine or in a dorsal recumbent position with arms down at sides and knees slightly bent. Place a small pillow under patient's knees.
 - e Move sheet or blanket to expose area from just above xiphoid process down to symphysis pubis.
 - f Maintain conversation during assessment except during auscultation. Explain steps calmly and slowly.
 - g Ask patient to point to tender areas.
- 2 Abdominal assessment:
 - a Identify landmarks that divide abdominal region into quadrants. Boundary begins at tip of xiphoid process to symphysis pubis with line crossing and intersecting umbilicus, dividing abdomen into four equal sections (see illustration).

Palpation of full bladder causes discomfort and feeling of urgency and makes it difficult for patient to relax.

Maintains patient's comfort during examination, promoting relaxation.

Promotes patient's comfort. Reduces risk of patient tensing abdominal muscles.

Placing arms under the head or keeping knees fully extended causes abdominal muscles to tighten. Tightening of muscles prevents adequate palpation.

Provides full visualization of abdomen.

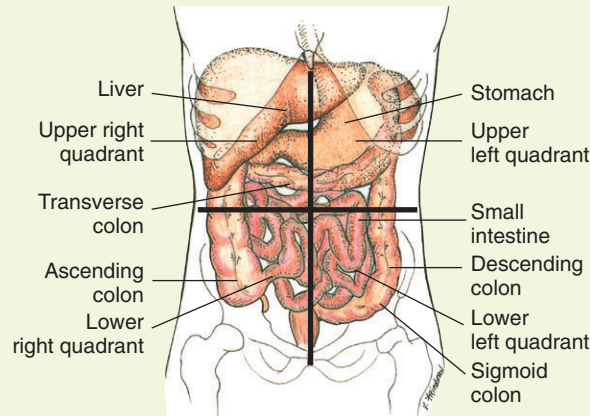

Patient's ability to relax during assessment improves accuracy of findings. Talking interferes with hearing bowel sounds.

Assess painful areas last. Manipulation of body part increases patient's pain and anxiety and makes remainder of assessment difficult to complete.

Location of findings by common reference point helps successive examiners confirm findings and locate abnormalities.

STEP

RATIONALE

STEP 2a Division of abdomen into quadrants.

- b** Inspect skin of surface of abdomen for color, scars, venous patterns, rashes, lesions, silvery white striae (stretch marks), and artificial openings (stomas). Observe skin lesions for characteristics described in [Skill 6-1](#).
- c** If you note bruising, ask if patient self-administers injections (e.g., heparin or insulin).
- d** Inspect contour, symmetry, and surface motion of abdomen. Note any masses, bulging, or distention. (Flat abdomen forms a horizontal plane from xiphoid process to symphysis pubis. Round abdomen protrudes in convex sphere from horizontal plane. Concave abdomen sinks into muscular wall. All are normal.)
- e** If abdomen appears distended, note if distention is generalized. Look at the flanks on each side.
- f** If you suspect distention, measure size of abdominal girth by placing tape measure under patient and around abdomen at level of umbilicus (see illustration). Use marking pen to indicate where tape measure was applied.
- Scars reveal evidence that patient has had past trauma or surgery. Striae indicate stretching of tissue from growth, obesity, pregnancy, ascites, or edema. Venous patterns reflect liver disease (portal hypertension). Artificial openings indicate bowel or urinary diversion (see [Chapter 35](#)).
- Frequent injections may cause bruising and hardening of underlying tissues. Bruising also indicates physical abuse, accidental injury, or bleeding disorders.
- Changes in symmetry or contour reveal underlying masses, fluid collection, or gaseous distention. An everted umbilicus (protruding outward) indicates distention. A hernia also causes the umbilicus to protrude upward.
- Distention may be caused by the nine F's (*fat, flatus, feces, fluids, fibroid, full bladder, false pregnancy, fatal tumor, and fetus*) ([Seidel et al., 2011](#)). If gas causes distention, flanks do not bulge. If fluid causes distention, flanks bulge. A tumor may cause a more unilateral bulging or distention. Pregnancy causes symmetric bulge in lower abdomen.
- Consecutive measurements show any increase or decrease in abdominal distention. Make all subsequent measurements at same level of umbilicus to provide objective means to evaluate changes. Use a water-based pen to make a mark on abdomen for subsequent measurements.

STEP 2f Measuring abdominal girth at level of umbilicus.

STEP

RATIONALE

- g** If patient has a nasogastric (NG) or nasointestinal (NI) tube connected to suction, turn off momentarily.
- h** To auscultate bowel sounds, place the diaphragm of the stethoscope lightly over each of the four abdominal quadrants. Ask patient not to talk. Listen until you hear repeated gurgling or bubbling sounds in each quadrant (minimum of once in 5 to 20 seconds). Describe sounds as normal, hyperactive, hypoactive, or absent. Listen 5 minutes over each quadrant before deciding that bowel sounds are absent.

Sound of suction obscures bowel sounds.

Normal bowel sounds occur irregularly every 5 to 15 seconds. Absence of sounds indicates cessation of gastric motility. Hyperactive bowel sounds not related to hunger or a recent meal may indicate diarrhea or early intestinal obstruction. Hypoactive or absent bowel sounds indicate paralytic ileus or peritonitis. It is common for bowel sounds to be hypoactive after surgery for 24 hours or more, especially following abdominal surgery.

Clinical Decision Point *Nausea and vomiting, increasing distention, and inability to pass flatus may accompany severe paralytic ileus.*

- i** Place the bell of the stethoscope over the epigastric region of the abdomen and each quadrant. Auscultate for vascular (whooshing) sounds.

Determines presence of turbulent blood flow (bruit) through thoracic or abdominal aorta, which may indicate an aneurysm.

Clinical Decision Point *If aortic bruit is auscultated, suggesting presence of an aneurysm, stop assessment and notify health care provider immediately. Percussion or palpation over abdominal bruit could cause rupture of an already weakened vessel wall in the presence of an abdominal aneurysm.*

- j** With patient supine, gently percuss each of the four abdominal quadrants systematically. Note areas of tympany and dullness.

Reveals presence of air or fluid in stomach and intestines. Normal percussion is tympanic because of swallowed air in GI tract. Presence of fluid or underlying masses is revealed by dull percussion.

- k** To determine if fluid or air is causing distention, percuss for a fluid wave. Ask a colleague to assist by pressing gently and firmly at midline of abdomen (see illustration). Place your fingertips along both sides of lower abdomen in lumbar region. Thrust quickly into patient's side with your dominant hand, keeping nondominant hand in place. If fluid is present, you will palpate a fluid wave with the nondominant hand.

If you do not feel a fluid wave, air is causing the distention. Presence of a fluid wave indicates ascites, found in cirrhosis, peritonitis, metastatic carcinoma, ovarian carcinoma, and pancreatitis. Jaundice, pruritus, dependent edema, and enlarged superficial abdominal veins often accompany ascites from liver congestion (Lewis et al., 2011).

STEP 2k Testing for fluid wave. (From Seidel HM et al: Mosby's guide to physical examination, ed 6, St Louis, 2006, Mosby.)

- l** Ask patient if abdomen feels unusually tight and determine if this is a recent development.

Continued sensation of fullness helps to detect distention. A feeling of fullness after a heavy meal causes only temporary distention. Tightness is not felt with obesity.

STEP

RATIONALE

m With patient sitting, gently but firmly percuss over each CVA along scapular lines (see illustration A). Use ulnar surface of fist indirectly by placing nondominant hand flat against CVA and percussing with dominant hand or percuss directly against patient's skin (see illustration B). Note if patient experiences pain.

Determines presence of kidney inflammation.

STEP 2m **A**, Position of kidney in relation to costovertebral angle. **B**, Direct percussion of kidney for costovertebral angle tenderness. (From Seidel HM et al: Mosby's guide to physical examination, ed 6, St Louis, 2006, Mosby.)

n Lightly palpate over each abdominal quadrant, laying palm of hand with fingers extended and approximated lightly on abdomen. Keep palm and forearm horizontal. The pads of the fingertips depress the skin no more than 1 cm ($\frac{1}{2}$ inch) in a gentle dipping motion (see illustration). Palpate painful areas last.

Detects areas of localized tenderness, degree of tenderness, and presence and character of underlying masses or fluid. Palpation of sensitive area causes guarding (voluntary tightening of underlying abdominal muscles).

STEP 2n Light palpation of abdomen.

- (1) Note muscular resistance, distention, tenderness, and superficial masses or organs while observing patient's face for signs of discomfort.
- (2) Note if abdomen is firm or soft to touch.

Patient's verbal and nonverbal cues may indicate discomfort from tenderness. Firm abdomen indicates active obstruction with buildup of fluid or gas.

Soft abdomen is normal or reveals that obstruction is resolving.

STEP

RATIONALE

- o Just below umbilicus and above symphysis pubis, palpate for a smooth, rounded mass. While applying light pressure, ask if patient has sensation of need to void.

Detects presence of dome of distended bladder.

Clinical Decision Point *Routinely check for distended bladder if patient has been unable to void, patient has been incontinent, or an indwelling Foley catheter is not draining well or has been removed recently.*

- p If masses are palpated, note size, location, shape, consistency, tenderness, mobility, and texture.
- q When tenderness is present, press one hand slowly and deeply into the involved area and let go quickly. Note if pain is aggravated.

Descriptive characteristics help to reveal type of mass.

Test determines if rebound tenderness is present. Results are positive if pain increases. This indicates peritoneal irritation such as appendicitis (Seidel et al., 2011).

EVALUATION

- 1 Compare assessment findings with previous assessment characteristics to identify changes.
- 2 Ask patient to describe signs and symptoms of colorectal cancer.

Determines presence of abnormalities.

Demonstrates learning.

Unexpected Outcomes

- 1 Abdomen is asymmetric, with palpable mass, and dull to percussion, suggesting a tumor.
- 2 Abdomen protrudes symmetrically with skin taut; patient complains of tightness, and/or bowel sounds are absent. GI motility has ceased. Patient is vomiting. Signs suggest an obstruction.
- 3 Hyperactive bowel sounds are evident with GI motility. Commonly they result from anxiety, diarrhea, overuse of laxatives, inflammation of the bowel, or reaction of the intestines to certain foods.
- 4 Rebound abdominal tenderness is noted.
- 5 Bladder is palpable over symphysis pubis and distended.
- 6 Patient is unable to describe signs and symptoms of colorectal cancer.

Related Interventions

- Report to health care provider.
- Keep patient on nothing by mouth (NPO) status and encourage ambulation.
- Notify health care provider.
- Gastric decompression following insertion of NG tube sometimes may be necessary.
- Patient may need to be NPO.
- Contact health care provider if patient needs antidiarrheal medication.
- Avoid palpating area.
- Notify health care provider if this is a new finding.
- Place patient on NPO status.
- Facilitate voiding by placing patient in sitting position or encouraging him or her to bear down (if not contraindicated); run water within hearing distance or have patient place hand in basin of warm water.
- Use bladder scan to determine extent of bladder fullness.
- If unable to void, urinary catheterization is necessary (see Chapter 33).
- Additional education is necessary.

Recording and Reporting

- Document appearance of abdomen, quality of bowel sounds, presence of distention, abdominal circumference, and presence and location of tenderness in nurses' notes, EHR, or flow sheet.
- Record patient's ability to void and defecate, including description of output.
- Record content of any patient instruction.
- Report serious abnormalities such as absent bowel sounds, presence of a mass, or acute pain to nurse in charge and health care provider.

Special Considerations

Teaching

- Explain that factors such as diet, regular exercise, limited use of over-the-counter drugs causing constipation, establishment of regular elimination schedule, and adequate fluid intake promote normal bowel elimination.

- If patient is a health care worker or has contact with blood or body fluids of affected people, encourage him or her to receive series of three HBV vaccine doses.

Pediatric

- Most common palpable abdominal mass in child is feces, usually palpated in right lower quadrant (Hockenberry and Wilson, 2011).
- Have a child stand erect and then lie supine during inspection of abdominal surface. Normal abdomen of infants and young children is cylindrical in erect position and flat in supine position. School-age children may have a rounded abdomen until 13 years of age when standing.
- In infants and children skin of abdomen is usually taut and without wrinkles or creases.
- Infants and children until the age of 7 years are abdominal breathers.

- Some children perceive superficial palpation as tickling. Drawing attention to their laughter only causes it to increase. Have the children help by placing their hand on top of yours or have them place their hand on their abdomen with their fingers separated and then palpate between their fingers.

Gerontologic

- Older adults often lack abdominal tone; underlying organs are more easily palpable.

- Constipation along with nausea, flatulence, and heartburn is common.
- Stress to older adults importance of adequate fluid intake, regular exercise, and a diet with at least four servings daily of fresh fruit, vegetables, and high-fiber food to promote normal defecation.

SKILL 6-6 Genitalia and Rectum Assessment

The best time to examine a patient’s external genitalia is while performing routine hygiene measures or preparing to insert or care for a urinary catheter. An examination of female and male external genitalia is part of preventive health screenings. You examine adolescent and young adults because of the growing incidence of sexually transmitted infections (STIs). The average age of menarche among girls has declined, and most male and female teenagers are sexually active by age 19 (Hockenberry and Wilson, 2011). You can easily combine rectal and anal assessments with this examination because the patient assumes a lithotomy or dorsal recumbent position.

Delegation and Collaboration

The skill of assessing the genitalia and rectum cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report changes in patient’s genitourinary function and presence of drainage in the perineal area.

Equipment

- Examination light
- Clean gloves (use nonlatex if necessary)
- Drapes

STEP RATIONALE

ASSESSMENT

STEP	RATIONALE
<p>1 Assessment: female patients:</p> <ul style="list-style-type: none"> a Determine if patient has signs and symptoms of vaginal discharge, painful or swollen perianal tissues, or genital lesions. b Determine if patient has symptoms or history of genitourinary problems, including burning during urination (dysuria), frequency, urgency, nocturia, hematuria, or incontinence. c Ask if the patient has had signs of bleeding outside of normal menstrual cycle or after menopause or has had unusual vaginal discharge. d Determine if patient has received human papillomavirus (HPV) vaccine. 	<p>These signs and symptoms are consistent with an STI or other pathologic condition.</p> <p>Urinary problems are associated with gynecologic disorders, including STIs.</p> <p>These are warning signs for cervical and endometrial cancer or a vaginal infection.</p>
<ul style="list-style-type: none"> e Determine if patient has history of HPV (condyloma acuminatum, herpes simplex, or cervical dysplasia); had first pregnancy before age of 17; smokes cigarettes; is obese; eats diet low in fruits and vegetables; has had multiple full-term pregnancies. f Determine if patient is older than 63; is obese; has history of ovarian dysfunction, breast or endometrial cancer, or endometriosis; has family history of reproductive cancer; has history of infertility or nulliparity; or uses estrogen (alone) as hormone replacement therapy. 	<p>The CDC (2011) recommends that all 11 or 12 year old girls get the 3 doses of HPV vaccine (Gardasil or Cervarix) to protect against cervical cancer. Gardasil also protects against most genital warts and some cancers of the vulva, vagina, and anus. Girls and young women ages 13 through 26 should get HPV vaccine if they have not received any or all doses when they were younger. CDC also recommends Gardasil for all boys aged 11 or 12 years, and for males aged 13 through 21 years who did not get any or all of the three recommended doses when they were younger. All men should confer with their doctor about vaccination.</p> <p>These are risk factors for cervical cancer (ACS, 2011c).</p> <p>These are risk factors for ovarian cancer (ACS, 2011d).</p>

STEP	RATIONALE
<p>g Determine if patient is postmenopausal, obese, or infertile; had early menarche or late menopause; has history of hypertension, diabetes mellitus, gallbladder disease, or polycystic ovary disease; has family history of endometrial, breast, or colon cancer; or has a history of estrogen-related exposure (estrogen replacement therapy, tamoxifen use).</p>	These are risk factors for endometrial cancer (ACS, 2011e).
<p>h Determine patient's knowledge of the risk factors and signs of cervical and other gynecologic cancers.</p>	Provides baseline for patient education.
2 Assessment of male patients:	
<p>a Review normal elimination pattern, including frequency of voiding; history of nocturia; character and volume of urine; daily fluid intake; symptoms of burning, urgency, and frequency; difficulty starting stream; and hematuria.</p>	Urinary problems are directly associated with genitourinary problems because of anatomic structure of men's reproductive and urinary systems.
<p>b Ask if patient has noted penile pain or swelling, genital lesions, or urethral discharge.</p>	These are signs and symptoms of STIs.
<p>c Determine if patient has noted heaviness or painless enlargement or irregular lumps of testis.</p>	These signs and symptoms are early warning signs for testicular cancer.
<p>d Determine if patient reports any enlargement in inguinal area and assess if intermittent or constant, associated with straining or lifting, and painful. Assess whether coughing, lifting, or straining at stool causes pain.</p>	Signs and symptoms indicate potential inguinal hernia.
<p>e Ask if patient has experienced weak or interrupted urine flow, inability to urinate, difficulty in starting or stopping urine flow, polyuria, nocturia, hematuria, or dysuria. Determine if patient has continuing pain in lower back, pelvis, or upper thighs.</p>	These are warning signs of prostatic cancer (ACS, 2011f). Symptoms also may indicate infection or prostate enlargement.
<p>f Assess patient's knowledge of risk factors and signs of prostate and testicular cancer.</p>	Provides baseline for patient education.
3 Assessment of all patients:	
<p>a Determine whether patient has rectal bleeding, black or tarry stools (melena), rectal pain, or change in bowel habits (constipation or diarrhea).</p>	These are warning signs of colorectal cancer (ACS, 2011g) or other GI alterations.
<p>b Determine whether patient has personal or strong family history of colorectal cancer, polyps, or chronic inflammatory bowel disease. Ask if patient is over age 50.</p>	These are risk factors for colorectal cancer (ACS, 2011g).
<p>c Inquire about dietary habits, including high fat intake, diet high in processed or red meats, diet high in meats cooked at high temperatures (frying, broiling, grilling), or deficient fiber content (inadequate fruits and vegetables).</p>	Colon cancer is often linked to dietary intake of fat, red meat, high cooking temperatures, or insufficient fiber intake (ACS, 2011g).
<p>d Determine if patient is obese, physically inactive, smokes, has type 2 diabetes, or consumes alcohol.</p>	These are risk factors for colorectal cancer (ACS, 2011g).
<p>e Assess medication history for use of laxatives or cathartic medications.</p>	Repeated use causes diarrhea and eventual loss of intestinal muscle tone.
<p>f Assess for use of codeine or iron preparations.</p>	Codeine causes constipation. Iron turns stool black and tarry.
<p>g Assess patient's knowledge of risks and signs of colorectal cancer.</p>	Provides baseline for patient education.

NURSING DIAGNOSES

- Deficient knowledge
- Ineffective health maintenance
- Pain (acute, chronic)
- Readiness for enhanced immunization status

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1** Expected outcomes following completion of procedure:
- Patient denies discomfort or worsening of existing discomfort following examination. Proper examination procedures have been implemented.
 - Patient is able to list warning signs of colorectal cancer: female patient: cervical, endometrial, and ovarian cancer; male patient: testicular and prostate cancer. Demonstrates learning.
 - Patient is able to discuss guidelines for HPV immunization. Demonstrates learning.

STEP	RATIONALE
2 Anticipate teaching topics so that during the exam, you can instruct patient about warning signs of colorectal cancer.	Prepares you for incorporating teaching into assessment activities.
3 Perform hand hygiene. Prepare necessary supplies.	Reduces transmission of infection.
IMPLEMENTATION	
1 Prepare patient for assessment:	
a Ask if patient needs to empty bladder or defecate.	Palpation of full bladder causes discomfort and feeling of urgency and makes it difficult for patient to relax.
b Keep upper chest and legs draped and keep room warm.	Maintains patient's comfort during examination, promoting relaxation.
c Position patient: Female should lie in a dorsal recumbent position with arms down at sides and knees slightly bent. Place a small pillow under her knees. Male should lie supine with chest, abdomen, and lower legs draped; or have him stand during examination.	Placing the arms under the head or keeping knees fully extended causes tightening of the abdominal muscles.
d Apply clean gloves.	
2 Female genitalia examination.	
a Expose perineal area, repositioning sheet.	
b Inspect surface characteristics of perineum and retract labia majora; observe for inflammation, edema, lesions, or lacerations. Note if there is any vaginal discharge. Presence of discharge may indicate need for a culture.	Skin of perineum is smooth, clean, and slightly darker than other skin. Mucous membranes are dark pink and moist. Labia majora are symmetric; may be dry or moist. Normally there is no vaginal discharge.
3 Male genitalia examination.	
a Expose perineal area. Observe genitalia for rashes, excoriations, or lesions.	Normally skin is clear without lesions.
b Inspect and palpate penile surfaces.	
(1) Inspect corona, prepuce (foreskin), glans, urethral meatus, and shaft. Retract foreskin in uncircumcised males. Observe for discharge, lesions, edema, and inflammation. Return foreskin to normal position.	Glans should be smooth and pink along all surfaces. Urethral meatus is slitlike and normally positioned at tip of glans. Foreskin should retract easily. Area between foreskin and glans is a common site for venereal lesions.
c Inspect and palpate testicular surfaces.	
(1) Inspect size, color, shape, and symmetry; also gently palpate for lesions and edema.	Left testicle is normally lower than right. Scrotal skin is usually loose, surface is coarse, and skin color is more deeply pigmented than body skin.
d Palpate testes.	
(1) Note size, shape, and consistency of tissue.	Testes are normally ovoid and approximately 2 to 4 cm (0.8 to 1.6 inches) in size; feel smooth and rubbery, and are free from nodules. Most common symptom of testicular cancer is an irregular, nontender fixed mass.
(2) Ask if patient experiences tenderness with palpation.	Testes are normally sensitive but not tender.
5 Assess rectum.	
a Female patient remains in dorsal recumbent position or assumes side-lying (Sims') position.	These positions allow for optimum visualization of the rectum.
b Male patient stands and bends forward with hips flexed and upper body resting across examination table; examine nonambulatory patient in Sims' position.	
c View perianal and sacrococcygeal areas by gently retracting buttocks using your nondominant hand.	Perianal skin is smooth, more pigmented, and coarser than skin covering buttocks.
d Inspect anal tissue for skin characteristics, lesions, external hemorrhoids (dilated veins that appear as reddened skin protrusion), ulcers, inflammation, rashes, and excoriation.	Anal tissues are moist and hairless; voluntary sphincter holds anus closed.
6 Remove and discard gloves. Discard disposable supplies. Assist patient to comfortable position. Perform hand hygiene.	Prevents transmission of infection.

EVALUATION

1 Compare assessment findings with previous assessment characteristics to identify changes.	Determines presence of abnormalities.
2 Ask patient to list warning signs of colorectal cancer: female patient: cervical, endometrial, and ovarian cancer; male patient: testicular and prostate cancer.	Demonstrates learning.
3 Ask patient to identify guidelines for HPV vaccination.	Demonstrates learning.

Unexpected Outcomes

- 1 Patient has vaginal/penile drainage and burning sensation during voiding. Women may have vaginal bleeding between menstrual periods. Symptoms may suggest STI.
- 2 Patient is unable to list warning signs of colorectal cancer: female patient: cervical, endometrial, and ovarian cancer; male patient: testicular and prostate cancer.

Recording and Reporting

- Record results of assessment in nurses' notes, EHR, or flow sheet.
- Record patient's ability to void, including description of output.
- Record content of any patient instruction.
- Report any abnormalities such as presence of a mass or acute pain to nurse in charge and health care provider.

Special Considerations

Teaching

- Discuss the guidelines of the [ACS \(2011g\)](#) for early detection of colorectal cancer for both men and women. The [ACS \(2011g\)](#) recommends the following examination schedules beginning at age 50:
 - 1 Tests that detect polyps and cancer; one of the following: (1) flexible sigmoidoscopy (every 5 years), (2) colonoscopy (every 10 years), (3) double-contrast barium enema (every 5 years), (4) computed tomographic colonoscopy (every 5 years).
 - 2 Tests that primarily detect cancer: (1) guaiac-based fecal occult blood test (gfobt), or fecal immunochemical test (FIT) with high sensitivity for cancer (every year), (2) stool deoxyribonucleic acid (DNA) (interval unclear).
- Discuss warning signs of colorectal cancer, including long-term progressive weight loss, change in bowel habits, and blood in stools.
- Discuss dietary planning and healthy lifestyle choice to maintain or improve colon health.

Female Health Teaching

- Instruct patient about purpose and recommended frequency of Papanicolaou (Pap) smears and GYN examinations.

Related Interventions

- Notify health care provider.
- Prepare to collect a culture of discharge.
- Provide additional education.

- Explain warning signs of STIs: pain or burning on urination, pain during sex, pain in pelvic area, bleeding between menstruation, itchy rash around vagina, and abnormal vaginal discharge.
- Teach measures to prevent STIs (e.g., male partner's use of condoms, restricting number of sexual partners, avoiding sex with persons who have several other partners, and perineal hygiene measures).
- Reinforce the importance of performing perineal hygiene (as appropriate).

Male Health Teaching

- Explain warning signs of STIs: pain on urination and during sex, abnormal penile discharge, swollen lymph nodes, or rash or ulcer on skin or genitalia.
- Teach measures to prevent STIs: use of condoms, avoiding sex with infected partner, avoiding sex with persons who have multiple partners, and using regular perineal hygiene. Tell patients with an STI to inform their sexual partners of the need to have an examination. Instruct patient to seek treatment as soon as possible if partner becomes infected with an STI.
- Instruct patient in how to perform genital self-examination (see [Box 6-2](#)).

Pediatric

- When examining the testes in a male infant, avoid stimulating the cremasteric reflex, which causes the testes to pull higher into the pelvic cavity.

SKILL 6-7 Musculoskeletal and Neurologic Assessment

You use the skills of inspection and palpation during the musculoskeletal and neurologic assessment. During the general survey you inspect gait, posture, and body position. A more thorough assessment of major bone, joint, and muscle groups and sensory, motor, and cranial nerve (CN) function is indicated in the presence of abnormalities. The assessment can be performed as you examine other body systems. For example, while assessing head and neck structures assess neck range of motion (ROM) and examine select CNs. Integrate assessment into routine activities of care (e.g., while bathing or positioning the patient). Assessment of these systems is important when a patient reports pain, loss of sensation, or impairment of muscle function. Prolonged illness or immobility may result in muscle weakness and atrophy. Neurologic assessment is often conducted simultaneously because muscles may be weakened as a result of nerve involvement.

Delegation and Collaboration

The skill of assessing musculoskeletal and neurologic function cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report patients' problems with gait, ROM, and muscle strength.
- Be informed of patients at risk for falls (unsteady gait, foot dragging, weakness of lower extremities).
- Assist patients with muscular weakness with transfer and ambulation.

Equipment

- Cotton balls or cotton-tipped applicators
- Penlight
- Opposite tip of cotton swab or tongue blade broken in half
- Tape measure
- Tongue blade
- Tuning fork
- Reflex hammer

STEP

RATIONALE

ASSESSMENT

<p>1 Review patient history for use of alcohol intake of more than 2 drinks/day; inadequate intake of protein, vitamin D, or calcium; thin and light body frame; family history of osteoporosis; white or Asian ancestry; sedentary lifestyle; long-term use of certain medications (e.g., corticosteroids, phenytoin [Dilantin], or heparin); and certain medical conditions (e.g., anorexia nervosa, hyperthyroidism) (Jaffe et al., 2011).</p>	<p>These factors increase the risk for osteoporosis.</p>
<p>2 Determine if patient has been screened for osteoporosis.</p>	<p>Women age 65 and older need routine screening for osteoporosis. There is insufficient evidence that men require screening for osteoporosis (Jaffe et al., 2011).</p>
<p>3 Ask patient to describe history of alteration in bone, muscle, or joint function (e.g., recent fall, trauma, lifting heavy objects, bone or joint disease with sudden or gradual onset) and location of alteration.</p>	<p>History assists in assessing nature of musculoskeletal problem. It is estimated that 25 million Americans have osteoporosis and an additional 34 million have osteopenia (USPSTF, 2011).</p>
<p>4 Assess nature and extent of patient’s musculoskeletal pain: location, duration, severity, predisposing and aggravating factors, relieving factors, and type of pain. If patient reports pain or cramping in lower extremities, ask if walking relieves or aggravates it. Assess distance walked and characteristics of pain before, during, and after activity.</p>	<p>Pain frequently accompanies alterations in bone, joints, or muscle. Pain has implications for comfort and also ability to perform activities of daily living. Pain caused by certain vascular conditions tends to increase with activity.</p>
<p>5 Assess height and weight (see Skill 6-1). Note if there is a decrease in women older than 50 by subtracting current height from recall of maximum adult height.</p>	<p>Body mass index less than 22 is a risk factor, and loss of height more than 7.5 cm (3 inches) is one of the first clinical signs of osteoporosis (Touhy and Jett, 2010).</p>
<p>6 Determine if patient uses analgesics, antipsychotics, antidepressants, nervous system stimulants, or recreational drugs.</p>	<p>These medications alter level of consciousness (LOC) or cause behavioral changes. Abuse sometimes causes tremors, ataxia, and changes in peripheral nerve function.</p>
<p>7 Determine if patient has recent history of seizures/convulsions: clarify sequence of events (aura, loss of muscle tone, falling, motor activity, loss of consciousness); character of any symptoms; and relationship to time of day, fatigue, or emotional stress.</p>	<p>Seizure activity often originates from central nervous system (CNS) alteration. Characteristics of seizure help determine its origin.</p>
<p>8 Screen patient for headache, tremors, dizziness, vertigo, numbness or tingling of body part; visual changes; weakness; pain; or changes in speech.</p>	<p>These symptoms commonly result from CNS dysfunction. Identifying patterns aids in diagnosis.</p>
<p>9 Discuss with spouse, family member, or friends any recent changes in patient’s behavior (e.g., increased irritability, mood swings, memory loss, change in energy level).</p>	<p>Behavioral changes may result from intracranial pathology.</p>
<p>10 Assess patient for history of change in vision, hearing, smell, taste, or touch.</p>	<p>Major sensory nerves originate from brainstem. These symptoms help to localize nature of problem.</p>
<p>11 If patient displays sudden acute confusion (delirium), review history for drug toxicity (e.g., anticholinergics, digoxin, antihistamines, antipsychotics, benzodiazepines, opioid analgesics, sedative/hypnotics, steroids); serious infections, metabolic disturbances (e.g., diabetes mellitus); heart failure; and severe anemia.</p>	<p>Delirium is one of the most common mental disorders in older persons (Touhy and Jett, 2010), but it also occurs in children.</p>
<p>12 Review history for head or spinal cord injury, meningitis, congenital anomalies, neurologic disease, or psychiatric counseling.</p>	<p>These neurologic symptoms or behavioral changes help to focus assessment on possible cause.</p>

NURSING DIAGNOSES

- | | | |
|---|---|--|
| <ul style="list-style-type: none"> • Activity intolerance • Impaired physical mobility • Impaired walking • Ineffective peripheral tissue perfusion | <ul style="list-style-type: none"> • Pain (acute, chronic) • Risk for injury • Risk for peripheral neurovascular dysfunction | <ul style="list-style-type: none"> • Risk for trauma • Self-care deficit (bathing/hygiene, dressing/grooming, feeding, or toileting) |
|---|---|--|

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient demonstrates erect posture; strong grasp; steady gait, with arms swinging freely at side. 	<p>Indicates normal alignment, gait, and neuromuscular muscle strength.</p>
---	---

STEP

RATIONALE

- There is bilateral symmetry of extremities in length, circumference, alignment, position, and skinfolds.
 - Full active ROM is present in all joints with good muscle tone and absence of contractures, spasticity, or muscular weakness.
 - Patient is alert and oriented to person, place, and time. Behavior and appearance appropriate for condition/situation.
 - Patient demonstrates normal pupil reaction to light and accommodation (see Skill 6-2); external ocular muscles (EOMs) intact; facial sensation intact; symmetric facial expressions; soft palate and uvula midline and rise on phonation; gag reflex intact; speech clear without hoarseness; no difficulty swallowing.
 - Patient distinguishes between sharp and dull sensations and light touch on symmetric areas of extremities. Position sense intact to lower extremities.
 - Gait coordinated, steady with appropriate stance and swing phases. Romberg test negative.
- 2** Perform hand hygiene. Prepare necessary supplies.

Indicates normal ROM of joints.

Indicates normal cerebral function.

Indicates normal functioning of CNs III, IV, V, VI, VII, IX, and X.

Indicates normal function of sensory nerves.

Indicates normal cerebellar and motor system functioning.

Reduces transmission of infection.

IMPLEMENTATION

1 Prepare patient:

- a** Integrate musculoskeletal and neurologic assessments during other portions of physical assessment or during nursing care (e.g., when patient moves in bed, rises from chair, or walks).
- b** Plan time for short rest periods during assessment.

2 Assess musculoskeletal system.

- a** Observe ability to use arms and hands for grasping objects (e.g., pen, utensils) (see illustration).
- b** Assess muscle strength of upper extremities by applying gradual increase in pressure to muscle group.
- c** To assess hand grasp strength, cross your hands and have patient grasp index and middle fingers of both of your hands and squeeze them as hard as possible (see illustration).

You can conduct the assessment as a patient performs activities or goes through movements required during complete physical examination. Integration with care conserves patient's energy and allows observation of patient performing more naturally. Movement of body parts and various maneuvers may tire patient. Always plan rest periods with older adult and very ill patients.

Assesses coordination and muscle strength.

Upper and lower extremity on patient's dominant side normally is stronger than that on nondominant side. Pain rather than weakness may cause reduced muscle strength; however, long-term pain can lead to muscle weakening.

It is common for the patient's dominant hand to be slightly stronger than nondominant hand. By crossing your hands, patient's right hand grasps your right hand. This helps with recall of which is patient's right/left hand.

STEP 2a Observe use of arms and hands.

STEP 2c Assessing strength of hand grasps, comparing sides.

STEP

RATIONALE

- d** Place hand on lower arm or leg and have patient move major joint (e.g., elbow, knee) against resistance (e.g., flex elbow). Have patient maintain pressure until told to stop. Compare symmetric muscle groups. Note weakness and compare right with left.
- e** Observe body alignment for sitting, supine, prone, or standing positions. Muscles and joints should be exposed and free to move to allow for accurate measurement.
- f** Inspect gait as patient walks. Have patient use his or her assistive device (e.g., cane, walker) if appropriate. Observe for foot dragging, shuffling or limping, balance, presence of obvious deformity in lower extremities, and position of trunk in relation to legs.
- g** Perform Get Up and Go Test: From a sitting position have patient stand without using arms for support. Observe gait and ability to stand.
- h** Stand behind patient and observe postural alignment (position of hips relative to shoulders). Look sideways at cervical, thoracic, and lumbar curves (see illustration).

Compares strength of symmetric muscle groups. Rate muscle strength on scale of 0 to 5 as follows:

- 0 No voluntary contraction
- 1 Slight contractility, no movement
- 2 Full ROM, passive
- 3 Full ROM, active
- 4 Full ROM against gravity, some resistance
- 5 Full ROM against gravity, full resistance

Each joint or muscle group requires different position for measurement.

Gait is more natural if patient is unaware of your observation. Assesses for a neuromusculoskeletal disorder.

The Get Up and Go Test is an assessment that should be conducted as part of a routine evaluation of older adults. The test detects risk for falls.

Abnormal curves of posture include lordosis (swayback, increased lumbar curvature), kyphosis (hunchback, exaggerated posterior curvature of thoracic spine), and scoliosis (lateral spinal curvature). Postural changes indicate muscular, bone, or joint deformity; pain; or muscular fatigue. Head should be held erect.

STEP 2h Observe spinal deformities. **A**, Kyphosis. **B**, Lordosis. **C**, Scoliosis. **D**, Scoliosis with patient bending forward.

- i** Make a general observation of extremities. Look at overall size, gross deformity, bony enlargement, alignment, and symmetry.
- j** Gently palpate bones, joints, and surrounding tissue in involved areas. Note any heat, tenderness, edema, or resistance to pressure.
- k** Ask patient to put major joint through its full ROM (Table 6-12). Patients with deformities, reduced mobility, joint fixation, or weakness will require passive ROM assessment. Observe equality of motion in same body parts:

General review pinpoints areas requiring in-depth assessment.

Reveals changes resulting from trauma or chronic disease. Do not attempt to move joint when fracture is suspected or joint is apparently “frozen” by lack of movement over a long period of time.

Assessment of patient’s normal ROM provides baseline for assessing later changes after surgery or inactivity.

TABLE 6-12 Assessing Range of Motion*

Body Part	Assessment Procedure	ROM
Upper Extremities		
Neck	Bend head forward and then backward. Bend neck side to side. Turn head to look over each shoulder.	Flexion, hyperextension, lateral flexion, rotation
Shoulders	Raise both arms to vertical position level at sides of head. Bring arm across upper chest to touch opposite shoulder. Place both hands behind neck, with elbows out to sides. Place both hands behind small of back. Have patient make small circles with hands, with arms extended at shoulder level.	Flexion Adduction External rotation and abduction Internal rotation Circumduction
Elbows	Bend and straighten elbows. Place hands at waist with elbows flexed.	Flexion and extension Internal rotation
Wrists	Flex and extend wrist (bend and straighten). Bend wrist to radial and then ulnar side. Turn palm upward and then downward.	Flexion and extension Radial and ulnar deviation Supination and pronation
Hands	Make a fist with both hands; open hand. Extend and spread fingers and thumb outward; bring back together.	Flexion and extension Adduction and abduction
Lower Extremities		
Hips (with patient supine)	With knees extended, raise one leg upward. Cross leg over other leg. Swing legs laterally. With knee flexed, hold ankle and rotate leg inward and outward.	Flexion: Expect 90 degrees Abduction: Expect 45 degrees Adduction: Expect 30 degrees Internal and external rotation: Expect 40-45 degrees
Knees (with patient sitting)	Raise foot, keeping knee in place.	Extension: Expect full extension and up to 15 degrees hyperextension
Ankles	With foot held off floor, point toes downward and bring them back toward knee.	Plantar flexion: Expect 45 degrees Dorsiflexion: Expect 20 degrees
Toes	Turn foot (sole) inward and sole outward. Bend toes down and back.	Inversion and eversion: Expect to reach 5 degrees Flexion and hyperextension: Expect to reach 40 degrees

AROM, Active range of motion; PROM, passive range of motion; ROM, range of motion.

*This may be done actively by the patient (AROM) or passively by the nurse (PROM).

STEP

RATIONALE

- | | |
|--|--|
| <p>(1) <i>Active motion</i>: (Patient needs no support or assistance and is able to move joint independently.) Instruct patient in moving each joint through its normal range. Sometimes it is necessary to demonstrate and ask patient to mimic your movements.</p> <p>(2) <i>Passive motion</i>: (Joint has full ROM, but patient does not have strength to move it independently.) Have patient relax and move same joints passively until end of range is felt. Support extremity at joint. Do not force joint if there is pain or muscle spasm.</p> <p>l Palpate joint for swelling, stiffness, tenderness, and heat; note any redness.</p> <p>m Assess muscle tone in major muscle groups. Normal tone causes mild, even resistance to movement through entire ROM.</p> <p>3 Neurologic assessment</p> <p>a Assess LOC and orientation by asking patient to identify name, location, day of week, and year; note behavior and appearance. This can be completed during the general survey.</p> | <p>Identifies muscle strength and detects limited ROM.</p> <p>Determines ability to perform joint motion in presence of muscle weakness. Forcing joint causes injury and pain.</p> <p>Indicates acute or chronic inflammation. ROM causes pain or injury.</p> <p>If muscle has increased tone (hypertonicity), any sudden movement of joint is met with considerable resistance. Hypotonic muscle moves without resistance. Muscle feels flabby.</p> <p>A fully conscious patient responds to questions spontaneously. As consciousness declines patient may show irritability, shortened attention span, or unwillingness to cooperate. As consciousness continues to deteriorate patient becomes disoriented to name, time, and place. Behavior and appearance reveal information about patient's mental status.</p> |
|--|--|

STEP	RATIONALE
<p>b Assess cranial nerves (CNs):</p> <ol style="list-style-type: none"> (1) For CNs III (oculomotor), IV (trochlear), and VI (abducens), assess extraocular movement (EOM). Ask patient to follow movement of your finger through the six cardinal positions of gaze; measure pupillary reaction to light reflex and accommodation (see Skill 6-2) using penlight. (2) For CN V (trigeminal), apply light sensation with a cotton ball to symmetric areas of face. (3) For CN VII (facial) note facial symmetry. Have patient frown, smile, puff out cheeks, and raise eyebrows. (4) For CNs IX (glossopharyngeal) and X (vagus), have patient speak and swallow. Ask him or her to say “ah” while using tongue blade and penlight. Check for midline uvula and symmetric rise of uvula and soft palate. Use tongue blade and place on posterior tongue to elicit gag reflex. 	<p>These CNs are those most likely to be affected by increasing intracranial pressure (ICP), which causes change in response or size of pupil; pupils may change shape (more oval) or react sluggishly. ICP impairs movements of EOMs. Accommodation is ability of the eye to adjust vision from near to far.</p> <p>Sensations should be symmetric; unilateral decrease or loss of sensation may be caused by CN V lesion.</p> <p>Expressions should be symmetric; Bell’s palsy causes drooping of upper and lower face; CVA causes asymmetry.</p> <p>Damage to CN IX causes impaired swallowing; damage to CN X causes loss of gag reflex, hoarseness, nasal voice. When palate fails to rise and uvula pulls toward normal side, this indicates a unilateral paralysis.</p>
<p>c Assess extremities for sensation. Perform all sensory testing with patient’s eyes closed so patient is unable to see when or where a stimulus strikes the skin.</p> <ol style="list-style-type: none"> (1) <i>Pain</i>: Ask patient to indicate when sharp or dull sensation is felt as you alternately apply sharp and blunt ends of tongue blade to skin surface. Apply in symmetric areas of extremities. (2) <i>Light touch</i>: Apply light wisp of cotton to different points along surface of skin in symmetric areas of extremities. (3) <i>Position</i>: Grasp finger or toe, holding it by its sides with your thumb and index finger. Alternate moving finger or toe up and down. Ask patient to state when finger is up or down. Repeat with toes. 	<p>Patient should be able to distinguish sharp or dull sensations. Impaired sensations indicate disorders of spinal cord or peripheral nerve roots.</p> <p>Patient should be able to distinguish when touched.</p> <p>Patient should be able to distinguish movements of a few millimeters. Decreased/absent position sense may occur in spinal anesthesia, paralysis, or other neurologic disorders.</p>
<p>d Assess motor and cerebellar function:</p> <ol style="list-style-type: none"> (1) <i>Gait</i>: Have patient walk across room, turn, and come back. Similarly note use of assistive devices. This is a good time to instruct on proper use of assistive devices. (2) <i>Romberg’s test</i>: Have patient stand with feet together, arms at sides, both with eyes open and eyes closed (for 20 to 30 seconds). Protect patient’s safety by standing at side; observe for swaying. 	<p>Neurologic and musculoskeletal disorders impair gait and balance.</p> <p>Romberg’s test should be negative; slight swaying is considered normal.</p>
<p>e Assess deep tendon reflexes (DTRs):</p> <ol style="list-style-type: none"> (1) In patients with back pain or surgery, CVA, or spinal cord compression, it is appropriate to monitor DTRs (Seidel et al., 2011). This requires an advanced level of skill. In most settings this is not part of routine physical assessment. (2) For each reflex tested, compare sides and assign a grade on the following scale: <ul style="list-style-type: none"> 0 No response 1+ Sluggish or diminished response 2+ Normal, active or expected response 3+ More brisk than expected; slightly hyperactive 4+ Very brisk; hyperactive, with clonus. (3) <i>Knee reflex</i>: Palpate patellar tendon just below patella. Tap pointed end of reflex hammer briskly on tendon (see illustration). (4) <i>Plantar response (Babinski’s reflex)</i>: Using handle end of reflex hammer, stroke lateral aspect of sole from heel to ball of foot. 	<p>Muscle spasticity and hyperactive reflexes may result from disorders such as stroke and paralysis. Diminished DTRs and muscle weakness may suggest electrolyte abnormalities or lower motor neuron disorders (e.g., amyotrophic lateral sclerosis [ALS] or Guillain-Barré syndrome).</p> <p>Grade indicates extent of neuron dysfunction.</p> <p>Clonus is described as repeated spasms of muscular contraction and relaxation.</p> <p>Knee reflex is the most common DTR assessment performed. The normal response is knee extension.</p> <p>Toes should flex inward and downward (see illustration).</p>

STEP

STEP 3e(3) Assessing knee reflex. Knee should extend.

(5) After stroking soles of feet, if Babinski's reflex is present, great toe dorsiflexes, accompanied by fanning of the other toes.

4 Dispose of supplies. Perform hand hygiene.

RATIONALE

STEP 3e(4) Assessing plantar response. Toes should flex inward and downward.

Indicates CNS dysfunction. Dorsiflexion of great toe and fanning of the others are normal in a child younger than age 2 (Hockenberry and Wilson, 2011).

Reduces transmission of infection.

EVALUATION

- 1 Compare muscle strength and ROM with previous physical assessment.
- 2 Compare neurologic status with previous physical assessment.
- 3 Evaluate level of patient's discomfort following procedure, using appropriate pain scale.

Determines presence of abnormalities.

Determines presence of abnormalities.

Determines if manipulation of musculoskeletal structures intensifies patient's discomfort.

Unexpected Outcomes

- 1 Joints are prominent, swollen, and tender with nodules or overgrowth of bone in distal joints, indicating signs of arthritis.
- 2 ROM is reduced in one or more major joints: shoulder, elbow, wrist, fingers, knee, hip.
- 3 Patient demonstrates weakness in one or more major muscle groups or has difficulty with gait or ability to walk and sit during Get Up and Go Test, indicating a fall risk.
- 4 Patient has changes in mental status and pupillary response or other neurological deficits.

Related Interventions

- Instruct patient in proper ROM.
- Determine patient's knowledge regarding use of antiinflammatory medications and nonpharmacologic measures (see Chapter 15).
- Assess further for pain during movement with joint unstable, stiff, painful, or swollen or with obvious deformity.
- Notify health care provider.
- Reduce mobility in extremity until cause of abnormal joint motion is determined.
- Place patient on fall precautions.
- Provide patient safety when ambulating (see Chapter 10).
- Notify health care provider.
- Notify health care provider immediately.
- Continue to assess patient's vital signs and LOC closely.
- Place on fall precautions.

Recording and Reporting

- Record posture, gait, muscle strength, and ROM in nurses' notes, EHR, or appropriate assessment flow sheet.
- Record LOC, orientation, pupillary response, sensation, and reflex responses in nurses' notes, EHR, or appropriate assessment flow sheet.
- Report to nurse in charge or health care provider acute pain or sudden muscle weakness, change in LOC, or change in size or pupillary reaction, which require immediate treatment.

Special Considerations

Teaching

- Instruct patient about correct postural alignment. Consult with physical therapist to provide patient with exercises for improving posture.
- To reduce bone demineralization, instruct older-adult patient in a proper weight-bearing exercise program (e.g., walking, low-impact aerobics) to be followed three or more times a week.
- Encourage intake of calcium to meet the recommended daily allowance. Increased vitamin D aids calcium absorption (400 to 800 international units daily). Recommendation for daily calcium supplements for adults over age 50: 1200 mg/day. Instruct patient to take no more than 500 mg of calcium supplements at one time (Touhy and Jett, 2010).
- Explain to patients with low back pain that they can benefit from modification of work-related risk factors (e.g., lifting heavy weights, use of protective equipment), regular aerobic exercise, exercises that strengthen the back and increase trunk flexibility, and learning how to lift properly.
- Explain measures to ensure safety (e.g., use of ambulation aids or safety bars in bathrooms or stairways) for patients with sensory or motor impairments.

Pediatric

- Examine infants carefully for musculoskeletal anomalies resulting from genetic or fetal insults. An examination includes review of posture, generalized movement, symmetry and skin creases of the extremities, muscle strength, and hip alignment.
- Normally the back of a newborn is rounded or C shaped from the thoracic and pelvic curves.
- Scoliosis, lateral curvature of the spine, is an important childhood problem, especially in females, usually identified at puberty. (For closer examination have child stand erect wearing only underclothes. Observe from behind, looking for asymmetry of shoulders and hips. Then observe from the back as child bends forward.) Uneven dress hems or trouser hems or uneven fit of clothing at the waist is an indication of scoliosis.
- Watching a child during play reveals information about musculoskeletal function.
- Children age 13 to 19 years need 1300 mg of calcium daily with 400 international units of vitamin D (Hockenberry and Wilson, 2011).

Gerontologic

- Instruct older adults about fall prevention. Make modifications in the home environment to reduce the risk of falls (see Chapter 42).
- Instruct older adults and those with osteoporosis in proper body mechanics, ROM exercises, and moderate weight-bearing exercises (e.g., swimming, walking) to minimize trauma.
- Functional assessment is a measurement of older person's ability to perform basic self-care tasks (Cress, 2012). When patient is unable to perform self-care easily, determine need for assistive devices (e.g., zippers on clothing instead of buttons, elevation of chairs to minimize bending of knees and hips).
- Older adults tend to assume a stooped, forward-bent posture with hips and knees somewhat flexed, arms bent at the elbows, and level of arms raised.

PROCEDURAL GUIDELINE 6-1 Monitoring Intake and Output

Video Clip

Measuring and recording intake and output (I&O) during a 24-hour period is part of the assessment database for fluid and electrolyte balance (Table 6-13). You are responsible for accurate recording of all intake (liquids taken orally, by enteral feedings, and parenterally) and all output (urine, diarrhea, vomitus, gastric suction, and drainage from surgical tubes). Monitoring a patient

on I&O requires cooperation and assistance from the patient and family. Accuracy is critical as physicians will use findings in prescription of medications and IV fluids.

Monitor I&O for patients with a fever or edema, receiving intravenous (IV) or diuretic therapy, or on restricted fluids. It is also important when a patient has electrolyte losses associated with vomiting, diarrhea, gastrointestinal drainage, or extensive open wounds such as burns. Total and evaluate I&O at the end

TABLE 6-13 Adult Average Fluid Gains and Losses

Fluid Intake and Output	Volume (mL)	Fluid Intake and Output	Volume (mL)
Fluid Intake		Fluid Output	
Oral fluids	1300	Kidneys	1500
Solid foods	1000	Skin	600
Oxidative metabolism	300	Lungs	300
		Gastrointestinal	200
Total gains	2600	Total losses	2600

From Metheny N: *Fluid and electrolyte balance: Nursing considerations*, ed 5, Sudbury, Mass, 2012, Jones and Bartlett.

PROCEDURAL GUIDELINE 6-1 Monitoring Intake and Output—cont'd

of each shift or at specified times such as every 8 hours. Significant alterations are apparent by comparing 24-hour totals over several days. Because fluid imbalance occurs at any time, be aware of I&O for all patients, even when documentation is not required.

Delegation and Collaboration

The skill of assessing I&O totals at the end of each shift; comparing 24-hour totals over several days; and monitoring and recording intravenous (IV) therapy, wound or chest tube drainage, and tube feedings cannot be delegated to nursing assistive personnel (NAP). The nurse emphasizes maintaining standard precautions related to body fluids, accurately measuring and recording I&O, and using the metric system with standard containers. The nurse directs the NAP to:

- Measure and record oral intake, urinary output, liquid diarrheal stools, vomitus, and wound drainage device output.
- Report changes in patient's condition such as alteration in intake or changes in color, amount, or odor of output.

Equipment

- Sign to alert personnel of I&O measurement
- Daily I&O record form or computer graphic
- Graduated measuring container
- Bedpan, urinal, bedside commode, or urine “hat” (a receptacle that fits under the toilet seat)
- Clean gloves
- Mask, eye protection, and gown (optional)

Procedural Steps

- 1 Identify patients with conditions that increase fluid loss (e.g., fever, diarrhea, vomiting, surgical wound drainage, chest tube drainage, gastric suction, major burns, or severe trauma).
- 2 Identify patients with impaired swallowing, unconscious patients, and patients with impaired mobility.
- 3 Identify patients on medications that influence fluid balance (e.g., diuretics and steroids).
- 4 Assess signs and symptoms of dehydration and fluid overload (e.g., bradycardia versus tachycardia, hypotension versus hypertension, and reduced skin turgor versus edema).
- 5 Weigh patients daily using the same scale, the same time of day, and with comparable clothing.
- 6 Monitor laboratory reports:
 - a Urine specific gravity (normal is 1.010 to 1.030)
 - b Hematocrit (Hct) (normal range is 38% to 47% for females and 40% to 54% for males).
- 7 Assess patient's and family's knowledge of purpose and process of I&O measurement.
- 8 Explain to patient and family the reasons that I&O are important.
- 9 Perform hand hygiene.
- 10 Measure and record all fluid intake:
 - a Liquids with meals, gelatin, custards, ice cream, popsicles, sherbets, ice chips (recorded as 50% of measured volume [e.g., 100 mL of ice chips equals 50 mL of water]). Convert household measures to the metric system: 1 ounce equals 30 mL; therefore 12 ounces (soda can) equals 360 mL.
 - b Count liquid medicines such as antacids and fluids with medications as fluid intake.
 - c Calculate fluid intake from tube feedings (see Chapter 31).

- d Calculate fluid intake from parenteral fluids, blood components, and total parenteral nutrition solutions (see Chapters 28 and 29).

Clinical Decision Point Record intake as soon as you measure it to maintain accuracy. If more than one patient is in the same room, each must have urine receptacles labeled with name and bed location.

- 11 Instruct patient and family to call you or the NAP to empty contents of urinal, urine hat, or commode each time patient uses it. Have patient and family monitor incontinence, vomiting, and excessive perspiration and report it to the nurse.
- 12 Inform patient and family that Foley catheter drainage bag and wound, gastric, or chest tube drainage are closely monitored, measured, and recorded and who is responsible for this. Each patient must have a graduated container clearly marked with name and bed location and used only for the patient indicated.
- 13 Apply clean gloves. Measure drainage at the end of the shift or as indicated, using appropriate containers and noting color and characteristics. If splashing is anticipated, wear mask, eye protection, and/or gown.
 - a Measure urine drainage using a “hat” into which patient voids or a graduated container (see illustration).
 - b Observe color and characteristics of urine in Foley tubing and drainage bag. Sometimes a measuring device is part of the drainage bag (see illustration). Otherwise measure using a graduated container.
 - c Measure chest tube drainage by marking and recording the time on the collection chamber at specified intervals (see illustration) (see Chapter 26). Chest tube collection devices are changed when they become full.
 - d Measure Jackson-Pratt/Hemovac drainage using a medicine cup (see illustration) (see Chapter 38).
 - e Measure gastric drainage or larger drainage pouches by opening clamp and pouring into graduated cup with a 240-mL capacity (see illustration).

STEP 13a Measuring and emptying the urine “hat.”

PROCEDURAL GUIDELINE 6-1 Monitoring Intake and Output—cont'd

STEP 13b Device for monitoring hourly urine output.

STEP 13d Measuring wound drainage through Jackson-Pratt drain.

STEP 13c Collection chamber for measuring chest tube drainage.

STEP 13e Measuring drainage from large drainage pouch.

- 14 Remove gloves and dispose of them in appropriate receptacle. Perform hand hygiene.
- 15 Note I&O balance or imbalance and report to health care provider any urine output less than 30 mL/hr or significant changes in daily weight.
- 16 Document on I&O forms or electronic record.

Critical Thinking Exercises

You are caring for Mrs. Williams, a 73-year-old retired schoolteacher who underwent a right hip arthroplasty. This is her first postoperative day on your clinical unit. The night nurse reported that patient had an “uneventful” night. She has an intravenous infusion in her right hand, a right hip dressing, Foley catheter to gravity, and a Jackson-Pratt surgical drain in place.

- 1 Which body systems would you assess for this patient? Describe key elements in these assessments.
- 2 On auscultation of her posterior lung field bases, you hear a crackling noise on inspiration. You also assess and note that her breathing is shallow. What is this sound, and what does it indicate? Which nursing diagnosis is a priority to consider at this time?
- 3 You next assess her cardiac status: she has a heart rate of 86 beats/min, rhythm regular. What does this assessment indicate?
- 4 Mrs. Williams complains of right hip pain and requests pain medication. After you administer the medication, you inspect and then auscultate her abdomen. After listening for 60 seconds at a site below and to the right of the umbilicus, you are unable to hear bowel sounds. What is the best assessment of this situation?
- 5 While assisting Mrs. Williams with the bath, you assess the peripheral neurovascular status of her lower extremities. Which key elements are included in this assessment? Which findings indicate deep vein thrombosis?

REVIEW QUESTIONS

- 1 A nurse in orientation is performing an abdominal assessment. Which action would indicate that further practice and study are indicated?
 - 1 The bowel is auscultated before being palpated.
 - 2 The nurse determines any tenderness before touching the patient.
 - 3 Inspection is done before percussion.
 - 4 The abdomen is palpated before auscultation is done.
- 2 A nurse is performing a neurologic assessment. Which approach is most effective in obtaining accurate data when testing sensory pathways?
 - 1 Perform each test quickly.
 - 2 Have the patient as relaxed as possible.
 - 3 Compare symmetric areas.
 - 4 Use a predictable order of assessment.
- 3 An older-adult female patient presents with a history of vomiting and diarrhea. Assessment findings reveal lethargy, decreased skin turgor, a weight loss of 5 pounds (2.27 kg) in 3 days, and a hematocrit of 51%. Which other assessment data would the nurse expect to find?
 - 1 Hypoactive bowel sounds and an elevated urine specific gravity of 1.026
 - 2 Concentrated urine and hyperactive bowel sounds
 - 3 Moist mucous membranes and a low urine specific gravity of 1.008
 - 4 Increased capillary refill time and brisk reactive pupils
- 4 During the respiratory assessment the nurse thinks that he hears some crackles in his older-adult patient. What should the nurse do to ensure that the assessment is correct?
 - 1 Ask patient if he has ever had crackles in his lungs
 - 2 Ask patient to breathe in through his nose
 - 3 Have patient breathe in deeper when bases are auscultated
 - 4 Check patient's medical record to determine if they were previously heard on auscultation
- 5 Calculate patient's intake in milliliters based on the following amounts: 3 ounces of orange juice, half carton of milk (240 mL per carton), 3-ounce popsicle, 12 ounces of cola, and an 8-ounce cup of ice.

- 6 In conducting a general survey of a patient, the nurse knows that the survey should include which of the following? (Select all that apply.)
 - 1 Appearance
 - 2 Obtaining peripheral pulses
 - 3 Measuring chest excursion
 - 4 Conducting a detailed history
 - 5 Behavior
 - 6 Pupillary response
 - 7 Posture
- 7 In teaching a patient about skin lesions, the nurse knows that teaching has been successful when the patient identifies which lesion as abnormal?
 - 1 A symmetric lesion
 - 2 A lesion with regular edges and borders
 - 3 One that is blue/black or varied in color
 - 4 One that is less than 7 mm in diameter
- 8 On respiratory assessment the nurse notes high-pitched, musical sounds on auscultation. The nurse interprets these sounds as:
 - 1 Normal; vesicular.
 - 2 Rhonchi.
 - 3 Crackles.
 - 4 Wheezes.
- 9 The nurse determines that the patient has an audible S₂ on auscultation during cardiovascular assessment. After documenting the finding, the nurse should:
 - 1 Reposition the patient for comfort.
 - 2 Report the finding to the health care provider.
 - 3 Initiate fluid restriction.
 - 4 Do nothing because this is a normal finding.
- 10 Place the following components of the abdominal assessment in the correct order:
 - 1 Palpation
 - 2 Inspection
 - 3 Auscultation
 - 4 Percussion

KEY TERMS

Asepsis	Infection	Health care–associated infection	Surgical asepsis
Aseptic technique	Invasive procedure	Pathogen	Transmission-based precautions
Colonized	Isolation	Rhinorrhea	
Contamination	Medical asepsis	Standard precautions	
Immunocompromised	Microorganism		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss how to apply critical thinking in the prevention of the transmission of infection.
- Explain the difference between medical and surgical asepsis.
- Identify nursing care measures intended to break the chain of infection.
- Explain how each element of the infection chain contributes to infection.
- Describe the factors that influence nursing staff compliance with hand hygiene.
- Perform proper procedures for hand hygiene.
- Perform correct isolation techniques.

Infection prevention and control practices that reduce or eliminate sources and transmission of infection help to protect patients and health care providers from disease. Patients in all health care settings are at risk of becoming colonized or infected as a result of an impaired immune response, exposure to an increased number of pathogenic organisms, and performance of invasive procedures (Fardo, 2011). Health care-associated infections (HAIs) result from delivery of health services in a health care setting and were not present at the time of admission. A hospital is one of the most likely settings for acquiring an HAI because staff, patients, and environmental factors support a high population of pathogens that are resistant to antibiotics. Health care workers transmit many HAIs by direct contact during the delivery of care. Although protecting patients from HAIs is an obvious priority, nurses are also at risk because of contact with infectious materials or exposure to a communicable disease.

The presence of a pathogen does not mean that an infection will occur. Infection occurs in a cycle, often referred to

as the *chain of infection*, which depends on the presence of all of the following elements:

- 1 An infectious agent or pathogen
- 2 A reservoir or source for pathogen growth
- 3 A portal of exit from the reservoir
- 4 A mode of transmission
- 5 A portal of entry to the host
- 6 A susceptible host

An infection develops if this chain remains intact (Fig. 7-1). In patient care it is important to use infection control practices to break an element of the chain so as not to transmit infection (Table 7-1). Steps taken to minimize the onset and spread of infection are based on asepsis and the principles of aseptic technique. Asepsis is the absence of pathogenic (disease-producing) microorganisms (Iwamoto, 2011). The two types of aseptic technique that nurses practice are medical and surgical asepsis.

Medical asepsis, or clean technique, includes procedures used for reducing the number of organisms and preventing

FIG 7-1 Chain of infection.

their transfer. Hand hygiene, barrier techniques, and routine environmental cleaning are examples of medical asepsis. Principles of medical asepsis are common in the home, as in the case of washing hands before preparing food.

Surgical asepsis, or sterile technique, includes procedures used to eliminate all microorganisms from an area. Sterilization destroys all microorganisms and their spores (Rutala and Weber, 2011). Nurses in the operating room, labor and delivery area, and procedural areas practice sterile technique when using sterile instruments and supplies.

Use sterile technique on nursing units when performing certain invasive procedures (e.g., insertion of a central line or an indwelling urinary catheter). The techniques for maintaining surgical asepsis is more rigid than those performed under medical asepsis (see Chapter 8).

TABLE 7-1 Breaking the Chain of Infection

Element of Infection Chain	Medical Asepsis Practices
Infectious agent (pathogenic organism capable of causing disease)	Clean contaminated objects. Clean, disinfect, and sterilize.
Reservoir (site or source of microorganism growth)	Control sources of body fluids and drainage. Perform hand hygiene. Bathe patient with soap and water or disposable bath. Change soiled dressings. Dispose of soiled tissues, dressings, or linen in moisture-resistant bags. Place syringes, uncapped hypodermic needles, and intravenous needles in designated puncture-proof containers. Keep table surfaces clean and dry. Do not leave bottled solutions open for prolonged periods. Keep solutions tightly capped. Keep surgical wound drainage tubes and collection bags patent. Empty and dispose of drainage suction bottles according to agency policy.
Portal of exit (means by which microorganisms leave a site)	Respiratory <ul style="list-style-type: none"> • Avoid talking, sneezing, or coughing directly over wound or sterile dressing field. • Cover nose and mouth when sneezing or coughing. • Wear mask if suffering respiratory tract infection. Urine, feces, emesis, and blood <ul style="list-style-type: none"> • Wear clean gloves when handling blood and body fluids. • Wear gowns and eyewear if there is a chance of splashing fluids. • Handle all laboratory specimens as if infectious.
Transmission (means of spread)	Reduce microorganism spread. <ul style="list-style-type: none"> • Perform hand hygiene. • Use personal set of care items for each patient. • Avoid shaking bed linen or clothes; dust with damp cloth. • Avoid contact of soiled item with uniform. • Discard any item that touches the floor. • Follow standard precautions or select transmission-based isolation precautions.
Portal of entry (site through which microorganism enters a host)	Skin and mucosa <ul style="list-style-type: none"> • Maintain skin and mucous membrane integrity, lubricate skin, offer frequent hygiene, turn and position. • Cover wounds as needed. • Clean wound sites thoroughly. • Dispose of used needles in puncture-proof container. Urinary <ul style="list-style-type: none"> • Keep all drainage systems closed and intact, maintaining downward flow.
Host (patient)	Reduce susceptibility to infection. Provide adequate nutrition. Ensure adequate rest. Promote body defenses against infection. Provide immunization.

EVIDENCE-BASED PRACTICE

For generations handwashing with soap and water was considered the best method to prevent transmission of infection from health care workers to patients. However, recent research shows that handwashing with plain soap sometimes results in paradoxical increases in bacterial counts on the skin (WHO, 2009). Alcohol-based products are more effective for standard handwashing or hand antisepsis than soap or antiseptic soaps (WHO, 2009). Alcohol-based hand sanitizers reduced infections in a variety of settings from intensive care units to long-term care facilities (Herud, 2009). Moreover, brisk alcohol-based rinses or gels containing emollients cause substantially less skin irritation and dryness than plain or antimicrobial soaps (Haas, 2011). Soap and water are still necessary for hand hygiene if hands are visibly soiled or when caring for patients infected with *Clostridium difficile* or multidrug-resistant organisms (MDROs) such as methicillin-resistant *Staphylococcus aureus* (MRSA) or vancomycin-resistant enterococcus (VRE). Studies show that health care workers with chipped nail polish or long or artificial nails have high numbers of bacteria on their fingertips.

- Health care workers should not wear artificial nails and extenders (Longtin et al., 2011)
- No rings or bracelets should be worn during patient care (Fagernes and Lingaas, 2009; Longtin et al., 2011).
- Fingernails should not be longer than 0.625 cm ($\frac{1}{4}$ inch) in length and nail polish should not be chipped. There are no recommendations regarding nail polish color (Cook, 2011).
- Whenever possible, use alcohol-based products that contain emollients (Longtin et al., 2011).

PATIENT-CENTERED CARE

As a nurse you are responsible for educating patients about infection prevention. Patient and family teaching needs to include information concerning signs and symptoms of infection, modes of transmission, and methods of prevention. Knowledge of the infectious process, disease transmission, and critical thinking skills associated with use of aseptic techniques and barrier protection is essential. The Joint Commission (TJC) National Patient Safety Goals (2012) support patients' rights to question health care workers about infection control and prevention practices, including hand hygiene. For example, it is believed that, if patients

ask health care providers if they have washed their hands, health care providers' compliance will increase. Through education you play a vital role in the prevention of infection.

When a patient requires isolation in a private room, remember that loneliness can easily develop. Isolation disrupts normal social relationships with visitors and caregivers. Some patients who suffer from an infectious disease also experience self-concept or body image changes. Other cultures rely on alternative health care practices (e.g., the use of Chinese herbs to treat illness and optimize health) (University of Minnesota, 2011). When a patient from another culture requires isolation, use caution to be sure that the patient and family understand the therapeutic purpose of isolation. For example, the isolation of a loved one is considered disrespectful and uncaring behavior in collectivistic cultures (Hispanics, Africans, and Asians). Unless you act to minimize feelings of psychological and physical isolation, the patient's emotional state could interfere with recovery.

Safety Guidelines

- 1 Hand hygiene with an appropriate alcohol-based hand antiseptic or soap and water is an essential part of patient care and infection prevention.
- 2 Always know a patient's susceptibility to infection. Age, nutritional status, stress, disease processes, and forms of medical therapy can place patients at risk.
- 3 Recognize the elements of the chain of infection and initiate measures to prevent its onset and spread.
- 4 Consistently incorporate the basic principles of asepsis into patient care.
- 5 Ensure that patients cover their mouth and nose when coughing or sneezing, use tissues to contain respiratory secretions, and dispose of tissues in the waste receptacle.
- 6 Use clean gloves when you anticipate contact with body fluids, nonintact skin, or mucous membranes when there is a risk of drainage.
- 7 Use gown, mask, and eye protection when there is a splash risk.
- 8 Protect fellow health care workers from exposure to infectious agents through proper use and disposal of equipment.
- 9 Be aware of body sites where HAIs are most likely to develop (e.g., urinary or respiratory tract). This enables you to direct preventive measures.

SKILL 7-1 Hand Hygiene

NSO Infection Control Module / Lessons 1 and 2

detergent preparations often have persistent antimicrobial activity (WHO, 2009).

The decision to perform hand hygiene depends on four factors: (1) the intensity or degree of contact with patients or contaminated objects, (2) the amount of contamination that may occur with the contact, (3) the patient or health care worker's susceptibility to infection, and (4) the procedure or activity to be performed (Haas, 2011). Longtin et al. (2011) found that hand-hygiene compliance among health care workers found an overall compliance rate below 40%. *Hand hygiene is not optional.* It is a critical responsibility for all health care workers. Follow these guidelines for hand hygiene (CDC, 2002; WHO, 2009):

The most important and basic technique in preventing and controlling transmission of infection is hand hygiene. Hand hygiene is a general term that applies to handwashing, antiseptic hand wash, antiseptic hand rub, or surgical hand antisepsis. Handwashing refers to washing hands with plain soap and water. An antiseptic hand wash is defined as washing hands with water and soap or other detergents containing an antiseptic agent. An antiseptic hand rub means applying an antiseptic hand rub product to all surfaces of the hands to reduce the number of microorganisms present. Surgical hand antisepsis is the use of an antiseptic hand wash or antiseptic hand rub before surgery by surgical personnel to eliminate transient and reduce resident hand flora. Antiseptic

- 1 Wash hands with either plain soap and water or an antibacterial soap and water when hands are visibly dirty, soiled with blood or other body fluids, before eating, and after using the toilet.
- 2 Wash hands if exposed to spore-forming organisms such as *Clostridium difficile* or *Bacillus anthracis*.
- 3 If hands are not visibly soiled, use an alcohol-based hand rub for routinely decontaminating hands in the following clinical situations:
 - a Before and after having direct contact with patients.
 - b Before applying sterile gloves and inserting an invasive device such as indwelling urinary catheters and peripheral vascular catheters
 - c After contact with body fluids or excretions, mucous membranes, and nonintact skin
 - d After contact with wound dressings (if hands are not visibly soiled)

- e When moving from a contaminated body site to a clean body site during patient care
- f After contact with inanimate objects (e.g., medical equipment) in the immediate vicinity of a patient
- g After removing gloves

Delegation and Collaboration

The skill of hand hygiene is performed by all caregivers. Hand hygiene is not optional.

Equipment

- Antiseptic hand rub
- Alcohol-based waterless antiseptic containing emollients
- Handwashing
 - Easy-to-reach sink with warm running water
 - Antimicrobial or regular soap
 - Paper towels or air dryer
 - Disposable nail cleaner (optional)

STEP	RATIONALE
------	-----------

ASSESSMENT

- 1 Inspect surface of hands for breaks or cuts in skin or cuticles. Cover any skin lesions with a dressing before providing care. If lesions are too large to cover, you may be restricted from direct patient care.
- 2 Inspect hands for visible soiling.
- 3 Inspect condition of nails. Natural tips should be no longer than 0.625 cm (1/4 inch) long. Be sure that fingernails are short, filed, and smooth.

Open cuts or wounds can harbor high concentrations of microorganisms. Agency policy may prevent nurses from caring for high-risk patients if open lesions are present on hands (WHO, 2009).
 Visible soiling requires handwashing with soap and water. Subungual areas of hand harbor high concentrations of bacteria. Long nails and chipped or old polish increase the number of bacteria residing on hands. Artificial applications increase microbial load on hands (Boyce and Pittet, 2008, CDC, 2002).

NURSING DIAGNOSES

This skill is required for patients with a variety of nursing diagnoses
Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Hands and areas under fingernails are clean and free of debris.

Transient bacteria have been removed.

IMPLEMENTATION

- 1 Push wristwatch and long uniform sleeves above wrists. Avoid wearing rings. If worn, remove during hand hygiene.
- 2 *Antiseptic hand rub*
 - a Dispense ample amount of product into palm of one hand (see illustration).

Provides complete access to fingers, hands, and wrists. Wearing rings increases number of microorganisms on hands (Longtin et al., 2011).

Many microorganisms on hands come from the subungual region (beneath fingernails). Use enough product to thoroughly cover hands.

STEP

RATIONALE

STEP 2a Apply waterless antiseptic to hands.

STEP 3b Turn on water.

STEP 2b Rub hands thoroughly.

STEP 3f Lather hands thoroughly.

- b** Rub hands together, covering all surfaces of hands and fingers with antiseptic (see illustration).
- c** Rub hands together until the alcohol is dry. Allow hands to completely dry before applying gloves.
- 3** *Handwashing using regular or antimicrobial soap*
 - a** Stand in front of sink, keeping hands and uniform away from sink surface. (If hands touch sink during handwashing, repeat sequence.)
 - b** Turn on water. Turn faucet on (see illustration) or push knee pedals laterally or press pedals with foot to regulate flow and temperature.
 - c** Avoid splashing water against uniform.
 - d** Regulate flow of water so temperature is warm.
 - e** Wet hands and wrists thoroughly under running water. Keep hands and forearms lower than elbows during washing.
 - f** Apply 3 to 5 mL of antiseptic soap and rub hands together (see illustration).

Provides enough time for product to work.

Ensures complete antimicrobial action.

Inside of sink is a contaminated area. Reaching over sink increases risk of touching edge, which is contaminated.

Knee pads within the operating room and treatment areas are preferred to prevent hand contact with faucet. Faucet handles are likely to be contaminated with organic debris and microorganisms (AORN, 2011).

Microorganisms travel and grow in moisture.

Warm water removes less of protective oils on hands than hot water.

Hands are most contaminated parts to wash. Water flows from least to most contaminated area, rinsing microorganisms into sink.

Ensure that all surfaces of hands and fingers are cleaned.

STEP

RATIONALE

- g** Perform hand hygiene using plenty of lather and friction for at least 15 to 20 seconds. Interlace fingers and rub palms and back of hands with circular motion at least 5 times each. Keep fingertips down to facilitate removal of microorganisms.
- h** Areas underlying fingernails are often soiled. Clean them with fingernails of other hand and additional soap or with disposable nail cleaner.

Soap cleans by emulsifying fat and oil and lowering surface tension. Friction and rubbing mechanically loosen and remove dirt and transient bacteria. Interlacing fingers and thumbs ensures that all surfaces are cleaned. Adequate time is needed to expose skin surfaces to antimicrobial agent.
Area under nails can be highly contaminated, which increases risk for transmission of infection from nurse to patient.

Clinical Decision Point *Do not tear or cut skin under or around nail.*

- i** Rinse hands and wrists thoroughly, keeping hands down and elbows up (see illustration).
- j** Dry hands thoroughly from fingers to wrists with paper towel, single-use cloth, or warm air dryer.
- k** If used, discard paper towel in proper receptacle.
- l** To turn off hand faucet, use clean, dry paper towel; avoid touching handles with hands (see illustration). Turn off water with foot or knee pedals (if applicable).

Rinsing mechanically washes away dirt and microorganisms.
Drying from cleanest (fingertips) to least clean (wrist) avoids contamination. Drying hands prevents chapping and roughened skin.
Prevents transfer of microorganisms.
Wet towel and hands allow transfer of pathogens from faucet by capillary action.

STEP 3i Rinse hands.

STEP 3l Turn off faucet.

- m** If hands are dry or chapped, use a small amount of lotion or barrier cream dispensed from an individual use container.

Helps to minimize skin dryness. There is risk of organism growth in lotion, so only apply after patient care activities are complete.

EVALUATION

- 1** Inspect surface of hands for obvious signs of dirt or other contaminants. Determines if hand hygiene is adequate.

Unexpected Outcomes

- 1 Hands or areas under fingernails remain soiled.
- 2 Repeated use of soaps or antiseptics causes dermatitis or cracked skin.

Related Interventions

- Repeat handwashing with soap and water.
- Rinse and dry hands thoroughly after using soap and water; avoid excessive amounts of soap or antiseptic; try various products.
- Use approved hand lotions or barrier creams. Small individual-use containers are preferred because large containers have been found to harbor pathogens.

Special Considerations

Teaching Considerations

- Instruct patient and family caregiver in proper techniques and situations for hand hygiene.
- When patients are educated about the risks for infections, they play an important role in improving hand hygiene compliance in health care settings by reminding visitors and health care workers to perform hand hygiene.

Gerontologic Considerations

- The impact of infections is greater in older adults. Hand hygiene by staff attending older adults is of utmost

importance and should be an ongoing continuing-education requirement.

Home Care

- Evaluate patient and primary caregiver to determine their understanding of the transmission of microorganisms and their ability and motivation to perform hand hygiene correctly.
- Evaluate the hand hygiene facilities in the home to determine the possibility of contamination, proximity of the facilities to the patient, and the ability to maintain supplies and equipment.

SKILL 7-2 Caring for Patients Under Isolation Precautions

Video Clip

When a patient has a known or suspected source of colonization or infection, health care workers follow specific infection prevention and control practices to reduce the risk of cross-contamination to other patients. Certain procedures performed at a patient's bedside require the application of personal protective equipment (PPE) such as a mask, cap, eyewear, gown, or gloves. Standard precautions require you to wear clean gloves before coming in contact with mucous membranes, nonintact skin, blood, body fluids, or other infectious material. You wear gloves routinely when performing a variety of procedures (e.g., nasogastric tube insertion). Masks are worn when there is the risk of splash during a procedure or when certain sterile procedures such as changing a central line dressing are performed. Protective eyewear and masks become important when there is a risk for splash of blood or other body fluids to the eyes or mouth.

The majority of organisms causing health care–associated infections are in the colonized body substances of patients, regardless of whether or not a culture has confirmed infection and a diagnosis has been made (Saint et al., 2008). Body substances such as feces, emesis, urine, mucus, and wound drainage contain potentially infectious organisms. Assess the need for PPE for each task you plan and for all patients, regardless of their diagnoses. Because of increased attention to the prevention of bloodborne pathogens and tuberculosis (TB) (Box 7-1), the Centers for Disease Control and Prevention (CDC) (2007a, 2007b) and the Occupational Safety and Health Administration (OSHA) (2010) have stressed the importance of barrier protection.

In 2007 the Hospital Infection Control Practices Advisory Committee (HICPAC) of the CDC published revised guidelines for isolation precautions. These recommendations were based on current epidemiologic information regarding disease transmission in health care settings. Although primarily intended for care of patients in acute care, you can apply the recommendations to patients in subacute care or long-term care facilities. HICPAC recommends that hospitals modify the recommendations according to their needs and as dictated by federal, state, or local regulations (CDC, 2007b).

The guidelines contain recommendations for respiratory hygiene/cough etiquette as part of standard precautions. Standard precautions, or tier one precautions, are for the care of all patients, regardless of risk or presumed infection status (Box 7-2). Standard precautions are the primary strategies for prevention of infection transmission and apply to contact with blood, body fluids, nonintact skin, and mucous membranes and with equipment or surfaces

BOX 7-1 Special Tuberculosis Precautions

In 1994 the Centers for Disease Control and Prevention (CDC) published guidelines for preventing tuberculosis (TB) transmission in health care agencies in response to a resurgence of TB in the United States associated with the increasing incidence of human immunodeficiency virus (HIV) infection, TB infection transmission in health care settings, and increasing immigration from countries with a high incidence of TB (CDC, 2011a). The current CDC guidelines for preventing and controlling TB focus on early detection of infection, preventing close contact with patients with active TB disease, and applying effective infection control measures in health care settings. Suspect TB in any patient with respiratory symptoms lasting longer than 3 weeks accompanied by other suspicious symptoms such as unexplained weight loss, night sweats, fever, and a productive cough often streaked with blood. Also consider the potential for infectious pulmonary or laryngeal TB from documented positive acid-fast bacilli (AFB) smear or culture, cavitation on chest x-ray film, or history of recent TB exposure. Isolation for patients with suspected or confirmed TB includes placing the patient on airborne precautions in a single-patient negative-pressure room.

Occupational Safety and Health Administration (OSHA) and CDC guidelines require health care workers who care for patients with suspected or confirmed TB to wear special respirators (e.g., N95 or P100) (CDC, 2010). These respirators are high-efficiency particulate masks that have the ability to filter particles at a 95% or better efficiency. Health care workers who use these respirators must be fit tested in a reliable way to obtain a face-seal leakage of 10% or less (Roberge, 2008). OSHA also requires employers to provide training concerning transmission of TB, especially in areas where the risk of exposure is high. In addition, the CDC now recommends the use of the QuantiFERON-TB Gold test (QFT-GIT) or the T-SPOT (CDC, 2011b), a blood test, in place of the traditional TB skin test. The advantages of the QFT-GIT test are that it does not boost responses measured by subsequent tests and the results are not subject to reader bias.

contaminated with these potentially infectious materials. The strategy of respiratory hygiene/cough etiquette applies to any person with signs of respiratory infection, including cough, congestion, rhinorrhea, or increased production of respiratory secretions when entering a health care site. Educating health care staff, patients, and visitors to cover the mouth and nose with a tissue when coughing, dispose properly of used tissues, and perform hand hygiene is among the elements of respiratory hygiene.

The second tier (see Box 7-2) includes precautions designed for care of patients who are known or suspected to be infected, or colonized, with microorganisms transmitted by the contact, droplet, or

BOX 7-2 Centers for Disease Control and Prevention Isolation Guidelines

Standard Precautions (Tier One) for Use with All Patients

- Standard precautions apply to blood, blood products, all body fluids, secretions, excretions (except sweat), nonintact skin, and mucous membranes.
- Perform hand hygiene before, after, and between direct contact with patients. (e.g., between contact: cleaning hands after a patient care activity, moving to a nonpatient care activity, and cleaning hands again before returning to perform patient contact).
- Perform hand hygiene after contact with blood, body fluids, secretions, and excretions; after contact with surfaces or articles in a patient room; and immediately after gloves are removed.
- When hands are visibly soiled or contaminated with blood or body fluids, wash them with either a nonantimicrobial soap or an antimicrobial soap and water.
- When hands are not visibly soiled or contaminated with blood or body fluids, use an alcohol-based hand rub to perform hand hygiene.
- Wash hands with nonantimicrobial soap and water if contact with spores (e.g., *Clostridium difficile*) is likely to have occurred.
- Do not wear artificial fingernails or extenders if duties include direct contact with patients at high risk for infection and associated adverse outcomes.
- Wear gloves when touching blood, body fluids, secretions, excretions, nonintact skin, mucous membranes, or contaminated items or surfaces is likely. Remove gloves and perform hand hygiene between patient care encounters and when going from a contaminated to a clean body site.
- Wear personal protective equipment when the anticipated patient interaction indicates that contact with blood or body fluids may occur.
- A private room is unnecessary unless the patient’s hygiene is unacceptable (e.g., uncontained secretions, excretions, or wound drainage).
- Discard all contaminated sharp instruments and needles in a puncture-resistant container. Health care agencies must make available needleless devices. Any needles should be disposed of uncapped; or a mechanical safety device is activated for recapping.
- Respiratory hygiene/cough etiquette—Have patients:
 - Cover the nose/mouth when coughing or sneezing.
 - Use tissues to contain respiratory secretions and dispose in nearest waste container.
 - Perform hand hygiene after contacting respiratory secretions and contaminated objects/materials.
 - Contain respiratory secretions with procedure or surgical mask.
 - Sit at least 91.4 cm (3 feet) away from others if coughing.

Transmission-Based Precautions (Tier Two) for Use With Specific Types of Patients

Category	Infection/Condition	Barrier Protection
Airborne precautions (droplet nuclei smaller than 5 microns)	Measles, chickenpox (varicella), disseminated varicella zoster, pulmonary or laryngeal tuberculosis	Private room, negative-pressure airflow of at least 6 to 12 exchanges per hour via HEPA filtration; mask or respiratory protection device, N95 respirator required (depending on condition)
Droplet precautions (droplets larger than 5 microns; being within 3 feet of patient)	Diphtheria (pharyngeal), rubella, streptococcal pharyngitis, pneumonia or scarlet fever in infants and young children, pertussis, mumps, <i>Mycoplasma pneumoniae</i> , meningococcal pneumonia or sepsis, pneumonic plague	Private room or cohort patients; mask or respirator required (depending on condition) (refer to agency policy)
Contact precautions (direct patient or environmental contact)	Colonization or infection with multidrug-resistant organisms such as VRE and MRSA, <i>Clostridium difficile</i> , <i>Shigella</i> , and other enteric pathogens; major wound infections; herpes simplex; scabies; varicella zoster (disseminated); respiratory syncytial virus in infants, young children, or immunocompromised adults	Private room or cohort patients (see agency policy), gloves, gowns
Protective environment	Allogeneic hematopoietic stem cell transplants	Private room; positive airflow with 12 or more air exchanges per hour; HEPA filtration for incoming air; mask to be worn by patient when out of room during times of construction in area

Modified from Centers for Disease Control and Prevention (CDC), Hospital Infection Control Practice Advisory Committee: Guidelines for isolation precautions in hospitals, *MMWR Morb Mortal Wkly Rep* 57/RR-16:39, 2007.
 HEPA, High-efficiency particulate air; MRSA, methicillin-resistant *Staphylococcus aureus*; VRE, vancomycin-resistant enterococcus.

airborne route (CDC, 2007a; Brisko, 2011) or by contact with contaminated surfaces. The three types of transmission-based precautions—airborne, droplet, and contact—may be combined for diseases that have multiple routes of transmission (e.g., chickenpox). When used either singly or in combination, you use them in addition to standard precautions. Box 7-2 summarizes the types of patients who are cared for under transmission-based precautions.

One important aspect of care for a patient in isolation is compliance with hand hygiene and the changing of gloves between exposures to body sites and patient equipment. Inadequate glove changes and hand hygiene can lead to contamination of previously uncolonized sites (Haas, 2011). Noncompliance with glove changing and hand hygiene increases the risk of HAIs.

Delegation and Collaboration

The skill of caring for patients on isolation precautions can be delegated to nursing assistive personnel (NAP). However, the nurse must assess the patient's status and isolation indications. The nurse instructs the NAP to:

- Take special precautions regarding individual patient needs such as transportation to diagnostic tests.
- Take precautions about bringing equipment into the patient's room.
- Be aware of high-risk factors for infection transmission that pertain to the assigned patient.

Equipment

- Barrier protection determined by type of isolation required; clean gloves, mask, eyewear or goggles, face shield, and gown (gowns may be disposable or reusable, depending on agency policy)
- Other patient care equipment (as appropriate) (e.g., hygiene items, medications, dressing supplies, sharps container, disposable blood pressure cuff)
- Soiled linen bag and trash receptacle
- Sign for door indicating type of isolation and/or for visitors to come to the nurses' station before entering room

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's medical history for possible indications for isolation (e.g., risk factors for TB, major draining wound, or purulent productive cough). Review precautions for the specific isolation system, including appropriate barriers to apply (see Box 7-2).
- 2 Review laboratory test results (e.g., wound culture, acid-fast bacillus [AFB] smears, changes in WBC count).
- 3 Consider types of care measures that you will perform while in patient's room (e.g., medication administration or dressing change).
- 4 Review nursing care plan notes or confer with colleagues regarding patient's emotional state and reaction/adjustment to isolation. Also assess patient's understanding of purpose of isolation.

Mode of transmission for infectious microorganism determines type and degree of precautions followed. Ensures adequate protection.

Reveals type of microorganism for which patient is being isolated, body fluid in which it was identified, and whether patient is immunosuppressed.

Allows you to organize care items for procedures and time spent in patient's room.

Determines patient's need for emotional support and teaching.

NURSING DIAGNOSES

- Deficient knowledge regarding purpose of isolation
- Impaired social interaction
- Risk for infection
- Ineffective protection

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient asks for information about disease transmission.
 - Patient explains purpose of isolation.

Active interaction reveals patient's willingness and/or ability to communicate and be taught and understand information.

Instruction about precautions improves patient's ability to cooperate in care.

IMPLEMENTATION

- 1 Perform hand hygiene (see Skill 7-1).
- 2 Prepare all equipment needed in patient's room. In many cases, dedicated equipment such as stethoscopes should remain in the room until patient is discharged.
- 3 Prepare for entrance into isolation room. Prior to applying PPE, step into patient's room and stay by door. Introduce yourself and explain the care that you are providing.
 - a Apply gown, being sure that it covers all outer garments. Pull sleeves down to wrist. Tie securely at neck and waist (see illustration).

Reduces transmission of microorganisms.

Prevents you from making more than one trip into room. The CDC recommends use of dedicated noncritical patient care equipment (CDC, 2007a).

Proper preparation ensures protection from microorganism exposure. Allows patient to see you without PPE and without exposing yourself to risk of infection transmission.

Prevents transmission of infection; protects you when patient has excessive drainage, discharges.

STEP

RATIONALE

STEP 3a Tie isolation gown.

STEP 3d Bring glove cuffs over edge of gown sleeves.

- b Apply either surgical mask or fitted respirator around mouth and nose (type and fit-testing depend on type of isolation and agency policy). You must have a medical evaluation and be fit-tested before using a respirator.
 - c If needed apply eyewear or goggles snugly around face and eyes. If you wear prescription glasses, side shields may be used.
 - d Apply clean gloves. (NOTE: Wear unpowdered gloves latex-free gloves if you, the patient, or another health care worker has a latex allergy.) Bring glove cuffs over edge of gown sleeves (see illustration).
- 4 Enter patient's room. Arrange supplies and equipment. (NOTE: if equipment will be reused, place on a clean paper towel).
 - 5 Explain purpose of isolation and precautions for patient and family to take. Offer opportunity to ask questions.
 - 6 Assess vital signs (see Chapter 5).
 - a Reusable equipment brought into room must be thoroughly disinfected when removed from room.
 - b If stethoscope is to be reused, clean earpieces and diaphragm or bell with 70% alcohol or agency-approved germicide. Set aside on clean surface.
 - c Use individual or disposable thermometers and blood pressure cuffs when available.

Prevents exposure to airborne microorganisms or microorganisms from splashing of fluids.

Protects you from exposure to microorganisms that may occur during splashing of fluids.

Reduces transmission of microorganisms.

Prevents extra trips entering and leaving room. Minimizes contamination of care items.

Improves patient's and family's ability to participate in care and minimizes anxiety. Identifies opportunity for planning social interaction and diversional activities.

Decreases the risk of infection being transmitted to another patient.

Systematic disinfection of stethoscopes with 70% alcohol or approved germicide minimizes chance of spreading infectious agents between patients (CDC, 2007b).

Prevents cross-contamination.

Clinical Decision Point If patient is infected or colonized with a resistant organism (e.g., vancomycin-resistant enterococcus [VRE], methicillin-resistant *Staphylococcus aureus* [MRSA]), equipment remains in room whenever possible (CDC, 2011c). This includes stethoscope and blood pressure cuff.

Clinical Decision Point If disposable thermometer indicates a fever, assess for other signs/symptoms of infection. Confirm fever using an alternative thermometer. Do not use electronic thermometer if patient is suspected or confirmed to have *Clostridium difficile* (Cohen et al., 2010).

- 7 Administer medications (see Chapters 20, 21, and 22).
 - a Give oral medication in wrapper or cup. Handle and discard supplies to minimize transfer of microorganisms.
 - b Dispose of wrapper or cup in plastic-lined receptacle.
 - c Wear gloves when administering an injection. Reduces risk of exposure to blood.
 - d Discard disposable syringe and uncapped or sheathed needle into designated sharps container. Reduces risk of needlestick injury.

STEP	RATIONALE
e Place reusable plastic syringe (e.g., Carpuject) on clean towel for eventual removal and disinfection.	Prevents added contamination of syringe.
f If you are not wearing gloves and hands contact a contaminated article or body fluids, perform hand hygiene as soon as possible.	Reduces transmission of microorganisms.
8 Administer hygiene, encouraging patient to ask any questions or express concerns about isolation. Provide informal teaching at this time.	Hygiene practices further minimize transfer of microorganisms. Quality time should be spent with patient when in room.
a Avoid allowing isolation gown to become wet; carry washbasin outward away from gown; avoid leaning against wet tabletop.	Moisture allows organisms to travel through gown to uniform.
Clinical Decision Point <i>When there is a risk for excess soiling, wear a gown impervious to moisture.</i>	
b Help patient remove own gown; discard in leak-proof linen bag.	Reduces transfer of microorganisms.
c Remove linen from bed; avoid contact with isolation gown. Place in leak-proof linen bag.	Handle linen soiled by patient's body fluids to prevent contact with clean items.
d Provide clean bed linen and set of towels.	
e Change gloves and perform hand hygiene if gloves become excessively soiled and further care is necessary. Reglove.	
9 Collect specimens (see Chapter 43).	
a Place specimen containers on clean paper towel in patient's bathroom.	Container will be taken out of patient's room; prevents contamination of outer surface.
b Follow agency procedure for collecting specimen of body fluids (see Chapter 43).	
c Transfer specimen to container without soiling outside of container. Place container in plastic bag and place label on outside of bag or per agency policy. Label specimen in front of patient (TJC, 2012). Perform hand hygiene and reglove if additional procedures are needed.	Specimens of blood and body fluids are placed in well-constructed containers with secure lids to prevent leaks during transport. Proper labeling prevents diagnostic error.
d Check label on specimen for accuracy. Send to laboratory (warning labels are often used, depending on agency policy). Label containers of blood or body fluids with a biohazard sticker (see illustration).	Ensures that health care providers who transport or handle containers are aware of infectious contents.
10 Dispose of linen, trash, and disposable items.	
a Use single bags that are impervious to moisture and sturdy to contain soiled articles. Use double bag if necessary for heavily soiled linen or heavy wet trash.	Linen or refuse should be totally contained to prevent exposure of personnel to infectious material.
b Tie bags securely at top in knot (see illustration).	
11 Remove all reusable pieces of equipment. Clean any contaminated surfaces with hospital-approved disinfectant (CDC, 2007b) (see agency policy).	All items must be properly cleaned, disinfected, or sterilized for reuse.

STEP 9d Place specimen container in biohazard bag.

STEP 10b Tie bag securely.

STEP

RATIONALE

- 12 Resupply room as needed. Have staff colleague hand new supplies to you.
- 13 Leave isolation room. Order of removal of PPE depends on what you wear in room. This sequence describes steps to take if all barriers are worn.
 - a Remove gloves. Remove one glove by grasping cuff and pulling glove inside out over hand. Hold removed glove in gloved hand (see illustration). Slide fingers of ungloved hand under remaining glove at wrist. Peel glove off over first glove. Discard gloves in proper container.
 - b Remove eyewear, face shield, or goggles. Handle by headband or earpieces. Discard in proper container.
 - c Untie neck strings and then untie back strings of gown. Allow gown to fall from shoulders (see illustration); touch inside of gown only. Remove hands from sleeves without touching outside of gown. Hold gown inside at shoulder seams and fold inside out into a bundle; discard in laundry bag.
 - d Remove mask. If mask secures over ears, remove elastic from ears and pull mask away from face. For a tie-on mask, untie *bottom* mask string and then top strings, pull mask away from face (see illustration), and drop into trash receptacle. (Do not touch outer surface of mask.)
 - e Perform hand hygiene.
 - f Retrieve wristwatch and stethoscope (unless items must remain in room) and record vital sign values on note paper.
 - g Explain to patient when you plan to return to room. Ask whether patient requires any personal care items. Offer books, magazines, audiotapes.
 - h Dispose of all contaminated supplies and equipment in manner that prevents spread of microorganisms to other persons (see agency policy). Perform hand hygiene.

- Limiting trips of personnel into and out of room reduces your and patient's exposure to microorganisms.
- Order of removal minimizes exposure to any infectious material on barriers.
- Technique prevents contact with outer surface contaminated of glove.
- Outside of goggles is contaminated. Hands have not been soiled.
- Hands do not come in contact with soiled front of gown.
- Ungloved hands will not be contaminated by touching only elastic or mask strings. Prevents top part of mask from falling down over uniform.
- Reduces transmission of microorganisms. Clean hands can contact clean items.
- Diversions can help to minimize boredom and feeling of social isolation.

STEP 13a Hold removed glove in gloved hand and pull remaining glove.

STEP 13c Remove gown by allowing it to fall from shoulders.

STEP 13d Pull mask away from face.

STEP

- i Leave room and close door if necessary. Close door if patient is on airborne precautions or in negative airflow room.

RATIONALE

Maintains negative airflow environment and reduces transmission of microorganisms.

EVALUATION

- 1 While in room, ask if patient has had sufficient chance to discuss health problems, course of treatment, or other topics important to him or her.
- 2 Ask patient to describe purpose of isolation and offer chance to ask questions.

Measures patient's perception of adequacy of discussions with caregivers.

Feedback demonstrates learning.

Unexpected Outcomes

- 1 Patient avoids social and therapeutic discussions.
- 2 Patient or health care worker may have an allergy to latex gloves.

Related Interventions

- Confer with family and/or significant other and determine best approach to reduce patient's sense of loneliness and depression.
- Notify physician/employee health and treat sensitivity or allergic reaction appropriately.
- Use latex-free gloves for future care activities.

Recording and Reporting

- Document procedures performed and patient's response to social isolation. Also document any patient education performed and reinforced.
- Document type of isolation in use and the microorganisms (if known).

Special Considerations

Teaching Considerations

- Teach visitors and family members how to follow the recommended isolation precautions when visiting a patient.

Pediatric Considerations

- Isolation creates a sense of separation from family and loss of control. Strange environment adds to the confusion that a child feels during isolation. Preschoolers are unable to understand cause-effect relationship for isolation. Older children may be able to understand cause but still fantasize.
- Children require simple explanations (e.g., "You need to be in this room to help you get better.") Show all barriers to a child.

Actively involve parents in any explanations. Nurses let child see their faces before applying masks so child does not become frightened.

Gerontologic Considerations

- Isolation can be a particular concern for older adults, especially those who have signs and symptoms of confusion or depression. Many times patients become more confused when they are confronted with a nurse using barrier precautions or when they are left in a room with the door closed. Nurses must assess need for closing door (negative-airflow room) along with safety of patient and additional safety measures that may need to be taken.
- Assess older adults for signs of depression such as loss of appetite or decrease in verbal communications. If necessary, report to the health care team for appropriate interventions.

Home Care Considerations

- Although isolation precautions followed in the hospital are not directly applicable to home care, caregivers should be aware of potential sources of contamination in the home (see Box 7-2).

PROCEDURAL GUIDELINE 7-1 Caring for Patients with Multidrug-Resistant Organisms (MDRO) and *Clostridium difficile*

Multidrug-resistant organisms (MDROs) such as methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant enterococcus (VRE) have become increasingly common as a cause of colonization and health care-associated infections (HAIs). MRSA is a frequently identified pathogen associated with increased mortality. In recent reports MRSA caused upward of 19% of health care-associated bloodstream infections (Becker and Kahl, 2011). VRE, another MDRO, poses a greater risk to immunocompromised and debilitated patients (Archibald, 2011). *Clostridium difficile* infection is one of the most common and costly HAIs (Gerding, 2011). In most instances patient susceptibility to *C. difficile* infection requires prior treatment with antibiotics.

Unlike MRSA and VRE, *C. difficile* is more difficult to eliminate from the environment because it is a spore-forming organism, meaning that it can remain on surfaces in its dormant state for long periods of time. No matter which MDRO is involved, the most common means of transmission is by way of a health care worker's hands. To reduce the risk of cross-contamination among patients, use contact precautions in addition to standard precautions when caring for these patients.

Delegation and Collaboration

Assessment of a patient's status and type of care required cannot be delegated to nursing assistive personnel (NAP). Basic care

PROCEDURAL GUIDELINE 7-1 Caring for Patients with Multidrug-Resistant Organisms (MDRO) and *Clostridium difficile*—cont'd

procedures performed using contact precautions can be delegated to NAP. The nurse instructs the NAP to:

- Clarify personal precautions used under contact precautions.
- Explain the type of clinical changes to report.

Equipment

- Clean gloves, gown, protective eyewear, surgical mask (based on patient's clinical condition)
- Basic care items (e.g., medication equipment, hygiene items)

Procedural Steps

- 1 Perform hand hygiene.
- 2 Prepare all equipment needed in patient's room.
- 3 Before entering room apply gown, being sure that it covers all outer garments. Pull sleeves down to wrists. Tie securely at neck and waist.
- 4 Apply clean gloves.
- 5 Explain purpose of contact precautions to patient and family.
- 6 Provide personal care and treatments.
- 7 Leave room after telling patient when you will return and asking if he or she has questions concerning his or her care.
- 8 Remove gloves and discard per agency policy.
- 9 Untie neck and waist ties on gown. Remove gown, allowing it to fall from shoulders. Discard in appropriate receptacle per agency policy.
- 10 Perform hand hygiene. If patient is being treated for *C. difficile* infection, clean hands with soap and water. Alcohol-based hand rubs are not effective against the spores of *C. difficile*.

Critical Thinking Exercises

Joe is assigned to care for Mr. Nesbitt, a 78-year-old nursing home resident. After greeting Mr. Nesbitt, Joe begins to conduct a physical assessment.

- 1 As Joe turns Mr. Nesbitt to check the condition of his skin, he notices moisture on his own hand. Joe looks more closely and realizes that the moisture is from an open, oozing lesion on Mr. Nesbitt's sacral area. What should Joe do next?
- 2 A few hours later Joe prepares to enter Mr. Nesbitt's room. Wearing gloves, he assesses the wound and quickly checks the position and function of Mr. Nesbitt's indwelling urinary catheter. He performs hand hygiene before leaving Mr. Nesbitt's room. Critique Joe's approach. Did he use correct aseptic technique?
- 3 After Joe places Mr. Nesbitt on contact precautions, he observes a student nurse preparing to go into the patient's room with a mask. Is the student nurse's use of a mask appropriate?

- 3 When a patient is to be placed on isolation precautions, there are many factors to consider regarding his or her care. (Select all that apply.)
 - 1 The need for social interaction
 - 2 The type of isolation required
 - 3 The patient's cultural background
 - 4 Education of family and friends regarding the isolation
 - 5 Organization of care to minimize trips in and out of the isolation room
 - 6 How the patient contracted an infection
- 4 The use of a mask when the nurse is closer than 3 feet to a patient involves which type of precautions?
 - 1 Airborne
 - 2 Droplet
 - 3 Contact
 - 4 Standard
- 5 A nurse goes in and out of a patient's room and only needs a gown when coming into contact with the patient. What should the nurse do on leaving the room? (Select all that apply.)
 - 1 Leave the used gown hanging on a hook inside the room for the next time it is needed
 - 2 Leave the used gown hanging on a hook outside the room for the next time it is needed
 - 3 Discard the gown after using it
 - 4 Perform hand hygiene
- 6 A nurse enters the room of a patient who has been diagnosed with pneumonia. The nurse instructs the patient to cover the mouth when coughing. This reduces transmission of infection by:
 - 1 Contact.
 - 2 Small droplets.
 - 3 Vector.
 - 4 Splashing.

REVIEW QUESTIONS

- 1 A health care worker has visible dirt on his hands. Which method of hand hygiene is most appropriate?
 - 1 Using an alcohol-based disinfectant
 - 2 Washing with water and then an alcohol-based hand rub
 - 3 Using an alcohol gel containing an emollient
 - 4 Washing with soap and water
- 2 Which aspect of handwashing is most effective to loosen dirt and transient bacteria?
 - 1 Using hot water instead of warm water
 - 2 Using plenty of lather with friction
 - 3 Drying the hands vigorously from wrists to fingers
 - 4 Applying lotion to the hands

- 7 A nurse applies clean gloves when collecting a urine specimen. How does this technique break the chain of infection? (Select all that apply.)
- 1 Blocks the portal of entry for microorganisms
 - 2 Blocks the portal of exit
 - 3 Reduces susceptibility of the host
 - 4 Controls a reservoir source of organisms
- 8 *C. difficile* organisms can be passed easily from patient to patient. An infection prevention practice used to reduce possible transmission includes:
- 1 Wearing a surgical mask when entering the patient's room.
 - 2 Using soap and water when performing hand hygiene.
 - 3 Instructing the patient on the source of the organism.
 - 4 Maintaining droplet precautions.
- 9 The most likely means of transmitting infection between patients is:
- 1 Exposure to another's cough.
 - 2 Sharing equipment among patients.
 - 3 Discarding soiled linen in a shared laundry bag.
 - 4 Contact with health care workers' hands.
- 10 A patient is isolated for pulmonary tuberculosis. The nurse notes that the patient seems angry but knows that this is a normal response to isolation. The best intervention is to:
- 1 Provide a dark, quiet room to calm the patient.
 - 2 Reduce the level of precautions to relax the patient.
 - 3 Explain the reason for isolation and answer the patient's questions.
 - 4 Limit family and caregiver visits to reduce the risk of spreading the infection.

KEY TERMS

Asepsis	Pathogenic microorganisms	Sterile field	Transmission-based precautions
Latex allergy reaction	Standard precautions	Strike through	
Microorganisms	Sterile	Surgical asepsis	

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss settings where surgical aseptic techniques are used.
- Describe conditions when surgical asepsis is used.
- Identify the principles of surgical asepsis.
- Explain the importance of organization and caution when using surgical aseptic techniques.
- Apply and remove a cap, mask, and protective eyewear correctly.
- Identify individuals at risk for a latex allergy.
- Perform the following skills: Applying sterile gloves using open-glove method, preparing a sterile field, and applying a sterile drape correctly.

Surgical asepsis or aseptic techniques and practices are designed to make and maintain objects and areas free from pathogenic microorganisms (Iwamoto, 2009). Sterilization destroys all microorganisms and their spores. The most common means of sterilizing objects used in the operating room (OR) is by steam sterilization. As in medical asepsis, hand hygiene with an appropriate cleaner or antiseptic is essential before the initiation of an aseptic procedure. Although nurses commonly practice surgical asepsis in ORs, labor and delivery areas, and major diagnostic or special procedure areas, they also use surgical aseptic techniques at a patient's bedside (Box 8-1) in three primary situations:

- During procedures that require intentional perforation of a patient's skin (e.g., insertion of central intravenous [IV] catheters [see Chapter 28])
- When the integrity of the skin is broken because of a surgical incision or burns (see Chapters 38 and 39)
- During procedures that involve insertion of devices or surgical instruments into normally sterile body cavities (e.g., insertion of a urinary catheter [see Chapter 33])

A nurse in an OR follows a series of steps to maintain sterile technique, including applying a mask, protective eyewear, and a cap; performing a surgical hand scrub; applying a sterile gown; and applying sterile gloves. In contrast, a nurse performing a sterile dressing change at a patient's bedside or in the home setting may only wash his or her hands and apply sterile gloves. In 2007 the Centers for Medicare and Medicaid Services (CMS) identified a list of conditions viewed to be reasonably preventable by applying evidence-based guidelines. Among these conditions are hospital-acquired vascular and urinary catheter-associated infections. Since October 1, 2008, hospitals receive no additional funds for treating these conditions. As of January 2012, CMS has identified 10 hospital-acquired conditions that are preventable based on evidence-based guidelines (CMS, 2012). In many instances this has led agencies to encourage staff to speak up if they see a break in sterile technique by a co-worker. Regardless of the procedures followed or the setting, all individuals involved in surgical asepsis have a responsibility to provide and maintain a safe environment by following aseptic principles (AORN, 2011; Iwamoto, 2009).

BOX 8-1 Principles of Surgical Asepsis

- 1 All items used within a sterile field must be sterile.
- 2 A sterile barrier that has been permeated by punctures, tears, or moisture must be considered contaminated.
- 3 Once a sterile package is opened, a 2.5-cm (1-inch) border around the edges is considered unsterile.
- 4 Tables draped as part of a sterile field are considered sterile only at table level.
- 5 If there is any question or doubt about the sterility of an item, the item is considered to be unsterile.
- 6 Sterile persons or items contact only sterile areas; unsterile persons or items contact only unsterile areas.
- 7 Movement around and in the sterile field must not compromise or contaminate the sterile field.
- 8 A sterile object or field out of the range of vision or an object held below a person's waist is contaminated.
- 9 A sterile object or field becomes contaminated by prolonged exposure to air; stay organized and complete any procedure as soon as possible.

In treatment areas and at the bedside it is important to have a patient's full cooperation to minimize contamination of a work area. Be sure to prepare a patient before any procedure. Certain patients may fear moving or touching objects during a sterile procedure, whereas others even try to assist. Explain how you will perform a procedure and what a patient can do to avoid contaminating sterile items, including avoiding sudden body movement, refraining from touching sterile supplies, and avoiding coughing or talking over a sterile area.

The Centers for Disease Control and Prevention (CDC) (2007) established standard precautions as the minimum standard for infection control (see Chapter 7). Use standard precautions for potential contact with blood and all body fluids. The use of standard precautions calls for wearing masks in combination with eye protection devices such as goggles or glasses with solid side shields whenever splashes, sprays, splatter, or droplets of blood or other potentially infectious fluids may occur. These barriers are not sterile but are designed to keep the eyes, nose, and mouth free from exposure. Similarly, you wear gowns when there is risk of being splattered with blood or other infectious materials. All health care agencies need to provide personal protective equipment (PPE) and instructions for their use to all employees at risk for exposure (OSHA, 1994).

EVIDENCE-BASED PRACTICE

In 1860 Joseph Lister promoted the use of carbolic acid as a surgical hand scrub. Since then using an antiseptic on the hands of surgical team members has been an accepted practice. Bacteria on the hands of health care workers can lead to wound infections when introduced into surgical wounds. Studies found that surgical staff may transmit pathogens from contact with patients or with contaminated items such as tourniquets, linens, or surfaces (e.g., door-knobs, countertops) (Cook, 2011). Studies show that antiseptics containing 60% to 90% alcohol alone or 50% to 95% alcohol when combined with other selected antiseptics (e.g., chlorhexidine) lower bacterial counts on the skin more effectively than do other antiseptics without alcohol (Cook, 2011). In addition, bacteria appear to reproduce slowly on the hands after a surgical scrub with alcohol. For this reason an alcohol-based hand rub may be

used as a preoperative hand scrub after an initial 15-second prewash with plain soap and water (AORN, 2011).

The subungual area (under a fingernail) of the hand is a source of high concentrations of bacteria, most frequently coagulase-negative staphylococci and gram-negative rods. Even after thorough hand hygiene, large numbers of potential pathogens exist under the subungual spaces (Cook, 2011). Health care workers who wear artificial nails or nail extenders are more likely to harbor gram-negative pathogens on their fingertips both before and after hand hygiene. Fungal growth frequently occurs under artificial nails as a result of moisture becoming trapped between the natural and artificial nail (AORN, 2011). Many health care agencies have banned artificial nails and extenders in all clinical areas, with the rationale that all patients are at risk for infection.

- Health care workers having direct contact with patients should not wear artificial nails (Church and Berjke, 2009; Cook, 2011).
- Use an additional antiseptic such as chlorhexidine to reduce bacterial count on the skin (AORN, 2011; Cook, 2011).
- Carefully clean under the fingernail during hand hygiene and before applying sterile gloves.
- Maintain fingernails no longer than $\frac{1}{4}$ inch in length, and nail polish should not be chipped (Cook, 2011).

PATIENT-CENTERED CARE

Whether performed in a hospital, ambulatory care setting, or health care provider's office, invasive procedures such as starting an IV line or inserting a urinary catheter pose a risk for infection. It is your responsibility to protect patients from infection by adhering strictly to the principles of surgical asepsis when performing such procedures and, when assisting with such a procedure, to intervene to stop it when a break in sterile technique occurs. The Joint Commission (TJC) encourages nurses to "speak up" in these instances (TJC, 2012).

Regardless of a patient's background, beliefs, or attitudes, it is important to maintain sterile asepsis for invasive procedures. In these cases patient-centered education of patients and families before any aseptic procedure reduces fears and misconceptions about any sterile asepsis attire. In addition, such education provides time for patients and families to ask any questions about their concerns. In some cases a person's cultural background requires gender-congruent care providers.

Safety Guidelines

- 1 Follow standard precautions with all patients.
- 2 Review agency policies and procedures before conducting a sterile procedure.
- 3 Assess a patient's potential for infection before choosing the barrier to be used such as masks or protective eyewear.
- 4 Use barrier techniques to decrease the transmission of microorganisms from health care personnel and the environment to a patient.
- 5 Remain organized while performing any sterile procedure; keep bedside surfaces clutter free.
- 6 Remember that hand hygiene is essential before initiating any sterile procedure.
- 7 Incorporate the principles of surgical asepsis when conducting any sterile procedure.

SKILL 8-1 Applying and Removing Cap, Mask, and Protective Eyewear

NSO Nursing Skills Online Infection Control Module / Lesson 1

Although masks and caps are usually worn in surgical procedure areas (e.g., the operating room [OR]), certain aseptic procedures performed at a patient's bedside also might require these barriers. For example, it may be agency policy for a nurse to wear a mask during the changing of a central line dressing or insertion of a peripherally inserted central catheter (PICC). Other policies might require that a nurse wear a mask and a cap to secure hair during dressing changes on a patient with extensive burns or a central line (Lynn-McHale Wiegand, 2011). When there is a risk of splattering blood or body fluid, there is also the need to apply protective eyewear (OSHA, 2012).

Assess a patient's potential for acquiring an infection before applying a mask (e.g., Does the patient have a large open wound? Do you have a respiratory infection? Is the patient immunosuppressed?). If you wear a mask, change it when it becomes moist or soiled (e.g., splattered with blood). Some nurses choose to wear a surgical cap to secure loose hair that might contaminate a sterile area (Church and Bjerke, 2009). Wear eyewear when there is a risk for body fluids splashing into your eyes.

Delegation and Collaboration

The skill of applying and removing cap, mask, and protective eyewear is required of all caregivers when working in sterile areas. However, the procedures performed at a patient's bedside that require cap and mask generally cannot be delegated to nursing assistive personnel (NAP). The nurse determines if protective barriers are necessary for the other staff. The nurse instructs the NAP about:

- The procedure to be performed and how to assist with positioning and obtaining supplies
- Performing hand hygiene after glove removal

Equipment

- Surgical mask (different types are available for people with different skin sensitivities)
- Surgical cap (NOTE: Use in OR or if agency policy requires. Use to secure hair if there is a possibility of contamination of a sterile field.)
- Hairpins, rubber bands, or both
- Protective eyewear (e.g., goggles or glasses with appropriate side shields)

STEP

RATIONALE

ASSESSMENT

- 1 Review type of sterile procedure to be performed and consult agency policy for use of mask/caps/protective eyewear.
- 2 If you have symptoms of a respiratory infection, either avoid participating in procedure or apply a mask.
- 3 Assess patient's actual or potential risk for infection when choosing barriers for surgical asepsis (e.g., older adult, neonate, or immunocompromised patient).

Not all sterile procedures require mask, cap, or protective eyewear. Ensures that nurse and patient are properly protected. A greater number of pathogenic microorganisms reside within the respiratory tract when infection is present. Some patients are at a greater risk for acquiring an infection; thus use additional barriers.

NURSING DIAGNOSES

- Ineffective protection
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcome following completion of procedure:
 - Patient does not develop signs of localized infection (e.g., redness, tenderness, edema, drainage) or systemic infection (e.g., fever, change in white blood cell [WBC] count) 24 hours after procedure.
- 2 Prepare equipment and inspect packaging for integrity and exposure to sterilization.

Indicates lack of microorganism transfer to patient and sterile field. Ensures availability of equipment and sterility of supplies before procedure begins.

IMPLEMENTATION

- 1 Perform hand hygiene
- 2 Apply a cap.
 - a If hair is long, comb back behind ears and secure.
 - b Secure hair in place with pins.
 - c Apply cap over head as you would apply hairnet. Be sure that all hair fits under edges of cap (see illustration).

Reduces transient microorganisms on skin. Cap must cover all hair entirely. Ensures that long hair does not fall down or cause cap to slip and expose hair. Loose hair hanging over sterile field or falling dander contaminates objects on sterile field.

STEP

RATIONALE

- 3** Apply a mask.
- Find top edge of mask, which usually has thin metal strip along edge.
 - Hold mask by top two strings or loops, keeping top edge above bridge of nose.
 - Tie two top strings at top of back of head, over cap (if worn), with strings above ears (see illustration). Alternatively place loops over ears.
 - Tie two lower ties snugly around neck with mask well under chin (see illustration).
 - Gently pinch upper metal band around bridge of nose.
- 4** Apply protective eyewear.
- Apply protective glasses, goggles, or face shield comfortably over eyes and check that vision is clear (see illustration).
 - Be sure that face shield fits snugly around forehead and face.
- 5** Apply sterile gloves if needed (see Skill 8-3).
- 6** Remove protective barriers.
- Remove gloves first if worn (see Skill 8-3).
 - Untie bottom strings of mask.
- Untie top strings of mask and remove mask from face, holding ties securely. Discard mask in proper receptacle (see illustrations).

Pliable metal fits snugly against bridge of nose.

Prevents contact of hands with clean facial portion of mask. Mask covers all of nose.

Position of ties at top of head provides tight fit. Strings over ears may cause irritation.

Prevents escape of microorganisms through sides of mask as you talk and breathe.

Prevents microorganisms from escaping around nose and eyeglasses from steaming up.

Positioning affects clarity of vision.

Ensures that eyes are fully protected.

Prevents contamination of hair, neck, and facial area.

Prevents top part of mask from falling down over uniform. If mask falls and touches uniform, uniform will be contaminated.

Avoids contact of nurse's hands with contaminated mask.

STEP 2c Apply cap over head, covering all hair.

STEP 3d Tie bottom strings of mask.

STEP 3c Tie top strings of mask.

STEP 4a Apply face shield over cap.

STEP

RATIONALE

STEP 6c A, Untie top mask strings. B, Remove mask from face. C, Discard mask.

- d Remove eyewear, avoiding placing hands over soiled lens.
If wearing face shield, remove it before removal of mask.
NOTE: A combination mask and eyewear is available in some agencies.
- e Grasp outer surface of cap and lift from hair.
- f Discard cap in proper receptacle and perform hand hygiene.

Prevents transmission of microorganisms.

Minimizes contact of hands with hair.
Reduces transmission of infection.

EVALUATION

- 1 Following the procedure, assess area of body treated for drainage, tenderness, edema, or change in temperature or color of skin.

Rules out presence of localized infection.

Unexpected Outcomes

- 1 Redness, heat, edema, pain, or purulent drainage develops at wound or treatment site, indicating possible infection.

Related Interventions

- Notify health care provider of change in condition of affected area and initiate appropriate treatments as ordered.

Recording and Reporting

- No recording or reporting is required for this set of skills. Record specific procedure performed in nurses' notes and electronic health record (EHR), and describe patient's status.

Special Considerations

Home Care

- Instruct family caregiver about specifics of when to apply cap, mask, and protective eyewear in the home.
- Determine ability of family caregiver to safely implement sterile procedure.
- Instruct patient and family caregiver about the signs and symptoms of infection.

SKILL 8-2 Preparing a Sterile Field

NSO Nursing Skills Online Infection Control Module / Lesson 3

When performing sterile aseptic procedures, you need a sterile work area in which objects can be handled with minimal risk for contamination. A sterile field provides a sterile surface for placement of sterile equipment. It is an area considered free of microorganisms and may consist of the inside of a sterile kit or tray, a work surface draped with a sterile towel or wrapper, or a table covered with a large sterile drape (Iwamoto, 2009). Sterile drapes establish a sterile field around a treatment site such as a surgical incision, venipuncture site, or site for introduction of an indwelling urinary catheter. Drapes also provide a work surface for placing sterile supplies and manipulating items with sterile gloves. They are available in cloth, paper, and plastic. They may be wrapped in individual sterile packages or included within sterile kits or trays. These kits or trays contain external and internal sterile (chemical) indicators that indicate that the item has completed a sterilization process. After the kit is opened, the inside surface of the cover can be used as a sterile field. Most drapes are fluid resistant.

Drapes come in various styles, shapes, and sizes. For example, bladder catheterization kits and tracheal suction kits contain sterile items that can be moved within the tray and containers into which sterile solutions can be poured. Once you create a sterile field, you

Video Clip

are responsible for performing the procedure without contaminating the field. The skill of preparing a sterile field includes opening sterile packages, preparing a sterile drape, adding sterile supplies to a field, and pouring sterile solutions.

Delegation and Collaboration

The skill of preparing a sterile field cannot be delegated to nursing assistive personnel (NAP). Surgical technicians may prepare a sterile field (see agency policy). However, NAP may assist in positioning patients and obtaining extra supplies. The nurse directs the NAP to:

- Assist with patient positioning and obtaining any necessary supplies.

Equipment

- Sterile pack (commercial or institution wrapped)
- Sterile drape or kit that is to be used as a sterile field
- Sterile gloves
- Sterile solution and equipment specific to a procedure
- Waist-high table/countertop surface
- Appropriate personal protective equipment (PPE): gown, mask, protective eyewear (see agency policy)

STEP

RATIONALE

ASSESSMENT

- 1 Verify that procedure requires surgical aseptic technique.
- 2 Assess patient's comfort, oxygen requirements, and elimination needs before preparing for procedure.
- 3 Instruct patient not to touch the work surface or equipment during procedure.
- 4 Assess for latex allergies.
- 5 Check sterile package integrity for punctures, tears, discoloration, moisture, or any other signs of contamination. If using commercially packaged supplies or those prepared by agency, check for sterilization indicator (a marker that changes color when exposed to heat or steam).
- 6 Anticipate number and variety of supplies needed for procedure.

Some procedures require medical rather than surgical aseptic technique.

Certain procedures that require a sterile field may last a long time. Anticipates patient's needs so patient can relax and avoid any unnecessary movement that might disrupt procedure.

Prevents contamination of sterile field.

A review may reveal latex allergies and determine use of latex-free supplies.

The inspection of packaging ensures that only sterile items are presented to sterile field (AORN, 2011).

Not all sterile kits contain sufficient amounts or types of supplies. Failure to have necessary supplies causes you to leave sterile field, increasing risk for contamination.

NURSING DIAGNOSES

- Ineffective protection
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - The sterile field is not contaminated.
 - Patient is not exposed to microorganisms.

Correct surgical aseptic practice is performed.

STEP

RATIONALE

- | | |
|---|---|
| <p>2 Complete all other priority tasks (e.g., medication administration, suctioning patient) before beginning procedure.</p> <p>3 Ask visitors to step out briefly during procedure. Discourage movement by staff assisting with procedure.</p> <p>4 Prepare equipment at bedside.</p> | <p>Prepare sterile fields as close as possible to time of use to reduce potential for contamination (AORN, 2011).</p> <p>Traffic or movement can increase potential for contamination through spread of microorganisms by air currents.</p> <p>Ensures availability before procedure and prevents break in sterile technique (Torch, 2011). [NOTE: Povidone-iodine and chlorhexidine are not considered sterile solutions and require separate work surfaces for prepping.]</p> |
| <p>5 Position patient comfortably for specific procedure to be performed. If a body part is to be examined or treated, position patient so area is accessible. Have NAP assist with positioning as needed.</p> | <p>Patient should be able to lie still in one position comfortably during procedure. Movement can contaminate sterile items.</p> |
| <p>6 Explain to patient purpose of procedure and importance of sterile technique.</p> | <p>Ensures patient's ability to cooperate. Teaching before procedure eliminates need to talk during procedure, which can cause air-droplet contamination of sterile area.</p> |

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Apply PPE as needed (consult agency policy) (see Skills 8-1 and 8-3).</p> <p>2 Select a clean, flat, dry work surface above waist level.</p> <p>3 Perform hand hygiene (see Chapter 7).</p> | <p>Controls spread of airborne microorganisms.</p> <p>A sterile object below person's waist is considered contaminated. Reduces carriage of microorganisms on hands, which may be transmitted to patient. Do not allow rinse water to run down arms onto clean hands (i.e., arms are considered dirty).</p> |
| <p>4 Prepare sterile work surface.</p> <p>a Using sterile commercial kit or pack containing sterile items.</p> <p>(1) Place sterile kit or pack containing sterile items on clean, dry, flat work surface above waist level.</p> <p>(2) Open outside cover (see illustration) and remove package from dust cover. Place on work surface.</p> <p>(3) Grasp outer surface of tip of outermost flap.</p> | <p>Items placed below waist level are considered contaminated.</p> <p>Inner kit remains sterile.</p> <p>Outer surface of package is considered unsterile. There is a 2.5-cm (1-inch) border around any sterile drape or wrap that is considered contaminated.</p> <p>Reaching over sterile field contaminates it.</p> |
| <p>(4) Open outermost flap away from body, keeping arm outstretched and away from sterile field (see illustration).</p> | |

STEP 4a(2) Open outside cover of sterile kit.

STEP 4a(4) Open outermost flap of sterile kit away from body.

STEP

- (5) Grasp outside surface of edge of first side flap.
- (6) Open side flap, pulling to side, allowing it to lie flat on table surface. Keep arm to side and not over sterile surface (see illustration).
- (7) Repeat Step (6) for second side flap (see illustration).
- (8) Grasp outside border of last and innermost flap (see illustration). Stand away from sterile package and pull flap back, allowing it to fall flat on table.

b Open sterile linen-wrapped package.

- (1) Place package on clean, dry, flat work surface above waist level.
- (2) Remove sterilization tape seal and unwrap both layers following same steps (see Steps 4a(2) through 4a(8)) as for sterile kit (see illustration).
- (3) Use opened package wrapper as sterile field.

RATIONALE

Outer border is considered unsterile.
Drape or wrapper should lie flat so it does not accidentally rise up and contaminate inner surface or sterile contents.

Outer border is considered unsterile.
Never reach over a sterile field.

Items placed below waist level are considered contaminated.

Linen-wrapped items have two layers. The first is a dust cover. The second layer must be opened to view chemical indicator. If item is dropped on floor, it is considered contaminated.

Inner surface of wrapper is considered sterile.

STEP 4a(6) Open first side flap, pulling to side.

STEP 4a(8) Open last and innermost flap.

STEP 4a(7) Open second side flap, pulling to side.

STEP 4b(2) Open sterile linen-wrapped package.

STEP

RATIONALE

c Prepare sterile drape.

- | | |
|--|--|
| <ol style="list-style-type: none"> (1) Place pack containing sterile drape on flat, dry surface and open as described (see Steps 4a(2) through 4a(8)) for sterile package. (2) Apply sterile gloves (<i>optional</i>, see agency policy). You may touch outer 2.5-cm (1-inch) border of drape without wearing gloves. (3) Grasp folded top edge of drape with fingertips of one hand. Gently lift drape up from its wrapper without touching any object. (4) Allow drape to unfold, keeping it above waist and work surface and away from body. (Carefully discard wrapper with other hand.) (5) With other hand grasp adjacent corner of drape. Hold drape straight over work surface (see illustration). (6) Holding drape, position bottom half over top half of intended work surface (see illustration). (7) Allow top half of drape to be placed over bottom half of work surface (see illustration). | <p>Ensures sterility of packaged drape.</p> <p>A sterile object remains sterile only when touched by another sterile object. Gloves are not necessary as long as fingers grasp the 2.5-cm (1-inch) unsterile border of the drape.</p> <p>If sterile object touches any nonsterile object, it becomes contaminated.</p> <p>Object held below waist or above chest is contaminated.</p> <p>Drape can now be placed properly with two hands.</p> <p>Prevents nurse from reaching over sterile field.</p> <p>Creates flat, sterile work surface for placement of sterile supplies.</p> |
|--|--|

STEP 4c(5) Hold corners of sterile drape up and away from body.

STEP 4c(6) Position bottom half of sterile drape over top half of work surface.

STEP 4c(7) Allow top half of drape to be placed over bottom half of work surface.

STEP

RATIONALE

STEP 5c Add items to sterile field.

STEP 6d Pour solution into receiving container on sterile field.

- 5 Add sterile items to sterile field.
 - a Open sterile item (following package directions) while holding outside wrapper in nondominant hand.
 - b Carefully peel wrapper over nondominant hand.
 - c Being sure that wrapper does not fall down on sterile field, place item onto field at an angle (see illustration). **Do not hold arm over sterile field.**

Clinical Decision Point Do not flip or toss objects onto sterile field.

- d Dispose of outer wrapper.
- 6 Pour sterile solutions.
 - a Verify contents and expiration date of solution.
 - b Be sure that receptacle for solution is located near table/work surface edge. Sterile kits have cups or plastic molded sections into which fluids can be poured.
 - c Remove sterile seal and cap from bottle in upward motion.
 - d With solution bottle held away from field and bottle lip 2.5 to 5 cm (1 to 2 inches) above inside of sterile receiving container, slowly pour needed amount of solution into container. Hold bottle with label facing palm of hand (see illustration).

Clinical Decision Point When liquids permeate sterile field or barrier, it is called strike through, resulting in contamination.

- Frees dominant hand for unwrapping outer wrapper.
- Item remains sterile. Inner surface of wrapper covers hand, making it sterile.
- Secured wrapper edges prevent flipping wrapper and contaminating contents of sterile field (AORN, 2011).

- Prevents accidental contamination of sterile field.
- Ensures proper solution and sterility of contents.
- Prevents reaching over sterile field during pouring of solution.
- Prevents contamination of bottle lip.
- Edge and outside of bottle are considered contaminated. Slow pouring prevents splashing. Sterility of contents cannot be ensured if cap is replaced.
- Prevents label from becoming wet and illegible

EVALUATION

- 1 Observe for break in sterile technique.

Break in sterile field requires you to set up new sterile field.

Unexpected Outcomes

- 1 Sterile field comes in contact with contaminated object or liquid splatters onto drape, causing strike through.
- 2 Sterile item falls off sterile field.

Related Interventions

- Discontinue field preparation and start over with new equipment.
- Open package containing new sterile item and add to field, unless field becomes contaminated.

Recording and Reporting

- No recording or reporting is required for this set of skills. Record sterile procedure performed in nurses' notes and EHR, and describe patient's status.

Special Considerations

Home Care

- Most care procedures in the home setting involve clean technique. In the event that a sterile environment is ordered,

patient and family need to be aware of the principles that apply to the sterile environment. For example, teach family how to correctly use package wrapper as a sterile drape/barrier when applying a sterile dressing or teach family the correct procedure for removing sterile item from package.

- Assess patient's and family's understanding and ability to provide a sterile environment when needed to perform a specific procedure.

SKILL 8-3 Sterile Gloving

NSO Nursing Skills Online Infection Control Module / Lesson 4

Sterile gloves help prevent the transmission of pathogens by direct and indirect contact. Nurses apply sterile gloves before performing sterile procedures such as inserting urinary catheters or applying sterile dressings. It is important to select the proper size glove. The gloves should not stretch so tightly over the fingers that they can easily tear, yet they need to be tight enough that objects can be picked up easily. Sterile gloves are available in various sizes (e.g., 6, 6½, 7). They are also available in a "one size fits all" style or in "small," "medium," and "large." Always remember that sterile gloves do not replace hand hygiene.

It is important to choose not only the right size of glove but also the correct material. Many patients and health care workers are allergic to latex, the natural rubber used in most gloves and other medical products (Church and Bjerke, 2009). Box 8-2 lists risk factors for a latex allergy. Latex proteins enter the body through skin or mucous membranes, intravascularly, or via inhalation. The powder that is used to make latex gloves slip on easily is a carrier of the latex proteins (AORN, 2011; Molinari and Harte, 2009). When you apply or remove gloves, the powder particles become airborne and can remain so for hours. The latex can then be inhaled or settle on clothing, skin, or mucous membranes. Reactions to latex are mild to severe (Box 8-3). For individuals at high risk or with suspected sensitivity to latex, it is important to choose latex-free or synthetic gloves. More health care agencies are implementing latex-safe environments for workers (AORN, 2011). If only sterile latex gloves are available, don a pair of synthetic gloves first because these provide a barrier between the skin and the latex gloves.

Once you apply gloves, always be conscious of the position of your hands during procedures. If a sterile glove touches a clean,

contaminated, or questionably contaminated object, it becomes unsterile, and a new sterile glove must be applied. It is helpful to interlock the fingers and hold the hands together in front of the body and above waist level while waiting to handle sterile items. If a tear develops in a sterile glove, apply a new glove immediately. Once gloved, keep your hands clasped about 30 cm (12 inches) in front of your body, above waist level and below the shoulders, until you are ready to perform the procedure.

Delegation and Collaboration

Assisting with skills that include the application and removal of sterile gloves may be delegated to nursing assistive personnel (NAP). However, many procedures that require the use of sterile gloves cannot be delegated to NAP. The nurse instructs the NAP about:

- The reason for using sterile gloves for a specific procedure.

Equipment

- ❑ Package of proper-size sterile gloves, latex or synthetic nonlatex (NOTE: Hypoallergenic, low-powder, and low-protein latex gloves may still contain enough latex protein to cause an allergic reaction [Molinari and Harte, 2009].)

BOX 8-2 Individuals at Risk for Latex Allergy

- Spina bifida
- Congenital or urogenital defects
- History of indwelling catheters or repeated catheterizations
- History of using condom catheters
- High latex exposure (e.g., health care workers, housekeepers, food handlers, tire manufacturers, workers in industries that use gloves routinely)
- History of multiple childhood surgeries
- History of food allergies

Modified from Molinari J, Harte J: Dental services. In Carrico R, editor: *APIC text of infection control and epidemiology*, Washington, DC, revised 2009, Association for Professionals in Infection Control and Epidemiology (APIC).

BOX 8-3 Levels of Latex Reactions

- The three types of common latex reactions (in order of severity) are:
- 1 **Irritant dermatitis:** A nonallergic response characterized by skin redness and itching.
 - 2 **Type IV hypersensitivity:** Cell-mediated allergic reaction to chemicals used in latex processing. Reaction, including redness, itching, and hives, can be delayed up to 48 hours. Localized swelling, red and itchy or runny eyes and nose, and coughing may develop.
 - 3 **Type I allergic reaction:** A true latex allergy that can be life-threatening. Reactions vary based on type of latex protein and degree of individual sensitivity, including local and systemic. Symptoms include hives, generalized edema, itching, rash, wheezing, bronchospasm, difficulty breathing, laryngeal edema, diarrhea, nausea, hypotension, tachycardia, and respiratory or cardiac arrest.

Cleveland Clinic: *Latex allergy*, 2012, available at <http://www.clevelandclinic.org/health/health-info/docs/1900/1955.asp?index=8623>, accessed February 19, 2012.

STEP

RATIONALE

ASSESSMENT

1 Consider the type of procedure to be performed and consult agency policy on use of sterile gloves.	Ensures proper use of sterile gloves when needed.
2 Consider patient's risk for infection (e.g., a preexisting condition and size or extent of area being treated).	Directs you to follow added precautions (e.g., use of additional protective barriers) if necessary.
3 Select correct size and type of gloves and then examine glove package to determine if it is dry and intact with no water stains.	Torn or wet package is considered contaminated. Signs of water stains on package indicate previous contamination by water.
4 Inspect condition of hands for cuts, hangnails, open lesions, or abrasions. In some settings you are allowed to cover any open lesion with a sterile, impervious transparent dressing (check agency policy). In some cases presence of such lesions may prevent you from participating in a procedure.	Cuts, abrasions, and hangnails tend to ooze serum, which possibly contains pathogens. Breaks in skin integrity permit microorganisms to enter and increase the risk for infection for both patient and nurse (AORN, 2011).
5 Assess patient for the following risk factors before applying latex gloves:	Determines level of patient's risk for latex allergy.
a Previous reaction to the following items within hours of exposure: adhesive tape, dental or face mask, golf club grip, ostomy bag, rubber band, balloon, bandage, elastic underwear, intravenous (IV) tubing, rubber gloves, condom	Items known to lead to latex allergy.
b Personal history of asthma, contact dermatitis, eczema, urticaria, rhinitis	
c History of food allergies, especially avocado, banana, peach, chestnut, raw potato, kiwi, tomato, papaya	
d Previous history of adverse reactions during surgery or dental procedure	Suggests allergic response.
e Previous reaction to latex product	Suggests allergic response.

NURSING DIAGNOSES

- Ineffective protection
- Risk for infection
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:	
• Patient does not develop signs or symptoms of infection after procedure.	Indicates that microorganisms are not introduced into sterile body cavities or sites (such as skin or urinary tract).
• Patient does not develop latex sensitivity or latex allergy reaction.	Patient at risk for latex allergy is not exposed to latex proteins.

Clinical Decision Point *Synthetic nonlatex gloves are necessary for patients at risk or if nurse has sensitivity or allergy to latex.*

IMPLEMENTATION

1 Apply sterile gloves.	
a Perform thorough hand hygiene. Place glove package near work area.	Reduces number of bacteria on skin surfaces and transmission of infection. Ensures availability before procedure.
b Remove outer glove package wrapper by carefully separating and peeling apart sides (see illustration).	Prevents inner glove package from accidentally opening and touching contaminated objects.
c Grasp inner package and lay on clean, dry, flat surface at waist level. Open package, keeping gloves on inside surface of wrapper (see illustration).	Sterile object held below waist is contaminated. Inner surface of glove package is sterile.

STEP

RATIONALE

- d Identify right and left glove. Each glove has a cuff approximately 5 cm (2 inches) wide. Glove dominant hand first.
- e With thumb and first two fingers of nondominant hand, grasp glove for dominant hand by touching only inside surface.
- f Carefully pull glove over dominant hand, leaving a cuff and being sure that cuff does not roll up wrist. Be sure that thumb and fingers are in proper spaces (see illustration).
- g With gloved dominant hand, slip fingers underneath cuff of second glove (see illustration).
- h Carefully pull second glove over nondominant hand (see illustration).

- Proper identification of gloves prevents contamination by improper fit. Gloving of dominant hand first improves dexterity.
- Inner edge of cuff will lie against skin and thus is not sterile.
- If outer surface of glove touches hand or wrist, it is contaminated.
- Cuff protects gloved fingers. Sterile touching prevents glove contamination.
- Contact of gloved hand with exposed hand results in contamination.

Clinical Decision Point Do not allow fingers and thumb of gloved dominant hand to touch any part of exposed nondominant hand. Keep thumb of dominant hand abducted back.

STEP 1b Open outer glove package wrapper.

STEP 1f Pick up glove at cuff for dominant hand and insert fingers; pull glove completely over dominant hand (example is for left-handed person).

STEP 1c Open inner glove package on work surface.

STEP 1g Pick up glove for nondominant hand.

STEP

RATIONALE

- i** After second glove is on, interlock hands together above waist level. The cuffs usually fall down after application. Be sure to touch only sterile sides (see illustration).
- 2** Remove gloves.
- a** Grasp outside of one cuff with other gloved hand; avoid touching wrist.
- b** Pull glove off, turning it inside out, and place it in gloved hand.
- c** Take fingers of bare hand and tuck inside remaining glove cuff (see illustration). Peel glove off inside out and over previously removed glove. Discard both gloves in receptacle
- d** Perform thorough hand hygiene.

Ensures smooth fit over fingers.

Minimizes contamination of underlying skin.

Outside of glove does not touch skin surface.

Fingers do not touch contaminated glove surface.

Protects health care worker from contamination resulting from any unseen tears or pinholes in gloves; also removes powder from hands to prevent skin irritation.

STEP 1h Pull second glove over nondominant hand.

STEP 1i Interlock gloved hands.

STEP 2c Remove second glove by turning it inside out.

STEP

RATIONALE

EVALUATION

- 1 Assess patient for signs of infection, focusing on area treated.
- 2 Evaluate patient for signs of latex allergy.

Improper technique contributes to development of an infection.
Establishes baseline for patient's reaction to latex.

Unexpected Outcomes

- 1 Patient develops localized signs of infection (e.g., urine becomes cloudy or odorous; wound becomes painful, edematous, or reddened with purulent drainage).
- 2 Patient develops systemic signs of infection (e.g., fever, malaise, increased white blood cell count).
- 3 Patient develops allergic reaction to latex (see [Box 8-3](#)).

Related Interventions

- Contact health care provider and implement appropriate treatments as ordered.
- Contact health care provider and implement appropriate treatments as ordered.
- Immediately remove source of latex.
- Bring emergency equipment to bedside. Have epinephrine injection ready for administration, and be prepared to initiate IV fluids and oxygen.

Recording and Reporting

- It is not necessary to record application of gloves. Record specific procedure performed and patient's response and status.
- In the event of a latex allergy reaction, record patient's response in nurses' notes, EHR, and vital sign flow sheet. Note type of response and patient's reaction to emergency treatment.

Special Considerations

Teaching

- Nurse or patient with a known latex allergy should wear a medical alert bracelet or tag and carry a wallet card stating "latex allergy."
- Individuals with known latex allergies should carry a quick-acting oral antihistamine and an epinephrine autoinjector at all times.

Critical Thinking Exercises

You are assigned to Mrs. Lorenzo, a 78-year-old grandmother who is blind and is being admitted for a cholecystectomy. You enter her room to begin a series of procedures: inserting an indwelling urinary catheter, irrigating a nasogastric tube, suctioning the oral cavity, and measuring the patient's blood pressure.

- 1 Which procedure requires use of sterile gloves?
- 2 Mrs. Lorenzo tells you that she has allergic reactions when she eats bananas or tomatoes. Based on this information, what would you ask Mrs. Lorenzo and which actions would you take?
- 3 Mrs. Lorenzo's physician is planning to insert a central venous line. You obtained the necessary equipment, prepared a sterile drape, and opened the sterile pack. You removed the outer wrapper and placed the item on the sterile field. While doing this, you noticed that the item touched the drape 5 cm (2 inches) from the border of the drape. What would you do next?

REVIEW QUESTIONS

- 1 A nurse with a latex allergy needs to perform a sterile procedure and finds that the only sterile gloves available are latex. Which action by the nurse would be most effective in solving the problem?
 - 1 Rubbing petroleum jelly on the hands to provide a barrier between the hands and the gloves
 - 2 Putting a pair of synthetic gloves on before donning the latex sterile gloves
 - 3 Using a larger pair of sterile gloves so they're not as tight
 - 4 Rinsing the hands with cold water before putting on the sterile gloves
- 2 When opening a sterile pack, which action compromises the sterility of the contents?
 - 1 Keeping the contents of the pack away from the table edge
 - 2 Holding or moving the object below the waist
 - 3 Opening the pack just before the procedure
 - 4 Allowing movement around the sterile field that does not touch near the sterile field
- 3 A nurse is preparing to change a dressing using sterile gloves. It is most important to remember which concept when putting them on?
 - 1 Grab only the inside of the glove with the ungloved hand.
 - 2 Grab only the cuffs of the gloves with the bare hand.
 - 3 Wear a glove that is as tight as possible.
 - 4 Keep the glove fingertips parallel to the body.
- 4 A teenager with spina bifida is to have a urinary catheter inserted. Which action is most important before performing this procedure?
 - 1 Washing the insertion area with soap and water before insertion of the catheter
 - 2 Positioning the patient as comfortably as possible
 - 3 Asking the patient if he or she is allergic to eggs
 - 4 Obtaining a nonlatex catheter for the procedure
- 5 A nurse is supervising a nursing student setting up for a sterile dressing change. Which action by the nursing student would require intervention from the nurse?
 - 1 The first flap of the sterile package is opened away from the student's body.
 - 2 The glove for the dominant hand is pulled on first.
 - 3 When pouring a solution on to the sterile field, the label of the solution bottle is facing the floor.
 - 4 The bottle of solution is kept above the student's waist.

- 6 Sterilization of surgical instruments and surgical dressings is accomplished by using:
- 1 An autoclave.
 - 2 Soap and water.
 - 3 Ethylene oxide gas.
 - 4 Chemicals such as alcohol.
- 7 A nurse has a cold and needs to change a dressing on a patient who is immunocompromised. Which action by the nurse would be most appropriate?
- 1 Asking another nurse to change the dressing
 - 2 Wearing a gown and mask when changing the dressing
 - 3 Performing hand hygiene for a longer time before putting on sterile gloves
 - 4 Asking the patient if it's all right with him if he changes the dressing
- 8 In setting up a sterile field, which of the listed actions would require intervention?
- 1 The bottle of solution is poured with the label facing up.
 - 2 The sterile drape is allowed to unfold above the waist.
 - 3 The first flap of the sterile package is opened toward the nurse.
 - 4 The glove for the dominant hand is pulled on first.
- 9 When performing a sterile procedure at the bedside, the NAP can help by assisting the nurse to _____ the patient.
- 10 Place an S next to the procedures requiring sterile (aseptic) technique. (Select all that apply.)
- 1 Urinary catheterization
 - 2 Insertion of a feeding tube
 - 3 Tracheal suctioning
 - 4 Lumbar puncture
 - 5 Insertion of a rectal suppository
 - 6 Sitz bath

KEY TERMS

Balance
Base of support
Body alignment
Body mechanics
Center of gravity
Drawsheet

Footdrop
Friction
Hand rolls
Hemiparesis
Hemiplegia

Hoyer lift (mechanical/
hydraulic lift)
Leverage
Line of gravity
Logrolling
Orthostatic hypotension

Paralysis
Paresis
Posture
Proprioceptive function
Weight

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe body mechanics and its importance in caring for patients.
- Describe principles of safe patient handling, transfer, and positioning.
- Describe normal body alignment for standing, sitting, and lying down.
- Assess for alterations in body alignment.
- Describe procedures for safety and use of equipment needed for lifting patients.
- Describe positioning techniques for the supported Fowler's, supine, prone, 30-degree lateral side-lying, and Sims' positions.
- Describe the procedures for helping a patient move up in bed, helping a patient to a sitting position, logrolling a patient, and transferring a patient from a bed to a chair.

Health care agencies are required to provide employees with safety information and training to use when transferring, positioning, and lifting patients. Refer to the policies and procedures of the agency in which you work. The National Institute of Occupational Safety and Health Administration (NIOSH) has guidelines for back safety and the prevention of musculoskeletal injuries (NIOSH, 2009).

Before lifting or transferring patients, consider principles of safe patient transfer and positioning (Box 9-1). Before lifting, assess the weight to be lifted and what assistance, if any, you need (Nelson et al., 2009; NIOSH, 2009). If you need help, assess if a second person is adequate or if mechanical assistance is needed. Once you assess the amount of assistance, use the following steps for proper body mechanics:

- Keep back, neck, pelvis, and feet aligned and avoid twisting. Twisting your spine can lead to serious injury.

- Tighten stomach muscles and tuck pelvis; this provides balance and protects the back.
- Bend at the knees; this helps to maintain your center of gravity and lets the strong muscles of the legs do the lifting.
- Keep the weight to be lifted as close to the body as possible; this action places the weight in the same plane as the lifter and close to the center of gravity for balance.
- Maintain the trunk erect and knees bent so multiple muscle groups work together in a synchronized manner.
- The best height for lifting vertically is approximately 2 feet off the ground and close to the lifter's center of gravity.
- The person with the heaviest load coordinates efforts of the personnel involved in lifting or transferring.

BOX 9-1 Principles of Safe Patient Transfer and Positioning

Mechanical lifts and lift teams are essential when the patient is unable to assist. When a patient is able to assist, remember these principles:

- The lower the center of gravity, the greater the stability of the nurse.
- The equilibrium of an object is maintained as long as the line of gravity passes through its base of support.
- Facing the direction of movement prevents abnormal twisting of the spine.
- Dividing balanced activity between arms and legs reduces the risk for back injury.
- Leverage, rolling, turning, or pivoting requires less work than lifting.
- When friction is reduced between the object to be moved and the surface on which it is moved, less force is required to move it.

Body mechanics is the coordinated effort of the musculoskeletal and nervous systems to maintain balance, posture, and body alignment during lifting, bending, moving, and performing activities of daily living (ADLs). Body mechanics also facilitates body movement so a person can carry out a physical activity without using excessive muscle energy.

Many patients have conditions resulting in immobility or require limitations in activity imposed by their treatment plan. It is an important nursing role to safely position and move patients effectively to reduce the risks related to immobilization. Positioning patients to maintain correct body alignment is essential in preventing complications. These complications include pressure ulcers (see [Chapter 18](#)), which can develop in less than 24 hours and require months to heal ([Institute for Healthcare Improvement, 2008](#)); and contractures, which can occur within a few days when muscles, tendons, and joints become less flexible because of lack of mobility and incorrect alignment. Pillows placed under the knees or an elevated knee Gatch can produce knee and hip contractures and increase pressure on the sacrum, thus creating risk for pressure ulcers.

Some patients are at high risk for complications from improper positioning and have increased risk for injury during transfer. Examples include patients with poor nutrition, poor circulation, loss of sensation, alterations in bone formation or joint mobility, and impaired muscle development. The application of proper body mechanics, alignment, and the use of safe patient transfer and positioning techniques help patients achieve an optimal level of independence without resultant injury to health care providers.

EVIDENCE-BASED PRACTICE

Musculoskeletal disorders are the most prevalent and debilitating occupational health hazard among nurses. There has been little improvement in the incidence of musculoskeletal injuries in health care workers. The total recordable injury incidence rate for hospitals is 5.2 per 100 full-time employees ([Bureau of Labor Statistics, 2011](#)). Back injuries among health care workers are estimated to cost \$10,689 per case; thus back injuries alone prove to be an economic burden and a major health concern ([CDC, 2009](#); [NIOSH, 2009](#)).

- Complete an ergonomics hazard assessment based on patient population, patient handling tasks, and physical environment.
- Train staff on devices, equipment, and handling policies.

- Organizations can develop a “no lift” policy that discourages manual lifting and requires the use of equipment and devices as needed ([ANA, 2011](#)).
- Use lift devices to reduce on-the-job injuries ([Kutash et al., 2009](#); [Sedlak et al., 2009](#); [Zadvinskis and Salsbury, 2010](#)).
- Knowledge about safe, efficient lifting techniques and proper use of assistive equipment and devices promotes safe patient transfer without injury to a patient or health care worker ([ANA, 2011](#)).

PATIENT-CENTERED CARE

Ultimately it is a patient’s choice to increase his or her mobility and activity level. Consider a patient’s knowledge, cultural beliefs, and circumstances surrounding the loss of independent activity when developing a plan of care. Take some time to assess a patient’s knowledge and provide information about the complications of immobility. This may be all that is needed to elicit a patient’s cooperation in ambulating after surgery. It is also important to consider a patient’s cultural and ethnic beliefs. Assessing these beliefs guides you to incorporate appropriate interventions that match them. For example, some patients have a fear of becoming addicted to a narcotic after one dose, but pain is preventing them from increasing their mobility. With this knowledge you can individualize the patient’s plan of care and explain the safe and proper use of narcotics for pain control. In addition, taking into consideration the circumstances surrounding the loss of independent activity and mobility is crucial in developing a plan of care that is realistic and attainable. For example, a patient with pulmonary disease who has recently undergone surgery may be expected to ambulate a prescribed number of feet on the second postoperative day. This information prompts the nurse to alter the patient’s plan of care based on his or her activity limitation to achieve a reasonable level of mobility and activity.

Safety Guidelines

- 1 Know how physiologic influences on body alignment and mobility affect patients throughout the life span. Inactive older adults are at risk for muscle atrophy, loss of bony mass, contractures of joints, and pressure ulcers ([Touhy et al., 2010](#)).
- 2 Know the pathologic conditions that affect a patient’s body alignment and mobility. Postural abnormalities affect body mechanics. For example, a patient with severe kyphosis cannot lie supine or lift an object safely because the center of gravity is not in alignment.
- 3 Know the history of underlying chronic conditions (e.g., diabetes, chronic obstructive pulmonary disease) or malnutrition. Patients with chronic conditions are at risk for skin breakdown and other hazards of immobility and as a result require more frequent position changes.
- 4 Control factors that indirectly affect body mechanics by altering the safety of the environment. Cluttered hallways and bedside areas increase a patient’s risk of falling (see [Chapters 13 and 41](#)).
- 5 Know a patient’s fluid balance status. Dehydration or edema may require more frequent position changes because patients are prone to skin breakdown. Dehydration also predisposes patients to orthostatic hypotension. Identify patients with incontinence or profuse sweating. Moisture from incontinence or sweating can alter the resiliency of skin to external forces ([Stechmiller et al., 2008](#)).

- 6 Know a patient’s range of motion. Contractures or spasticity limit joint and muscle mobility; take care not to position a patient’s limb in an unnatural position. This could result in injury or dysfunction of the affected limb (see [Chapter 10](#)).
- 7 Determine a patient’s level of sensory perception. Loss of sensation increases vulnerability to the hazards of immobility because

of the inability to sense pain or need for repositioning. Patients with decreased sensation must have their positions evaluated and changed frequently to avoid damage to the integumentary and musculoskeletal systems.

SKILL 9-1 Using Safe and Effective Transfer Techniques

NSO *Nursing Skills Online: Safety Module / Lesson 3*

- Assisting and supervising when moving patients who are transferred for the first time after prolonged bed rest, extensive surgery, critical illness, or spinal cord trauma.
- Explaining the patient’s mobility restrictions, changes in blood pressure, or sensory alterations that may affect safe transfer.
- Explaining what to observe and report back to the nurse, such as dizziness or the patient’s ability to assist.

Transferring is a nursing skill to help a dependent patient or a patient with restricted mobility attain positions to regain optimal independence as quickly and safely as possible. Physical activity maintains and improves joint motion, increases strength, promotes circulation, relieves pressure on skin, and improves urinary and respiratory functions. It also benefits a patient psychologically by increasing social activity and mental stimulation and providing a change in environment (Janelli et al., 2009; Schneider et al., 2008).

One of the major concerns during transfer is the safety of the patient and the nurse. The nurse prevents self-injury by using correct posture, minimal muscle strength, effective body mechanics and lifting techniques, and appropriate lift devices. Consider individual patient problems during transfer. For example, a patient who has been immobile for several days or longer may be weak or dizzy or may develop orthostatic hypotension (a drop in blood pressure) when transferred. If there is any doubt about safe transfer, use a transfer belt and obtain assistance when transferring patients.

Delegation and Collaboration

The skill of effective transfer techniques can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP by:

Equipment

- Transfer belt, sling, or lap board (as needed)
- Nonskid shoes, bath blankets, pillows
- Slide board (friction-reducing board)
- Bedside chair with arms or wheelchair: Position chair at 45-degree angle to bed, lock brakes, remove footrests, lock bed brakes
- Stretcher: Position next to bed, lock brakes on stretcher, lock brakes on bed
- Optional: Mechanical/hydraulic lift: Use frame, canvas strips or chains, and hammock or canvas strips; stand-assist lift device
- Sphygmomanometer and stethoscope

STEP **RATIONALE**

ASSESSMENT

<ol style="list-style-type: none"> 1 Assess physiologic capacity of a patient to transfer and the need for special adaptive techniques (see Chapter 6). Assess the following: <ol style="list-style-type: none"> a Muscle strength (legs and upper arms) b Joint mobility and contracture formation c Paralysis or paresis (spastic or flaccid) d Bone continuity (trauma, amputation), or calcium loss from long bones 2 Assess presence of weakness, dizziness, or postural hypotension. 	<p>Determines patient’s ability to tolerate and assist with transfer and whether special adaptive techniques are necessary.</p> <p>Immobile patients have decreased muscle strength, tone, and mass. Affects ability to bear weight or raise body.</p> <p>Immobility or inflammatory processes (e.g., arthritis) may lead to contracture formation and impaired joint mobility.</p> <p>Patient with central nervous system (CNS) damage may have bilateral paralysis (requiring transfer by swivel bar, sliding bar, mechanical lift) or unilateral paralysis, which requires belt transfer to strong side. Weakness (paresis) requires stabilization of knee while transferring. Flaccid arm must be supported with sling during transfer.</p> <p>Patients with trauma to one leg or hip may be non-weight bearing when transferred. Amputees may use sliding board to transfer. Osteoporosis increases risk for injury.</p> <p>Determines risk for fainting or falling during transfer. The move from supine to vertical position redistributes about 500 mL of blood; immobile patients may have decreased autonomic nervous system response to equalize blood supply, resulting in orthostatic hypotension (Lewis et al., 2011).</p>
---	--

STEP	RATIONALE
<p>3 Assess level of endurance:</p> <p>a Assess level of fatigue during activity.</p> <p>b Assess vital signs.</p>	<p>Ability to transfer may be limited by fatigue. Estimates ability to participate in transfer. Assess endurance by patient's participation in activities of daily living (ADLs). Planned rest periods before transfer may enhance function.</p> <p>Vital sign changes such as increased pulse and respiration may indicate activity intolerance (see Chapter 5). Patient with low blood pressure may not tolerate sudden position change and is at risk for orthostatic hypotension.</p>
<p>4 Assess patient's proprioceptive function (awareness of posture and changes in equilibrium):</p> <p>a Ability to maintain balance while sitting in bed or on side of bed</p> <p>b Tendency to sway or position self to one side</p>	<p>Determines stability of patient's balance for transfer.</p> <p>Determines risk for fainting or falling during transfer.</p> <p>Patients with brain dysfunction may have proprioceptive losses. This may cause them to lean to one side or lose balance during transfer.</p>
<p>5 Assess patient's sensory status, including adequacy of central and peripheral vision, adequacy of hearing, and presence of peripheral sensation loss.</p>	<p>Determines influence of sensory loss on ability to make transfer. Visual field loss decreases patient's ability to see in direction of transfer. Peripheral sensation loss decreases proprioception. Patients with visual and hearing losses need transfer techniques adapted to deficits. Patients with cerebrovascular accident (CVA) may lose area of visual field, which profoundly affects vision and perception.</p>
<p>Clinical Decision Point Patients with hemiplegia may “neglect” one side of the body (inattention to or unawareness of one side of body or environment), which distorts perceptions of the visual field.</p>	
<p>6 Assess patient for pain (e.g., joint discomfort, muscle spasm) and measure level of pain using scale of 0 to 10. Offer prescribed analgesic 30 minutes before transfer.</p>	<p>Pain reduces patient's motivation and ability to be mobile. Pain relief before transfer enhances patient participation (Quinlan-Colwell, 2009).</p>
<p>7 Assess patient's cognitive status:</p> <p>a Ability to follow verbal instructions</p> <p>b Short-term memory</p> <p>c Recognition of physical deficits and limitations to movement</p>	<p>Determines patient's ability to follow directions and learn transfer techniques.</p> <p>May indicate patient is at risk for injury.</p> <p>Patient with short-term memory deficit may have difficulty with transfer, initial learning, or consistent performance.</p> <p>Patient's knowledge of deficits can help you plan a safe transfer.</p>
<p>8 Assess patient's level of motivation, such as his or her eagerness versus unwillingness to be mobile.</p>	<p>Altered psychological states often reduce patient's desire to engage in activity.</p>
<p>9 Assess previous mode of transfer (if applicable).</p>	<p>Determines mode of transfer and assistance required to provide continuity. Transfer (gait) belts should be used with patients who need assistance (Nelson et al., 2009; OSHA, 2011).</p>
<p>10 Determine if a lift device is needed and the number of people needed to assist with transfer. Do not start procedure until all required caregivers are available.</p>	<p>Ensures safe patient transfer.</p>

NURSING DIAGNOSES

- Activity intolerance
- Acute or chronic pain
- Acute confusion
- Risk for falls
- Impaired physical mobility
- Impaired skin integrity
- Risk for injury

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient dangles legs or sits without dizziness, weakness, or orthostatic hypotension. • Patient tolerates increased activity. • Patient can bear more weight. • Patient transfers without injury. • Patient is more motivated to be mobile. • Patient transfers with minimal discomfort. <p>2 Explain procedure to patient. Repeat instructions simply and with continuity to patient with cognitive dysfunction.</p> | <p>Precautions during transferring prevent vascular compromise.</p> <p>Gradual increase in number of transfers and period of time out of bed increases tolerance and endurance.</p> <p>Repeated transfers usually result in improved endurance and greater independence of patient.</p> <p>Proper techniques avoid injury.</p> <p>Transfer procedures performed correctly.</p> <p>Promotes understanding and cooperation, reducing anxiety.</p> |
|--|---|

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Perform hand hygiene.</p> <p>2 Assist patient to sitting position (bed at waist level):</p> | <p>Reduces transfer of microorganisms.</p> |
|--|--|

Clinical Decision Point *If patient is in hospital bed, use electrical controls to raise him or her to a sitting position in bed.*

- | | |
|--|--|
| <p>a Place patient in supine position.</p> <p>b Face head of the bed at 45-degree angle and remove pillows.</p> <p>c Place feet in wide base of support with foot closer to head of bed in front of other foot.</p> <p>d Place hand nearer head of bed under patient's shoulders, supporting patient's head and cervical vertebrae.</p> <p>e Place other hand on bed surface.</p> <p>f Raise patient to sitting position by shifting weight from front to back leg.</p> <p>g Push against bed using arm that is placed on bed surface.</p> <p>3 Assist patient to sitting position on side of bed with bed in low position, using electrical bed:</p> <p>a With patient in supine position, raise head of bed 30 degrees.</p> <p>b Turn patient onto side, facing you on side of bed on which patient will be sitting (see illustration).</p> <p>c Stand opposite patient's hips. Turn diagonally so you face patient and far corner of foot of bed.</p> <p>d Place feet apart in wide base of support with foot closer to head of bed in front of other foot (see illustration).</p> <p>e Place arm nearer head of bed under patient's shoulders, supporting head and neck.</p> <p>f Place other arm over patient's thighs (see illustration).</p> <p>g Move patient's lower legs and feet over side of bed. Pivot toward rear leg, allowing patient's upper legs to swing downward.</p> <p>h At same time shift weight to rear leg and elevate patient (see illustration).</p> | <p>Enables you to assess patient's body alignment continually and administer additional care such as suctioning or hygiene needs.</p> <p>Proper positioning reduces twisting of your body when moving patient. Pillows may cause interference when patient is sitting up in bed.</p> <p>Improves balance and allows transfer of body weight while moving patient to sitting position.</p> <p>Maintains alignment of head and cervical vertebrae and allows for even lifting of patient's upper trunk.</p> <p>Provides support and balance.</p> <p>Improves balance, overcomes inertia, and transfers your weight in direction in which patient is moved.</p> <p>Divides activity between your arms and legs and protects back from strain. By bracing one hand against mattress and pushing against it as patient is lifted, part of weight that would be lifted by your back muscles is transferred through your arms onto mattress.</p> <p>Decreases amount of work needed by patient and nurse to raise patient to sitting position.</p> <p>Prepares patient to move to side of bed and protects from falling.</p> <p>Places your center of gravity nearer patient. Reduces twisting of body because you are facing direction of movement.</p> <p>Increases balance and allows you to transfer weight as patient is brought to sitting position on side of bed.</p> <p>Maintains alignment of head and neck as you bring patient to sitting position.</p> <p>Supports hip and prevents patient from falling backward during procedure.</p> <p>Decreases friction and resistance. Weight of patient's legs when off bed allows gravity to lower legs, and weight of legs assists in pulling upper body into sitting position.</p> <p>Allows you to transfer weight in direction of motion.</p> |
|--|--|

STEP

RATIONALE

STEP 3b Side-lying position.

STEP 3f Nurse places arm over patient's thighs.

STEP 3d Proper foot placement.

STEP 3h Nurse shifts weight to rear leg and elevates patient.

Clinical Decision Point *Remain in front until patient regains balance and continue to provide physical support to weak or cognitively impaired patient.*

4 Transfer patient from bed to chair with bed in the low position:

- a If patient has partial weight bearing with upper body strength, use bariatric transfer aid with minimum of two or three caregivers (see illustration).

The use of mechanical lift devices is strongly recommended to transfer a patient to reduce risk for musculoskeletal injury (Baptiste et al., 2008; Nelson et al., 2009).

STEP

RATIONALE

STEP 4a Stand-assist lift device. (Courtesy Waverly Glen Systems, a Prism Medical Co.)

Clinical Decision Point *If patient demonstrates weakness or paralysis of one side of the body, place chair on patient's strong side.*

- b** If patient has normal weight bearing and upper body strength, first assist him or her to sitting position on side of bed (see Steps 3a to h). Have chair in position at 45-degree angle to bed. If using wheelchair, make sure that wheels are locked. Allow patient to sit on side of bed (dangling) for a few minutes before transferring to chair. Ask if he or she feels dizzy. Do not leave patient unattended during dangling.
- c** Apply transfer belt (see illustration) or use transfer board. Place board across bed to chair so patient can slide across it. Patient's arm should be in sling if flaccid paralysis is present.

Positions chair within easy access for transfer. Dangling or allowing a patient to sit on side of bed before transfer helps equilibrate blood pressure by preventing a sudden change in position, reducing risk for dizziness or fainting when standing (Thompson et al., 2011).

Transfer belt allows you to maintain stability of patient during transfer and reduces risk for falling (OSHA, 2011). Transfer board makes sliding over to chair easy with less physical effort. Transfer belt is contraindicated after abdominal surgery.

STEP 4c Transfer belt with handles. (Courtesy The Posey Company, Arcadia, Calif.)

- d** Help patient apply stable, nonskid shoes. Place patient's weight-bearing, or strong, leg forward, with weak foot back.
- e** Spread your feet apart.
- f** Flex hips and knees, aligning knees with patient's knees (see illustration).

Nonskid soles decrease risk for slipping during transfer. Always have patient wear shoes during transfer; bare feet increase risk for falls. Patient will stand on stronger, or weight-bearing, leg. Ensures balance with wide base of support. Flexing knees and hips lowers your center of gravity to object to be raised; aligning knees with patient's allows for stabilization of knees when patient stands.

STEP

- g** Grasp transfer belt along patient's sides.
- h** Rock patient up to standing position on count of three while straightening hips and legs and keeping knees slightly flexed (see illustration). While rocking patient in back-and-forth motion, make sure that your body weight is moving in the same direction as patient's to ensure that you and patient are moving in same direction simultaneously. Unless contraindicated, patient may be instructed to use hands to push up if applicable.
- i** Maintain stability of patient's weak or paralyzed leg with your knee.
- j** Pivot on foot farther from chair.
- k** Instruct patient to use armrests on chair for support and ease into chair (see illustration).
- l** Flex hips and knees while lowering patient into chair (see illustration).

STEP 4f Nurse flexes hips and knees, aligns knees with patient's knee, and grasps transfer belt.

RATIONALE

- Transfer belt allows you to move patient at center of gravity. Patients should never be lifted by or under arms.
- Rocking motion gives patient's body momentum and requires less muscular effort to lift him or her.
- Ability to stand can often be maintained in paralyzed or weak limb with support of knee to stabilize.
- Maintains support of patient while allowing adequate space for patient to move.
- Increases patient stability.
- Prevents injury from poor body mechanics.

STEP 4h Nurse rocks patient to standing position.

STEP

RATIONALE

STEP 4k Patient uses armrests for support.

STEP 4l Nurse eases patient into chair.

- m Assess patient for proper alignment in sitting position. Provide support for paralyzed extremities. Lap board or sling supports flaccid arm. Stabilize leg with bath blanket or pillow.
- n Proper alignment for sitting position: head is erect, and vertebrae are in straight alignment. Body weight is evenly distributed on buttocks and thighs. Thighs are parallel and in horizontal plane. Both feet are supported on floor, and ankles are comfortably flexed. A 2.5- to 5-cm (1- to 2-inch) space is maintained between edge of seat and popliteal space on posterior surface of knee.
- o Praise patient's progress, effort, and performance.

5 Perform horizontal transfer from bed to stretcher using slide board or friction-reducing board (see illustration):

Prevents injury to patient from poor body alignment.

Prevents stress on intravertebral joints. Prevents increased pressure over bony prominences and reduces damage to underlying musculoskeletal system.

Continued support and encouragement provide incentive for patient perseverance.

The three-person lift for horizontal transfer from bed to stretcher is no longer recommended and in fact is discouraged (NIOSHA, 2009; Waters et al., 2011). Physical stress can be decreased significantly by using slide board or friction-reducing board positioned under drawsheet beneath patient. In addition, patient is more comfortable using this method.

STEP 5 Slide board.

STEP

RATIONALE

- | | |
|---|---|
| <p>a Determine number of staff required to horizontally transfer patient safely (three nurses recommended).</p> <p>b Lower head of bed as much as patient can tolerate. Be sure to lock bed brakes.</p> <p>c Cross patient's arms on chest.</p> <p>d Lower side rails. To place slide board under patient, position two nurses on side of bed to which patient will be turned. Position third nurse on other side of bed.</p> <p>e Fanfold drawsheet on both sides.</p> <p>f On count of three turn patient onto side toward the two nurses. Turn patient as one unit with a smooth, continuous motion.</p> <p>g Place slide board under drawsheet (see illustration).</p> | <p>During any patient transferring task, if any caregiver is required to lift more than 15.9 kg (35 lbs) of a patient's weight, the patient is considered fully dependent, and an assist device is used.</p> <p>Maintains alignment of spinal column. Ensures that bed does not move inadvertently.</p> <p>Prevents injury to arms during transfer.</p> <p>Distributes weight equally between nurses.</p> <p>Provides strong handles to grip drawsheet without slipping.</p> <p>Maintains body in alignment, preventing stress on any part.</p> <p>Prevents friction from contact of skin with board.</p> |
|---|---|

STEP 5g Placing slide board under drawsheet.

- | | |
|---|--|
| <p>h Gently roll patient back onto slide board.</p> <p>i Line up stretcher with bed. Lock brakes on stretcher.</p> <p>j Two nurses position themselves on side of stretcher while the third nurse positions self on side of bed without stretcher.</p> | <p>Ensures that stretcher does not move inadvertently during transfer.</p> |
|---|--|

Clinical Decision Point A nurse may also be positioned at the head of patient's bed to protect and support his or her head and neck if patient is weak or unable to assist.

- | | |
|--|---|
| <p>k Fanfold drawsheet; using count of three, the two nurses pull drawsheet with patient onto stretcher while the third nurse holds slide board in place (see illustration).</p> <p>l Position patient in center of stretcher. Raise head of stretcher if not contraindicated. Raise stretcher side rails. Cover patient with blanket.</p> | <p>Slide board remains stationary and provides slippery surface to reduce friction and allows patient to transfer easily to stretcher.</p> <p>Provides for patient comfort.</p> |
|--|---|

STEP

RATIONALE

6 Use mechanical/hydraulic lift to transfer patient from bed to chair:

Research supports use of mechanical lifts to prevent musculoskeletal injuries (ANA, 2011; Nelson et al., 2009). Use of ceiling-mounted lifts is becoming more popular choice because of availability of lift in each patient's room (see illustration).

STEP 5k Transfer of patient to stretcher using slide board.

STEP 6 Ceiling lift. (Courtesy Waverly Glen Systems, a Prism Medical Co.)

- a** Bring lift to bedside or lower ceiling lift and position properly.
- b** Position chair near bed and allow adequate space to maneuver lift.
- c** Raise bed to high position with mattress flat. Lower side rail on side near chair.
- d** Raise opposite side rail unless a second nurse is assisting.
- e** Roll patient on side away from you.
- f** Place hammock or canvas strips under patient to form sling. With two canvas pieces, lower edge fits under patient's knees (wide piece), and upper edge fits under patient's shoulders (narrow piece).
- g** Raise bed rail.
- h** Go to opposite side of bed and lower side rail.
- i** Roll patient to opposite side and pull hammock (strips) through and smooth over bed surface.
- j** Roll patient supine onto canvas hammock.
- k** Remove patient's glasses if appropriate.
- l** Place horseshoe bar of lift under side of bed (on side with chair).
- m** Lower horizontal bar to sling level by following manufacturer directions. Lock valve if required.
- n** Attach hooks on strap (chain) to holes in sling. Short chains or straps hook to top holes of sling; longer chains hook to bottom of sling.
- o** Elevate head of bed.
- p** Fold patient's arms over chest.
- q** Pump hydraulic handle using long, slow, even strokes until patient is raised off bed (see illustration). For ceiling lift turn on control device to move lift.

- Ensures safe elevation of patient off bed.
- Prepares environment for safe use of lift and subsequent transfer.
- Allows you to use proper body mechanics.
- Maintains patient safety.
- Positions patient for placement of lift sling.
- Two types of seats are supplied with mechanical/hydraulic lift: hammock style is better for patients who are flaccid, weak, and need support; canvas strips can be used for patients with normal muscle tone. Hooks should face away from patient's skin. Place sling under patient's center of gravity and greatest portion of body weight.
- Maintains patient safety.
- Completes positioning of patient on mechanical/hydraulic sling.
- Sling should extend from shoulders to knees (hammock) to support patient's body weight equally.
- Swivel bar is close to patient's head and could break eyeglasses.
- Positions lift efficiently and promotes smooth transfer.
- Positions hydraulic lift close to patient. Locking valve prevents injury to patient.
- Secures hydraulic lift to sling.
- Positions patient in sitting position.
- Prevents injury to patient's arms.
- Ensures safe support of patient during elevation.

STEP

- r** Use steering handle to pull lift from bed and maneuver patient to chair.
- s** Roll base around chair.
- t** Release check valve slowly (turn to left) and lower patient into chair (see illustration). For ceiling lift again use control device to lower patient.

STEP 6q Sling under patient and attached to lift.

RATIONALE

Moves patient from bed to chair.

Positions lift in front of chair into which patient is to be transferred. Safely guides patient into back of chair as seat descends.

STEP 6t Use of hydraulic lift to lower patient into chair.

- u** Close check valve or turn off control device as soon as patient is down and straps can be released.
 - v** Remove straps and mechanical/hydraulic lift.
 - w** Check patient's sitting alignment, and correct if necessary (see Step 4n).
- 7** Perform hand hygiene.

If valve is left open or device left on, boom may continue to lower and injure patient.
Prevents damage to skin and underlying tissues from canvas or hooks.
Prevents injury from poor posture.
Reduces transmission of microorganisms

EVALUATION

- 1** Monitor vital signs. Ask if patient feels dizzy or fatigued.
- 2** Note patient's behavioral response to transfer.
- 3** Ask if patient experienced pain during transfer.
- 4** Have patient who transfers to chair attempt to bear weight with nurse at side.

Evaluates patient's response to postural changes and activity.
Reveals level of motivation and self-care potential.
Determines need for additional pain control or alteration in technique of transferring (e.g., additional assistance).
Determines tolerance to weight bearing.

Unexpected Outcomes

- 1** Patient is unable to comprehend and follow directions for transfer.
- 2** Patient sustains injury on transfer.
- 3** Patient's level of weakness does not permit active transfer.
- 4** Patient is unable to stand for time required to transfer.

Related Interventions

- Reassess continuity and simplicity of instruction.
- Transfers may be difficult when patient is fatigued or in pain; assess before transfer (allow for a rest period before transferring or medicate for pain if indicated).
- Evaluate incident that caused injury (e.g., inadequate assessment, change in patient status, improper use of equipment).
- Complete incident report according to agency policy.
- Increase bed activity and exercise to heighten tolerance.
- Provide for additional nurses to provide adequate assistance during transfer.

Recording and Reporting

- Record procedure, including pertinent observations: weakness, ability to follow directions, weight-bearing ability, balance, ability to pivot, number of personnel needed to assist, and amount of assistance (muscle strength) required.
- Report transfer ability and assistance needed to next shift or other caregivers. Report progress or remission to rehabilitation staff (physical therapist, occupational therapist).

Special Considerations

Teaching

- Teach family and patient transfer skills, including principles of body mechanics and hazards of immobility. Incorporate return demonstration in discharge planning.

Pediatric

- Whenever possible, transporting child by stretcher, stroller, or wheelchair outside confines of room increases environmental stimuli and provides social contact with others (Hockenberry et al., 2011).
- Children confined to bed for any length of time such as those in traction need to have dependent skin surfaces assessed at least three times in a 24-hour period.

Gerontologic

- A major health concern that threatens the function of an older adult is the risk for falls (Touhy et al., 2010). Concern increases when an older adult enters a hospital. Assess the patient for the risk for falls on admission and implement a protocol to prevent falls (Lewis et al., 2011) (see Chapter 13).
- Use a drawsheet to avoid shearing force during repositioning in bed. This protects an older adult patient who has fragile skin.

Home Care

- Have family or caregiver practice transfer in hospital to achieve success before taking patient home. Alternatively have patient (if living alone) practice transfer skills in bed that will be used at home. Teach patient to transfer to chair with arms for ease of rising and sitting.
- Home should be free of hazards (e.g., throw rugs, electric cords, slippery floors). If wheelchair is used, access must be possible through all doors, and space for transfer must be available in bedroom and bathroom (see Chapter 41).
- Aids that enhance transfer ability are shower stools, commode elevators, handrails on tub, and nonskid shower surface. Many self-care devices are available for wheelchair-bound patients or patients with weak or poor muscle function. Medical supply stores provide excellent information and catalogs of such supplies.

PROCEDURAL GUIDELINE 9-1 Wheelchair Transfer Techniques

Transferring a patient from a bed to a wheelchair encompasses many of the same principles discussed in Skill 9-1. The following procedural guideline focuses on the safety precautions that need to be considered when using a wheelchair. Several additional steps must be taken to maintain safety of a patient and nurse to prevent injury when transferring from or to a wheelchair (Pierson and Fairchild, 2008). Check wheelchair locks and footplates for proper functioning before use.

Delegation and Collaboration

The skill of transferring a patient to or from a wheelchair can be delegated to nursing assistive personnel (NAP). The nurse directs NAP by:

- Assisting and supervising when moving patients who are transferring for the first time after prolonged bed rest, extensive surgery, critical illness, or spinal cord trauma.
- Explaining the patient's mobility restrictions, changes in blood pressure, or sensory alterations that may affect safe transfer.
- Reminding NAP to back a wheelchair into or out of an elevator to avoid tipping forward.

Equipment

- Transfer belt, nonskid shoes, wheelchair

1 Transferring patient from a wheelchair to bed (patient is cooperative and weight bearing)

- Adjust the height of the bed to the level of the seat of the wheelchair.
- Position wheelchair at a 45-degree angle next to the bed.
- Face the wheelchair toward the foot of the bed midway between the head and foot of the bed.
- Lock the wheelchair. Locks are located above the rims of the wheels. Push handle forward to lock.

- Raise the footplates.
- Place transfer belt on patient.
- Assist patient to move to the front of the wheelchair.
- Position yourself slightly in front of patient to guard and protect him or her throughout the transfer. If patient has sufficient upper body strength, use a slide board during transfer (see illustration).

STEP 1h Transfer from wheelchair to bed using a slide board.

- Coordinate transfer to bed by having patient stand and then pivot to the side of the bed. Then have patient sit on the side of the mattress.
- With patient sitting on the side of the bed, place your arm nearest the head of the bed under his or her shoulder while supporting the head and neck. Place your other arm under patient's knees. Bend your knees and keep your back straight.

PROCEDURAL GUIDELINE 9-1 Wheelchair Transfer Techniques—cont'd

- k Tell patient to help lift the legs when you begin to move. On a count of three, standing with a wide base of support, raise patient's legs as you pivot his or her body and lower the shoulders onto the bed. Remember to keep your back straight.
- 2 Transferring a patient from a bed to a wheelchair**
- a Adjust the height of the bed to the level of the seat of the wheelchair.
 - b Position the wheelchair at a 45-degree angle next to the same side of the bed as patient's strong side.
 - c Face the wheelchair toward the foot of the bed midway between the head and foot of the bed.
 - d Lock the wheelchair. Locks are located above the rims of the wheels. Push handle forward to lock.
 - e Raise the footplates.
- f Sit patient on the side of the bed (see Skill 9-1).
 - g Place transfer belt on patient.
 - h Assist patient to move to the edge of the mattress.
 - i Position yourself slightly in front of patient to guard and protect him or her throughout the transfer.
 - j Coordinate transfer to chair with patient by counting to three (see Skill 9-1).
 - k Lower the footplates after transfer and place patient's feet on them.
 - l Unlock the wheelchair. Pull lock toward you to release.
 - m Ensure that patient is positioned well back in the seat.
- 3** Monitor vital signs as needed. Ask if patient feels dizzy or fatigued.
- 4** Note patient's behavioral response to transfer.

SKILL 9-2 Moving and Positioning Patients in Bed

NSO Nursing Skills Online: Safety Module / Lesson 4

**Equipment**

- Pillows, drawsheet
- Friction-reducing device
- Therapeutic boots/splints (optional)
- Trochanter roll
- Sandbag
- Hand rolls

Correctly positioning patients is crucial for maintaining body alignment and comfort; preventing injury to the musculoskeletal and integumentary systems; and providing sensory, motor, and cognitive stimulation. A patient with impaired mobility, decreased sensation, impaired circulation, or lack of voluntary muscle control can develop damage to the musculoskeletal and integumentary systems while lying down. You must minimize this risk by maintaining unrestricted circulation and correct body alignment while moving, turning, or positioning a patient. The term *body alignment* refers to the condition of the joints, tendons, ligaments, and muscles in various body positions. When the body is aligned, whether standing, sitting, or lying, no excessive strain is placed on these structures. Body alignment means that the body is in line with the pull of gravity and contributes to body balance. Without this balance the center of gravity is displaced, which increases the force of gravity and predisposes a person to falls and injuries. Body balance is achieved when a wide base of support exists, the center of gravity falls within the base of support, and a vertical line can be drawn from the center of gravity through the base of support (Fig. 9-1).

Delegation and Collaboration

The skills of moving and positioning patients in bed and maintaining correct body alignment can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP by:

- Explaining about any moving and positioning restrictions (e.g., avoid prone position, patient has one-sided weakness).
- Designating specific times throughout the shift that NAP must reposition the patient.
- Providing information regarding patient's individual needs for body alignment (i.e., patient with spinal cord injury).

FIG 9-1 Body alignment when standing.

STEP

RATIONALE

ASSESSMENT

<p>1 Assess patient’s range of motion (ROM) (see Chapter 10), body alignment, and comfort level while patient is lying down.</p> <p>2 Assess for risk factors that contribute to complications of immobility:</p> <p>a <i>Sensation</i>: Decreased from cerebrovascular accident (CVA), paralysis, neuropathy.</p> <p>b <i>Impaired mobility</i>: Traction, arthritis, hip fracture, joint surgery, or other contributing disease processes</p> <p>c <i>Impaired circulation</i>: Arterial insufficiency</p> <p>d <i>Age</i>: Very young, older adult</p> <p>3 Assess patient’s level of consciousness.</p> <p>4 Assess condition of patient’s skin, especially over bony prominences.</p> <p>5 Assess patient’s physical ability to help with moving and positioning, which may be affected by age, level of consciousness, disease process, strength, ROM, and coordination.</p> <p>6 Assess for presence of incisions, drainage tubes, and equipment (e.g., traction). Empty drainage bags before positioning.</p> <p>7 Assess motivation of patient and ability of family caregivers to participate in moving and positioning.</p> <p>8 Check health care provider’s orders before positioning patient.</p>	<p>Provides baseline data for later comparisons. Determines ways to improve position and alignment.</p> <p>Increased risk factors require patient to be repositioned more frequently.</p> <p>Paralysis impairs movement; muscle tone changes; sensation is affected. Because of difficulty in moving and poor awareness of involved body part, patient is unable to position body part and protect it from pressure.</p> <p>Traction, bone fractures, surgery, or arthritic changes of affected extremity result in decreased ROM.</p> <p>Decreased circulation predisposes patient to pressure ulcers.</p> <p>Premature and young infants require frequent turning because their skin is fragile. Normal physiologic changes associated with aging predispose older adults to greater risks for developing complications of immobility.</p> <p>Determines need for special aids or devices. Patients with altered levels of consciousness may not understand instructions and may be unable to help.</p> <p>Provides baseline to determine effects of positioning.</p> <p>Enables you to use patient’s mobility, strength, and coordination. Determines need for additional help. Ensures patient and nurse safety.</p> <p>Alters positioning procedure and type of positions to use. Determines approach needed for instruction. Eliminates barrier to moving patient.</p> <p>Indicates whether instruction is necessary before discharge.</p> <p>Some positions may be contraindicated in certain situations (e.g., spinal cord injury; hip fracture; respiratory difficulties; certain neurologic conditions; presence of incisions, drains, or tubing).</p>
---	--

NURSING DIAGNOSES

- Activity intolerance
- Acute confusion
- Impaired physical mobility
- Impaired skin integrity
- Risk for impaired skin integrity

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient retains ROM. • Patient’s skin shows no evidence of breakdown. • Patient’s comfort level increases. • Patient’s level of independence in completing activities of daily living (ADLs) increases. <p>2 Raise level of bed to comfortable working height.</p> <p>3 Remove all pillows and devices used in previous position.</p> <p>4 Get extra help as needed.</p> <p>5 Explain procedure to patient.</p>	<p>Correct positioning allows patient to achieve optimal joint mobility and alignment.</p> <p>Frequent position changes decrease risk for skin breakdown.</p> <p>Proper positioning reduces stress on joints.</p> <p>Maintaining good body alignment and joint mobility increases patient’s overall mobility. Patient with inadequate joint mobility may need assistance to carry out ADLs.</p> <p>Raises level of work toward nurse’s center of gravity and reduces risk for back injuries.</p> <p>Reduces interference from bedding during positioning procedure.</p> <p>Provides for patient and nurse safety.</p> <p>Helps to decrease anxiety and increase cooperation.</p>
---	--

STEP

RATIONALE

IMPLEMENTATION

- 1 Perform hand hygiene.
- 2 Close door to room or bedside curtains.
- 3 **Help patient move up in bed:**
 - a Can patient assist?
 - (1) Fully able to assist, nurse assistance is not needed; nurse stands by to assist.
 - (2) Partially able to assist; patient can assist using positioning cues or aides (e.g., drawsheet or friction-reducing device).
- 4 **Help patient move up in bed using a drawsheet (two to three nurses assist):**
 - a Place patient supine with head of bed flat. Place height of bed appropriate for all staff. A nurse stands on each side of bed.
 - b Remove pillow from under head and shoulders and place it at head of bed.
 - c Turn patient side to side to place drawsheet under him or her, extending from shoulders to thighs.
 - d Return patient to supine position.
 - e Fanfold drawsheet on both sides, with each nurse grasping firmly near patient.
 - f Place feet apart with forward-backward stance. Flex knees and hips. On count of three, shift weight from front to back leg and move patient and drawsheet to desired position in bed (see illustrations).

- Reduces transmission of infection.
Provides for patient privacy.
This is not a one-person task unless patient can fully assist (NIOSHA, 2009).
Determines degree of risk in repositioning patient and technique required to safely assist patient.
- Enables you to assess body alignment. Reduces pull of gravity on patient's upper body.
Prevents striking patient's head against head of bed.
Supports patient's body weight and reduces friction during movement.
Even distribution of weight makes lifting easier.
Provides strong handles to grip drawsheet without slipping.
Facing direction of movement ensures proper balance. Shifting weight reduces force needed to move patient. Flexing knees lowers nurses' center of gravity and uses thighs instead of back muscles.

STEP 4f Moving immobile patient up in bed with drawsheet.

- 5 **Help patient move up in bed using a friction-reducing device (two or three nurses assist):**
 - a Position patient as in Steps 4a-c.
 - b Place friction-reducing device under drawsheet by having patient turn side to side.

- A minimum of three or four caregivers is recommended if the patient's weight is greater than 71.4 kg (157 lbs) (Waters et al., 2011).
Supine position on drawsheet prepares patient for placement of friction-reducing device.
Prevents friction from contact of skin with board.

STEP **RATIONALE**

- c Move patient up in bed by having two nurses grasp drawsheet, and one nurse holds onto friction-reducing device. Follow Steps 4e and f, moving patient up in bed. Slide board remains stationary, provides a slippery surface to reduce friction, and allows patient to move up in bed easily.

Clinical Decision Point *Protect patient's heels from shearing force by having another caregiver lift heels while moving patient up in bed.*

- 6 Position patient in one of the following positions using correct body alignment. Protect pressure areas. Begin with patient lying supine and move up in bed following either Step 4 or 5. Prevents injury to musculoskeletal system.

a Position patient in supported semi-Fowler's (see illustration) or Fowler's position:

STEP 6a Supported semi-Fowler's position.

- (1) With patient lying supine, elevate head of bed 45 to 60 degrees if not contraindicated. Increases comfort, improves ventilation, and increases patient's opportunity to socialize or relax.
- (2) Rest head against mattress or on small pillow. Prevents flexion contractures of cervical vertebrae.
- (3) Use pillows to support arms and hands if patient does not have voluntary control or use of hands and arms. Prevents shoulder dislocation from effect of downward pull of unsupported arms, promotes circulation by preventing venous pooling, and prevents flexion contractures of arms and wrists.
- (4) Position small pillow at lower back. Supports lumbar vertebrae and decreases flexion of vertebrae.
- (5) Place small pillow or roll under thigh. Prevents hyperextension of knee and occlusion of popliteal artery from pressure from body weight.
- (6) Support calves with pillows. Heels should not be in contact with bed to prevent prolonged pressure of mattress on heels. This is sometimes referred to as floating heels.

b Position hemiplegic patient in supported semi-Fowler's or Fowler's position:

- (1) Position patient in supine position. Elevate head of bed 45 to 60 degrees. Increases comfort, improves ventilation, and increases patient's opportunity to relax. Adjust head of bed according to patient's condition. For example, those with increased risk for pressure ulcers remain at 30-degree angle (see Chapter 18).
- (2) Position patient in Fowler's position as straight as possible. Counteracts tendency to slump toward affected side. Improves ventilation and cardiac output; decreases intracranial pressure. Improves patient's ability to swallow and helps prevent aspiration of food, liquids, and gastric secretions.
- (3) Position head on small pillow with chin slightly forward. If patient is totally unable to control head movement, avoid hyperextension of neck. Prevents hyperextension of neck. Too many pillows under head may cause or worsen neck flexion contracture.
- (4) Provide support for involved arm and hand by placing arm away from patient's side and supporting elbow with pillow. Paralyzed muscles do not automatically resist pull of gravity as they do normally. As a result, shoulder subluxation, pain, and edema may occur.
- (5) Place rolled blanket (trochanter roll) firmly alongside patient's legs. Ensures proper alignment. Prevents external rotation of hips, which contributes to contractures.
- (6) Support feet in dorsiflexion with therapeutic boots or splints. Prevents plantar flexion contractures or footdrop by positioning patient's ankle in neutral dorsiflexion. Position foot so heel is aligned in opening of splint to prevent pressure. Other therapeutic boots or splints are manufactured with thick padding to cushion heel and prevent pressure ulcers.

c Position patient in supported supine position:

- (1) Place patient supine with head of bed flat. Necessary for properly aligning patient.
- (2) Place small rolled towel under lumbar area of back. Provides support for lumbar spine.
- (3) Place pillow under upper shoulders, neck, and head. Maintains correct alignment and prevents flexion contractures of cervical vertebrae.

STEP

RATIONALE

- | | |
|--|---|
| (4) Place trochanter rolls or sandbags parallel to lateral surface of patient's thighs. | Reduces external rotation of hip. |
| (5) Place patient's feet in therapeutic boots or splints. | Maintains feet in dorsiflexion. Prevents plantar flexion contractures or footdrop. |
| (6) Place pillows under pronated forearms, keeping upper arms parallel to patient's body (see illustration). | Reduces internal rotation of shoulder and prevents extension of elbows. Maintains correct body alignment. |

STEP 6c(6) Supine position with pillows in place.

- | | |
|---|---|
| (7) Place hand rolls in patient's hands. Consider physical therapy referral for use of hand splints. | Reduces extension of fingers and abduction of thumb. Maintains thumb slightly adducted and in opposition to fingers. |
| d Position hemiplegic patient in supine position: | |
| (1) Place head of bed flat. | Necessary for positioning in supine position. |
| (2) Place folded towel or small pillow under shoulder or affected side. | Decreases possibility of pain, joint contracture, and subluxation. Maintains mobility in muscles around shoulder to permit normal movement patterns. |
| (3) Keep affected arm away from body with elbow extended and palm up. Position the affected hand in one of recommended positions for flaccid or spastic hand. (Alternative is to place arm out to side, with elbow bent and hand toward head of bed.) | Maintains mobility in arm, joints, and shoulder to permit normal movement patterns. (Alternative position counteracts limitation of ability of arm to rotate outward at shoulder [external rotation]. External rotation must be present to raise arm over head without pain.) |
| (4) Place folded towel under hip of involved side. | Diminishes effect of spasticity in entire leg by controlling hip position. |
| (5) Flex affected knee 30 degrees by supporting it on pillow or folded blanket. | Slight flexion breaks up abnormal extension pattern of leg. Extensor spasticity is most severe when patient is supine. |
| (6) Support feet with soft pillows at right angle to leg. | Maintains foot in dorsiflexion and prevents footdrop. Pillows prevent stimulation to ball of foot by hard surface, which has tendency to increase muscle tone in patient with extensor spasticity of lower extremity. |
| e Position patient in prone position, using two nurses: | |
| (1) With head of bed flat and one nurse standing on each side of bed, roll patient to one side while placing arm on side to be turned alongside of body. For patients with hemiplegia, move toward unaffected side. | In certain patients with pulmonary conditions such as acute respiratory distress syndrome use of prone position can help improve oxygenation. |
| (2) Roll patient over arm positioned close to body, with elbow straight and hand under hip. Position on abdomen in center of bed. | Prepares patient for positioning. |
| (3) Turn patient's head to one side and support head with small pillow. | Positions patient correctly so alignment can be maintained. |
| (4) Place small pillow under patient's abdomen below level of diaphragm. | Reduces flexion or hyperextension of cervical vertebrae. |
| | Reduces pressure on breasts of some female patients and decreases hyperextension of lumbar vertebrae and strain on lower back. Improves breathing by reducing mattress pressure on diaphragm. |

STEP

RATIONALE

- | | |
|--|--|
| (5) Support arms in flexed position level at shoulders. | Maintains proper body alignment. Support reduces risk for joint dislocation. |
| (6) Support lower legs with pillow to elevate toes (see illustration). | Prevents footdrop. Reduces external rotation of legs. Reduces mattress pressure on toes. |

STEP 6e(6) Prone position with pillows supporting lower legs.

f Position hemiplegic patient in prone position using two nurses:

- | | |
|--|--|
| (1) Move patient toward unaffected side. | Ensures proper alignment in center of bed when patient is rolled onto abdomen. |
| (2) While rolling patient onto side, place pillow on patient's abdomen. | Prevents sagging of abdomen when patient is rolled over; decreases hyperextension of lumbar vertebrae and strain on lower back. |
| (3) With one nurse standing on each side of bed, roll patient onto abdomen by positioning involved arm close to patient's body, with elbow straight and hand under hip. Roll patient carefully over arm. | Prevents injury to affected side. |
| (4) Turn head toward involved side. | Promotes development of neck and trunk extension, which is necessary for standing and walking. |
| (5) Position involved arm out to side with elbow bent, hand toward head of bed, and fingers extended (if possible). | Counteracts limitation of ability of arm to rotate outward at shoulder (external rotation). External rotation must be present to raise arm over head without pain. |
| (6) Flex knees slightly by placing pillow under legs from knees to ankles. | Flexion prevents prolonged hyperextension, which could impair joint mobility. |
| (7) Keep feet at right angle to legs by using pillow high enough to keep toes off mattress. | Maintains feet in dorsiflexion. |

g Position patient in 30-degree lateral (side-lying) position (one nurse):

- | | |
|--|--|
| (1) Lower head of bed completely or as low as patient can tolerate. | Provides position of comfort for patient and removes pressure from bony prominences on back. |
| (2) Lower side rail and position patient on side of bed opposite direction toward which patient is to be turned. Move upper trunk, supporting shoulders first; then move lower trunk, supporting hips. | Provides room for patient to turn to side. |
| (3) Raise side rail and go to opposite side of bed. | Use of leverage makes turning to side easy. |
| (4) Flex patient's knee that will not be next to mattress. Keep foot on mattress. Place one hand on patient's upper bent leg near hip, and place other hand on patient's shoulder. | Rolling decreases trauma to tissues. In addition, patient is positioned so leverage on hip makes turning easy. |
| (5) Roll patient onto side toward you. | Maintains alignment. Reduces lateral neck flexion. Decreases strain on sternocleidomastoid muscle. |
| (6) Place pillow under patient's head and neck. | Prevents patient's weight from resting directly on shoulder joint. |
| (7) Place hands under patient's dependent shoulder and bring shoulder blade forward. | |

STEP

RATIONALE

- | | |
|--|---|
| (8) Position both arms in slightly flexed position. Support upper arm with pillow level with shoulder; other arm, by mattress. | Decreases internal rotation and adduction of shoulder. Supporting both arms in slightly flexed position protects joint. Ventilation improves because chest is able to expand more easily. |
| (9) Place hands under dependent hip and bring hip slightly forward so angle from hip to mattress is approximately 30 degrees. | The 30-degree lateral position reduces pressure on trochanter; designed to prevent pressure ulcer. |
| (10) Place small tuck-back pillow behind patient's back. (Make by folding pillow lengthwise. Smooth area is slightly tucked under patient's back.) | Provides support to maintain patient on side. |
| (11) Place pillow under semiflexed upper leg level at hip from groin to foot (see illustration). | Flexion prevents hyperextension of leg. Maintains leg in correct alignment. Prevents pressure on bony prominences. |

STEP 6g(11) Thirty-degree lateral position with pillows in place.

- | | |
|--|---------------------------------|
| (12) Place sandbags parallel to plantar surface of dependent foot. May use ankle-foot orthotic on feet if available. | Maintains dorsiflexion of foot. |
|--|---------------------------------|

h Position patient in Sims' (semiprone) position (one nurse):

- | | |
|---|--|
| (1) Lower head of bed completely. | Provides for proper body alignment while patient is lying down. |
| (2) Place patient in supine position and position him or her on side of bed opposite direction toward which he or she is to be turned. Move upper trunk, supporting shoulders first, followed by moving lower trunk, supporting hips. | Prepares patient for position. |
| (3) Move to other side of bed and turn patient on side. Position in lateral position, lying partially on abdomen, with dependent shoulder lifted out and arm placed at patient's side. | |
| (4) Place small pillow under patient's head. | Maintains proper alignment and prevents lateral neck flexion. |
| (5) Place pillow under flexed upper arm, supporting arm level with shoulder. | Prevents internal rotation of shoulder. Maintains alignment. |
| (6) Place pillow under flexed upper legs, supporting leg level with hip. | Prevents internal rotation of hip and adduction of leg. Flexion prevents hyperextension of leg. Reduces mattress pressure on knees and ankles. |
| (7) Place sandbags parallel to plantar surface of foot (see illustration). | Maintains foot in dorsiflexion. Prevents plantar flexion contractures or footdrop. |

STEP 6h(7) Sandbag supporting right foot in dorsiflexion.

STEP

RATIONALE

i Logroll patient (three nurses):

Clinical Decision Point A nurse should supervise and aid NAP when there is a health care provider's order to logroll a patient. Patients with a spinal cord injury or who are recovering from neck, back, or spinal surgery often need to keep the spinal column in straight alignment to prevent further injury.

- | | |
|--|---|
| <ul style="list-style-type: none"> (1) Place small pillow between patient's knees. (2) Cross patient's arms on chest. (3) Position two nurses on side toward which patient is to be turned and one nurse on side where pillows are to be placed (see illustration). (4) Fanfold drawsheet alongside of patient that will be turning. (5) With one nurse grasping drawsheet at lower hips and thighs and the other nurse grasping drawsheet at patient's shoulders and lower back, roll patient as one unit in a smooth, continuous motion on count of three (see illustration). (6) Nurse on opposite side of bed places pillows along length of patient for support (see illustration). (7) Gently lean patient as a unit back toward pillows for support. <p>7 Perform hand hygiene.</p> | <p>Prevents tension on spinal column and adduction of hip.
Prevents injury to arms.
Distributes weight equally between nurses during turning.</p> <p>Provides strong handles to grip drawsheet without slipping.
Maintains proper alignment by moving all body parts at the same time, preventing tension or twisting of spinal column.</p> <p>Maintains patient in side-lying position.</p> <p>Ensures continued straight alignment of spinal column, preventing injury.

STEP 6i(3) Preparing patient for logrolling.

STEP 6i(5) Logrolling patient.

STEP 6i(6) Place pillows along patient's back for support.

STEP

RATIONALE

EVALUATION

- 1 Assess patient's body alignment, position, and level of comfort. Patient's body should be supported by adequate mattress, and vertebral column should be without observable curves.
- 2 Measure ROM.
- 3 Observe for areas of erythema or breakdown involving skin.

Determines effectiveness of positioning. Additional supports (e.g., pillows, bath blankets) may be added or removed to promote comfort and correct body alignment.

Determines if joint contracture is developing.

Provides ongoing observation regarding patient's skin and musculoskeletal systems. Indicates complications of immobility or improper positioning of body part.

Unexpected Outcomes

- 1 Joint contractures develop or worsen.
- 2 Skin shows localized areas of erythema and breakdown.
- 3 Patient avoids moving.

Related Interventions

- Increase frequency of ROM exercises to affected and immobilized areas (see Chapter 10).
- Increase frequency of repositioning.
- Place turning schedule above patient's bed.
- Medicate with analgesia as ordered by health care provider to ensure patient's comfort before moving.
- Allow pain medication to take effect before proceeding.

Recording and Reporting

- Record procedure and observations (e.g., condition of skin, joint movement, patient's ability to assist with positioning).
- Report observations at change of shift and document in nurses' notes and electronic health record (EHR).
- Record time and position change of patient throughout shift.

Special Considerations

Teaching

- Teach family members how to position patient, especially when caring for infant, young child, or confused or unconscious patient.
- Teach patient ways to help with positioning and provide opportunity for return demonstration.
- Teach patient and family signs and symptoms of pressure ulcers and contractures.

Pediatric

- Children who are unable to move require passive exercise and movement (see Chapter 10).

Gerontologic

- Reposition older adult patients at least every 1 to 2 hours and maintain a regular program of ROM exercises (Touhy et al., 2010).

Home Care

- Assess ability and motivation of patient, family members, and primary caregiver to participate in moving and positioning patient in bed.
- Assess home to determine compatibility of environment with assistive devices (e.g., over-bed trapeze, Hoyer lift, hospital bed).

Long-Term Care

- Patients who have maintained bed rest for a long period may revert back to a favorite position. Frequently assess these patients and turn more often as needed.

Critical Thinking Exercises

Mr. Clark is a 37-year-old man who suffered a spinal cord injury in a motor vehicle accident. He has sustained multiple deep lacerations on his face and trunk and facial fractures of the maxillary and zygomatic bones. He rates his pain at 9 on a scale of 0 to 10. He weighs approximately 88 kg (193.6 lbs). You are preparing to transfer him to a stretcher.

- 1 The emergency department nurse was extremely busy and was unable to provide a complete report. Which other information would you obtain about this patient before transferring him to a stretcher?
 - 2 Mr. Clark is scheduled immediately for a computed tomography (CT) scan of the head and spine. He refuses to allow you to move him onto the stretcher. Which interventions would you select to elicit his cooperation? (Select all that apply.)
 - 1 Administer pain medication as ordered by the physician.
 - 2 Explain the purpose and importance of the CT scan.
 - 3 Describe the method by which you will move him onto the stretcher.
 - 4 Tell him that it is the health care provider's order and must be carried out.
- Explain your choice(s).

- 3 The NAP states to the nurse that he or she will turn Mr. Clark. What is the appropriate, safe action in response to turning Mr. Clark? Explain your answer.
- 4 The results of Mr. Clark's CT scan showed no injuries to his spine or neck and log rolling was no longer needed. Considering his weight and other injuries sustained from the accident, what is the safest method to transfer him from the stretcher to the bed? Explain your answer.

REVIEW QUESTIONS

- 1 A 65-year-old patient who weighs 998 kg (260 lbs) is to be transferred from his bed to a stretcher. The patient is unable to bear full weight on one leg. His upper body strength is good. Which technique is the *least* appropriate technique for transfer?
 - 1 Use of a transfer board
 - 2 Use of a bariatric transfer device
 - 3 Use of a three-person carry
 - 4 Use of a ceiling lift

- 2 A patient who has suffered a stroke will be taken care of by his daughter at home. Which statement by the daughter regarding body mechanics indicates that learning has occurred?
- 1 "I'm glad I have a strong back."
 - 2 "As I twist to place my father in his chair, I'll make sure that he doesn't fall."
 - 3 "I'll keep my knees bent and trunk erect so my muscles work together."
 - 4 "I'll tighten my back muscles and push my pelvis forward to provide balance when lifting my father."
- 3 The nurse is transferring a patient from the bed to the chair for the first time after abdominal surgery. Which initial step in the transfer is most appropriate for the nurse and the patient?
- 1 Apply a transfer belt around the patient's waist.
 - 2 Use the under-axilla support technique to prevent pulling on the abdominal area.
 - 3 Have the patient sit on the side of the bed and dangle for a few minutes.
 - 4 Observe this patient's response while she transfers to increase his or her independence.
- 4 A patient has arrived on the unit after undergoing extensive abdominal surgery. He is awake and alert but refuses to be repositioned in bed. What should the nurse assess first to determine the reason for his refusal to move?
- 1 Oxygen saturation level
 - 2 Pain level
 - 3 Level of consciousness
 - 4 The amount of equipment present
- 5 A young adult is admitted with an unstable spinal cord injury. What is the most appropriate method of moving this patient from her side to her back?
- 1 Use a slide board to move her from side to side.
 - 2 Logroll the patient using three people.
 - 3 Allow the patient to move herself to promote independence.
 - 4 Use a step-by-step method: move the trunk, then the hips, and finally the leg.
- 6 A patient has been on bed rest for several days. When he attempted to stand from a sitting position, he became dizzy and nauseated. These symptoms indicate which of the following conditions?
- 1 Rebound hypertension
 - 2 Orthostatic hypotension
 - 3 Dysfunctional proprioception
 - 4 Central nervous system rebound hypotension
- 7 A patient who weighs 145.5 kg (320 lbs) is being transferred from his bed to a chair. The patient is on partial weight bearing as a result of bilateral reconstructive knee surgery. Which of the following is the best technique for transfer?
- 1 Transfer board
 - 2 Stand-assist device
 - 3 Three-person carry
 - 4 Ceiling lift
- 8 An adolescent has been admitted with an unstable spinal cord injury sustained from a motor vehicle accident. The patient needs to be taken to the operating room. What is the most appropriate method to move this patient to a stretcher for transport?
- 1 Use a step-by-step method: move the trunk, then the hips, and finally the legs.
 - 2 Logroll the patient; place a slide board; and slide the patient to the stretcher as one unit, maintaining body alignment.
 - 3 Allow the patient to stand and transfer to the stretcher.
 - 4 Use a mechanical lift device to transfer to the stretcher.
- 9 To increase stability during patient transfer, you increase the base of support by performing which action?
- 1 Leaning slightly backward
 - 2 Tensing and tightening the back muscles
 - 3 Keeping the knees in a locked position
 - 4 Spacing your feet farther apart
- 10 Two NAPs ask for the nurse's assistance to transfer a 56.8 kg (125 lbs) patient from the bed to the stretcher. The patient is unable to assist. What is the best response?
- 1 "As long as we use proper body mechanics, no one will get hurt."
 - 2 "The patient only weighs 125 pounds. You don't need my assistance."
 - 3 "The three-man lift technique is recommended to ensure your safety and that of the patient."
 - 4 "Use the slide board; it is more comfortable for the patient and will lessen the chance of injury to us."

KEY TERMS

Abduction	Crutch gait	Foot pump	Opposition
Active range-of-motion exercises	Crutch palsy	Gait	Orthostatic hypotension
Active-assisted range-of-motion exercises	Deep vein thrombosis (DVT)	Gait belt	Osteoblastic
Activity tolerance	Dorsal	Hyperextension	Osteoclastic
Adduction	Dorsiflexion	Immobility	Passive range-of-motion exercises
Atrophy	Eversion	Internal rotation	Plantar flexion
Bed rest	Exercise	Inversion	Pronation
Circumduction	Extension	Isometric contraction	Rotation
Contractures	External rotation	Isometric exercise	Supination
	Flexion	Lateral flexion	Thrombus
		Mobility	

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss indications for assisting with ambulation or using devices to assist with ambulation.
- Discuss indications for performing range-of-motion and isometric exercises.
- Identify complications that may develop in a patient wearing either elastic stockings or a sequential compression device.
- Identify significant assessment data to be noted before and during the use of a continuous passive motion machine.
- Identify significant assessment data to be noted before assisting with ambulation and range-of-motion and isometric exercises.
- Demonstrate the following skills on selected patients: assisting with ambulation, assisting with ambulation with the use of an ambulation aid, assisting with range-of-motion exercises, assisting with isometric exercises, applying a continuous passive motion machine, and applying elastic stockings and sequential compression device.
- Develop teaching plans for selected patients for safety precautions to use at home while using an ambulation aid, applying and monitoring effects of elastic stockings and sequential compression devices, using the continuous passive motion machine, and performing range-of-motion and isometric exercises.

Mobility refers to an ability to move about freely, whereas immobility refers to a person's inability to move about freely. Mobility and immobility are best understood as the end points on a continuum, with many degrees of partial mobility in between. Some patients move back and forth on the mobility-immobility continuum as a result of disease or injury. Other patients experience immobility for an indefinite period.

The level of mobility has a significant impact on an individual's physiological, psychosocial, and developmental well-being (Janelli et al., 2009). When mobility is altered, many body systems are at risk for impairment. Impaired mobility can result in altered cardiovascular functioning, disruption of normal metabolic functioning, increased risk for pulmonary complications, the development of pressure ulcers, and urinary elimination alterations (Huether and McCance 2008; Lewis et al., 2011).

The severity of mobility impairment depends on a patient's age, overall health status, nutritional status, and degree of immobility experienced. For example, pronounced effects of immobility develop more quickly in older adults with chronic illness than in younger patients (Touhy et al., 2010). Older adults are at greater risk for developing orthostatic hypotension, syncope, confusion, increased risk for fractures, and functional incontinence as a result of decreased mobility from bed rest (Craig et al., 2010; Johnson et al., 2009). Increase in activity and exercise may reduce length of stay and cost for hospitalized older adults.

Alterations in mobility may have profound psychosocial and developmental effects. Immobilization often leads to emotional, intellectual, sensory, and sociocultural alterations. For young and older adults, immobility may alter employment, family role functions, and social interactions. Such changes can lead to altered self-concept, lowered self-esteem, and depression. Children also are affected by immobility. Activity for them is a way of releasing energy and expressing themselves. When deprived of physical activity, children become restless and may even show signs of anger and aggression (Hockenberry and Wilson, 2011).

Changes in a patient's mobility result from a variety of health problems. For example, musculoskeletal conditions such as fractured extremities or muscle sprains, neurologic conditions such as spinal cord trauma, degenerative neurologic conditions such as myasthenia gravis, and head injuries. Some patients are immobilized for therapeutic reasons (e.g., prescribed bed rest or reduced activity). Nursing measures attempt to maintain and/or restore optimal mobility and decrease the hazards associated with immobility. Frequent repositioning, deep-breathing and coughing exercises, muscle and joint exercises, increased fluid intake, and dietary intake of foods containing fiber are examples of measures that help to reduce the hazards of immobility.

EVIDENCE-BASED PRACTICE

Older adults have a decline in physical activity and some changes in joints that may predispose them to problems with mobility. In a recent study, time spent in active physical activities, even ½ hour per day, resulted in significantly lower (15% to 35%) mortality risks

compared with no time in active activities (Paganini-Hill et al., 2011). There is strong evidence that exercise and physical activity help older adults maintain an active lifestyle, improve quality of life, and prevent injury (see [Procedural Guideline 10-1](#)).

- Implement and provide resources for planned exercise programs. Weight-bearing and resistance exercises slow further bone loss and prevent fractures in the older adult with osteoporosis (De Kam et al., 2009; Touhy et al., 2010).
- Recommend resistance- and agility-training programs. These forms of exercise reduce fear of falling and increase sense of well-being in older adults (De Kam et al., 2009; Sherrington et al., 2008).
- Consult a health care provider before beginning an exercise program, particularly in the presence of heart or lung disease and other chronic illnesses (Chodzko-Zajko et al., 2009).
- When developing an exercise program for any older adult, consider not only the person's current activity level, range of motion, muscle strength and tone, and response to physical activity, but also their interests, capacities, and limitations.

PATIENT-CENTERED CARE

Assess each patient's expectations concerning activity and exercise and determine his or her perception of what is normal or acceptable is of utmost importance. For example, one of the factors affecting physical activity is freedom from pain. If exercising is painful or tiresome to a patient, commitment to the desired interventions may be lacking. It is important to consider that some patients are content with their present physical activity and fitness and do not perceive a need for improvement.

When assisting with range-of-motion exercises or ambulation, keep in mind that these activities may place patients in positions that can be embarrassing. Provide a garment that protects a patient's privacy. Many cultures emphasize modesty, and patients from these cultures may not participate in treatment measures for fear of being exposed. For example, Muslim females need to be fully covered when in public because of the emphasis on *hijab*, or female modesty (Simpson et al., 2008).

Safety Guidelines

- 1 Obtain and become familiar with any type of assistive device to be used. Knowledge of proper preparation and use of devices is needed to teach patients to use them safely and correctly.
- 2 Prepare patients. Make sure that they are rested and not fatigued. Obtain extra personnel to assist; use safety devices and flat, nonskid shoes for a patient.
- 3 Address a patient's fear of falling if present.
- 4 Determine the type and frequency of intervention. Activity that is appropriate for 1 day or one shift can change, resulting in an increased or decreased need for assistance with ambulation or a change in the type of intervention.
- 5 Know a patient's home care plan. A patient may need to continue the exercise regimen or use an assistive device at home.

PROCEDURAL GUIDELINE 10-1 Performing Range-of-Motion Exercises

Range-of-motion (ROM) exercises may be active, passive, or active assisted. They are active if a patient is able to perform the exercise independently and passive if the exercises are performed for a patient by the caregiver. In every aspect of activities of daily living (ADLs), encourage patients to be as independent as possible. Encourage and supervise patients to perform active and passive ROM exercises. Incorporate active ROM exercises in a patient's ADLs (Table 10-1). Incorporate passive ROM into bathing and feeding activities. Collaborate with a patient to develop a schedule for ROM activities.

Delegation and Collaboration

The skill of performing ROM exercises can be delegated to nursing assistive personnel (NAP). Patients with spinal cord or orthopedic trauma usually require ROM exercises by professional nurses or physical therapists. The nurse directs the NAP to:

- Perform exercises slowly and provide adequate support to each joint being exercised.
- Not exercise joints beyond the point of resistance or to the point of fatigue or pain.
- Discuss a patient's individual limitations or preexisting conditions such as arthritis, which may affect ROM.

Equipment

- No mechanical or physical equipment needed
- Clean gloves (*optional*)

Procedural Steps

- 1 Review patient's chart for physical assessment findings, health care provider's orders, medical diagnosis, medical history, and progress.
- 2 Obtain data on patient's baseline joint function. Observe for limitations in joint mobility, redness, or warmth over joints; joint tenderness; deformities; or crepitus produced by joint motion.
- 3 Determine patient's or family caregiver's readiness to learn. Explain all rationales for the ROM exercises and describe and demonstrate exercises to be performed.
- 4 Assess patient's level of comfort (on a scale of 0 to 10 with 10 being the worst pain) before exercises. Determine if patient would benefit from pain medication before beginning ROM exercises.
- 5 Perform hand hygiene and apply clean gloves if wound drainage or skin lesions are present.
- 6 Help the patient to a comfortable position, preferably sitting or lying down.
- 7 When performing active-assisted or passive ROM exercises (Table 10-2), support joint by holding distal portion of extremity or using cupped hand to support joint (see illustration).

TABLE 10-1 Incorporating Active Range-of-Motion Exercises into Activities of Daily Living

Joint Exercised	Activity of Daily Living	Movement
Neck	Nodding head yes Shaking head no Moving right ear to right shoulder Moving left ear to left shoulder	Flexion Rotation Lateral flexion Lateral flexion
Shoulder	Reaching to turn on overhead light Reaching to bedside stand for book Rotating shoulders toward chest Rotating shoulders toward back	Flexion, extension Hyperextension Abduction Adduction
Elbow	Eating, bathing, shaving, grooming	Flexion, extension
Wrist	Eating, bathing, shaving, grooming	Flexion, extension, ulnar/radial deviation
Fingers and thumb	All activities requiring fine-motor coordination (e.g., writing, eating, painting)	Flexion, extension, abduction, adduction, opposition
Hip	Walking Moving to side-lying position Moving from side-lying position Rolling feet inward Rolling feet outward	Flexion, extension, hyperextension Flexion, extension, abduction Extension, adduction Internal rotation External rotation
Knee	Walking Moving to and from side-lying position	Flexion, extension Flexion, extension
Ankle	Walking Moving toe toward head of bed Moving toe toward foot of bed	Dorsiflexion, plantar flexion Dorsiflexion Plantar flexion
Toes	Walking Wiggling toes	Extension, hyperextension Abduction, adduction

PROCEDURAL GUIDELINE 10-1 Performing Range-of-Motion Exercises—cont'd

STEP 7 **A**, Support joint by holding distal and proximal areas adjacent to joint. **B**, Support joint by cradling distal portion of extremity. **C**, Use cupped hand to support joint.

- 8** Complete exercises in head-to-toe sequence. Repeat each movement 5 times during exercise period. Inform patient how these exercises can be incorporated into ADLs (see Table 10-1). If worn, remove gloves. Perform hand hygiene.
- 9** Observe patient performing ROM activities.
- 10** Measure joint motion as needed.
- 11** Monitor pain throughout ROM exercise period.

Clinical Decision Point When resistance is noted within a joint, do not force joint motion. Consult with health care provider or physical therapist.

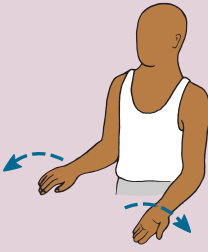

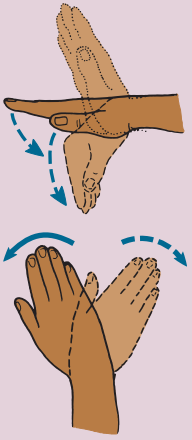

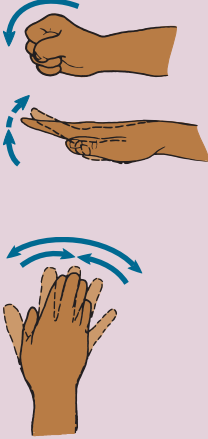

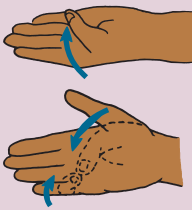

TABLE 10-2 Range-of-Motion Exercises

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Neck, cervical spine		Flexion: Bring chin to rest on chest.	45	Sternocleidomastoid
		Extension: Return head to erect position.	45	Trapezius
		Hyperextension: Bend head back as far as possible.	10	Trapezius
		Lateral flexion: Tilt head as far as possible toward each shoulder.	40-45	Sternocleidomastoid
		Rotation: Turn head as far as possible in circular movement.	180	Sternocleidomastoid, trapezius

TABLE 10-2 Range-of-Motion Exercises—cont'd

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Shoulder	Ball and socket	Flexion: Raise arm from side position forward to position above head.	45-60	Coracobrachialis, deltoid, pectoralis major
		Extension: Return arm to position at side of body.	180	Latissimus dorsi, teres major, triceps brachii
		Hyperextension: Move arm behind body, keeping elbow straight.	45-60	Latissimus dorsi, teres major, deltoid
		Abduction: Raise arm to side to position above head with palm away from head.	180	Deltoid, supraspinatus
		Adduction: Lower arm sideways and across body as far as possible.	320	Pectoralis major
Shoulder	Ball and socket	Internal rotation: With elbow flexed, rotate shoulder by moving arm until thumb is turned inward and toward back.	90	Pectoralis major, latissimus dorsi, teres major, subscapularis
		External rotation: With elbow flexed, move arm until thumb is upward and lateral to head.	90	Infraspinatus, teres major, deltoid
		Circumduction: Move arm in full circle, (circumduction is combination of all movements of ball-and-socket joint).	360	Deltoid, coracobrachialis, latissimus dorsi, teres major
		Elbow	Hinge	Flexion: Bend elbow so lower arm moves toward its shoulder joint and hand is level with shoulder.
Elbow	Hinge	Extension: Straighten elbow by lowering hand.	150	Triceps brachii

TABLE 10-2 Range-of-Motion Exercises—cont'd

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Forearm	Pivotal 	Supination: Turn lower arm and hand so palm is up. Pronation: Turn lower arm so palm is down.	70-90 70-90	Supinator, biceps brachii Pronator teres, pronator quadratus
Wrist	Condyloid 	Flexion, move palm toward inner aspect of forearm. Extension: Move fingers and hand posterior to midline. Hyperextension: Bring dorsal surface of hand back as far as possible. Radial deviation: Bend wrist medially toward thumb. Ulnar deviation: Bend wrist laterally toward fifth finger.	80-90 80-90 80-90 Up to 30 30-50	Flexor carpi ulnaris, flexor carpi radialis Extensor carpi radialis brevis, extensor carpi radialis longus, extensor carpi ulnaris Extensor carpi radialis brevis, extensor carpi radialis longus, extensor carpi ulnaris Flexor carpi radialis brevis, extensor carpi radialis brevis, extensor carpi radialis longus Flexor carpi ulnaris, extensor carpi ulnaris
Fingers	Condyloid hinge 	Flexion: Make fist. Extension: Straighten fingers. Hyperextension: Bend fingers back as far as possible. Abduction: Spread fingers apart. Adduction: Bring fingers together.	90 90 30-60 30 30	Lumbricales, interosseus volaris, interosseus dorsalis Extensor digiti quinti proprius, extensor digitorum communis, extensor indicis proprius Extensor digitorum Interosseus dorsalis Interosseus volaris
Thumb:	Saddle 	Flexion: Move thumb across palmar surface of hand. Extension: Move thumb straight away from hand. Abduction: Extend thumb laterally (usually done when placing fingers in abduction and adduction). Adduction: Move thumb back toward hand. Opposition: Touch thumb to each finger of same hand.	90 90 30 30	Flexor pollicis brevis Extensor pollicis longus, extensor pollicis brevis Abductor pollicis brevis and longus Adductor pollicis obliquus, adductor pollicis transversus Opponens pollicis, opponens digiti minimi

Continued

TABLE 10-2 Range-of-Motion Exercises—cont'd

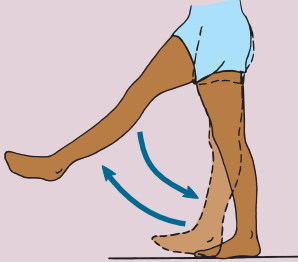

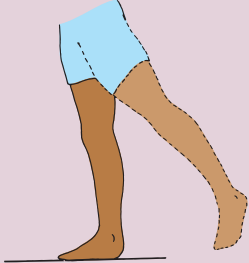

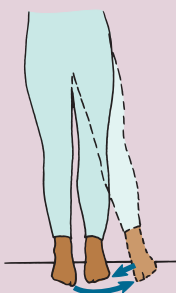

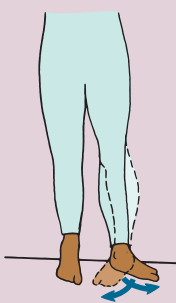

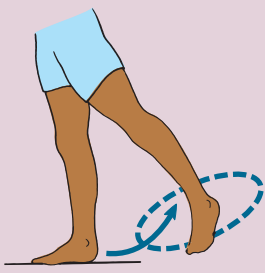

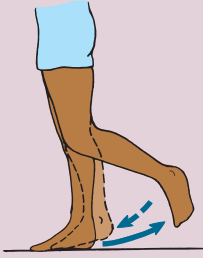

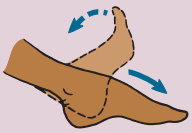

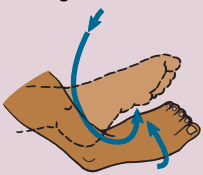

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles	
Hip	Ball and socket	Flexion: Move leg forward and up. Extension: Move leg back beside other leg.	90-120 90-120	Psoas major, iliacus, sartorius Gluteus maximus, semitendinosus, semimembranosus	
			Hyperextension: Move leg behind body as far as possible.	30-50	Gluteus maximus, semitendinosus, semimembranosus
			Abduction: Move leg laterally away from body. Adduction: Move leg back toward medial position and beyond if possible. Internal rotation: Turn foot and leg toward other leg.	30-50 30-50 90	Gluteus medius, gluteus minimus Adductor longus, adductor brevis, adductor magnus Gluteus medius, gluteus minimus, tensor fasciae latae
			External rotation: Turn foot and leg away from other leg.	90	Obturatorius internus, obturatorius externus, quadratus femoris, piriformis, gemellus superior and inferior, gluteus maximus
			Circumduction: Move leg in circle.	120-130	Psoas major, gluteus maximus, gluteus medius, adductor magnus
					

TABLE 10-2 Range-of-Motion Exercises—cont'd

Body Part	Type of Joint	Type of Movement	Range (Degrees)	Primary Muscles
Knee	Hinge 	Flexion: Bring heel back toward back of thigh. Extension: Return leg to floor.	120-130 120-130	Biceps femoris, semitendinosus, semimembranosus, sartorius Rectus femoris, vastus lateralis, vastus medialis, vastus intermedius
Ankle	Hinge 	Dorsal flexion: Move foot so toes are pointed upward. Plantar flexion: Move foot so toes are pointed downward.	20-30 45-50	Tibialis anterior Gastrocnemius, soleus
Foot	Gliding 	Inversion: Turn sole of foot medially. Eversion: Turn sole of foot laterally.	10 or less 10 or less	Tibialis anterior, tibialis posterior Peroneus longus, peroneus brevis
Toes	Condylloid 	Flexion: Curl toes downward. Extension: Straighten toes. Abduction: Spread toes apart. Adduction: Bring toes together.	30-60 30-60 15 or less 15 or less	Flexor digitorum, lumbricalis pedis, flexor hallucis brevis Extensor digitorum longus, extensor digitorum brevis, extensor hallucis longus Abductor hallucis, interosseus dorsalis Adductor hallucis, interosseus plantaris

SKILL 10-1 Performing Isometric Exercises

In addition to range-of-motion (ROM) exercises, some immobilized patients are able to perform muscle-strengthening exercises. Isotonic muscle contractions cause a change in muscle length. Examples of exercises that cause isotonic muscle contractions are walking, performing aerobics, and moving arms and legs against light resistance. Performing these types of exercises regularly positively affects heart and lung function, improves muscle tone, and has beneficial effects on the entire body if performed properly (Burtin et al., 2009; Chrysant, 2010; Granacher et al., 2011). Some individuals are unable to tolerate such increases in activity. For these individuals isometric exercises are more appropriate and are easily accomplished when patients are in bed. Isometric or static exercises involve tightening or tensing of muscles without moving body parts (isometric contractions). They increase muscle tension but do not change the length of muscle fibers.

Isometric exercises involve the contraction of a muscle while pushing against a stationary object or resisting the movement of an object. Examples are performing push-ups and hip lifting. In hip lifting the individual, who is in a sitting position, pushes with the hands against a sitting surface such as a chair to raise the hips. Isometric exercises help to promote muscular strength and provide

the necessary stress for bone maintenance and growth. Without sufficient stress against bone, osteoclastic activity (activity by cells responsible for bone tissue absorption) increases over osteoblastic activity (activity by bone-forming cells) (Huether and McCance, 2008). The result is demineralization of the bone and eventual osteoporosis.

Delegation and Collaboration

The skill of performing isometric exercises can be delegated to nursing assistive personnel (NAP). However, patients with cardiovascular disease or musculoskeletal disorders require assessment by a nurse when initially performing these exercises. The nurse directs the NAP by:

- Discussing the amount of time and frequency of the prescribed isometric exercises.
- Reminding NAP to perform exercises slowly at a patient's pace.
- Discussing a patient's individual limitations or preexisting conditions such as arthritis, which may affect ROM needed for isometric exercises.

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Review patient's chart for contraindications to isometric exercises such as cardiovascular disease. 2 Assess patient's baseline vital signs. 3 Assess patient's baseline muscle strength: <ol style="list-style-type: none"> a Ask patient to perform task against resistance (e.g., push one foot against palm of hand). b Assess grasp strength by having patient grasp your hands. Note whether hand grasps are equal. c Have patient grasp two fingers of your right hand with patient's left hand and two fingers of your left hand with patient's right hand. d Observe patient's ability to do daily activities (e.g., whether patient has adequate strength to bathe self, pull self up in bed, move from bed to chair). e Obtain patient's subjective statements related to muscle strength. Does he or she feel weaker? 4 Assess patient's nutritional status. 5 Assess level of comfort: pain severity (using a scale of 0 to 10). <i>Option:</i> Administer ordered analgesic 30 to 60 minutes before exercise. 6 Assess patient's or family caregiver's understanding of isometric exercises to be used. | <p>Isometric exercises may raise blood pressure and pulse. The presence of a preexisting medical condition such as a history of cardiac problems may be a contraindication.</p> <p>Isometric exercises may raise blood pressure. Baseline vital signs offer a measure for determining whether exercises cause deterioration in vital signs (Huether and McCance, 2008).</p> <p>Allows you to compare muscle strength before and after exercise.</p> <p>Proper nutrition is essential if patient is to be able to perform exercises. Promotion of protein anabolism involves conservation and replenishment of energy stores (Touhy, 2010).</p> <p>Pain may reduce patient's motivation to perform isometric exercises. Pain relief before attempting exercises may enhance patient's participation.</p> <p>Allows patient to verbalize concerns and identifies educational needs of patient or caregiver.</p> |
|--|---|

NURSING DIAGNOSES

- | | |
|---|--|
| <ul style="list-style-type: none"> • Activity intolerance • Deficient knowledge regarding exercises | <ul style="list-style-type: none"> • Fatigue • Impaired physical mobility • Pain (acute, chronic) |
|---|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient increases number of exercise repetitions. • Vital signs remain stable. 2 Explain procedure and demonstrate exercises. 3 Help patient to comfortable position. | <p>Patient gradually becomes stronger and is able to increase number of repetitions.</p> <p>Documents patient's activity tolerance.</p> <p>Relieves anxiety and encourages patient cooperation.</p> <p>Reduces stress and promotes patient participation.</p> |
|--|---|

IMPLEMENTATION

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Provide privacy. 2 Instruct patient to perform the following isometric exercises usually prescribed by a physical therapist. Each exercise prescription is individualized according to patient's needs and limitations. Exercises are as follows: | <p>Prevents patient embarrassment.</p> <p>Gradual build-up of exercise repetitions improves both muscle strength and endurance (Peterson et al., 2011).</p> |
|--|---|

Clinical Decision Point Teach patients to exhale while exerting effort during isometric exercises. Many persons hold their breath (Valsalva maneuver), which increases intrathoracic pressure, causing a decrease in venous return to heart.

- | | |
|---|---|
| <ol style="list-style-type: none"> a Quadriceps isometric exercises: | <p>Quadriceps muscles enable person to ambulate and get out of chair; large muscles of thigh (quadriceps) must be strong enough for patient to extend knees and stabilize them.</p> |
|---|---|

STEP	RATIONALE
------	-----------

- (1) Assist patient to supine recumbent position.
- (2) Instruct patient to press back of knee against mattress while trying to lift heel from bed (see illustration).
- (3) Hold muscles tightly contracted for 5 to 15 seconds and then relax completely for several seconds.

Nurse can assist patient in learning this exercise by placing hand between back of patient's knee and mattress and asking patient to press hand against mattress with back of knee.

- (4) Repeat exercise five times.

b Gluteal muscle isometric exercises:

Improves patient's balance when sitting.

- (1) Help patient to supine position.
- (2) Instruct patient to pinch buttocks muscles together and hold for 5 to 15 seconds and then relax completely for several seconds (see illustration).
- (3) Repeat exercise five times.

c Abdominal muscle isometric exercises:

Improves trunk stability.

- (1) Have patient pull abdominal muscles in as tightly as possible (see illustration)
- (2) Hold for 5 to 15 seconds. Release muscles gradually.
- (3) Repeat exercise five times.

d Foot muscle isometric exercises:

Increases muscle activity in leg and thereby promotes venous return to heart.

- (1) Instruct patient to flex foot toward and away from knee, holding muscles tightly in each position for 5 to 15 seconds.
- (2) Repeat exercise five times.

e Hand muscle isometric exercises:

Strengthens grip to hold onto crutch or walker more effectively.

- (1) Obtain sponge rubber ball. (Size of ball depends on size of patient's hand.)
- (2) Have patient grip ball with entire hand 5 to 10 times.
- (3) Dig each fingertip, one at a time, into ball 5 to 10 times each.
- (4) Gradually increase frequency of exercise until patient can grip ball. Exercise once or twice a day.

f Biceps isometric exercises:

Strengthens biceps and thereby helps with ambulation if ambulatory assistive device is used.

- (1) Have patient raise arms to shoulder height and interlock fingertips of both hands.
- (2) Use arm muscles to try to pull hands apart.
- (3) Hold for 5 to 15 seconds.
- (4) Relax muscles.
- (5) Repeat exercise five times.

STEP 2a(2) Lift heels while pressing back of knees against mattress.

STEP 2b(2) Pinch gluteal muscles together.

STEP 2c(1) Pull abdominal muscles in tightly.

STEP

RATIONALE

g Triceps muscle isometric exercises:

- (1) Arm exercises (see illustration)
 - (a) Have patient raise arms to shoulder height.
 - (b) Make fist with one hand and place against palm of other hand.
 - (c) Push hands together as hard as possible and hold for 5 to 15 seconds.
 - (d) Relax and repeat exercise five times.
- (2) Sitting exercises (see illustration)
 - (a) Help patient to sitting position on edge of bed or in chair. If mattress is soft, place blocks or books on bed under patient's hands.
 - (b) Instruct patient to try to lift buttocks off bed or seat of chair by pressing down on mattress or chair seat with hands.
 - (c) Hold muscles tight for 5 to 15 seconds and then relax.
 - (d) Repeat exercise as tolerated.

STEP 2g(1) Triceps muscle isometric exercises.

Strengthens triceps to assist with transfer techniques and use of crutches or walker. Patient must have enough strength to extend and stabilize elbows when lifting or shifting body weight.

To use crutches or walker effectively, patient must have enough strength in triceps to extend and stabilize elbows while lifting or shifting body weight.

STEP 2g(2) Triceps muscle resistive isometric exercises.

EVALUATION

- 1 Observe patient's ability to perform exercises.
- 2 Evaluate patient's level of energy, muscular strength, and comfort following exercises.
- 3 Obtain vital signs after one or two repetitions.
- 4 Ask patient to rate pain level on a scale of 0-10.

Demonstrates patient's learning.
 Determines whether patient is performing exercises accurately and whether exercises are increasing muscle strength.
 Determines patient's tolerance to activity.
 Determines patient's pain status post isometric exercises and if pre exercise analgesia was effective.

Unexpected Outcomes

- 1 Patient is unable to perform exercises. Patient may be too weak.
- 2 Patient is unwilling to perform exercises.
- 3 Muscular strength is not increasing.
- 4 Patient's blood pressure and heart rate increase significantly during exercises.

Related Interventions

- Continue ROM exercises and reposition patient to try to increase strength.
- Make sure that nutrition and rest are adequate.
- Lack of understanding of significance of exercises may be the problem.
- Stress importance of exercises.
- Be sure that patient is not experiencing distracting symptoms such as nausea or pain.
- Patient may not be performing exercises as described or as often as instructed.
- Stress importance of following routine.
- Patient may not be able to tolerate procedure.
- Discontinue exercises and consult health care provider.

Recording and Reporting

- Record in the nurses' notes and electronic health record (EHR) the type of isometric exercises used; length of time contractions held; number of repetitions of each exercise; assessment of patient's muscular strength and comfort after exercises, vital signs, subjective statements regarding muscular strength, and ability to perform exercises.

Special Considerations

Teaching

- Instruct patient to perform exercises before regular activities such as breakfast or work. Building exercises into routine activities increases likelihood of adherence to exercise program.
- Instruct patient to gradually increase exercise activity each day.

Pediatric

- Incorporate exercises into a child's activity plan.
- Children are more likely to exercise as part of a game or in groups as opposed to exercising alone (Hockenberry and Wilson, 2011).

Gerontologic

- Physical exercise is important for older adults to maintain health, preserve functional status, and improve general quality of life (Peterson et al., 2011; Touhy, 2010).
- For the older adult who has not previously participated in exercise, it is important to start with only 5 minutes of exercise and gradually work up to a 20- to 30-minute daily routine (Peterson et al., 2011).

SKILL 10-2 Continuous Passive Motion Machine

The continuous passive motion (CPM) machine is designed to exercise various joints such as the hip, ankle, knee, shoulder, and wrist. The CPM machine is most commonly used after knee surgery. It is usually prescribed on the day of surgery or the first postoperative day, depending on the surgeon's preference and patient's condition (Lewis et al., 2011). An initial setting is typically 20 to 30 degrees of flexion and full extension at two cycles per minute. However, this setting varies according to a patient's condition and health care provider's preference (Ignatavicius and Workman, 2009). The purpose of the CPM machine is to mobilize the joint to prevent contractures, muscle atrophy, venous stasis, and thromboembolism (Long, 2008). It helps to alleviate pain, edema, stiffness, and dislocation and potentially can shorten a patient's hospital stay.

The electronically controlled CPM machine flexes and extends a joint to a prescribed degree and at a set speed as ordered by the

health care provider. Velcro straps secure the extremity. When the device is turned on, the frame slides slowly back and forth, gently moving the joint through a preset range of motion (ROM). The CPM machine can weigh up to 25 pounds. Using two hospital personnel to lift the machine reduces the risk for caregiver back strain and prevents risk of damage to a patient's extremity.

Delegation and Collaboration

The skill of using the CPM machine cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP by:

- Instructing them to immediately report increase in patient's pain, skin breakdown, or joint inflammation.

Equipment

- CPM machine
- Clean gloves

STEP

RATIONALE

ASSESSMENT

- 1 Assess CPM machine for electrical safety. If you suspect a problem, notify the electrical safety department.
- 2 Assess setup of machine before placing on bed: check stability of frame, flexion/extension controls, padding of exposed metal parts or hard surfaces, and on/off switch.
- 3 Assess patient's pain on a scale of 0 to 10 (10 being the worst pain) before and during use.
- 4 Assess patient's vital signs.
- 5 Assess patient's knowledge about CPM and ability and willingness to learn about CPM machine.
- 6 Assess nature of patient's condition and ROM limits prescribed by health care provider.

- All electrical equipment in health care settings is checked routinely for safety. Routine observation of electrical cord and functioning of equipment each time it is used further monitors safety.
- Ensures that all pieces of equipment are operational and prevents damage to patient's joint. Ensures that metal parts are padded to prevent skin breakdown or chafing of skin rubbing against metal or hard surfaces.
- Establishes comfort baseline. Determines how patient tolerates CPM machine and need for analgesia.
- Provides baseline to measure exercise tolerance.
- Determines readiness to learn, reduces anxiety, and promotes patient participation.
- Procedure must be ordered by health care provider.

NURSING DIAGNOSES

- Activity intolerance
- Acute pain
- Deficient knowledge regarding CPM machine
- Fatigue
- Impaired physical mobility

Related factors are individualized based on patient's condition or needs.

|---|---|

EVALUATION

- | | |
|---|---|
| <p>1 Inspect bony prominences and areas of skin in contact with machine at least every 2 hours.</p> <p>2 Ask patient to rate pain on scale of 0 to 10.</p> <p>3 Check patient's alignment and positioning at least every 2 hours.</p> <p>4 Observe patient and CPM machine with each increase in flexion and extension.</p> | <p>Identifies potential skin breakdown.</p> <p>Determines if analgesia is effective.</p> <p>Promotes comfort and ensures proper extension and flexion of joint.</p> <p>Prevents complications and ensures that CPM machine is functioning properly.</p> |
|---|---|

Unexpected Outcomes

- 1 Patient does not tolerate increase in flexion or extension.

- 2 Patient experiences increased pain when using CPM machine.

- 3 Patient develops reddened areas on bony prominences or extremity.

Related Interventions

- Consult with health care provider and physical therapist to plan additional therapies to increase flexion and extension of joint.
- Provide rest periods throughout day to rest the joint.
- Consider modification of current analgesia plan before using CPM machine.

- Determine efficacy of current analgesia and obtain new orders to change dosage or medication.
- Determine cause of increased pain.

- Determine if hard surfaces on CPM machine are well padded.
- Monitor patient's alignment and positioning at least every 2 hours.
- Provide skin care at least every 2 hours.

Recording and Reporting

- Record in the nurses' notes and EHR the patient's tolerance for CPM machine, rate of cycles per minute, degree of flexion and extension used, condition of extremity and skin, condition of operative site if present, length of time CPM machine in use.
- Report immediately to nurse in charge or health care provider any resistance to range of motion; increased pain; swelling, heat, or redness in joint.

Special Considerations

Teaching

- Instruct patient in the use and importance of the CPM machine, including length of time that CPM is used and any adverse conditions such as increased pain, swelling, or redness in joint. Instruct a patient to call the health care provider if any of these conditions is present.

Pediatric

- During therapy arrange for social or creative activities that are developmentally appropriate for the child's age (Hockenberry and Wilson, 2011).
- Relieve a child's anxiety by demonstrating use of the CPM machine, using a large doll or stuffed animal, before applying it.

Gerontologic

- Older adults have increased risk for skin breakdown because of decreased elasticity and fragility of the skin. Pressure from the CPM machine increases the risk for pressure ulcers, especially on the heel (Touhy, 2010).

- Encourage older adults to move at their own speed. Relaxation exercises decrease anxiety, ease muscle tension, and assist with pain relief (Christo et al., 2011). Special attention to nonverbal cues and additional instruction in pain management are often necessary to ensure an older adult's comfort.

Home Care

- Home care physical therapist may assist patient/family in continuing CPM machine in the home.
- Patient/family must have specific instructions regarding the use of the CPM machine, length of time for each session, and expected outcomes.

PROCEDURAL GUIDELINE 10-2 Applying Elastic Stockings and Sequential Compression Device

**Video Clip**

A patient may develop a deep vein thrombosis (DVT) for many reasons. Some common risk factors include injury to a vein from a fracture or surgery, immobility caused by a cast or prolonged sitting, inherited clotting disorders, obesity, smoking, and a family history (Harvard Health Publications, 2009). Three factors (known as *Virchow's triad*): hypercoagulability of the blood, venous wall damage, and blood flow stasis, contribute to DVT development (Lewis et al., 2011). If a DVT is suspected, keep the patient calm and quiet in bed, and notify the health care provider. Prevention, which can include anticoagulant medications, is the best approach for DVTs; however, movement of the extremities, wearing compression stockings, and use of foot pumps are equally important. Elastic stockings help reduce blood stasis and venous wall injury by promoting venous return and limiting venous dilation, which decreases the risk of endothelial tears. Sequential compression devices (SCDs) pump blood into deep veins, thus removing pooled blood and preventing venous stasis. Another venous plexus foot pump promotes circulation by mimicking the natural action of walking (Fig. 10-1).

Delegation and Collaboration

The skill of applying elastic stockings and SCDs may be delegated to nursing assistive personnel (NAP). The nurse initially determines the size of elastic stockings and assesses the patient's lower extremities for any signs and symptoms of DVTs or impaired circulation. The nurse directs the NAP to:

- Remove the SCD sleeves before allowing a patient to get out of bed.
- Report to the nurse if a patient's calf appears larger than the other or is red or hot or if there are signs of allergic reactions to elastic (redness, itching, irritation).

Equipment

- Tape measure
- Powder or cornstarch (optional)
- Elastic support stockings
- SCD motor, disposable SCD sleeve(s), tubing assembly

Procedural Steps

- 1 Assess patient for risk factors in Virchow's triad:
 - a Hypercoagulability (e.g., clotting disorders, fever, dehydration)
 - b Venous wall abnormalities (e.g., orthopedic surgery, varicose veins, atherosclerosis)
 - c Blood stasis (e.g., immobility, obesity, pregnancy)
- 2 Observe for contraindications for use of elastic stockings or SCDs:
 - a Dermatitis or open skin lesions
 - b Recent skin graft to lower leg
 - c Decreased arterial circulation in lower extremities as evidenced by cyanotic, cool extremities and/or gangrenous conditions affecting the lower limb(s)
- 3 Assess condition of patient's skin and circulation to the legs (e.g., presence of pedal pulses, edema, discoloration of skin, temperature, lesions).
- 4 Obtain health care provider's order.
- 5 Perform hand hygiene.
- 6 Identify patient using at least two patient identifiers (e.g., name and birthday or name and account number, according to agency policy). Compare identifiers with information on patient's identification bracelet.
- 7 Explain procedure and reason for applying elastic stockings and SCDs.
- 8 Position patient in supine position. Elevate head of bed to comfortable level. Use tape measure to measure patient's leg to determine proper elastic stocking or SCD size.
- 9 *Option:* Apply a small amount of powder or cornstarch to legs provided patient does not have sensitivity.
- 10 Apply elastic stocking:
 - a Turn elastic stocking inside out by placing one hand into sock, holding heel of sock with other hand, and pulling. Pull until reaching the heel (see illustration).

FIG 10-1 Venous plexus foot pump with bedside controls. (Courtesy Tyco Healthcare Group LP.)

PROCEDURAL GUIDELINE 10-2 Applying Elastic Stockings and Sequential Compression Device—cont'd

- b Place patient's toes into foot of elastic stocking up to heel, making sure that sock is smooth (see illustration).
 - c Slide remaining portion of sock over patient's foot, making sure that toes are covered. Make sure that foot fits into toe and heel position of sock. Sock will now be right side out (see illustration).
 - d Slide sock up over patient's calf until sock is completely extended. Be sure that sock is smooth and that no ridges or wrinkles are present (see illustration).
 - e Instruct patient not to roll socks partially down.
- 11** Apply SCD sleeve(s):
- a Remove SCD sleeves from plastic cover; unfold and flatten.
 - b Arrange SCD sleeve under patient's leg according to leg position indicated on inner lining of sleeve (see illustration).
 - c Place patient's leg on SCD sleeve. Back of ankle should line up with ankle marking on inner lining of sleeve.
 - d Position back of knee with popliteal opening on sleeve (see illustration).
 - e Wrap SCD sleeve securely around patient's leg. Check fit of SCD sleeve by placing two fingers between patient's leg and sleeve (see illustration).
- 12** Attach SCD sleeve connector to plug on mechanical unit. Arrows on connector line up with arrows on plug from mechanical unit (see illustration).
- 13** Turn mechanical unit on. Green light indicates that unit is functioning. Monitor functioning SCD through one full cycle of inflation and deflation.
- 14** Remove elastic stockings or SCD sleeves at least once per shift (e.g., long enough to inspect skin for irritation or breakdown).

STEP 10a Turn stocking inside out; hold heel and pull through.

STEP 10c Slide remaining portion of sock over foot.

STEP 10b Place toes into foot of stocking.

STEP 10d Slide sock up leg until completely extended.

PROCEDURAL GUIDELINE 10-2 Applying Elastic Stockings and Sequential Compression Device—cont'd

STEP 11b Correct positioning of leg on inner lining of SCD.

STEP 11e Check fit of SCD sleeve.

STEP 11d Position back of patient's knee with the popliteal opening.

STEP 12 Align arrows when connecting to mechanical unit.

SKILL 10-3 Assisting with Ambulation and Use of Canes, Crutches, and Walker

Video Clip

Patients who are immobile for even a short time may require assistance with ambulation. Have patients wear gait belts and stand on their stronger side. Then, if the patient begins to fall, you can pull him or her toward you on the stronger side. Whenever assisting a patient up and out of bed or a chair, there is a risk for orthostatic hypotension. Orthostatic hypotension or postural hypotension is a drop in blood pressure that occurs when a patient changes from a horizontal to a vertical position. A drop in blood pressure greater than 20 mm Hg in systolic pressure or 10 mm Hg in diastolic pressure with symptoms of dizziness, light-headedness, nausea, tachycardia, pallor, and fainting indicates orthostatic hypotension (Lewis et al., 2011; Thompson et al., 2011). Before ambulating patients use interventions to maintain muscle tone, increase venous return to the heart, and decrease stasis of blood in the lower extremities. Use safety precautions before and during ambulation to control for orthostatic hypotension and subsequent falling.

A patient may require the use of an assistive device to aid in ambulation. Use of an assistive device increases stability, supports

weak extremities, or reduces the load on weight-bearing structures such as hips, knees, or ankles. These devices range from standard canes, which provide balance and minimal physical support, to crutches and walkers, which are used by patients with weight-bearing limitations on one or more of their legs. When assisting a patient to ambulate while using an assistive device, have the person wear a gait belt and stand on the person's weak side. Selection of the appropriate device depends on a patient's age, diagnosis, muscular coordination, and ease of maneuverability (Pierson and Fairchild, 2008). Use of assistive devices may be temporary (e.g., during recuperation from a fractured extremity or orthopedic surgery) or permanent (e.g., a patient with paralysis or permanent weakness of the lower extremities).

Canes are lightweight, easily movable devices that extend approximately waist high and are made of wood or metal. They help to maintain balance by widening the base of support. They are indicated for patients with hemiparesis and are used to ease the strain on weight-bearing joints. Canes are not recommended for patients with bilateral leg weakness; crutches or walkers are more appropriate for such patients (Pierson and Fairchild, 2008). There are three types of commonly used canes. The *standard crook cane*

provides the least support and is used by patients requiring only minimal assistance to walk. It has a half-circle handle, which allows it to be hooked over chairs. The *tripod cane* (pyramid cane) has three legs, and the *quad cane* has four legs; the additional legs provide a wide base of support. These types of canes are useful for patients with unilateral or partial leg paralysis. They also have the advantage of standing alone, freeing the arms to help a patient rise from a chair.

A crutch is a wooden or metal staff that reaches from the ground almost to the axilla. Crutches remove weight from one or both legs. They are used by patients who must transfer more weight to their arms than is possible with canes. There are three types of crutches: *axillary*, *Lofstrand*, and *platform*. Patients of all ages often use an axillary crutch on a short-term basis. The Lofstrand crutch has a handgrip and a metal band that fits around a patient's forearm. Both the metal band and the handgrip are adjusted to fit a patient's height. This type of crutch is useful for patients with a permanent disability such as paraplegia. The metal armband stabilizes and helps to guide the crutch. It also offers other advantages. First, the encircling armband allows patients to use their hands for other activities such as opening doors without dropping the crutches. Second, the anterior opening of the band allows patients to free themselves of the crutches if a fall occurs. Patients who are unable to bear weight on their wrists use a platform crutch. It has a horizontal trough on which patients can rest their forearms and wrists and a vertical handle for patients to grip.

A walker is an extremely lightweight, movable device that stands about waist high, consisting of a metal frame with handgrips, four widely placed sturdy legs, and one open side. Because it has a

wide base of support, the walker provides great stability and security. A walker can be used by a patient who is weak or has problems with balance (Pierson and Fairchild, 2008). In addition to the standard walker, several other models are available: a foldable version that is easy to transport, one with a fold-down seat, and one with wheels on the front legs. Walkers with wheels are useful for patients who have difficulty lifting the walker as they walk because of limited balance or endurance. However, the disadvantage is that the walker can roll forward when weight is applied.

Delegation and Collaboration

The skill of assisting patients with ambulation can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP by:

- Instructing them to have a patient dangle following lying in bed before ambulation (see Chapter 9).
- Instructing them to immediately return a patient to the bed or chair if he or she is nauseated, dizzy, pale, or diaphoretic and to report these signs and symptoms to the nurse immediately.
- Discussing the importance of applying safe, nonskid shoes and ensuring that the environment is free of clutter and there is no moisture on the floor before ambulating patient.

Equipment

- Ambulation device (crutch, walker, cane)
- Safety device (gait belt)
- Well-fitting, flat, nonskid shoes for patient
- Robe
- Goniometer (*optional*)

STEP **RATIONALE**

ASSESSMENT

- 1 Review patient's chart, including:
 - a Patient's medical history.
 - b Patient's previous activity level.
 - c Current activity order
- 2 Assess patient's physical readiness:
 - a Obtain patient's heart rate; blood pressure; and orientation to time, place, and person.
 - b Assess range of motion (ROM), muscle strength, coordination, and whether there is the presence of foot deformities.
 - c Assess patient for any visual, perceptual, or sensory deficits.
 - d Assess environment for potential threats to patient safety.
 - e Assess patient's pain on a scale of 0-10, 10 being the worst pain.
- 3 Determine patient's or family caregiver's understanding of technique of ambulation to be used.
- 4 Determine optimal time for ambulation.
- 5 Assess degree of assistance that patient needs.

Certain medications, chronic illness, and history of falling may influence patient's ability to ambulate independently. Identifies patient's activity tolerance. Patient may tire easily or be prone to orthostatic hypotension if bed rest has been prolonged. Verifies if an ambulation aid is needed and specifies amount of activity permitted.

Ambulation following immobility can be fatiguing and stressful. Baseline is needed to detect orthostatic hypotension. Baseline vital signs also offer a means for comparison after exercise. The oriented patient is able to understand instructions. Determines if patient has enough flexibility and muscle strength to ambulate safely and if he or she needs muscle-strengthening exercises. Determines presence of foot deformities affecting ambulation.

Determines if patient can use assistive device safely. Ambulation after immobility can be fatiguing and stressful. Protects patient from potential injury. Patient may be in pain or fear pain resulting from exercise. If necessary, administer analgesic 30 to 60 minutes before exercise. Allows patient to verbalize concerns. Patients who have been immobile for a long time may be hesitant to ambulate. Caregiver may be hesitant to learn how to help with ambulation. Patient's personal habits must be considered when planning activities.

For safety, another person may be needed initially to assist with patient ambulation. Allow patient as much independence as possible.

STEP

RATIONALE

NURSING DIAGNOSES

- | | | |
|---|---|-------------------|
| • Activity intolerance | • Fatigue | • Risk for falls |
| • Decreased cardiac output | • Impaired physical mobility | • Risk for injury |
| • Deficient knowledge regarding use of assistive device | • Ineffective peripheral tissue perfusion | |

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Patient ambulates without injury.
- Patient is able to ambulate without excessive fatigue or dizziness.
- Patient demonstrates correct gait.
- Patient resumes social and self-care activities.

Precautions prevent orthostatic hypotension. Appropriate level of assistance on device ensures patient's safety. Assistive device chosen requires minimal exertion.

Demonstrates learning.

Progressive ambulation increases patient's endurance and independence.

2 Preparing patient for ambulation:

- a Explain reasons for exercise and demonstrate specific gait technique to patient or family caregiver.
- b Decide with patient how far to ambulate.
- c Schedule ambulation around patient's other activities.
- d Place bed in low position and slowly help patient to Fowler's upright position (see [Chapter 9](#)). If in chair, have patient sit upright with feet flat on floor.
- e Help patient in bed to dangling position on side of bed (see illustration). Apply gait belt.

Teaching and demonstration enhance learning, reduce anxiety, and encourage cooperation.

Determines mutual goal.

Taking scheduled rest periods between activities reduces patient fatigue.

Allows a few minutes for circulation to equilibrate. Prevents orthostatic hypotension and potential injuries.

Movement of legs in dangling position promotes venous return.

STEP 2e Assisting patient to side of bed.

- f Help sitting patient to standing position and allow to stand until balance is gained. Support by holding gait belt.
- g Ask if patient feels dizzy or light-headed. If patient appears light-headed, sit him or her back down and recheck blood pressure.
- h Care must be taken if patient has intravenous (IV) tubing or a Foley catheter. Obtain an IV pole with wheels that can be pushed as patient walks. Urinary catheter drainage bags must stay at or below level of bladder; a second person may be needed to assist.

Allows you to detect orthostatic hypotension before ambulation begins.

Allows patient to ambulate unencumbered.

Urine in tubing must not reenter bladder, which would increase risk of infection.

STEP

RATIONALE

Clinical Decision Point Remove obstacles from pathways, including throw rugs, and wipe up any spills immediately. Avoid crowds. Crowds increase the risk of the crutch, cane, or walker being kicked or jarred and patient losing balance.

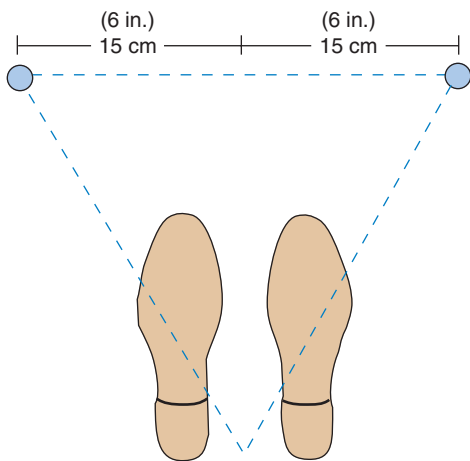

- 3** Determining appropriate height of ambulation device, if used:
- a** *Crutch measurement:* Includes three areas: Patient's height, distance between crutch pad and axilla, and angle of elbow flexion. Use one of two methods:
 - (1) *Standing:* Position crutches with crutch tips at 15 cm (6 inches) to side and 15 cm in front of patient's feet (tripod position) and crutch pads 5 cm (2 inches) below axilla (Pierson and Fairchild, 2008) (see illustration).
 - (2) *Supine:* Crutch pad is approximately 5 cm (2 inches) or two-to-three finger widths under axilla with crutch tips positioned 15 cm (6 inches) lateral to patient's heel (Pierson and Fairchild, 2008) (see illustration).
 - (3) Instruct patient to report any tingling or numbness in upper torso.
 - (4) Following correct crutch adjustment, two to three fingers must fit between top of crutch and axilla (see illustration).

Promotes optimal support and stability.

Radial nerve passes under axillary area superficially. If crutch is too long, it can cause pressure on axilla and radial nerve. Injury to radial nerve causes paralysis of elbow and wrist extensors, commonly called *crutch palsy*. In addition, if crutch is too long, shoulders are forced upward, and patient cannot push body off the ground. If ambulation device is too short, patient is bent over and uncomfortable.

May mean that crutches are being used incorrectly or that they are wrong size.

Adequate space prevents crutch palsy.

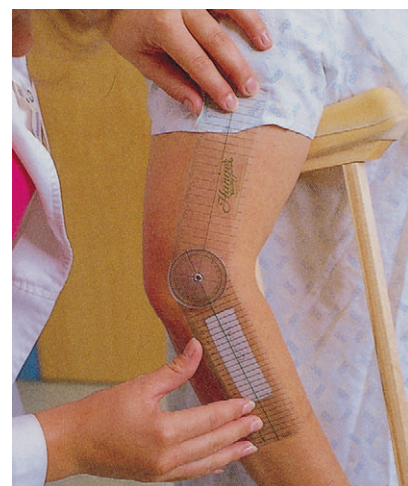

STEP 3a(1) Tripod position.

STEP 3a(4) Top of crutch.

STEP 3a(2) Supine method.

STEP 3a(5) Elbows flexed. Verification of elbow flexion.

STEP	RATIONALE
(5) With either measurement method, elbows are flexed 15 to 30 degrees. Verify elbow flexion with goniometer (see illustration).	Angle ensures that arms can push body off ground. Obtain goniometer from physical therapy department.
(6) In addition to overall <i>length</i> of axillary crutch, <i>height</i> of handgrip is important. Both dimensions are adjustable on a well-made crutch, and ability to adjust these dimensions is an important feature for a growing child. Adjust handgrip so patient's elbow is slightly flexed.	If handgrip is too low, radial nerve damage can occur even if overall crutch length is correct because extra length between handgrip and axillary bar can force bar up into axilla as patient stretches down to reach handgrip. If handgrip is too high, patient's elbow is sharply flexed, and strength and stability of arms are decreased.
b <i>Cane measurement:</i> Patient holds cane on uninvolved side 10 to 15 cm (4 to 6 inches) to side of foot. Cane extends from greater trochanter to floor while it is held 15 cm (6 inches) from foot. Allow approximately 15 to 30 degrees of elbow flexion.	Offers most support when cane is placed on stronger side of body. Cane and weaker leg work together with each step. If cane is too short, patient has difficulty supporting weight and is bent over and uncomfortable. As weight is taken on by hand and affected leg is lifted off floor, complete extension of elbow is necessary.
c <i>Walker measurement:</i> Top of walker should match crease in wrist when patient stands up straight (<i>American Academy of Orthopaedist Surgeons, 2011</i>). Elbows are flexed at approximately 15 to 30 degrees when patient is standing inside walker with hands on handgrips.	Walker should be at proper height so patient does not bend forward.
4 Make sure that ambulation device has rubber tips.	Rubber tips prevent device from slipping.
5 Make sure that surface patient will walk on is clean and dry. Remove any objects that might obstruct pathway.	Prevents falls and injuries.

IMPLEMENTATION

1 Assisted ambulation with one nurse:

- a** Before beginning ambulation, reconfirm that patient does not feel light-headed.
- b** Perform hand hygiene. Be sure gait belt is secure. Help patient to standing position; observe balance.
- c** Have patient take a few steps while you stand on his or her stronger side. If assistive device (e.g., cane, walker) is used, stand on patient's weak side.
- d** Stand and grasp gait belt in middle of patient's back.
- e** Take a few steps forward with patient. Then assess for strength and balance.
- f** If patient becomes weak or dizzy, return him or her to bed or chair, whichever is closer.
- g** If patient begins to fall, gently ease him or her to floor by holding firmly onto gait belt; stand with feet apart to provide broad base of support, extend leg, and let patient gently slide to floor. As patient slides, bend your knees to lower body (see illustrations).

2 Assisted ambulation with two nurses:

- a** Follow Steps 1a and b.
- b** Have a nurse stand on either side of patient.
- c** Both nurses grasp gait belt in middle of patient's back.
- d** Step forward in unison with patient, keeping speed and step size same as patient's.
- e** Gradually increase distance walked.
- f** If patient becomes weak or dizzy, follow Step 1f.

- Helps patient gain balance before attempting ambulation and ensures that patient will not become faint while walking.
- Reduces transmission of microorganisms. Prevents injury. Gait belt encircles patient's waist and has space for you to hold while patient walks. If patient appears weak or unsteady, return him or her to bed.
- If patient has hemiplegia (one-sided paralysis) or hemiparesis (one-sided weakness), stand next to patient's strong, unaffected side and support him or her by placing arm closest to him or her on gait belt.
- If patient begins to fall, this position allows you to move him or her to stronger side and reduce injury. Provides support at waist so patient's center of gravity remains midline.
- Ensures that patient has satisfactory strength and balance to continue.
- Allows patient to rest.
- You can cause more damage to self and patient by trying to catch patient.

- Provides secure grip for each nurse.
- Ensures patient's stability.

- Strengthens muscles, increases endurance, and prevents patient from becoming too fatigued.

STEP

RATIONALE

3 Ambulation with assistive devices:

a Help patient crutch walk by choosing appropriate crutch gait:

(1) Four-point gait:

- (a) Begin in tripod position. Place crutches 15 cm (6 inches) in front and 15 cm (6 inches) to side of each foot. Have patient place weight on handgrips, not under arms [see Planning Step 3a(1)].
- (b) Move right crutch forward 10 to 15 cm (4 to 6 inches) (see illustration A).
- (c) Move left foot forward to level of left crutch (see illustration B).
- (d) Move left crutch forward 10 to 15 cm (4 to 6 inches) (see illustration C).
- (e) Move right foot forward to level of right crutch (see illustration D).
- (f) Repeat above sequence.

(2) Three-point gait:

- (a) Begin in tripod position (see illustration A).
- (b) Advance both crutches and affected leg (see illustration B).
- (c) Move stronger leg forward, stepping on floor (see illustration C).
- (d) Repeat sequence.

To use crutches, patient supports self with hands and arms; therefore strength in arm and shoulder muscles, ability to balance body in upright position, and stamina are necessary. Type of gait patient uses in crutch walking depends on amount of weight that he or she is able to support with one or both legs.

This is the most stable crutch gait because it provides at least three points of support at all times. Patient must be able to bear weight on both legs. Patient moves each leg alternately with each opposing crutch so that three points of support are on the floor all the time. Often used when patient has some form of paralysis, such as for children with spastic cerebral palsy (Hockenberry and Wilson, 2011). May also be used for arthritic patients.

Improves patient's balance by providing wide base of support. Patient should have a posture of erect head and neck, straight vertebrae, and extended hips and knees.

Crutch and foot position is similar to arm and foot position during normal walking.

Requires patient to bear all weight on one foot. Weight is borne on strong leg and then on both crutches. Affected leg does not touch ground during early phase of three-point gait. May be useful for patient with broken leg or sprained ankle.

Improves patient's balance by providing wide base of support.

STEP 1g A, Stand with feet apart to provide broad base of support. B, Extend one leg and let patient slide against it to the floor. C, Bend knees to lower body as patient slides to floor.

STEP

RATIONALE

- (3) Two-point gait:
- Begin in tripod position (see illustration A).
 - Move left crutch and right foot forward (see illustration B).
 - Move right crutch and left foot forward (see illustration C).
 - Repeat sequence.
- (4) Swing-to gait:
- Begin in tripod position.
 - Move both crutches forward.
 - Lift and swing legs to crutches, letting crutches support body weight.
 - Repeat two previous steps.
- (5) Swing-through gait:

Requires at least partial weight bearing on each foot. Is faster than the four-point gait. Requires more balance because only two points support body at one time.

Improves patient's balance by providing wide base of support. Crutch movements are similar to arm movement during normal walking; patient moves crutch at same time as opposing leg.

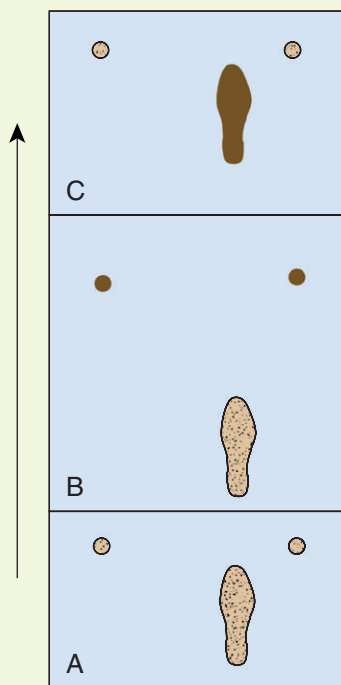

Frequently used by patients whose lower extremities are paralyzed or who wear weight-supporting braces on their legs.

This is the easier of two swinging gaits. It requires ability to partially bear body weight on both legs.

Requires that patient have ability to bear partial weight on both feet.

STEP 3a(1)(b-e) Four-point gait. Solid feet and crutch tips show foot and crutch tip movement in each of four phases. (Read from bottom to top.) **A**, Right tip moves forward. **B**, Left foot moves toward left crutch. **C**, Left crutch tip moves forward. **D**, Right foot moves toward right crutch.

STEP 3a(2)(a-c) Three-point gait with weight borne on unaffected right leg. Solid foot and crutch tips show weight bearing in each phase. (Read from bottom to top.)

STEP

RATIONALE

- (a) Begin in tripod position.
- (b) Move both crutches forward.

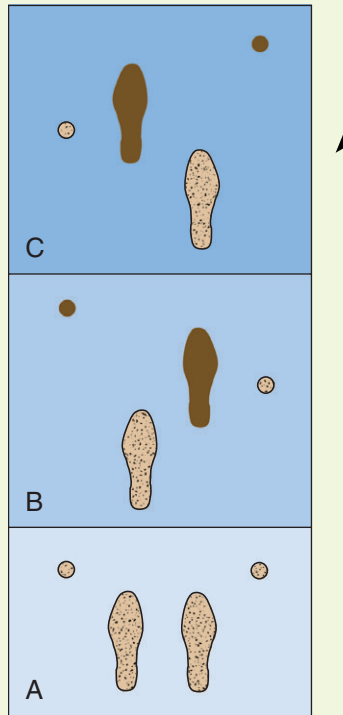

Improves patient's balance by providing wide base of support. Initial placement of crutches is to increase patient's base of support so, when the body swings forward, patient is moving center of gravity toward additional support provided by crutches.

- (c) Lift and swing legs through and beyond crutches.

b Helping patient climb stairs with crutches:

- (1) Begin in tripod position.
- (2) Patient transfers body weight to crutches (see illustration).

Improves patient's balance by providing wide base of support. Prepares patient to transfer weight to strong leg when ascending first stair.

STEP 3a(3)(a-c) Two-point gait. Solid areas indicate weight-bearing leg and crutch tips. (Read from bottom to top.)

STEP 3b(2) Transfer body weight to crutches.

STEP 3b(3) Advance unaffected leg to stair.

STEP 3b(4) Align crutches with unaffected leg.

STEP

RATIONALE

- (3) Patient advances strong, unaffected leg to stair (see illustration).
- (4) Both crutches are aligned with strong, unaffected leg on stairs (see illustration).
- (5) Repeat sequence until patient reaches top of stairs.

Crutch adds support to affected leg. Patient then shifts weight from crutches to strong leg.

Maintains balance and provides wide base of support.

c Helping patient descend stairs with crutches:

- (1) Begin in tripod position.
- (2) Patient transfers body weight to unaffected, strong leg, and aligns with crutches (see illustration).
- (3) With weight on unaffected, strong leg, patient positions crutches firmly on lower stair and steps down with affected leg. Weight is supported by crutches (see illustration).
- (4) Unaffected leg is brought down to lower stair, aligned with crutches, and tripod position is resumed (see illustration).
- (5) Repeat sequence until stairs are descended.

Improves patient's balance by providing wide base of support.

Prepares patient to release support of body weight maintained by crutches.

Maintains balance and provides base of support.

d Helping patient ambulate with walker (see illustration):

- (1) Have patient stand straight in the center of walker and grasp handgrips on upper bars.
- (2) Have patient lift walker; move it 15 to 20 cm (6 to 8 inches) forward; and then set it down, making sure that all four feet of walker stay on floor. Patient then takes a step forward with either foot and follows through with the other leg.
- (3) After walker is advanced, if unilateral weakness is present, instruct patient to step forward with weaker leg, support self with arms, and follow through with strong leg. If patient is unable to bear weight on one leg, after advancing walker have patient swing into it, supporting weight on hands.

Patients who are able to bear partial weight use walkers. Walkers do need to be picked up, so patient needs sufficient strength to be able to pick it up. Four-wheeled models do not need to be picked up; however, they are not as stable.

Patient balances self before attempting to walk.

Provides broad base of support between walker and patient. Patient then moves center of gravity toward walker. Keeping all four feet of walker on floor is necessary to prevent tipping walker.

STEP 3c(2) Body weight is transferred to unaffected leg.

STEP 3c(3) Transfer weight to crutches.

STEP 3c(4) Move unaffected leg and align crutches.

STEP

RATIONALE

e Helping patient ambulate with cane (steps are same with standard or quad canes) (see illustrations):

- | | |
|--|--|
| (1) Begin by having patient place cane on side of strong leg. | Provides added support for weak or impaired side. |
| (2) Place cane forward 15 to 25 cm (6 to 10 inches), keeping body weight on both legs. | Distributes body weight equally. |
| (3) Have patient stand straight, look straight ahead, and move involved leg forward, even with cane. | Body weight is supported by cane and uninvolved leg. |
| (4) Advance strong leg past cane. | Body weight is supported by cane and strong leg. |

STEP 3d Walker.

STEP 3e A, Standard cane. B, Quad cane.

STEP

- (5) Move involved leg forward, even with strong leg.
- (6) Repeat these steps.

RATIONALE

Aligns patient's center of gravity. Returns patient's body weight to equal distribution.

EVALUATION

- 1 After ambulation, obtain patient's vital signs, observe skin color, and ask about patient's level of comfort and energy level.
- 2 Evaluate patient's subjective statements regarding experience.
- 3 Evaluate gait of patient, observing body alignment in standing position and balance.
- 4 Observe patient's ability to perform self-care activities.

Evaluates how patient tolerated procedure and whether there was progress in ambulation. Assesses stage of patient's illness and degree of convalescence when evaluating the process.
Evaluates activity tolerance.
Determines if patient is using supportive aids for ambulation correctly. Keep in mind patient's previous manner of ambulating when assessing gait.
Level of ambulation progresses.

Unexpected Outcomes

- 1 Patient is unable to ambulate because of fear of falling, physical discomfort, upper body muscles that are too weak to use ambulation device, and lower extremities that are too weak to support body.
- 2 Patient sustains injury.
- 3 When using cane or walker, patient bends over, does not stand straight.

Related Interventions

- Initiate isometric exercise program to strengthen upper body muscles.
- Provide analgesia if needed.
- Notify health care provider. Return patient to bed if injury stable.
- Reinforce correct posture.

Recording and Reporting

- Record in the nurses' notes and EHR the type of gait patient used, assist device, amount of assistance required, distance walked, and activity tolerance.
- Immediately report any injury sustained during attempts to ambulate, alteration in vital signs, or inability to ambulate to nurse in charge or health care provider.

Special Considerations

Teaching

- Instruct patient that exercises such as squeezing a rubber ball, raising and lowering both arms in a slow and rhythmic manner while holding weights, pushups, and pull-ups help to strengthen the upper extremities.
- Teach patients using walkers to examine the frame daily. When inspecting a walker, the patient should observe for signs of bending or deformation of the frame, protruding screws that can scratch, and loose or missing screws that weaken the joints of the frame. Assess handgrips for any cracks or signs of being loose.
- Instruct patients to use the arms of a chair rather than the walker to give them leverage when getting up from a chair; the walker is likely to tip if used for this purpose.
- Blistering or soreness of the hands can result from continual pressure between the hand and the handle of a crutch. Advise patient to release pressure intermittently and wear gloves or pad the handle to reduce friction.

- Instruct patient that, if wearing shoes with varying heel sizes, the crutches need to be adjusted to maintain two-to-three fingers between the axilla and the crutch.

Pediatric

- For rehabilitation of a small child who has not yet learned to walk or who is unsteady, special crutches with three or four legs provide needed stability to allow the child to maintain an upright posture and learn to walk (Hockenberry and Wilson, 2011).
- Another option for children who are just learning to walk would be front- or rear-rolling walkers.

Gerontologic

- The older adult may require additional time in the morning before resuming activities.

Home Care

- Teach patient how to use the ambulation aid on various terrains (e.g., carpet, stairs, rough ground, inclines). Teach him or her how to maneuver around obstacles such as doors and how to use the aid when transferring to and from a chair, toilet, and tub.
- Teach family caregivers how to assist and what to observe to ensure that an assistive device is used correctly.

Long-Term Care

- Conduct safety and maintenance checks of ambulation devices on a routine basis.
- Perform periodic assessments to ensure that the patient is using the ambulation device properly.

Critical Thinking Exercises

Mr. Timber, 78 years old, is hospitalized for a right total knee replacement. He has a medical history of diabetes mellitus. He is now 1 day postoperative following right knee replacement. He rates his pain as 8 on a scale of 0 to 10. Postoperative orders include ambulating with crutches today and using the continuous passive motion (CPM) machine 4 times a day.

- As you discuss the plan of care with Mr. Timber for the day, you include the need for ambulation with crutches. He states, "I'm not getting out of bed; I hurt and just had surgery." Discuss nursing interventions that will facilitate this patient's cooperation and participation.
- Mr. Timber has several risk factors associated with the occurrence of orthostatic hypotension. Identify the nursing interventions needed to minimize orthostatic hypotension.
- You are preparing to apply the CPM machine to Mr. Timber's right leg. Discuss several measures to ensure proper and safe functioning of this machine before application.
- Mr. Timber needs crutches for approximately 4 to 6 weeks during his recovery. He is allowed no weight bearing on his right leg for the first week. What is the appropriate crutch gait for Mr. Timbers? Discuss several teaching considerations associated with the use of crutches.

REVIEW QUESTIONS

- The nurse notes that a patient's left elbow is resistant to extension and flexion while performing range-of-motion exercises. What is the appropriate nursing action at this time?
 - Move the joint through the full range of motion.
 - Perform range of motion to the left elbow only until resistance is met.
 - Omit all the range-of-motion exercises until the health care provider is notified.
 - Tell the health care provider that the patient is uncooperative with exercising.
- A patient has been immobile for more than 2 weeks. He notices dizziness the first time the nurse has him sit up, and he states feeling tired. He is now able to begin performing isometric exercises. Which nursing diagnosis best relates to the safety of this patient?
 - Fatigue
 - Impaired skin integrity
 - Disturbed body image
 - Risk for activity intolerance
- The nurse suspects that a patient has a deep vein thrombosis (DVT) in the left lower leg. What is the priority nursing intervention at this time?
 - Perform test for Homans' sign immediately.
 - Massage the area gently to promote circulation.
 - Keep the patient calm and quiet in bed; notify physician.
 - Apply the ordered elastic stockings and sequential compression devices.
- Which of the following activities may be delegated to nursing assistive personnel (NAP) related to helping patients with ambulation?
 - Checking the patient's medications to determine if they may influence the ability to ambulate independently
 - Instructing the patient about the correct use of a walker
 - Inspecting the environment for potential threats to patient safety
 - Evaluating the patient's ability to perform crutch walking
- The nurse is preparing to ambulate a patient with left-sided weakness. Which action demonstrates appropriate care of this patient during ambulation?
 - Assign the strongest health care worker to ambulate her.
 - Stand on the left side of the patient during ambulation.
 - The patient holds her cane in her left hand while the nurse is behind her during ambulation.
 - The nurse should walk on the patient's right side.
- A patient who is going to be using crutches asks about wearing shoes with varying size heels. What statement by the nurse is most accurate?
 - "You should wear shoes with the same size heel."
 - "Try to wear the same shoes for stability and safety."
 - "If you change heel sizes, the crutches will need adjusting."
 - "Wearing shoes with different heel sizes is fine as long as you're comfortable."
- A patient with a left-sided weakness uses a cane. Where should the nurse stand while ambulating this patient?
 - On the patient's left side
 - On the patient's right side
 - Slightly in front on the patient's left side
 - Slightly behind the patient's right side
- A patient is being taught how to get up from the chair to his walker. The nurse knows that teaching has been successful when the patient statement includes which of the following?
 - "Use the walker's handgrips to give myself leverage."
 - "Get toward the back of the chair."
 - "Rock myself several times to get up."
 - "Use the arms of the chair to push up to the walker."
- A patient using a continuous passive motion (CPM) machine reports a sore area on the heel of the affected leg. Which intervention by the nurse would be done first?
 - Checking the functioning of the CPM machine
 - Performing skin care on the affected extremity
 - Notifying the health care provider
 - Assessing the skin on both lower extremities
- The nurse is helping a patient to the side of the bed and recognizes that the patient is experiencing orthostatic hypotension. Which of the following signs and symptoms alert the nurse to this condition? (Select all that apply.)
 - Pallor
 - Bradycardia
 - Nausea
 - Dizziness
 - Irritability

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss the purposes of different orthopedic immobilization devices.
- Describe neurovascular assessments for a patient with an orthopedic injury.
- Describe how to assist in the application of a cast.
- Describe how to care for a patient with a casted extremity.
- Explain the purposes of placing a patient into skeletal or skin traction.
- Explain turning and positioning techniques for patients with impaired mobility.
- Describe strategies to prevent complications from immobility.
- Discuss nursing considerations for the patient with an immobilization device.

Trauma or disease to the musculoskeletal system often requires immobilization, stabilization, and support to affected body parts. Traction, casts, and immobilization devices are examples of methods used to accomplish these purposes and enhance the healing process. When using any of these devices, it is essential that integumentary tissues must remain healthy and intact, both inside and outside of a device. Assessment of the skin includes the detection of pressure, inflammation, irritation, or lesions that could lead to the development of pressure ulcers or infection. Turning, positioning, and range-of-motion (ROM) exercises help to maintain the health of the integumentary tissues and the comfort of the extremity. Orthopedic devices are used to correct or improve deformities or joint contractures. They are also used to treat joint dislocation; reduce, immobilize, and align a fracture (Box 11-1); and prevent and manage muscle spasms. By controlling spasms

and fractured bones, these devices prevent further soft tissue damage. Finally preoperative and postoperative positioning and alignment, skeletal lengthening, and rest of a damaged joint are managed using one or more of these devices.

Traction involves a pulling force applied through use of weights on a part of the body while a second force called *counter traction* pulls in the opposite direction. Age, condition of a patient, and purpose of the traction determine the amount of weight on the pulling force. In straight or running traction the force pulls against the long axis of the body while a patient's body supplies the counter traction. In balanced-suspension skeletal traction (BSST) the amount of force in the traction is equal to the amount of force in the counter traction. A sling or hammock and a system of weights attached to an over-bed frame support the affected part while weight is attached to the pin or wire traversing the femoral bone.

BOX 11-1 Types of Fractures

Closed fracture: Skin intact over fracture
Open or compound fracture: Skin punctured by bone ends
Comminuted: Having three or more bone fragments
Depressed: Bone fragments pushed inward
Displaced: Two parts of fracture that have moved out of alignment
Impacted: Bone ends pushed into one another
Longitudinal: Fracture that runs parallel with bone
Oblique: Fracture that slants across bone
Pathologic: Results from minor stress applied to pathologically weakened bone
Segmental: Segment of bone fractured and detached
Spiral: Twisting around the bone
Transverse: Across the bone

Although there are many types of traction, there are six general principles of traction care: (1) maintain the established line of pull, (2) maintain the traction equipment, (3) maintain counter traction, (4) maintain continuous traction unless otherwise ordered, (5) maintain correct body alignment, and (6) prevent friction and pressure on the skin (Whiting, 2008).

A second treatment method for immobilization involves the use of a cast (Fig. 11-1). Applied externally, a cast immobilizes injured or deformed musculoskeletal tissues in proper position to promote healing. Therefore tissue structures must be in optimal position for healing when the cast is applied. An advantage of using a cast is that it permits early ambulation and in some cases partial weight bearing on the injured extremity.

A third treatment device used with musculoskeletal injury or disorder is the orthotic device. These devices immobilize a body part, prevent deformity, protect against injury, relieve pain and muscle spasm, maintain position until healing is complete, and assist with function. Immobilization devices are applied externally to the body and are available in many varieties, ranging from arm slings to back braces and finger splints. They are made from different materials such as rubber, leather, metal, and plastic.

Walker boots manage soft tissue injury, sprains, stable toe and ankle fractures, and promote postoperative early weight bearing for internal fixation with ligament tears. They provide musculoskeletal stabilization and support through the use of pneumatics. Research has shown that there is no loss of stability when a walker boot is used (Hyer et al., 2010).

EVIDENCE-BASED PRACTICE

The treatment of complicated fractures often includes the use of pins and plates to stabilize the bones and promote healing. The use of external fixation devices allows for early mobilization of patients, increase in patient comfort and compliance, and discharge to home. One of the most common complications is pin tract infections; thus meticulous pin care is essential. To date there is insufficient evidence to be able to identify a single effective strategy of pin-site care that minimizes infection rates (Lethaby et al., 2011). The level of evidence for pin-site care is low, but guidelines outlined by Voda (2011) parallel recommendations made by the National Association of Orthopedic Nurses (Holmes & Brown, 2005):

- Perform pin-site care once a day, twice a day, or weekly, depending on the amount of drainage, the stability of the bone, and pin sites.
- Clean pin site with chlorhexidine 2 mg/mL solution on stable pins (0.9% sodium chloride solution is used in many

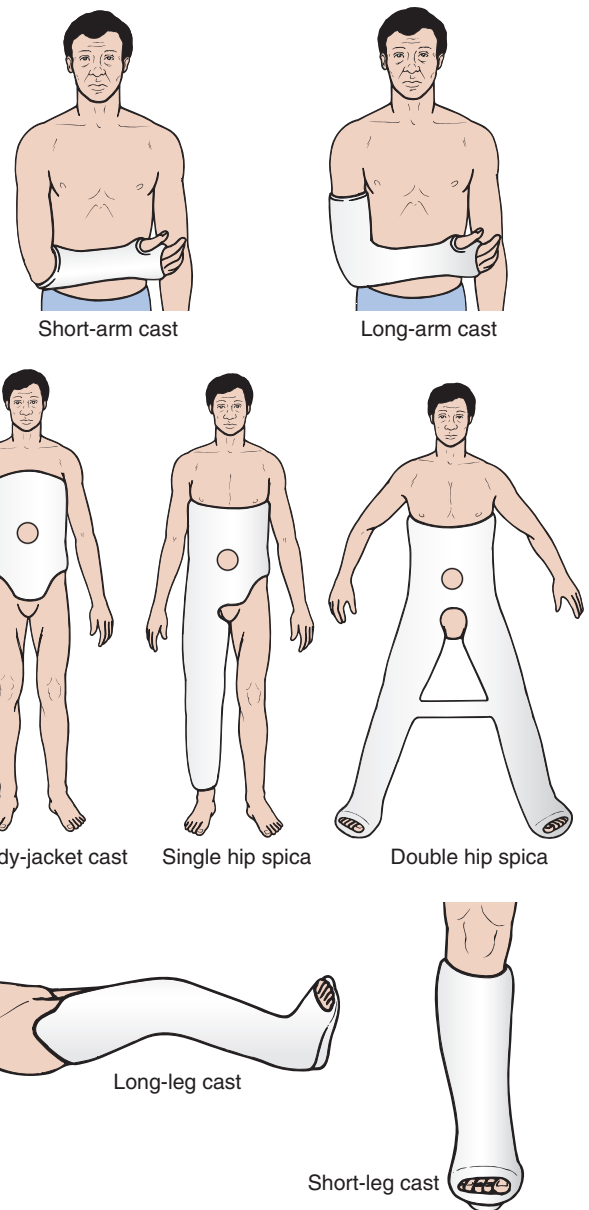

FIG 11-1 Common types of casts.

agencies but has not been shown to be more effective than chlorhexidine).

- Antimicrobial ointment may be ordered for pin sites.
- Cover pin sites with sterile gauze or leave open to air.

PATIENT-CENTERED CARE

When a patient has had a musculoskeletal injury, patient-centered care focuses on minimizing pain managing stabilization and immobilization devices competently and recognizing how the injury affects a patient's general well-being. Routine assessment ensures that you can identify pain early and find appropriate comfort measures.

Explanation of procedures helps to minimize a patient's anxiety and fear. With orthopedic injuries the treatment often results in some degree of immobility and restriction. Lack of ability to function in a normal role may lead to feelings of frustration and even depression.

It is also important to understand a patient's cultural beliefs and values related to issues of immobility. For example, Muslim patients do not accept instructions regarding the use of the alternative hand for hygiene after toileting since in that culture the right hand is traditionally used for clean tasks, and the left for dirty tasks.

Maintain privacy of a patient in a cast or in traction by draping him or her adequately and closing the bedside curtain. Most likely the extremity will be elevated, which may inadvertently leave the patient exposed. Female modesty is valued in many cultures (Spector, 2008).

Safety Guidelines

- 1 Frequently assess a patient's neurovascular status to identify early impairment of any sensory changes. It is essential to monitor the five P's (pain, pallor, pulselessness, paresthesia, and paralysis) of neurovascular status because permanent damage results if circulation is not maintained or restored.

- 2 Determine the permitted ROM for the extremity in a cast or traction. Although it is important to maintain the mobility of the joint, do not move the extremity beyond the limitations of the cast or traction device. Excessive movement impairs wound healing, limits new bone growth, and affects alignment of the extremity.
- 3 Determine a patient's prior level of functioning. Knowing what a patient was able to do assists in determining what level of assistance is now required.
- 4 Determine a patient's normal pattern of elimination. Immobility and analgesics can alter it.
- 5 Review the type of analgesic frequency ordered for the patient by the health care provider. During the first few days the patient may experience acute continuous pain as part of the inflammatory stage, with or without muscle spasms, and needs aggressive pain assessment and management (Voda, 2011).

SKILL 11-1 Assisting with Cast Application

A cast immobilizes an injured extremity to protect it from further injury, provides alignment of a fracture by holding the bone fragments in reduction and alignment during the healing process, and promotes comfort. In addition, a cast maintains a limb in alignment to prevent or correct deformity. Casts are used in many different ways. The use and type of application materials depend on the anatomic area of injury.

Casts materials are natural (plaster of Paris), synthetic acrylic, fiberglass free, latex-free polymer, or a combination of materials. Plaster of Paris is composed of several layers of open-weave cotton roll or strips covered with calcium sulfate crystals. When moistened with water, this material molds easily during application; but drying takes anywhere from 24 to 72 hours, depending on the size of the cast. During drying the cast must be exposed to air, well supported on a firm surface, handled with palms (not fingertips) to avoid indentations, and turned regularly so it dries evenly. Weight bearing is delayed until a cast is completely dry.

Synthetic casting materials are composed of open-weave fiberglass tape covered with a polyurethane resin that is activated by water. This cast sets very quickly, in approximately 15 minutes, and withstands pressure and weight bearing after 20 minutes. It forms a lightweight, sturdy cast that is radiolucent and waterproof. Different colors of this casting material are also available (e.g., pink, purple, navy), which appeal to children and help to maintain the appearance of the cast. These casts are more expensive than plaster casts.

This skill includes frequent assessments before, during, and after cast application, including peripheral neurovascular status. In addition, optimal skin care is important, including removal of dirt and debris before cast application and removal of any plaster crumbs after application.

Delegation and Collaboration

The skill of assisting with cast application may be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP by:

- Instructing them in the method of positioning a specific patient with mobility restrictions.
- Explaining the patient self-reports (e.g., pain, numbness in fingers or toes) to report to a nurse as soon as possible.

Equipment (may be on cast cart) (Fig. 11-2)

- Plaster rolls (sizes include 2-, 3-, 4-, and 6-inch rolls) or cast materials such as fiberglass, casting tape, or plastic, depending on purpose of cast or specific patient condition
- Padding material (felt, stockinette, Webril, or gore lining)
- Plastic-lined bucket or basin filled three-fourths full with warm water
- Clean gloves, apron, or protective cover
- Cart, chair, and fracture table scissors
- Paper or plastic sheets
- Cast cutter (if old cast is to be removed)
- Clean cast saw blades

FIG 11-2 Casting materials.

STEP

RATIONALE

ASSESSMENT

- | | | |
|---|--|--|
| 1 | Assess patient's ability to cooperate and level of understanding concerning the cast application process. | Sudden movement during procedure could cause injury. |
| 2 | Inspect condition of skin that will be under the cast. Specifically note any areas of skin breakdown, rashes, bruising, or incisional wound. | Determines need for additional skin care before cast application. Provides baseline for close observation after cast is applied. |

Clinical Decision Point *Patients with skin breakdown or skin lesions may not be candidates for casting.*

- | | | |
|---|--|--|
| 3 | Assess neurovascular status of area to be casted. Specifically note alteration of motor and sensory function and skin color, temperature, and capillary refill. Compare with opposite extremity or surrounding tissues. Pay attention to tissues distal to the cast. | Changes in neurovascular status may occur after casting; thus it is important to know baseline status. |
| 4 | Assess patient's pain status on a scale of 0 to 10. | Pain scale provides baseline to determine efficacy of nursing comfort measures. |
| 5 | Determine extent to which patient will be able to use casted extremity. | Predicts degree of assistance that is needed for self-care and/or ambulation. |
| 6 | Assess patient's understanding of the normal bone healing process. | Serves as a baseline for teaching patient how to care for casted extremity in the home. |

NURSING DIAGNOSES

- | | | |
|---|--|--|
| <ul style="list-style-type: none"> • Acute pain • Bathing, dressing, and toileting self-care deficit • Deficient knowledge | <ul style="list-style-type: none"> • Impaired home maintenance • Impaired physical mobility • Ineffective peripheral tissue perfusion • Risk for impaired skin integrity | <ul style="list-style-type: none"> • Risk for injury • Risk for peripheral neurovascular dysfunction |
|---|--|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | | |
|---|--|--|
| 1 | Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient has edema of $\geq 1+$, soreness, mild pain, and some limitation of range of motion (ROM), but less than 25% decrease in active ROM of affected extremity after cast application. • Skin of tissues below cast is warm and pink, with capillary refill of less than 2 seconds. Pulses distal to cast are palpable, strong, and regular. • Patient verbalizes no abnormal or unusual sensations and is able to move fingers or toes below casted part. • Cast remains clean, without indentations or fraying, until removal. • Patient requires minimal assistance with usual activities of daily living (ADLs) after extremity is casted. • Patient verbalizes comfort after cast in place. Rates pain less than 4 on a scale of 0 to 10. • Patient verbalizes cast care techniques. | Cast limits normal function of affected tissues. |
| 2 | Instruct patient, parent, and other caregivers how to facilitate application of cast by maintaining affected part in desired position. | Neurovascular function to body part is maintained (Boyd et al., 2009). |
| | | Skin is free of pressure and friction from cast edges. |
| | | Cast may interfere with ability to dress, feed, or bathe oneself. |
| | | Injured tissues and bone are stabilized. |
| | | Verbalizes cast care instructions and techniques. |
| | | Cast holds tissues in position in which they are held during cast application. Patient teaching reduces anxiety and increases cooperation. |

IMPLEMENTATION

- | | | |
|---|---|---|
| 1 | Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (2012). |
| 2 | Administer analgesic before cast application: oral (PO), 30 to 40 minutes before; intramuscular (IM), 20 to 30 minutes before; intravenous (IV) 2 to 5 minutes before. If patient has a patient-controlled analgesic pump (PCA), instruct him or her to administer a dose 2 to 5 minutes before the cast application. | Reduces pain during cast application. Provides optimal analgesic effect. Often muscle spasms are treated more effectively with skeletal muscle relaxants than with opioids. |

STEP

RATIONALE

- 3 Perform hand hygiene and apply clean gloves. NOTE: Use latex-free gloves if there is a risk of an allergic reaction.
- 4 Help health care provider or certified technician position patient and injured extremity as desired, depending on type of cast to be used and area to be casted.
- 5 Prepare skin that will be enclosed in cast. Clean skin with mild soap and water and change dressing (if present). Skin must be completely dry before application of cast.
- 6 Explain that patient may experience warmth during cast application process.

- 7 Assist with application of padding material around body part to be casted (see illustration). Apply minimum of four layers of padding. Avoid wrinkles or uneven thickness.
- 8 Hold body part or parts to be casted or assist with preparation of cast materials.
 - a *Plaster cast:* Mark end of roll by folding one corner of material under itself. With your thumb under outer edge, submerge plaster roll under water in casting bucket or plastic basin until bubbles stop; squeeze slightly and hand roll to person applying cast.
 - b *Synthetic cast:* Submerge cast roll in lukewarm water for 10 to 15 seconds. Squeeze to remove excess water. You can use a water bottle to apply water to casting material.
- 9 Continue to hold body part(s) as necessary as cast is applied (see illustration) or supply additional rolls of casting tape as needed.

- Reduces transmission of microorganisms. Synthetic cast can leave glue-like resin on hands. Prevents exposure to latex allergen. Parts to be casted must be supported and in optimal alignment.
- Reduces complications to underlying tissues after casting. Gentle manipulation prevents pain or additional injury.
- Plaster and fiberglass cast materials give off heat from a chemical reaction when drying. This warmth usually dissipates after approximately 15 to 30 minutes. Make sure there that is enough padding to decrease chance of thermal injury as cast is setting (Boyd et al., 2009).
- Prevents pressure points under cast. Four layers of padding have been shown to decrease incidence of burning when cast is removed (Satryb et al., 2011).
- Support of body part may also require application of slight manual traction.
- Once dampened, the end of the casting tape may be difficult to find. Dampened plaster rolls are unrolled and molded to fit extremity or body part being casted.
- The polyurethane prepolymer is activated by the application of water.
- Support of body part involves applying slight manual traction, if desired, to maintain optimal position. Thickness of cast determines strength.

STEP 7 Padding under cast is smooth.

STEP 9 Supporting extremity during cast application.

- 10 Hold body part while casting tape is applied and molded. Synthetic tape is applied with slight tension. When wrapping is complete, gently compress with hands (see illustration).

Casting tape has synthetic adhesive or glass-fiber materials that dry quickly and are lightweight. Compression promotes bonding of cast layers. Plaster cast materials are smoothed at the end to finish outside of cast and ensure that plaster has bonded to other layers as well.

STEP

RATIONALE

STEP 10 Applying synthetic cast roll.

- | | |
|--|---|
| <p>11 Provide walking heel, cast brace, bar, or other cast stabilization material as requested by health care provider.</p> <p>12 Assist with “finishing” cast by folding edge of stockinette over outer edge of cast to provide smooth edge. Unroll dampened plaster roll over stockinette to hold it in place. Cushion any rough edges of cast with tape or moleskin.</p> <p>13 Using scissors, trim cast around fingers, toes, or thumb as necessary.</p> <p>14 Depending on tissue to be casted:</p> <ul style="list-style-type: none"> a Elevate casted tissue to heart level on two or three cloth-covered pillows or in a sling. Avoid completely encasing cast. Air dry. If ice is ordered, place to the side of casted extremity to prevent indentations on the top. b When applying a sling, ensure that sling supports but does not encase cast. <p>15 Remove and dispose of gloves and other disposable equipment into appropriate receptacle. Perform hand hygiene.</p> <p>16 Using palms of hands to support casted areas, help patient with transfer to stretcher or wheelchair for return to nursing unit or preparation for discharge. Use additional personnel to transfer patient safely, especially in spica or other body cast.</p> | <p>Ambulation may be permitted with partial weight bearing on affected extremity after cast has dried. Bars stabilize spica cast, or “posts” (metal poles) stabilize four-poster cast. Braces incorporated into cast assist in joint motion and mobility. Smooth edges decrease chance of skin irritation or tissue injury. By finishing cast with stockinette, later petaling with tape is not required when cast is dry (Boyd et al., 2009).</p> <p>Cast should be snug but should not constrict uninvolved joint movement or circulation.</p> <p>Pillows prevent indentations, which could harden and cause underlying pressure. Elevation enhances venous return and decreases edema. Covering cast delays or impedes drying.</p> <p>Covering (encasing) impedes air movements and delays drying.</p> <p>Reduces transmission of microorganisms.</p> <p>Safety in transfer requires additional personnel, use of pillows to support cast, side rails, and in some cases restraints.</p> |
|--|---|
- Clinical Decision Point** Synthetic casts are dry or set in 7 to 15 minutes. Soft tissues around affected area may swell from processes of “reducing” or manipulating before cast was applied.
- | | |
|---|--|
| <p>17 Reposition patient every 2 hours. Do not rest heel of the cast on bed or pillow.</p> <p>18 Inform patient to notify care provider of any alteration in sensation, numbness, tingling, burning, pain on passive motion, or inability to move fingers or toes in affected extremity (Voda, 2011).</p> | <p>Prevents any one area of cast from receiving continuous pressure. Avoids indentation of cast.</p> <p>Edema within casted extremity causes pressure on nerves, blood vessels, and muscle tissue. This leads to compartment syndrome, neurovascular deficit, and tissue necrosis.</p> |
|---|--|

STEP

RATIONALE

EVALUATION

- | | |
|---|---|
| <p>1 Observe patient for signs of pain or anxiety: ask him or her to rate pain on a scale of 0 to 10, observe for discolored or pale fingers or nail beds, inability to move body parts distal to cast, pain on passive motion of distal body parts, hyperventilation, nausea and/or vomiting, tachycardia, and blood pressure elevation.</p> <p>2 Perform neurovascular assessment every 1 to 2 hours for first 24 hours. Assess for pain, pallor, pulselessness, paresthesia, and paralysis (Table 11-1). Compare findings with precasting application neurovascular assessment (see illustration).</p> | <p>These are signs of compartment syndrome, cast syndrome, or severe claustrophobia (common for patients in spica or body cast) from snugness of cast. Reposition patient and reassess extremity. If unresolved, need to immediately notify health care provider.</p> <p>Neurovascular status reflects vascular supply or pressure to tissues, indicating functioning and viability of tissues.</p> |
|---|---|

STEP 2 Assessing capillary refill.

- | | |
|--|---|
| <p>3 Observe condition of cast and assess for edema of tissues distal to cast.</p> <p>4 Palpate temperature of tissues around casted area for warmth and assess hot spots, which could indicate underlying infection.</p> <p>5 Ask patient to perform ADLs and ROM within limitations of cast. Compare ROM in noncasted extremity.</p> <p>6 After cast is dry, observe patient perform and verbalize knowledge of cast care.</p> | <p>Broken edges of cast can cause skin irritation. Drainage on cast can indicate underlying infection. Edema results from trauma or venous stasis. Rarely does heat from plaster drying contribute to development of edema.</p> <p>Warmth of tissues distal to cast usually indicates adequate perfusion.</p> <p>Determines change in ROM or ability to perform self care.</p> <p>Return demonstration objectively measures patient's learning.</p> |
|--|---|

Unexpected Outcomes

- 1 Patient experiences impaired mobility related to cast application.
- 2 Patient develops pressure ulcer over bony prominence, or skin irritation occurs at cast edges.
- 3 Patient reports increased severity in pain after cast application.

Related Interventions

- Assist with ROM exercises every 3 to 4 hours.
- Teach isometric exercises.
- Position off bony prominence and turn frequently.
- Health care provider may split, window, bivalve, or remove cast.
- Cut small pieces (petals) of adhesive tape or moleskin 2.5 to 5 cm (1 to 2 inches) and tape smoothly over edge of cast. Pay close attention to edges where there may be more movement such as around fingers and toes.
- Elevate casted extremity on a pillow. Adjust elevation of pillows as necessary.
- Apply ice bags along sides of cast.
- Increase frequency of neurovascular checks.
- Assess tightness of cast by checking with two fingers around edges. Cast should be snug but not tight.
- If pain continues, notify health care provider before administering analgesics (analgesics do not relieve edema and could mask symptoms).

- 4 Patient develops compartment syndrome with severe pain unrelieved by analgesics; change in neurovascular status such as cold extremity, decreased capillary refill, swelling, pallor, diminished pulse, numbness, tingling, or altered motion of distal parts occurs.
 - 5 Patient in body or hip spica cast develops nausea, vomiting, feeling of abdominal fullness or pain, which indicate cast syndrome (superior mesenteric artery syndrome), in which the duodenum is compressed between the superior mesenteric artery and the spine.
 - 6 Patient is unable to demonstrate cast care.
- Notify health care provider immediately.
 - Prepare to bivalve cast using cast cutter. Cut through underlying wadding and padding.
 - Change patient from supine to prone position.
 - Give nothing by mouth.
 - Notify health care provider and prepare to cut abdominal window, bivalve cast, and/or insert nasogastric tube.
 - Reinstruction is necessary. May need to incorporate teach-back method to ascertain level of understanding.

Recording and Reporting

- Document cast application, condition of the skin, status of circulation (before and after application), and motion of distal part.
- Record instructions given to patient and family.
- Report abnormal or unusual findings from neurovascular assessments and symptoms of compartment syndrome immediately.
- Record odor and drainage from cast. Report to health care provider.

Special Considerations

Teaching

- Teach patient to realign pillows to promote cast drying.
- Teach patient about effects of pressure from cast on underlying skin and tissue.
- Prepare patient for itching sensations under cast. Patient should avoid sticking objects down or in cast to scratch because these objects can cause breaks in underlying skin and subsequent infections. The patient's health care provider can order medication to control itching. May teach patient to tap onto cast, blow cold air with hair dryer at sides of cast (Musher, 2010), or try scratching on the opposite extremity.

- If patient must use crutches, instruct in crutch-walking techniques (see Chapter 10).
- Teach patient proper ROM and isometric exercises for affected extremity.
- Caution patient against drying wet cast with hair dryer; this can cause plaster to crack or skin underneath to be damaged. Using a hair dryer does not dry the cast thoroughly and leads to development of mold.

Pediatric

- Teach parents or other caregivers to protect cast from moisture or unnecessary wear. Plastic wrap placed around perineal area during urination or defecation prevents soiling. Protect cast with a plastic bag or plastic wrap when the child bathes or showers. With a spica cast, tuck the ends of a small disposable diaper around the edges of the casted area to cover and protect the perineum in babies (Hockenberry and Wilson, 2011).
- Children are particularly prone to placing objects into casts to scratch. Assess edges of cast to ensure that the child has not done this (Hockenberry and Wilson, 2011).
- Use antihistamines and a hair dryer set to cool for itching (Hockenberry and Wilson, 2011).

TABLE 11-1 Five P's of Neurovascular Assessment

Criteria	Assessment	Rationale
Pain	Determine amount and severity of pain if present. Ask patient for descriptions; avoid coaching patient with words to describe pain.	Manipulation and reduction may produce dull, aching pain as a result of pressure on nerve endings. Patients vary in perception and tolerance of pain. Further assess pain on passive motion, unrelenting pain, or pain out of proportion because it may signify compartment syndrome. Sudden increase in pain may signify thrombus formation.
Pallor	Observe color of tissues distal to cast. Older adults may have bluish color normally; however, no other signs of circulatory compromise should be present.	Pink indicates that arterial perfusion is normal, whitish color signifies decreased arterial supply, and bluish color signifies venous stasis.
Pulselessness	When possible, palpate distal pulse of casted extremity; note presence and strength of pulse. Assess capillary refill by pressing on toenail or fingernail (if cast is on extremity), releasing, and noting "pinkening" of nail; nail should "pink up" in 2 seconds or less.	Weak or absent pulse may indicate decreased circulation to casted area. Blanching on pressure with subsequent capillary refill indicates arterial perfusion. Capillary refill is too sluggish if refill takes more than 3 seconds. It takes 2 seconds to say "capillary refill" slowly and 4 seconds to repeat it once.
Paresthesia	Assess for numbness, tingling, or abnormal sensations.	Abnormal sensations may indicate nerve damage and/or development of compartment syndrome.
Paralysis	Assess for ability to move fingers, toes, or extremity.	Paralysis may indicate nerve damage and/or development of compartment syndrome.

Gerontologic

- Some older nonverbal patients do not express pain, leading you to believe that there is none. Patients may express pain through crying, agitation, or restlessness (Ebersole et al., 2008). Older adults with changes in mental status make pain assessment difficult.
- Lightweight, synthetic casts are better for older adults. Cast is less restrictive, and the light weight assists patients to maintain better balance.
- Age-related decreased muscle strength in older adults is a result of loss of skeletal muscle and may cause difficulty in ambulating with a cast.
- Some older adults have reduced sensation as a result of decreased skin receptors and are less able to detect compression.

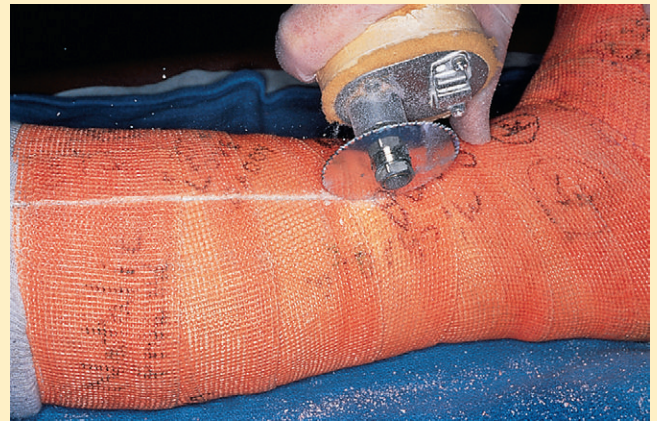

Home Care

- Instruct patient that rest, ice, and elevation of affected extremity help to reduce swelling. Instruct him or her to place ice on either side of cast, not directly on top.

- Inform patient to inspect cast daily and petal any rough edges to reduce risk for trauma to underlying skin and need for cast changes.
- Have patient inspect cast daily for foul odor, which indicates skin excoriation or infection under cast; monitor neurovascular status, paying particular attention to blueness or paleness of nails, pain, feeling of tightness, numbness, or tingling sensation.
- Instruct patient to keep plaster of Paris cast dry. When bathing, patient must not submerge casted extremity because cast absorbs water, which can lead to its crumbling. If cast becomes wet, dry immediately. Instruct patient to inform health care provider of wet or damaged cast.
- Clean synthetic casts with warm water and mild soap.

PROCEDURAL GUIDELINE 11-1 Care of a Patient During Cast Removal

When caring for patients with casts, it is also important to understand the techniques for cast removal, which consist of removing the cast and padding, followed by skin care to the affected areas. The cast is removed with a noisy cast saw, but the procedure is painless because the saw vibrates and does not cut the skin. However, it is necessary to adequately prepare the patient for cast removal. A small child or confused patient may need gentle restraint during removal to prevent any injury. When removing a synthetic cast (with gore lining), it is important to remove gently to prevent burns from the heat generated by the vibrating saw. After cast removal the patient may experience some tenderness, soreness, muscle weakness and atrophy, and a buildup of dead skin cells.

STEP 3 Vibration of cast cutter generates heat.

Delegation and Collaboration

The skill of assisting with cast removal can be delegated to nursing assistive personnel (NAP) who have specific training; but the nurse is responsible for assessing the patient's condition. The nurse directs the NAP by:

- Informing them about preferred positioning methods for specific patients.
- Informing them about the proper method of treating the skin following cast removal.

- 4 Describe the expected appearance of the extremity. Skin under cast is often scaly with dead cells that slough off. Muscle atrophy occurs from disuse.
- 5 Describe and demonstrate the loud noise of the cast saw.
- 6 Perform hand hygiene. Apply clean gloves and eye goggles or protective glasses to self and patient.
- 7 Stay with patient and explain progress of procedure as cast and underlying padding are removed (see illustration).

Equipment

- Cast saw
- Plastic sheets or paper
- Cold water enzyme wash
- Skin lotion
- Basin, water, washcloths, and towels
- Scissors
- Clean gloves
- Eye protection for patient and health care provider

STEP 7 Cutting through wadding under cast with scissors.

Procedural Steps

- 1 Assess patient's understanding of and response to upcoming cast removal.
- 2 Help with positioning patient.
- 3 Describe the physical sensations to expect during cast removal (vibration of cast saw generates heat) (see illustration).

PROCEDURAL GUIDELINE 11-1 Care of a Patient During Cast Removal—cont'd

- 8 Inspect tissues underlying cast after removal.
- 9 If skin is intact, apply cold-water enzyme wash (if available) to skin and leave on for 15 to 20 minutes. Use oil or mild soap and water to soften crusts. Do not scrub skin.
- 10 Gently wash off enzyme wash or soap and water. If possible, immerse tissues in basin or tub to assist in dead cell removal.
- 11 Pat extremity dry. Apply generous coat of lotion to patient's skin.
- 12 Dispose of used supplies and equipment. Remove and dispose of gloves. Perform hand hygiene.
- 13 After cast removal, explain and provide written skin care procedures for patient before discharge (Box 11-2).
- 14 Obtain health care provider order to perform active and passive range of motion and clarify level of activity allowed.
- 15 Instruct patient to observe for swelling and continue to elevate extremity no higher than the heart to manage edema (Sattryb et al., 2011).

BOX 11-2 Care After Cast Removal

Skin Care

- Apply enzyme wash solution such as Woolite or Delicare and leave in place for at least 20 minutes. The enzymes in the solution loosen dead cells and emulsify fatty or crusty lesions but cause no skin irritation.
- After 20 minutes, immerse the area in warm water and gently swab with a soft cloth.
- Rinse with clear warm water and pat dry.
- Apply a moisturizing skin lotion or a little oil, gently massaging it in to help maintain the integrity of the tissues.
- Repeat these steps in 24 to 48 hours, after which the area should need no special care.

Relieving Edema

- Apply cloth-covered ice bags if there is significant edema. Do not apply ice directly to the skin.
- Elevate affected extremity for 24 hours or when swelling occurs.

Managing Tenderness, Weakness, and Discomfort

- Take prescribed analgesic every 3 to 4 hours to develop a therapeutic blood level and continue the medication for 24 to 48 hours.
- Immerse the part or the entire body in warm water and gently exercise the muscles under water.
- Begin to reuse affected tissue and muscles slowly to decrease resulting pain. Explain that usually it takes twice as long as the part was in a cast to regain full function.
- Perform prescribed muscle exercises with 5 to 10 repetitions every 4 hours while awake to aid in regaining muscle strength. Take a non-narcotic analgesic and soak in warm water before exercise if muscle soreness persists. Soreness should lessen as muscle gains strength. Health care provider may prescribe a consultation with a physical therapist to prescribe appropriate exercises to increase mobility and strength.

SKILL 11-2 Care of a Patient in Skin Traction

Skin traction is the application of a pulling force directly to the skin and soft tissue that indirectly pulls on the skeletal system. It immobilizes a fracture and relieves muscle spasms and pain through the use of continuous traction. Skin traction is usually used for temporary immobilization until the fracture can be repaired surgically by open reduction and internal fixation (ORIF) or by skeletal traction (Wheeles, 2011). The health care provider issues written orders for specific traction weights, bed position, and turning regimen. Skin traction is applied by skilled practitioners with appropriate knowledge (Jester et al., 2011). There are several types of skin traction.

- 1 *Buck's extension*: It is the most common type of adult skin traction. It is applied to one or both legs using straps or a commercially prepared foam boot with Velcro straps (Fig. 11-3). This is then attached to a spreader bar, and a weight is attached to the end of the extremity. No more than 7 lbs of weights are used. Buck's extension provides temporary immobilization of hip fracture and reduces muscle spasms, contractures, and dislocations.
- 2 *Dunlop's traction*: This type of traction applies 7 to 10 lbs of weight to an upper limb for treatment of contractures or fractures of the humerus or elbow (Fig. 11-4).
- 3 *Russell's traction*: This type of traction uses skin traction on the lower leg; a padded sling is placed under the knee. There are two lines of pulling force: one is along the longitudinal plane of the lower leg, and one is perpendicular to the leg. The hip and knee are immobilized in a flexed position (Fig. 11-5).

FIG 11-3 Buck's extension.

FIG 11-4 Dunlop's traction.

FIG 11-5 Russell's traction.

FIG 11-6 Cervical traction.

4 Cervical traction: Cervical traction uses a head halter with a cutout for the ears and face. The halter cradles the chin and has straps leading to a bar attached to ropes, pulleys, and weights (Fig. 11-6). Between 7 and 10 lbs of weight are applied. Cervical traction immobilizes conditions of the cervical vertebrae, not fractures. It may be removed periodically.

The more weight applied to traction, the greater the risk of skin breakdown. Contraindications to the use of skin traction include pressure ulcers, dermatitis, burns, or abrasions. Older patients and patients with tissue perfusion problems are at increased risk of skin breakdown.

When caring for patients in skin traction, regularly monitor them for correct maintenance of the traction device and proper musculoskeletal alignment. Agency policy may specify the frequency of assessment, but it should be at least every 4 hours. Traction maintenance involves monitoring the weights, the direction of pull, the ropes and pulleys, and all connections (Box 11-3).

BOX 11-3 Traction Assessment

1 Maintain the Established Line of Pull

The direction of pull should be along the long axis of the bone. Weights hang freely, not hitting the bed or resting on the floor. Recheck the position of the weights if the level of the bed is altered. Avoid (1) bumping against the weights when walking near the bed, and (2) allowing the weights to sway. Both movements can cause pain for a patient in traction. It is preferred that the weights not hang over a patient; if this is necessary, tape the ropes so the weights will not fall on a patient.

2 Maintain Traction Equipment

Traction rope rests in the groove of the pulley and moves easily. Monitor the rope for fraying. Securely tie the knots in the traction rope and tape the rope ends. Ensure that the rope knots are not lodged against the pulley because this will interfere with the line of pull. Ensure that the pulley, spreader bar, and footplate do not rest against the foot of the bed.

3 Maintain Counter traction

To provide traction ensure that counter traction is maintained by the weight of the patient's body, the pull of the weights in the opposite direction, or elevation of the bed. For example, the feet of a patient in Buck's traction do not touch the foot of the bed; or, if a patient is in cervical traction, the head does not touch the head of the bed.

4 Maintain Continuous Traction Unless Ordered Otherwise

Maintain continuous traction unless the health care provider orders intermittent traction. To change a patient's position in bed, do not lift or adjust the weights if traction is continuous. Ensure that the correct amount of weight is used. For intermittent traction gently place and slowly remove the weights, avoiding jerking or suddenly moving the weights because these could jar a patient.

5 Maintain Correct Body Alignment

Be sure patients have correct body alignment while lying centered in the bed. Instruct patients about any restricted positions. Be sure that a patient does not angle the body or lean off the side of the bed because the line of traction pull would then be changed or interrupted.

6 Prevent Friction to the Skin

Remove skin traction and reapply daily. The usual amount of weight used for skin traction in adult patients is 5 to 8 lbs. With any traction monitor the skin for evidence of redness, bruising, or skin breakdown. Avoid friction or pressure from the equipment.

Delegation and Collaboration

Neurovascular assessment of the patient's condition cannot be delegated. The skill of assisting with application of skin traction may be delegated to nursing assistive personnel (NAP) who have had specific training. The nurse instructs the NAP by:

- Instructing how to adapt the skill for specific patients.
- Instructing to inform the nurse if patient demonstrates any change in skin condition or complains of discomfort.

Equipment

- ❑ Overhead frame for attachment of traction
- ❑ Traction bar
- ❑ Cross clamp and pulley
- ❑ Buck's extension boot or moleskin and elastic bandages
- ❑ 1- to 7-lb weights
- ❑ Spreader bar

STEP

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <p>1 Assess patient's knowledge of reason for traction.</p> <p>2 Assess patient's overall health condition, including degree of functional mobility, current medical conditions, and ability to perform activities of daily living (ADLs).</p> <p>3 Assess integrity and condition of skin before application of traction.</p> <p>4 Assess patient's position in bed: supine, perpendicular to ends of bed, with affected limb in proper body alignment.</p> <p>5 Assess patient's severity of pain using scale of 0 to 10 and determine need for analgesics before application of traction.</p> <p>6 Assess neurovascular status of extremity distal to traction, including skin color, temperature, capillary refill, presence of distal pulses, sensation, and patient's ability to move digits.</p> <p>7 Review medical record for amount of weight to be used in traction.</p> | <p>Determines concerns and need for further teaching.</p> <p>Determines patient's ability to tolerate traction, self-care ability, and need for assistance.</p> <p>Establishes baseline for skin integrity.</p> <p>Ensures that pull of traction is at proper angle in relation to patient's body.</p> <p>Analgesics decrease patient's discomfort while traction is applied, and assessment serves as baseline for later comparison and evaluation.</p> <p>Establishes baseline for early detection of neurovascular deficits.</p> <p>Ensures appropriate weight is applied at all times.</p> |
|--|--|

NURSING DIAGNOSES

- | | | |
|--|--|---|
| <ul style="list-style-type: none"> • Acute pain • Bathing, dressing, and toileting self-care deficit | <ul style="list-style-type: none"> • Ineffective peripheral tissue perfusion • Deficient knowledge • Impaired physical mobility | <ul style="list-style-type: none"> • Risk for impaired skin integrity • Risk for peripheral neurovascular dysfunction |
|--|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient participates in ADLs as much as possible within limitations. • Skin under traction boot or elastic wrap remains intact, without redness or breakdown. • Patient verbalizes increase in comfort after traction application and rates pain as 4 or lower on a scale of 0 to 10 after repositioning and administering analgesics. • Neurovascular status remains stable. Distal skin tissue remains warm, pink, with capillary refill of 3 seconds or less. Patient verbalizes no abnormal sensations and is able to move fingers or toes distal to fracture site. • Patient verbalizes understanding of procedure, including traction setup and mobility restrictions. • Patient moves all extremities independently by discharge date. | <p>Activities are performed safely and without injury.</p> <p>Skin is free of pressure and/or pulling.</p> <p>Injured tissues and bone are stabilized.</p> <p>There is no evidence of increased pressure within muscle compartment and no neurovascular deficit (Parvizi, 2010).</p> <p>Promotes cooperation and reduces anxiety. Having patient teach back procedure allows for assessment of understanding.</p> <p>No neuromuscular injury occurs.</p> |
|---|--|

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Prepare patient by discussing procedure.</p> <p>3 Administer analgesic for acute pain and a muscle relaxant for spasms in advance of traction application.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Assists with decreasing anxiety.</p> <p>Allows drugs to reach peak effect at time of traction application, thereby reducing pain and resultant muscle spasm.</p> |
|--|---|

STEP	RATIONALE
<p>4 Perform hand hygiene.</p> <p>5 <i>Buck's extension</i>: Position patient supine and nearly flat with no more than 30 degrees of elevation, with affected leg halfway between edge and middle of bed.</p> <p>6 Apply clean gloves and wash affected extremity gently and pat dry. Do not shave extremity.</p> <p>7 Apply foam boot, moleskin, or elastic bandages to affected extremity, proceeding from distal to proximal. For <i>Buck's extension</i>:</p> <p>a Before placing foam boot, wrap leg in soft roll. Ensure that boot fits snugly.</p> <p>b Seat heel properly in traction boot. Do not pad at heel.</p>	<p>Reduces transmission of microorganisms.</p> <p>Maintains pull of traction at proper angle in relation to patient's body.</p> <p>Shaving might nick skin, which could become inflamed and infected under traction straps.</p> <p>Applying in distal-to-proximal pattern prevents trapping of blood in distal region.</p> <p>Boot that is too tight applies pressure to skin, peroneal nerve, and vasculature structures.</p> <p>Prevents pressure on patient's heel.</p>
<p>Clinical Decision Point <i>Skin traction that is too tight puts pressure on nerves and vascular structures, putting patient at risk for an irreversible neurovascular deficit. Skin traction that is too loose will slip.</i></p>	
<p>c Do not apply traction boot over sequential pneumatic compression devices. Instead use foot pumps.</p> <p>8 Attach weight to boot gradually and gently at end of bed. Health care provider determines exact amount of weight to be applied and position to be maintained.</p>	<p>Causes pressure on tissues and does not allow compression device to function.</p> <p>Traction is applied slowly to avoid muscle spasm or pain for patient.</p>
<p>Clinical Decision Point <i>Assess for peroneal nerve damage by noting if there is decreased sensation between patient's great and second toes and an inability to dorsiflex the foot and extend the toes.</i></p>	
<p>9 Inspect traction equipment, making sure that:</p> <ul style="list-style-type: none"> • Knots are secure. • Ropes are in pulleys and not frayed. • Weights are hanging freely, not caught on bed or resting on floor. • Bed linens and bedclothes are not interfering with traction equipment. • Check the four P's of traction maintenance: pounds, pressure, pull, and pulleys. <p>10 Before health care provider leaves, assess patient's position and ask about additional permissible positions for patient and bed.</p> <p>a <i>Buck's extension</i>: Patient is primarily on back but may be allowed to turn to unaffected side for brief periods (10 to 15 minutes).</p> <p>b <i>Dunlop's traction</i>: Patient must lie on back. Bed may be tilted on low shock blocks toward side opposite traction. Head of bed is kept flat.</p> <p>c <i>Russell's traction</i>: Patient lies on back; head of bed may be elevated 30 to 45 degrees, depending on injury.</p> <p>11 Release and reapply traction and provide skin care according to health care provider's order. Traction boot is removed every 4 to 8 hours.</p> <p>12 Remove and dispose of gloves. Perform hand hygiene. Gather unused materials and return to storage areas.</p>	<p>Observation of these checkpoints maintains the appropriate amount of traction and effective immobilization.</p> <p>Ensures patient's safety and position for effective traction.</p> <p>Positioning on side permits back care and relief of pressure to tissues.</p> <p>Tilting uses body for some countertraction.</p> <p>Low-Fowler's position creates most effective traction pull.</p> <p>Permits visualization of skin and opportunity to provide skin care.</p> <p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Observe patient's ability to perform ADLs.</p>	<p>Encourages level of independence in self-care activities to give patients a sense of accomplishment.</p>
<p>2 Frequently assess condition of skin around traction straps or bandages for signs of pressure, color changes, edema, or tenderness.</p>	<p>Ensures early identification of irritation or breakdown. Patient is limited in making minor adjustments in positioning and may need assistance.</p>
<p>3 Observe patient for correct alignment.</p>	<p>Ensures that traction is being maintained.</p>

STEP	RATIONALE
4 Ask patient to rate discomfort on scale of 0 to 10 and to report muscle spasms.	May indicate misalignment of bones or presence of muscle spasms. Initial reaction may be slight increase in soreness or pain until patient is able to relax and allow traction to perform as designed.
5 Assess neurovascular status of extremity distal to traction every 30 minutes after application of skin traction twice, then every 2 hours for 24 hours, and every 4 hours thereafter (see agency policy). Check skin temperature, capillary refill, presence of distal pulses, sensation, and patient's ability to move digits.	Provides objective data concerning peripheral perfusion to tissues.
6 Observe patient's use of trapeze and ability to reposition self correctly.	Prevents pressure ulcers and gives early feedback regarding skin condition.

Unexpected Outcomes

- 1 Patient complains of increased pain, soreness, or stiffness after traction is applied.
- 2 Patient experiences muscle spasms from traction.
- 3 Patient experiences reddened areas on extremity under traction.

Related Interventions

- Administer analgesics as prescribed.
- Remove traction (if permitted by health care provider) and reapply.
- Realign body and/or extremity.
- If pain is unrelieved or occurs on passive motion, notify health care provider of possible neurovascular deficit.
- Administer skeletal muscle relaxants.
- Obtain health care provider order to remove foam boot for 1 hour to relieve pressure.
- Ensure that you can insert one finger between patient's skin and foam boot.
- Increase frequency of skin assessment.
- Apply protective barrier agent (e.g., Aloe Vista or Sween cream) to affected extremity.
- Ensure that heels do not rest on bed or pillow.

Recording and Reporting

- Record assessment of skin underneath traction apparatus, type of traction, and nursing interventions to maintain skin integrity.
- Record neurovascular assessment on flow sheet or nurses' notes and electronic health record (EHR).
- Record length of time that patient is in or out of specific traction.
- Report any neurovascular deficits to health care provider immediately.

Special Considerations

Teaching

- When traction time is decreased or discontinued, teach patient to ambulate slowly within medical guidelines, gradually increasing length of time out of bed and distance walked.
- Teach patient to alert health care provider of changes in level of pain, muscle spasms, and increased numbness.

Pediatric

- Infants and young children have difficulty remaining still and in alignment.

Gerontologic

- Some older adults may have keratoses, rashes, or other lesions that become irritated in skin traction; thus skin traction should not be used in these cases.

- Some older adults have long-standing conditions of musculo-skeletal tissues such as arthritis or gout that could lead to inflamed tissues and skin breakdown.
- Older and chronically ill patients may have increased need for position changes as a result of limitations caused by osteoporosis, osteomalacia, weakened muscles, or increased risk for skin breakdown.
- Older adults' skin heals more slowly, tears more easily, loses its elasticity, and becomes thinner than that of a younger adult (Ebersole et al., 2008). Use pressure-relief devices to reduce the risk for skin breakdown.

Home Care

- Before discharge home, teach family or family caregivers how to manage traction, including positioning, level of mobility, rest, and nutritional considerations.
- Teach family caregivers how to maintain integrity of traction by inspecting at least once daily; weights are free hanging; traction ropes rest in groove of pulley and hang freely; not caught on bed or resting on floor.

SKILL 11-3 Care of a Patient in Skeletal Traction and Pin Site Care

Skeletal traction immobilizes fractures of the cervical spine, fractures of the femur below the trochanter, and some fractures of the bones of the arm or ankle. It is also used for immobilizing the femoral head when there is an acetabular fracture. Skeletal traction is being used less frequently because of newer surgical repair procedures and new trauma management (Musher, 2010). This type of traction is used for patients with multiple traumas who cannot have an immediate surgical repair.

A common form of skeletal traction is balanced-suspension skeletal traction (BSST), which is used for a fractured femur (Fig. 11-7). BSST relieves muscle spasms, realigns the fracture fragments, and promotes callus formation. Callus formation is the development of new supportive bone around the injured site. BSST temporarily stabilizes the patient's condition while waiting for surgical insertion of an internal fixation device such as a plate, screw, or nail. Balanced suspension involves a sling attached to splints around the leg and a Steinmann pin or Kirschner wire supplying the traction (Fig. 11-8, A and B). Sufficient weight to overcome the quadriceps and hamstring muscle spasms ranges between 30 to 40 lbs.

Other common forms of skeletal traction are sidearm traction (with a pin drilled through the lower humerus) and external fixation (used for comminuted fractures with soft tissue injury, skull and facial fractures, and pelvic fractures). For cervical spine fractures, Crutchfield or Garner-Wells tongs are inserted into the skull. Halo traction is frequently used for neurologically intact patients, stabilizing the spinal vertebra and preventing further injury to the spinal cord (Fig. 11-9).

External fixation is a form of skeletal traction that consists of a frame or apparatus to hold pins placed into or through bones above and below a fracture site. External fixation promotes early ambulation and use of other joints while maintaining immobilization of

affected bones. A variety of external fixation devices are used for skull and facial fractures, ribs, bones of the extremities, and pelvic bones (Fig. 11-10).

Skeletal traction involves piercing the skin at the site where the pin enters and exits (Fig. 11-8, C). In the case of external fixation or halo traction, the device attaches to the bone through the skin (Sarro et al., 2010). Slow healing requires longer periods of traction (6 to 8 weeks) to promote bone repair. This prolonged immobilization influences nursing care, which is focused on activities of daily living (ADLs), maintaining traction, and preventing fat embolism and complications of immobility (e.g., skin breakdown, pulmonary emboli).

Because skeletal traction involves placement of a pin, meticulous pin-site care reduces the risk for pin-tract infections. Up to 10% of external fixation pins develop infections (Parvizi, 2010).

FIG 11-7 Balanced-suspension skeletal traction. Traction is applied via Kirschner wire through proximal portion of tibia. Limb is supported by Thomas splint beneath thigh and Pearson attachment beneath lower leg. Footplate attachment prevents footdrop. Weights apply countertraction to Thomas splint and suspend its lower end. Patient can shift position of hips without change in amount of traction.

FIG 11-8 A, Steinmann pin and holder. B, Kirschner wire and tractor. C, Steinmann pin placed in tibial plateau for treatment of distal femoral fracture.

FIG 11-9 Halo traction and vest. (Image courtesy Össur Americas. All rights reserved.)

Pin-site care can reduce the risk of infection and must be implemented using current evidence-based practice guidelines (Rose, 2010). Some agencies have policies outlining pin-site care. Chlorhexidine 2 mg/mL solution or 0.9% sodium chloride solution is recommended for stable pins (Voda, 2011). Some agencies require health care provider orders that specify the frequency of pin care and the cleaning agent to be used.

Delegation and Collaboration

Assessment of the patient's condition and status in skeletal traction cannot be delegated. The skill of assisting with insertion of skeletal pins and pin site care may be delegated to nursing assistive personnel (NAP) once adequately trained in the principles of surgical asepsis. The nurse directs the NAP by:

- Instructing to report any signs and symptoms of inflammation or infection at the pin insertion site.

FIG 11-10 External fixator,

Equipment

Balanced-Suspension Skeletal Traction

- Ropes, pulleys, weights, weight holders
- Thomas splint
- Pearson attachment with sheepskin padding
- Footplate
- Trapeze bar
- Clean gloves

Halo Traction

- Halo ring with four pins
- Molded vest jacket
- Vertical metal bars connecting ring to jacket
- Tracheostomy tray (for emergency resuscitation)
- Allen wrench (allows removal of screws for resuscitation)

Pin-site Care

- Sterile cotton-tipped applicators
- Prescribed cleaning agent. Preferred agent chlorhexidine, 2 mg/mL solution, or 0.9% sodium chloride solution (check agency policy)
- Split 2 × 2-inch gauze barrier (*optional*)
- Topical antibiotic ointment (check agency policy)
- Clean gloves

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's knowledge of the reason for traction, including nonverbal behaviors and responses.
- 2 Inspect integrity and condition of skin over bony prominences and under devices in use. Consider need for special bed or mattress.
- 3 Assess for proper alignment of extremity.
- 4 Assess patient's degree of mobility, ability to reposition and perform ADLs, and current medical condition.
- 5 Assess patient's level of pain using scale of 0 to 10 and determine need for analgesics before procedure begins.
- 6 Following application, assess traction setup: weights hanging freely, ordered amount of weight applied, ropes move freely through pulleys, all knots tight in roles and away from pulleys.

Determines anxiety and need for further teaching.

Determines baseline status of dependent tissues at risk for pressure ulcer formation.

Ensures that pull of traction is at proper angle in relation to patient's body.

Determines baseline status of patient's health status.

Decreases patient's discomfort during traction application and serves as baseline for later comparison.

Ensures that traction functions correctly.

STEP	RATIONALE
7 Prior to application, assess neurovascular status of extremity distal to traction, including skin color, temperature, capillary refill, presence of distal pulses, sensation, and patient's ability to move digits.	Provides baseline information and detects neurovascular deficits.
8 Following pin insertion, assess pin sites for redness, edema, discharge, and odor.	Provides baseline for condition of pin insertion site.
9 Assess respiratory rate, depth, rhythm, and chest expansion.	Pulmonary embolus can occur in patients with spinal cord injury or on prolonged bed rest. Fat embolism syndrome (FES) can occur with long-bone fractures.

NURSING DIAGNOSES

- | | | |
|---|---|--|
| <ul style="list-style-type: none"> • Acute pain • Anxiety • Bathing, dressing, and toileting self-care deficit | <ul style="list-style-type: none"> • Deficient knowledge • Impaired physical mobility • Risk for impaired skin integrity • Risk for infection | <ul style="list-style-type: none"> • Risk for injury • Risk for peripheral neurovascular dysfunction |
|---|---|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient's skeletal deformity is reduced, alignment is maintained, and injury is healed. • Patient performs ADLs independently to all unaffected areas. • Patient's skin remains intact without redness, inflammation, or purulent drainage, especially over pressure points. • Patient is free of neurovascular deficits following application of skeletal traction. Patient verbalizes no abnormal sensations and is able to move fingers or toes below fracture site. • Patient performs range of motion in unaffected extremities. • Patient demonstrates correct use of trapeze. • Patient describes purpose of skeletal traction and follows activity restrictions. 	<p>Skeletal traction promotes healing of fractures.</p> <p>Self-care activities help patient to reduce risk for complications of immobility and give him or her a sense of control.</p> <p>Indicates no development of pressure ulcers or infection.</p> <p>Adequate neurovascular functioning is essential to health and well-being of extremity (Parvizi, 2010).</p> <p>Routine exercise prevents contractures and muscle wasting.</p> <p>Prevents injury, allows patient to participate in repositioning.</p> <p>Demonstrates learning and acceptance of restrictions. Able to repeat back purpose of traction and associated restrictions.</p> <p>No pin site infection present.</p>
<ul style="list-style-type: none"> • Skin around pin sites remains free of redness, edema, or drainage. 	

IMPLEMENTATION

<p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy). Compare identifiers with information on patient's identification bracelet.</p>	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
<p>2 Discuss procedure with patient.</p>	Decreases patient anxiety.
<p>3 Perform hand hygiene.</p>	Reduces transmission of infection.
<p>4 Initial traction setup:</p> <p>a Apply clean gloves and position patient per health care provider's order. Support limb at joint above and below fracture to be placed in traction. Do not move distal parts unnecessarily. Patient will likely be placed in supine position with head of bed slightly elevated.</p> <p>b Health care provider wears sterile gloves and gown while cleaning skin over pin sites and injecting local anesthetic.</p> <p>c Assist (usually by holding spreader bar, splint, or Pearson attachment) while health care provider continues to use drill to insert number of pins needed for traction. Support area of joints not at injury site. Do not move distal portion unnecessarily.</p> <p>d Once traction setup is applied, attach weights and gently lower until rope is taut.</p>	<p>Ensures proper alignment during and after traction application. Movement can cause severe pain or additional trauma.</p> <p>Anesthetic desensitizes pin insertion area. Patient feels pressure during drilling but should not experience pain. Procedure requires surgical asepsis.</p> <p>Movement can cause severe pain or additional trauma.</p> <p>Reduces spasm and discomfort.</p>

STEP	RATIONALE
<p>e Inspect traction setup; ensure that:</p> <ul style="list-style-type: none"> • Knots are secure and footplate is in place. • Ropes and pulleys are not frayed. • Weights are hanging freely, not caught on bed or resting on floor. • Bedclothes are not interfering with traction apparatus. 	Ensures that traction and immobilization are effective.
<p>Critical Decision Point <i>Irreversible muscle and tissue damage can occur within 6 to 8 hours (Hockenberry and Wilson, 2011).</i></p>	
<p>5 Provide pin-site care according to agency policy or health care provider's order.</p>	
<p>a Apply clean gloves and remove gauze dressings from around pins and discard in appropriate receptacle.</p>	
<p>b Inspect pin sites for redness, edema, or purulent drainage. NOTE: Clear drainage and crusting are expected findings. Remove and discard gloves and perform hand hygiene.</p>	<p>These are signs and symptoms of infection. Reduces transmission of infection.</p>
<p>c Prepare supplies.</p>	
<p>d Apply clean gloves and clean each pin site with prescribed cleaning solution by placing tip of moistened sterile applicator close to pin and cleaning away from insertion site. Dispose of applicator. Use new sterile applicator for each swipe.</p>	Removes infectious material without contaminating pin site.
<p>e Repeat process for each pin site.</p>	
<p>f Using sterile applicator, apply small amount of topical antibiotic ointment to pin site (see health care provider order or according to agency policy).</p>	<p>May reduce development of infection. Some health care providers prefer plain soap and water for cleaning pins.</p>
<p>g Cover with sterile 2×2-inch split gauze dressing or leave site open to air (see health care provider order or according to agency policy).</p>	
<p>6 Provide routine traction care.</p>	
<p>a Inspect skin (bony prominences, heels, elbows, sacrum, and areas under appliances) for signs of pressure. Use pressure-relief devices as appropriate. Try to reposition any areas under pressure if possible. Do not massage areas of pressure if there is tenderness, reactive hyperemia (increase in blood flow), or areas of skin breakdown.</p>	Massage to compromised tissues increases risk for breakdown.
<p>7 Provide nonpharmacologic and pharmacologic pain relief as indicated (see Chapter 15).</p>	<p>Pain relief will improve patient's ability to remain active within mobility limitations.</p>
<p>8 Encourage use of unaffected extremities for ADLs and active and passive exercises. Encourage use of trapeze bar for repositioning.</p>	<p>Prevents muscle atrophy and maintains muscle tone for later ambulation.</p>
<p>9 For elimination, provide a fracture pan if needed.</p>	<p>Smaller bedpan is more comfortable and easier to place under patient.</p>
<p>10 Raise appropriate number of side rails as needed.</p>	<p>Provides for patient's safety. Side rails can be considered a restraint.</p>
<p>11 Remove and dispose of gloves if used, gather equipment and supplies, and return to proper storage places. Perform hand hygiene.</p>	<p>Provides for safety and cleanliness and prevents transmission of infection.</p>

EVALUATION

<p>1 Inspect body part in traction for correct alignment.</p>	<p>Determines if traction is functioning as desired.</p>
<p>2 Monitor neurovascular status and peripheral tissue perfusion every 2 hours for the first 24 hours and every 4 hours thereafter (see agency policy).</p>	<p>Permanent neurovascular deficits can occur in as little as 6 hours. Edema in muscle compartment is most likely to develop in first 24 hours after injury. Determines peripheral perfusion to tissues and identifies any neurovascular deficits.</p>
<p>3 Evaluate for presence of pain and muscle spasms on scale of 0 to 10.</p>	<p>Determines response to traction and need for analgesics and muscle relaxants.</p>
<p>4 Observe for local and systemic signs of infection, including purulent drainage and inflammation of pin sites; fever; elevated white blood cell count; continuous, dull, aching pain; redness; or warmth in extremity.</p>	<p>May indicate signs of osteomyelitis (infection of the bone) (Miller, 2008).</p>

STEP

- 5 Monitor respiratory status for FES, atelectasis, and pulmonary embolism every shift.
- 6 Inspect skin, especially around ankle, elbow, foot, or distal tibia, for fracture blisters. Do not rupture blister. Apply hydrocolloid dressing to ruptured blister (see Chapter 39).

RATIONALE

Restlessness, tachycardia, and petechiae of chest are early signs of FES (Miller, 2008).
Fracture blisters are associated with increased interstitial pressure from posttraumatic edema.

Unexpected Outcomes

- 1 Patient has severe edema; marked increase in pain; inability to actively move joints; or increased pain on passive movement, indicating compartment syndrome.
- 2 Patient develops signs of infection or osteomyelitis. This is especially a concern with open fractures and extensive soft tissue injury.
- 3 Patient experiences nerve damage:
 - Peroneal nerve: Footdrop with inability to evert and dorsiflex foot.
 - Radial or median nerve at wrist: Inability to approximate thumb and fingers (radial) and numbness and tingling of thumb, index, middle fingers (median) with wrist drop.
- 4 Patient experiences FES, which is common in pelvic and long-bone fractures. Symptoms include hypoxia, restlessness, mental changes, tachycardia, tachypnea, dyspnea, hypotension, and petechial rash over upper chest and neck.
- 5 Patient experiences deep vein thrombosis with possible pulmonary embolus. Symptoms include dyspnea, chest pain, tachypnea, apprehension, tachycardia, cyanosis, and circulatory collapse.

Related Interventions

- Compartment syndrome is an emergent situation. Notify health care provider immediately.
- Cultures of drainage may be ordered by health care provider.
- Notify health care provider.
- Be prepared to administer ordered intravenous (IV) antibiotics and/or irrigate site with antibiotic solution.
- Encourage fluid intake and provide comfort measures for fever.
- Notify health care provider.
- Eliminate pressure if possible according to type of traction in place.
- Maintain foot in dorsiflexion according to health care provider order (e.g., pillows or orthotic).
- This is a life-threatening emergency. Notify health care provider and initiate resuscitation efforts if indicated.
- Do not massage lower extremity.
- Elevate head of bed (if conscious), administer oxygen, and notify health care provider immediately.

Recording and Reporting

- Record in nurses' notes and EHR the type of traction, site to which traction was applied, time of application, amount of weights, and patient's initial response. It may be helpful to draw a diagram for the chart and post in the room to maintain the correct traction configuration while the patient remains in traction.
- Record in nurses' notes and EHR the site care performed and appearance of pin sites.
- Record on flow sheet specific assessments and frequency of assessments.

Special Considerations

Teaching

- Before discharge teach patient use of ambulatory aid (cane, walker, or crutches); give written instructions to patient and family caregivers.
- Supply patient with dietary instructions with emphasis on protein and calcium to aid in bone and tissue healing.
- Teach patient to notify health care provider of any increase in pain; muscle spasms; increased numbness or tingling; appearance of drainage, redness, or soreness at operative or traction pin sites; and increased temperature over 101° F (38.3° C).

Pediatric

- Blood loss from a fracture poses a greater danger because the blood volume in a child is 70% to 85% of total body weight and only about 60% in an adult (Hockenberry and Wilson, 2011).
- Parents and other caregivers must work together to prevent boredom for children in traction. Parents need to be aware of the possibility of regressive behaviors. School work can be obtained when the child is able to perform those tasks.
- Assure children that someone will always be available to help them while they are in traction.

Gerontologic

- Older adults need lower initial doses of opioids because of the physiologic changes of aging (Meiner, 2011).
- Loss of functional independence may lead to depression (Meiner, 2011).

Home Care

- Following removal of skeletal traction, teach patient to dangle before ambulation, proceed slowly with ambulation, and gradually increase the time and distance ambulated.
- Teach family and patients home safety methods to prevent further injury.

SKILL 11-4 Care of a Patient with an Immobilization Device

Immobilization devices increase stability, support an extremity, or reduce the load on weight-bearing structures such as hips, knees, or ankles. A splint immobilizes and protects a body part. Temporary splints reduce pain and prevent tissue damage from further motion immediately after an injury such as a fracture or sprain. Air splints, Thomas splints, and improvised splints from material on hand are examples of temporary splints applied in emergency situations. Upper-extremity fractures are sometimes managed with splints such as hand and digital splints or sugar-tong splints. Slings support splints, casts, or injured upper extremities (Fig. 11-11). They are available commercially or can be made for almost any body part. Velcro or buckle closures permit these devices to be adjusted to fit a body part of almost any size and shape.

The abduction splint or pillow, used after hip replacement surgery, maintains a patient's legs in an abducted position (Fig. 11-12). This permits a patient to be turned without changing the position of the healing limb and prevents dislocation of the hip prosthesis. The splint is removed easily for nursing care (e.g., skin care, dressing changes, and neurovascular assessments) and ambulation with physical therapy. A posterior splint with elastic wraps is sometimes used to support an extremity.

Cloth and foam splints, known as *immobilizers*, provide long-term immobilization (Fig. 11-13). Immobilizers treat sprains

and dislocations that do not require complete and continuous immobilization in a cast or traction. Other common types of immobilizers include cervical collars (hard or soft), vinyl wrist forearm splints, belt-type shoulder immobilizers, and knee immobilizers. Molded splints made of plastic provide support to patients with chronic injuries or diseases such as arthritis. They maintain the body part in a functional position to prevent contractures and minimize muscle atrophy during periods of disuse. Splints and immobilizers can be removed quickly for assessment of the skin or a wound.

Braces support weakened structures during weight bearing. For this reason they are made of sturdy materials such as leather, metal, and molded plastic. Chest and abdominal braces such as the Boston brace immobilize the thoracic and lumbar vertebral column to treat scoliosis (curvature of the spine). The brace does not correct the curve but instead prevents progression. Lumbar braces support lumbar and sacral tissues after spinal surgery. Leg braces hold the thigh, leg, and foot in functional positions for weight bearing and ambulation. Both short- and long-leg braces support weak leg muscles, aid in the control of involuntary muscle movement, and maintain surgical correction during the postoperative healing process.

Delegation and Collaboration

The skill of caring for a patient wearing a brace, sling, splint, or other immobilization device can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP by:

FIG 11-11 Sling for shoulder/arm immobilization. (Courtesy Wanda Dubuisson.)

FIG 11-12 Abduction pillow.

FIG 11-13 Examples of immobilizers. A, Shoulder immobilizer. B, Soft cervical collar. C, Hard cervical collar. D, Knee immobilizer.

- Reviewing correct application of the brace/splint/sling and positioning of any ties or straps.
- Reviewing prescribed schedule of wear and activities permitted while in the brace/splint/sling.
- Instructing to inform the nurse if the patient complains of any pain, rubbing, or pressure from the brace or immobilization device or if a change occurs in the patient's skin condition.

Equipment

- Brace/splint/commercially prepared sling or triangular bandage and safety pin
- Cotton shirt or gown
- Clean gloves

STEP

RATIONALE

ASSESSMENT

1 Review patient's medical history; previous and current activity level; and description of condition requiring immobilization.	Reveals patient's current and previous health status and purpose for brace/splint/sling.
2 Determine patient's previous experience with braces/splints/slings.	Provides patient's baseline knowledge and need for instruction.
3 Assess patient's level of pain using a scale of 0 to 10.	Provides baseline to determine if immobilization device affects comfort.
4 Assess patient's understanding of reason for brace/splint/sling and its care, application, and schedule of wear.	Determines level of instruction needed. Ask patient to teach back to determine level of understanding
5 Inspect areas of skin that will be in contact with support device.	Provides baseline to monitor patient for skin breakdown. Immobilized and older patients are particularly vulnerable to skin breakdown (Meiner, 2011).
6 Refer to occupational or physical therapy consultation to determine type of brace to be used, desired position, and amount of activity and movement permitted.	Ensures proper use of device.
7 Assess patient's additional need for an assistive device such as walker, cane, or crutches.	Patients may need an assistive device to provide support and promote balance during ambulation.

NURSING DIAGNOSES

- | | | |
|--|------------------------------------|---|
| • Acute pain | • Impaired home maintenance | • Risk for peripheral neurovascular dysfunction |
| • Bathing and dressing self-care deficit | • Impaired physical mobility | • Risk for ineffective tissue perfusion |
| • Deficient knowledge | • Risk for impaired skin integrity | |
| • Disturbed body image | • Risk for injury | |

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:	
• Patient and family caregiver verbalize purpose, correct application, and care of device.	Demonstrates learning and ability to manage self-care.
• Patient reports transitory increase in pain on a scale of 0 to 10 during device application.	Indicates proper fit of device and permits safer ambulation.
• Skin distal to brace/splint/sling is intact, warm to touch, without signs of pressure, and with normal sensation.	Reveals that there are no neurovascular deficits following application of device.
• Patient uses device correctly, including schedule of wear, activity limitations, and positioning.	Demonstrates correct application of principles of immobilization device.

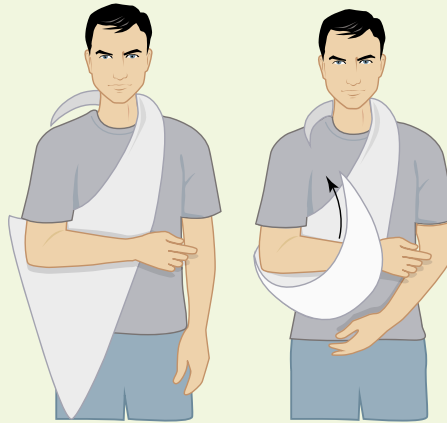

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2 Explain reasons for brace/splint/sling and demonstrate how device works.	Teaching and demonstration enhance learning, reduce anxiety, and encourage cooperation.
3 Perform hand hygiene. Help patient to a comfortable position: apply upper-extremity braces/splints/slings with patient sitting upright; apply lower-extremity braces with patient lying down.	Reduces transmission of infection. Facilitates correctly aligned brace.
4 Apply clean gloves and prepare skin that will be enclosed in brace/splint/sling with soap and water, rinse, pat dry, and change any dressings (if present). If applying back brace, put thin cotton shirt or gown on patient. Ensure that there are no wrinkles to cause pressure.	This protects skin and keeps brace/splint/sling clean. Smooth cotton clothing between device and skin protects skin from irritation and absorbs moisture.

STEP

RATIONALE

|---|--|
| <p>b Take remaining bandage and place material against chest and under and over affected arm, cradling arm.</p> <p>c Position pointed end of triangle toward elbow.</p> <p>d Tie two ends of triangle at side of neck.</p> <p>e Fold pointed end of sling at elbow in front and secure with safety pin, closing end of sling.</p> <p>f Be sure that sling supports limb comfortably without interfering with circulation.</p> <p>8 Remove and dispose of gloves. Perform hand hygiene.</p> <p>9 Teach patient prescribed schedule of wear and activities while in brace/splint/sling as directed by health care provider, physical therapist, or occupational therapist.</p> <p>10 Reinforce instruction regarding signs of skin breakdown, pressure, or rubbing to report.</p> <p>11 Help patient ambulate with brace/splint/sling in place.</p> <p>12 Have patient or family caregiver apply and remove brace/splint/sling.</p> | <p>Position supports arm.</p> <p>Avoids placing knot over cervical spine, causing pressure and discomfort.</p> <p>Prevents skin irritation and pressure to back of neck.</p> <p>Reduces transmission of infection.</p> <p>Proper use of brace/splint/sling facilitates healing and mobility and reduces pain and stress.</p> <p>Brace/splint/sling may need to be adjusted. Changes may be required because of growth or atrophy, when muscles regain or lose strength, or after reconstructive surgery.</p> <p>Ensures patient safety during ambulation and assesses fit of device.</p> <p>Promotes patient independence; demonstration confirms level of learning skill.</p> |
|---|--|

EVALUATION

- | | |
|---|--|
| <p>1 Inspect areas of skin underneath brace/splint/sling for signs of pressure, including redness or breakdown.</p> <p>2 Observe patient using brace/splint/sling.</p> <p>3 Ask patient to rate level of pain on scale of 0 to 10 after brace/splint/sling application.</p> <p>4 Palpate temperature, pulse, and sensation of extremity distal to brace/splint/sling.</p> <p>5 Inspect alignment of limb after device application.</p> | <p>Ensures early identification of irritation or breakdown.</p> <p>Reinforces learning of permitted activities and related restrictions.</p> <p>Indicates proper fit of device to ensure safe ambulation.</p> <p>Neurovascular status reflects vascular supply or pressure on tissues.</p> <p>Ensures proper application of device to promote healing.</p> |
|---|--|

Unexpected Outcomes

- 1 Patient is unable to use brace/splint/sling correctly.
- 2 Patient develops areas of pressure, redness, or skin breakdown.
- 3 Patient reports increased severity of pain after application of device.

Related Interventions

- Reassess patient for correct fit.
- Reassess level of comfort.
- Assess muscle strength in uninvolved extremities.
- Obtain referral for physical or occupational therapy.
- Reconsult orthotist if brace not performing as designed.
- Inspect device for proper fit and positioning and for areas of damage, wear, or rough edges.
- Inform health care provider.
- Inform orthotist, physical therapist, or occupational therapist so adjustments to brace/splint can be made.
- Reposition extremity.
- Administer analgesics as ordered to maintain comfort.
- Increase frequency of neurovascular checks.
- Inform health care provider.

Recording and Reporting

- Record specific assessments related to skin integrity, neurovascular status, type of brace/splint/sling applied, schedule of wear, activity level and movement permitted, and patient's tolerance of procedure in nurses' notes and EHR.
- Document instructions given to patient and family.
- Record observations regarding patient's ability to apply, ambulate, and remove the brace/splint/sling.
- Immediately report any injury sustained by patient while using the brace/splint/sling.

Special Considerations**Teaching**

- Teach patient and family caregiver how to care for brace/splint/sling:
 - When not in use, store metal braces upright in safe but easily accessible location to prevent bending or deforming.
 - Store splints of molded materials away from heat.
 - Treat leather braces or splints with a leather preservative to prevent drying and cracking.
 - Keep immobilization devices clean, dry, and in good working order. Clean plastic parts with damp cloth. Clean metal joints with pipe cleaner and oil weekly (using oil recommended by manufacturer). Remove rust with steel wool and clean metal parts with proper solvent.

- Refer to brace manufacturer or orthotist if brace is in need of maintenance or repair.
- Teach patients to avoid lotions or powders that may irritate skin.
- Teach patient appropriate range-of-motion exercises within limitation of device.
- Instruct patient and family caregiver of signs and symptoms of impaired skin integrity to report.

Pediatric

- Recognize that bracing in an adolescent affects body image and self-esteem.
- Adolescents may seek out chat rooms or social networking sites to share experiences with peers.
- Monitor children closely to ensure that they do not remove the immobilization device.

Geriatric

- Lightweight immobilization devices are less restrictive.
- Older adults may have decreased sensation (Ebersole, 2008).

Home Care

- Assess for environmental factors that interfere with safe ambulation in the home (e.g., scatter rugs).
- Remind patient to inspect and clean braces/splints/slides weekly.
- Remind patient to inspect skin daily for pressure or areas of breakdown.

? Critical Thinking Exercises

An 85-year-old woman is admitted to the orthopedic unit after falling down 12 steps. She sustained an intertrochanteric fracture of her right femur and a right Colles fracture of her right wrist. A fiberglass cast is placed on her right forearm in the emergency department, and 5 lbs of Buck's traction applied to her right leg. The plan is for an open reduction and internal fixation (ORIF) of her femur fracture in the morning.

- 1 Which of the following describes the correct way to position the casted arm?
 - 1 Carefully with palms of your hands to ensure that there are no indentations.
 - 2 On a plastic-covered pillow to prevent the linens from becoming damp.
 - 3 On several pillows, elevating the casted extremity with the hand higher than the elbow to decrease swelling.
 - 4 With a cradle over it to ensure air flow for proper drying.

- 2 The patient is using a patient-controlled analgesic (PCA) pump for pain control and receiving an opioid analgesic intravenously. She is using the pump appropriately, administering her doses of opioids; but, as the afternoon progresses, she complains of increased pain and a jumping, squeezing feeling in her right thigh. As her nurse, you would first:
 - 1 Massage her right thigh to relax her muscles.
 - 2 Medicate her with a muscle relaxant to decrease muscle spasms.
 - 3 Medicate her with a bolus dose of opioid analgesic for breakthrough pain.
 - 4 Release the Buck's traction briefly to decrease the pain.

- 3 It has been 12 hours, and the patient's fingers are becoming more swollen. Her cast has been further elevated to the level of her heart, and ice packs have been applied to either side of the cast. In spite of these interventions, her pain continues to increase. Which action should you take?
- 1 Apply a heating pad circumferentially.
 - 2 Apply additional ice packs to the top and bottom of the cast.
 - 3 Obtain an order to change the analgesic to another one.
 - 4 Notify the physician, and prepare for bivalving the cast.

REVIEW QUESTIONS

- 1 To assist in caring for a short-arm plaster cast, the nurse recommends to a family that they should do which of the following:
- 1 Completely cover the cast with plastic wrap to keep it clean.
 - 2 Cushion any sharp edges of the cast with tape or moleskin.
 - 3 Scrape rough edges off the cast with a blunt knife.
 - 4 Blow dry the cast following a shower.
- 2 Place the steps of cast removal in the correct order.
- A Describe the vibration of the cast saw and the feeling of warmth the saw causes.
 - B Help with positioning the patient.
 - C Inspect the tissues underlying the cast.
 - D Gently wash intact skin with cold-water enzyme.
 - 1 A, B, C, D
 - 2 B, A, C, D
 - 3 A, B, D, C
 - 4 B, A, D, C
- 3 The nurse is helping to apply a traction boot for Buck's extension; he or she should perform the following actions. (Select all that apply.)
- 1 Shave the affected leg
 - 2 Ensure that the boot fits snugly
 - 3 Pad the heel of the traction boot
 - 4 Attach weight to the boot gradually and gently at the end of the bed
 - 5 Reassess neurovascular status of the extremity proximal to the traction
- 4 In the first 24 hours following application of skeletal traction, how often should the nurse perform neurovascular assessment distal to the traction? (Short answer)
- 5 After application of a cast, the patient develops severe pain and swelling of the tissues beneath it. Identify the appropriate actions the nurse should take: (Select all that apply.)
- A Assess tightness of cast.
 - B Elevate casted extremity on pillows.
 - C Increase frequency of neurovascular checks.
 - D Lower the casted extremity.
 - E Notify health care provider before administering analgesics.
 - F Apply warm compresses to sides of cast.
 - G Apply ice bags along sides of cast.
- 6 The nurse is teaching a patient how to use and care for a back brace. Which of the following directions should he or she provide the patient?
- 1 Place no clothing between the brace and the skin.
 - 2 Inspect the brace for wear, damage, or rough edges daily.
 - 3 Clean the metal joints with a small steel brush and apply emollient cream to the joints weekly.
 - 4 Clean the plastic parts of the brace with ammonia weekly.
- 7 Which of the following may indicate an infection from a Steinmann pin inserted for skeletal traction?
- 1 Crusting
 - 2 Ashen skin color
 - 3 Clear drainage at the pin sites
 - 4 Erythema at the pin sites

- 8 Which of the following nurses' actions are appropriate when assessing a patient's balanced-suspension skeletal traction (BSST) setup?
- 1 Adding weight to the traction if it does not seem to be exerting enough force
 - 2 Adjusting the position of the weights if they are not hanging freely at the end of the bed
 - 3 Altering the line of pull of the ropes to ensure that they are at a 45-degree angle
 - 4 Reinserting a slipped Steinmann pin back into place
- 9 In developing a plan of care for a patient in skeletal traction to the leg, the nurse would take which precaution?
- 1 Avoid using an overhead trapeze.
 - 2 Remove weights when moving the patient in bed.
 - 3 Maintain alignment of the injured limb with the trunk.
 - 4 Release the traction for 15 minutes every 8 hours.
- 10 Which instructions should the nurse provide to a casted patient experiencing itching under the cast?
- 1 "The health care provider can provide medication for the itching."
 - 2 "If you can reach the area with your fingers, it is appropriate to itch that area."
 - 3 "You should not physically scratch under the cast; itching is part of the healing process."
 - 4 "You should use a tongue blade to itch instead of your fingernails."

Air-fluidized bed

Egg-crate mattress

Kinesthetic

Rotokinetic bed

Air-suspension bed

Flotation pad

Pressure ulcers

Waffle mattress

Bariatric bed

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify the different types of support surfaces and specialty beds used for pressure redistribution.
- Explain why preventive nursing care is still essential when using support surfaces and specialty beds.
- Describe guidelines for placing patients on support surfaces and specialty beds.
- Compare and contrast differences between mattress overlays and mattress replacements.
- Describe mechanisms by which skin breakdown can occur on an air-suspension or an air-fluidized bed, a bariatric bed, a Rotokinetic bed, or a support surface mattress or wheelchair seat cushion.
- Describe the steps for correct placement of a patient on an air-fluidized bed, an air-suspension bed, a bariatric bed, a Rotokinetic bed, or a support surface mattress.

Despite increasing technologic advances in health care, pressure ulcers remain a major problem that affects patient comfort, length of stay in a health care agency, and health care costs. Although an interdisciplinary team approach is key to reducing pressure ulcers, you are at the forefront of prevention and treatment of pressure ulcers in health care settings (WOCN, 2010). The National Pressure Ulcer Advisory Panel (NPUAP, 2009) defines pressure ulcers as localized injury to the skin and/or underlying tissue, usually over a bony prominence, as a result of pressure or pressure in combination with shear and/or friction. Pressure ulcers occur in any age-group or ethnic population, regardless of socioeconomic status. The occurrence of pressure ulcers is a serious and expensive health care problem in the United States. The National Quality Forum (NQF, 2010) considers prevention of pressure ulcers safe practices and development of pressure ulcers, especially stage III and IV ulcers, in a care setting a serious reportable event.

The pressure ulcer objective in *Healthy People 2020* is to reduce the rate of pressure ulcer–related hospitalizations among older adults to show a 10% improvement in pressure ulcer–related hospitalizations compared to baseline (USDHHS, 2011). To meet this challenge, along with the challenges of health care reform and cost reduction, it is essential to identify patients at risk for skin breakdown and pressure ulcer formation. Factors contributing to pressure ulcer formation are both extrinsic (e.g., pressure, moisture, friction, and shear) and intrinsic (e.g., malnutrition, loss of sensation, impaired mobility, aging skin, impaired mental status, infection, incontinence, and low arteriolar pressure).

The major cause of pressure ulcers is unrelieved pressure. The greater the pressure and the longer it is applied, the greater the likelihood for pressure ulcer development. To stay healthy, body tissues require an adequate supply of oxygen and nutrients and removal of carbon dioxide and other waste products of metabolism. This requires maintenance of adequate

blood flow through the capillaries, which is normally 12 to 32 mm Hg. When external pressure on the tissues exceeds 32 mm Hg (the capillary closing pressure), the network of capillaries collapses. This interrupts the supply of oxygen and nutrients to the cells and the removal of metabolic waste products. As a result, there is tissue ischemia and, if unrelieved, tissue death or necrosis.

Support surfaces are one important aspect of pressure ulcer prevention. The NPUAP (2009) defines support surfaces as specialized devices for “pressure redistribution designed for management of tissue loads, micro-climate, and/or other therapeutic functions (e.g., any mattresses, integrated bed system, mattress replacement, overlay, or seat cushion or seat cushion overlay).” Several types of support surfaces can be used in beds or wheelchairs.

Thus support surfaces have differing purposes, including pressure redistribution, repositioning, and support of morbidly obese patients. They are used in acute, rehabilitative, long-term, and home care settings. Support surfaces are essential to help prevent pressure ulcers or promote wound healing by reducing capillary closing pressure. They reduce pressure by redistributing it over a larger surface area. The extent to which a support surface reduces pressure is characterized in two ways. The first is preventive, in which pressure is not consistently reduced below 32 mm Hg (e.g., foam, air, or gel overlay). The second is therapeutic, in which pressure is consistently reduced below 32 mm Hg (e.g., powered overlay air mattress or low-air-loss mattress). Preventive surfaces are for patients at risk for skin breakdown and partial-thickness ulcers. Therapeutic surfaces are for patients with stage III and IV pressure ulcers (NPUAP, 2009). Support surfaces are one intervention for redistributing pressure; they are used in conjunction with other pressure ulcer risk-reduction strategies (see Chapter 18). Although the effectiveness of certain general interventions to prevent pressure ulcers is well documented, you should tailor these interventions to individual patients based on the specific risk factors identified during assessment (Anton, 2012).

At-risk patients left sitting in chairs sometimes develop deeper and more serious pressure ulcers than patients left in their beds because a patient’s body is exerting greater pressure on a smaller surface area (i.e., the buttocks). A patient lying in bed has pressure distributed over a greater surface area but is also at risk for developing pressure ulcers over bony prominences because they receive greater pressure than other parts of the body. Never place patients at high risk for pressure ulcer development on ordinary chairs or hospital mattresses. Use specialized support surfaces (e.g., foam, air, or gel mattresses, beds, and cushions) to reduce pressure. Pressure-redistribution surfaces are classified as nonpowered (formerly called *static*) support surfaces or powered (formerly called *dynamic*) support surfaces (NPUAP, 2009). Nonpowered support surfaces include mattresses or mattress overlays filled with air, water, gel, foam, or a combination of any of these. Powered support surfaces change the pressure beneath a patient, reducing the duration of any applied pressure. Many studies have reported the benefits demonstrated by pressure-redistribution surfaces in the prevention of pressure ulcers (McInnes et al., 2011).

Several support surfaces also reduce friction, shear, and moisture. Support surfaces with a slick surface help decrease friction and shear. Surfaces with porous covers allow airflow, which reduces moisture, resulting in decreased risk for skin maceration. Table 12-1 provides a comparison of support surfaces.

Frequent repositioning, which temporarily relieves pressure, is the backbone of prevention protocols. No bed or mattress totally eliminates the need for competent nursing care. It is your responsibility to use appropriate turning schedules for patients in bed or

in a chair. Use lift teams and lifting devices to transfer patients from a regular bed to a special support surface (see Chapter 9). Although useful, turning devices still injure soft tissues, requiring a nurse to be especially observant for signs of pressure formation.

EVIDENCE-BASED PRACTICE

Sustained pressure on areas that support the body leads to reduced blood supply and eventually necrosis of the skin and underlying muscles. Pressure reduction and relief are major nursing interventions for the prevention of pressure ulcers (McInnes et al., 2011; WOCN, 2010). The three approaches to pressure redistribution are frequent positioning of the patient to reduce sustained pressure, use of support surfaces to distribute the body weight over a large area, and use of an alternating support surface where inflatable cells alternately inflate and deflate. Pressure-redistribution surfaces need to serve as adjuncts and not replacements for repositioning protocols (WOCN, 2010).

Systematic reviews of existing research have concluded that there is insufficient evidence to recommend one support surface over another (McInnes et al., 2011; Reddy et al., 2008).

- Encourage patients to be up as soon as medically possible in a specialty chair or wheelchair equipped with a tailored support surface for pressure relief.
- Measure seat cushions so they are properly fitted to the person’s body type and chair size to prevent friction and pressure.
- Use support surfaces in the operating room for patients at high risk for pressure ulcer development.
- During the postoperative period observe the skin for signs of breakdown or injury.
- Instruct patients who had their surgeries in ambulatory care settings to observe for signs of skin injury.

PATIENT-CENTERED CARE

When making decisions about the best support surface for a patient, you must first complete thorough patient assessment, including individual needs, health care provider needs, and location of the patient. Ultimately the features of the support surface must match a patient’s unique needs. Always describe to a patient and family members which interventions will be instituted and allow time for questions as needed. Some cultural groups may hesitate to question or ask for help, especially when they have limited English communication. If a patient or family members will be permitted to use any of the features of the support surface, you should provide for demonstration and return demonstration of these features.

Safety Guidelines

- 1 Perform complete assessment to determine patient’s risk for pressure ulcers and selection of appropriate special mattresses and beds. A complete patient assessment includes use of appropriate pressure ulcer risk scales, which include factors such as presence of shear and friction and a patient’s mobility and continence status (see Chapter 18).
- 2 Know the reason for and extent of a patient’s reduced mobility. A patient who is not easy to reposition or who has pressure ulcers involving multiple surfaces benefits from pressure-redistribution support devices.
- 3 The use of incontinence pads increases peak pressure by 20% to 25%. Have an incontinence management plan in place (Norton et al., 2011).

TABLE 12-1 Support Surfaces

Category and Mechanism of Action	Indications for Use	Advantages	Disadvantages
Support Surfaces and Overlays			
<i>Foam Overlay (Available as an Overlay or in a Full Mattress)</i>			
Reduces pressure; the cover (top) can reduce friction and shear. Base height of 7.5-10 cm (3-4 inches); see manufacturer guidelines regarding amount of body weight supported.	Use for moderate- to high-risk patients.	One-time charge No setup fee Cannot be punctured Available in various sizes (e.g., bed, chair, operating room table) Little maintenance Does not need electricity	Elevated body temperature Hot and may trap moisture Limited life span Plastic protective sheet needed for incontinent patients or patients with draining wounds Not indicated for those with existing stage III or IV pressure ulcers
<i>Water Overlay (Available as an Overlay or in a Full Mattress)</i>			
Reduces pressure and pressure points because surface provides flotation with pressure reduction by evenly redistributing patient's weight over entire support surface.	Use for high-risk patients.	Readily available Some control over motion sensations Easy to clean	Easily punctured Heavy Fluid motion may make procedures (e.g., dressing changes, CPR) difficult Maintenance needed to prevent microorganism growth Patient transfers out of bed are difficult Difficult to raise and lower head of bed
<i>Gel Overlay</i>			
Reduces pressure and pressure points because surface provides flotation by evenly redistributing patient's weight over entire support surface.	Use for moderate- to high-risk patients. Use for patients who are wheelchair dependent.	Low maintenance Easy to clean Multiple-patient use Impermeable to needle punctures	Heavy Expensive Lacks air flow for moisture control Variable friction control
<i>Nonpowered Air-Filled Overlay</i>			
Reduces pressure by lowering mean interface pressure between patient's tissue and mattress.	Use for moderate- to high-risk patients. Use for patients who can reposition themselves.	Easy to clean Multiple-patient use Low maintenance Potential repair of some air-filled products Durable	Damaged by punctures from needles and sharps Requires routine monitoring to determine adequate inflation pressure Patient transfers out of bed are difficult
<i>Low-Air-Loss Overlay (Available as an Overlay or in a Full Mattress)</i>			
Maintains constant and slight air movement against skin to prevent buildup of moisture and skin breakdown.	Use for moderate- to high-risk patients.	Easy to clean Maintains a constant inflation Deflates to facilitate transfer and CPR Moisture control Fabric covering overlay is air permeable, bacteria impermeable, and waterproof Reduces shear and friction Setup provided by manufacturer	Damaged by needles and sharps Noisy Requires electricity, but some are available with short backup battery In home may need to purchase backup generator in case of loss of electrical power
Specialty Beds			
<i>Air-Fluidized Bed</i>			
Bed frame contains silicone-coated beads and incorporates both air and fluid support. Silicone-coated beads become fluidized when air is pumped through beads.	Use for high-risk patients. Use for patients with stage III or IV pressure ulcers or burns.	Less frequent turning or repositioning Improved patient comfort Quickly becomes firm for CPR or other treatments when device is turned "off" Reduces shear, friction, and edema to site May facilitate management of copious wound drainage or incontinence Setup provided by manufacturer	Continuous circulation of warm, dry air may increase patient risk for dehydration Possible increase in room temperature Patient may experience disorientation Patient transfer difficult Heavy Expensive May not be wide enough for use with obese patients or patients with contractures Patient cannot lay prone because of risk of suffocation

Continued

TABLE 12-1 Support Surfaces—cont'd

Category and Mechanism of Action	Indications for Use	Advantages	Disadvantages
Low-Air-Loss Bed			
Bed frame with series of connected air-filled pillows. Amount of pressure in each pillow is controlled and can be calibrated to patient need.	Use for patients who need pressure relief, those who cannot be repositioned frequently, or those who have skin breakdown on more than one surface. Contraindicated in patients with unstable spinal column.	Can raise and lower head and foot of bed Easy transfer in and out of bed Less frequent turning schedule Pillows can be transferred to stretcher with patient Setup provided by manufacturer	Portable motor is noisy Bed surface material is slippery; patients can easily slide down mattress or out of bed when being transferred
Kinetic Therapy			
Provides continuous passive motion to promote mobilization of pulmonary secretions and low air loss, which provides pressure relief.	Use primarily for patients needing spinal stabilization. Should not be used when the patient is hemodynamically unstable.	Reduces pulmonary complications associated with restricted mobility Reduces the risk for urinary stasis and urinary tract infections Reduces venous stasis	Does not reduce shear or moisture Cannot be used with cervical or skeletal traction Possible motion sickness initially Possible sensations of claustrophobia

CPR, Cardiopulmonary resuscitation.

Data from Wound, Ostomy and Continence Nurses (WOCN): *Guideline for prevention and management of pressure ulcers*, Glenview, Ill: 2010, The Association; McInnes E, et al: Support surfaces for pressure ulcer prevention, *Cochrane Database Syst Rev* 13(4):CD001735, 2011.

- 4 Continue to provide basic prevention care measures against the hazards of immobility (e.g., regular skin assessment, turning, correct positioning, or range-of-motion exercises).
- 5 Use safe patient-handling techniques and proper body mechanics when positioning or working with patients (see [Chapter 9](#)).
- 6 Follow all safety measures to prevent injury to patients from accidental falls or improper positioning when placing them on special beds or mattresses.
- 7 Encourage patients to remain as mobile as possible within the limits of their physical conditions and prescribed activity levels.
- 8 Educate family caregivers about the advantages/disadvantages and methods of operation of all support devices to ensure their proper use in all settings.
- 9 Collaborate and consult with health care professionals who have expertise in this area.

PROCEDURAL GUIDELINE 12-1 Selection of Pressure-Reducing Support Surfaces

Delegation and Collaboration

The selection of a pressure-reducing support device cannot be delegated to nursing assistive personnel (NAP).

Equipment

- Pressure ulcer risk assessment tool (see agency policy) (see [Chapter 18](#))
- Body chart, tape measure, and/or camera to document existing areas of impaired skin integrity
- Documentation form or electronic health record
- Skin care products

Procedural Steps

- 1 Assess patient's risk for skin breakdown using a risk assessment tool (e.g., Braden Scale).
- 2 Assess patient's existing pressure ulcers, including location, stage, areas of blistering, abnormal reactive hyperemia, and abrasion.
- 3 Assess patient's level of comfort using a pain scale of 0 to 10.
- 4 Determine the need for a pressure-reduction surface from assessment data. Place "at risk" patients on a pressure-reduction surface and not an ordinary mattress (McInnes et al., 2011).
- 5 Identify patient factors when selecting an appropriate surface ([Fig. 12-1](#)):
 - a Does patient need pressure redistribution (e.g., you cannot reposition the patient, or there is an existing pressure ulcer)?
 - b Is the surface needed for short- or long-term care? A short-term surface is usually needed for an acute illness and hospitalization. A long-term surface is usually needed for extended or home care.
 - c What is the potential comfort level achieved by the surface? If patient is sensitive to noise, a device with a loud motor will increase his or her discomfort.
 - d Are the patient, family, and caregivers cooperative and adherent to repositioning? In addition, are they aware that a support surface should never replace repositioning? Is adequate assistance available for repositioning? In a home setting a support surface is often necessary when the family, caregiver, or patient is unable to independently reposition or assist with repositioning.
 - e Does the support surface have a potential to interfere with patient's independent functioning? The height of the overlay and its soft edge may affect patient's ability to

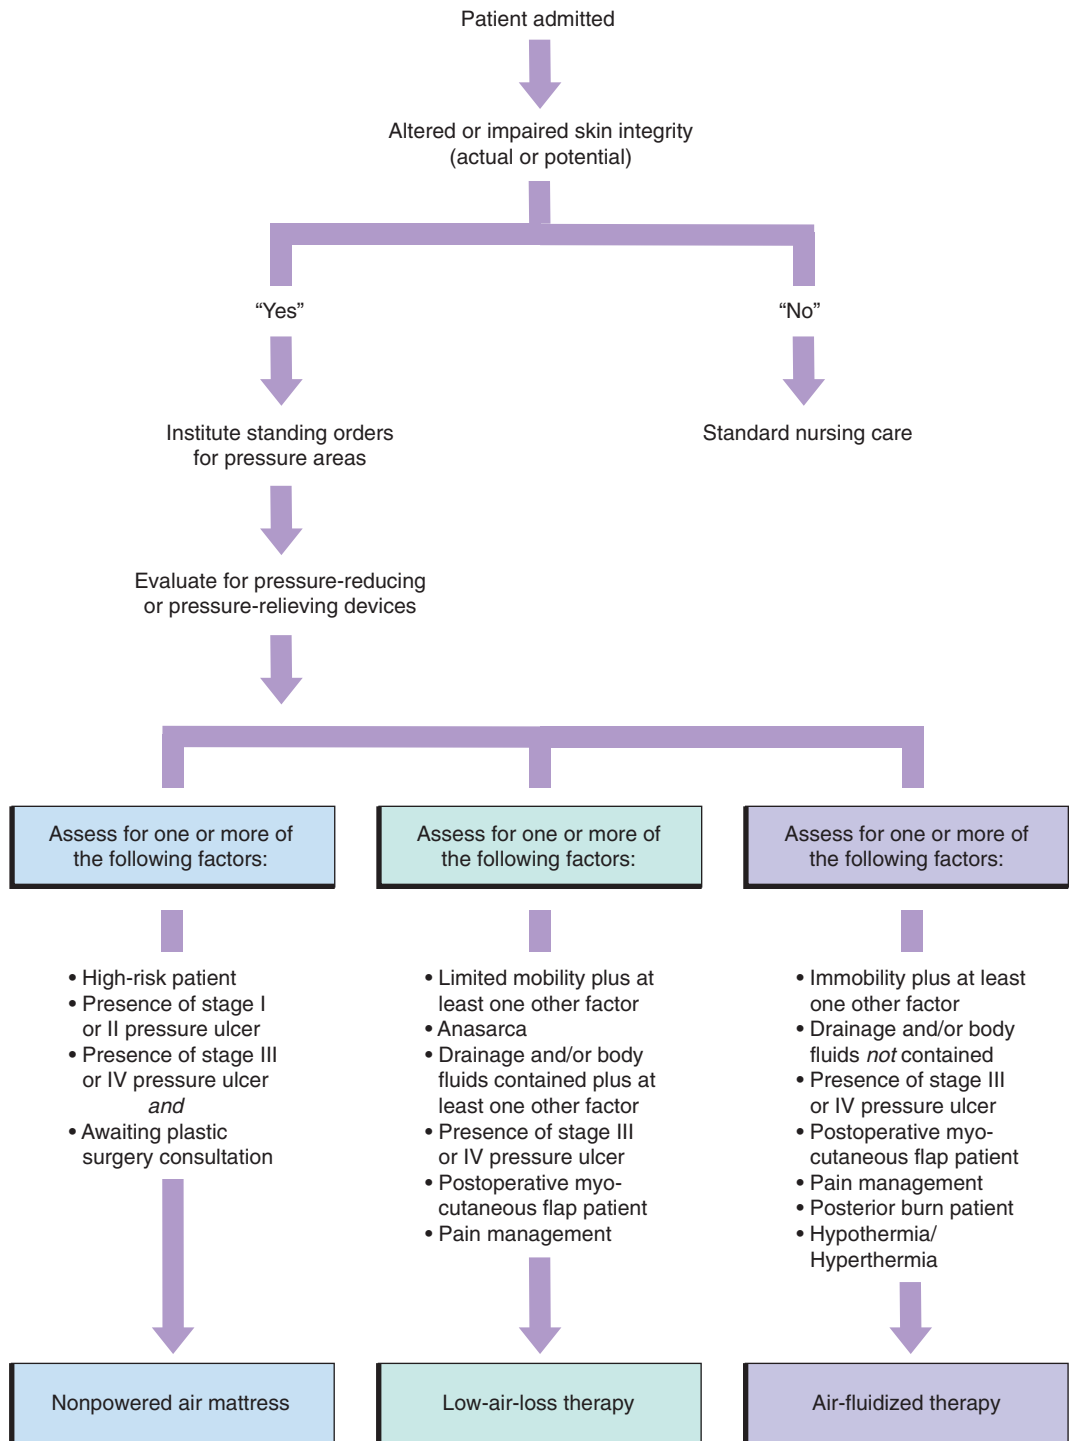

FIG 12-1 Flow diagram for ordering specialty beds.

PROCEDURAL GUIDELINE 12-1 Selection of Pressure-Reducing Support Surfaces—cont'd

- transfer, and a high-air-loss bed is not appropriate for a patient who needs to get in and out of bed frequently.
- f What are patient's financial limitations?
- g If the patient is using the device in the home, what are the environmental limitations? Will the home and existing electrical service accommodate the surface selected? Can the caregivers and family in the home manage the surface?
- h How durable is the product? Is the surface easily subjected to puncture? How easily can the surface be cleaned?
- i Does patient need pressure-relief surfaces in a chair/wheelchair? Has the family or caregiver been instructed on appropriate inflation of the device?
- 6 Choose the appropriate surface (see Table 12-1).
 - a Pressure-redistribution devices redistribute pressure over bony prominences. Surfaces providing pressure redistribution include therapeutic mattress replacements, nonpowered and powered (i.e., moving) surfaces, low-air-loss beds and mattresses, and air-fluidized beds (WOCN, 2010).

PROCEDURAL GUIDELINE 12-1 Selection of Pressure-Reducing Support Surfaces—cont'd

- Pressure-redistribution surfaces are also used in the operating room for individuals who are at high risk or for lengthy procedures (McInnes et al., 2011).
- b Use a nonpowered support surface if patient can assume a variety of positions without bearing weight on a pressure ulcer without bottoming out. Bottoming out makes the support surface ineffective. To assess for bottoming out, place a hand (palm up) under the mattress or cushion below the area of risk for pressure areas (e.g., patient's pressure points when lying or sitting on surface). If there is less 2.5 cm (1 inch) of support material felt, patient has bottomed out (WOCN, 2010).
 - c Select a powered support surface when patient cannot assume a variety of positions without bearing weight on a pressure ulcer, if patient fully compresses the static support surface, or if the pressure ulcer does not show evidence of healing. Alternating or powered mattresses are associated with lower incidence of pressure ulcers compared with standard mattresses (Gray, 2009; WOCN, 2010).
 - d High-specification foam is effective in decreasing the incidence of pressure ulcers in fairly high-risk patients, including older adults and patients with fractures of the neck of the femur (McInnes et al., 2011; WOCN, 2010).
 - e Patients with stage III or IV pressure ulcers on multiple turning surfaces often benefit from an air-fluidized bed (WOCN, 2010).
 - f There is limited evidence that low-air-loss beds reduce the incidence of pressure ulcers in intensive care (WOCN, 2010).
- g When excess moisture is a potential risk, a support surface that provides airflow is important in drying the skin and reducing the incidence of pressure ulcers (NPUAP, 2009).
- 7 Check agency policy regarding implementing a support surface.
 - a Obtain a health care provider's order. This is usually required for a patient to obtain third-party reimbursement.
 - b Consult with agency case manager or social worker to assist with patient's financial eligibility and terms and length of third-party reimbursement for the surface.
 - c Consult with agency home care or discharge planning if the device is anticipated for long-term use. Specific procedures and evaluations are needed for continuity of surface when patient is transferred to extended care or discharged home.
 - 8 Perform hand hygiene. Inspect condition of skin regularly according to agency policy to evaluate changes in skin and effectiveness of therapy.
 - 9 Inspect existing pressure ulcers for evidence of healing.
 - 10 Observe for side effects associated with specific pressure-reducing surface (e.g., nausea, dizziness).
 - 11 Document pressure ulcer risk assessment and skin assessment in patient's record. Document the support surface selected and patient response to the surface (see specific skills for recording and reporting details).

SKILL 12-1 Placing a Patient on a Support Surface

Numerous support surfaces reduce pressure on tissues overlying bony prominences. These devices are recommended for preventive measures for patients with reduced mobility and risk for developing pressure ulcers. Most of the devices are easy to apply and keep clean. The extent to which the devices actually reduce pressure and prevent skin breakdown is highly variable.

Support surfaces are categorized as mattress (or wheelchair) overlays (Fig. 12-2), mattress replacements, or specialty beds. An overlay rests on top of a hospital mattress and uses foam, air, water,

gel, or combinations of these products to provide pressure relief. Mattress overlays and mattress replacements are either nonpowered (e.g., foam, gels) or powered (e.g., alternating-pressure surfaces).

A flotation pad is made of a silicone or polyvinyl chloride gel enclosed in a vinyl-covered square. The pad serves as an artificial layer of fat to protect bony surfaces such as the sacrum and greater trochanters. These flotation pads are available for the bed or wheelchair (Fig. 12-3).

FIG 12-2 ROHO cushion for a wheelchair. (©ROHO Group. Reprinted with permission. All rights reserved.)

FIG 12-3 Gel cushion for wheelchair. (©Skil-Care Corp. Reprinted with permission. All rights reserved.)

There are two types of foam mattresses. One is the foam mattress overlay, which has a flat smooth surface, foam rubber peaks (egg-crate, Fig. 12-4), or a cut surface. Place one on top of a bed mattress and place a sheet over the foam mattress pad overlay to prevent soiling and provide ease of cleaning. The second type is the foam specialty mattress, which completely replaces the hospital mattress and is covered by a loose-fitting cover intended to protect the mattress and minimize friction and shear. Foam mattresses are used more for comfort than for pressure redistribution. Some of the newer foam mattresses have memory and an increased life span. The memory foam molds to the shape of the body and reduces pressure to the area in contact with the foam.

One type of air mattress is fully integrated into the hospital bed or designed to be placed in a wheelchair (Fig. 12-5). You can adjust this bed surface to a patient's comfort level by adding or removing air through buttons within the patient's reach, or you can automatically adjust pressures to a patient's position and movement when in the automatic mode. Always use a bedsheet to cover an air mattress to prevent skin from touching the plastic surface.

Air mattress overlays are either nonpowered or powered and consist of interconnected air cells or cushions inflated by the use of a motorized blower (Fig. 12-6). More complex air mattresses contain several layers of tubes or support cells. These mattresses

use a pressure-cycling device to intermittently inflate and deflate or to maintain a constant inflation and slight air movement in the mattress.

A nonpowered mattress is inflated with a simple air blower after placing the mattress on a bed. An integrated air mattress connects with a pressure-cycling device that intermittently inflates and deflates sections of the mattress, creating a cycling effect that minimizes pressure on bony prominences (Fig. 12-7).

Replacement mattresses have foam, gel, air, or fluid sections that you can customize to the needs of a specific patient with moderate-to-high risk for skin breakdown. Another available option is an air-integrated replacement mattress instead of the conventional mattress. These mattresses may also be fully integrated into the bed. Air mattresses are usually for patients with moderate-to-high risk for skin breakdown. You must deflate air mattresses before initiating cardiopulmonary resuscitation (CPR). Many agencies have purchased replacement mattresses to replace their standard hospital mattresses because of improved skin and wound outcomes.

Another preventive intervention is a low-pressure seat cushion (Fig. 12-8) overlaid on a wheelchair or a dry, nonpowered flotation

FIG 12-4 Egg-crate foam overlay is primarily for comfort.

mattress system (Fig. 12-9) that you overlay on a bed. Through a system of controlled dynamics, a cushion maintains low pressures by distributing pressure across a patient's body surface, reducing friction and shear.

Support surfaces aid in reducing pressure on a patient's skin but do not replace regular repositioning, meticulous skin care, or range-of-motion exercises. The decision to place a patient on a pressure-redistribution surface and the selection of this surface is a nursing responsibility (see [Procedural Guideline 12-1](#)).

Delegation and Collaboration

The skill of placing a patient on a support surface can be delegated to nursing assistive personnel (NAP). However, you must first complete the assessment, determine the need for a support surface, and select the specific surface. Some types of support surfaces require that a manufacturer's representative set up and maintain the support system. The nurse directs the NAP to:

- Notify the nurse of any changes in a patient's skin; the nurse then evaluates condition of the skin.

- Continue to regularly turn and reposition a patient and seek assistance for patient position changes as necessary in bed or wheelchair.
- Monitor the normal functioning of the support device such as inflation and deflation cycles and report to the nurse any changes in these cycles or leakage of air, water, or gel.

Equipment

- Pressure ulcer risk assessment tool (see agency policy) (see [Chapter 18](#))
- Mattress and/or chair overlay support surface of choice: foam overlays, air mattress overlay, bed with integrated surface, air-integrated replacement mattress
- Sheet(s)
- Clean gloves (if soiled linen is being handled)
- Standard bed frame (with mattress) if overlay is to be used (*optional*)

STEP

RATIONALE

ASSESSMENT

- 1 Perform hand hygiene.
- 2 Determine patient's risk for pressure ulcer formation using a valid assessment tool (e.g., Braden Scale) and assess for risk factors for pressure ulcers (e.g., nutritional deficits, shear stress, friction, alterations in mobility and sensory perception, moisture, and abnormal serum albumin and hemoglobin levels) (see [Chapter 18](#)).

Reduces transmission of microorganisms.
Risk assessment tools provide an objective measure of risk consistent over time ([WOCN, 2010](#)).

Clinical Decision Point Patients with unstable conditions do not always tolerate turning or positioning required for thorough assessment or the application of a support surface mattress.

- 3 Perform skin assessment (see [Chapter 18](#)). Inspect condition of skin, especially over dependent sites and bony prominences (see [Chapter 18](#)).
- 4 Assess patient's level of comfort using a pain scale of 0 to 10.

Provides baseline to determine a change in skin integrity or in an existing pressure ulcer.

Provides baseline to determine patient's response to therapy and comfort needs.

STEP

RATIONALE

Clinical Decision Point *Some patients experiencing pain need pain medication before application of support surface of choice or transfer to another bed (NPUAP, 2009).*

- | | |
|--|--|
| <p>5 Assess patient's understanding of purpose of support surface.</p> <p>6 Verify health care provider's order for type of support surface.</p> | <p>Misconceptions affect patient's cooperation in use of mattress.</p> <p>Health care provider's order is usually required to ensure third-party payment of support surface.</p> |
|--|--|

NURSING DIAGNOSES

- | | | |
|---|--|--|
| <ul style="list-style-type: none"> • Deficient knowledge regarding use of support surface mattress • Impaired physical mobility | <ul style="list-style-type: none"> • Impaired skin integrity • Ineffective tissue perfusion • Pain (acute, chronic) | <ul style="list-style-type: none"> • Risk for impaired skin integrity • Risk for infection |
|---|--|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient's skin is without erythema or mottling. • Existing pressure ulcer shows signs of healing. • Patient expresses improved level of comfort. • Patient is removed from therapeutic surface when risk for pressure ulcers decreases. <p>2 Explain purpose of mattress and method of application to patient and family caregiver.</p> | <p>Mottling represents hypoxia, which is an abnormal physiologic response in tissues under pressure.</p> <p>Skin remains free of new pressure ulcers. Support surface does not interfere with circulation to dependent areas.</p> <p>Equalized pressures have eliminated localized areas of discomfort. Provides for efficient, cost-effective care while maintaining high-quality outcomes.</p> <p>Reduces anxiety and promotes cooperation.</p> |
|--|---|

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Close room door or bedside curtain.</p> <p>2 Perform hand hygiene. Apply clean gloves (if linens are soiled or wet). Obtain assistance to position patient and/or mattress as needed.</p> <p>3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>4 Apply support surface to bed or prepare alternative bed (bed may be occupied or unoccupied). Keep sharp objects away from air mattress or air-surface bed.</p> <p>a Replacing mattress:</p> <ul style="list-style-type: none"> (1) Apply mattress to bed frame after removing standard hospital mattress. (2) Apply sheet over mattress. Keep linens between surfaces to a minimum. <p>b Preparing an air mattress/overlay:</p> <ul style="list-style-type: none"> (1) Apply deflated mattress flat over surface of bed mattress. (There may be directions on pad indicating which side to place up.) (2) Bring any plastic strips or flaps around corners of bed mattress. (3) Attach connector on air mattress to inflation device. Inflate mattress to proper air pressure determined by air pump or blower. (4) Place sheet over air mattress, being sure to eliminate all wrinkles. (5) Check air pumps to be sure that pressure cycle alternates. (6) Help patient transfer in and out of bed. | <p>Provides patient privacy and considerate care during application of mattress to bed or transfer to alternative bed.</p> <p>Prevents transmission of microorganisms. Assistance from other caregivers reduces risk for friction and shear in transfer to new surface.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Hospital mattress needs to be stored. In some instances mattress replacements are standard procedure.</p> <p>Sheet reduces soiling. Multiple layers decrease surface effectiveness in reducing pressure (WOCN, 2010).</p> <p>Provides smooth, even surface.</p> <p>Secures air mattress in place.</p> <p>Mattresses vary as to requiring one-time or continuous inflation cycle. Check inflation daily. Manufacturer directions indicate desired air pressure designed to distribute patient's body weight evenly. Directions are included with each mattress.</p> <p>Prevents soiling of mattress, reduces direct contact of skin with plastic surface. Wrinkles can cause pressure.</p> <p>Alternating airflow mattress produces intermittent cycling, inflating only parts of mattress at any one time. Intermittent cycle continually alternates pressure against skin and soft tissue.</p> <p>Mattress surface is less firm and slippery. This makes it difficult for some patients to transfer from bed to chair/stretcher.</p> |
|--|--|

STEP	RATIONALE
<p>c Using an air-surface bed:</p> <p>(1) Obtain and place linen on bed.</p> <p>(2) Place switch in the “prevention” mode.</p>	<p>In some instances an air-surface bed is available in patient rooms. If not, an ordering system exists to obtain one as needed (see agency policy).</p> <p>In the “prevention” mode, surface pressures change automatically with patient position to equalize pressure and eliminate points of pressure.</p>
<p>Clinical Decision Point <i>Most pressure-relieving beds in the hospital and home care are equipped with a CPR switch to instantly lower head section from an elevated position and deflate the mattress to provide a firm surface for chest compressions (Fig. 12-10). Note this on the Kardex.</i></p>	
<p>5 Position patient comfortably as desired over support surface. Reposition routinely.</p>	<p>Location of existing pressure ulcer might influence type of positioning (WOCN, 2010).</p>
<p>6 Remove and dispose of gloves and perform hand hygiene.</p>	<p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Reassess patient’s risk for pressure ulcer formation at routine intervals.</p>	<p>Documents change in status, which is critical for evaluating continued need for therapeutic surface.</p>
<p>2 Inspect and compare condition of patient’s skin every 8 hours or according to agency policy to determine changes in skin integrity, pressure ulcer status, and effectiveness of support surface.</p>	<p>Determines if pressure sores develop or if condition of existing sores changes.</p>
<p>3 Ask patient to rate comfort on a scale of 0 to 10.</p>	<p>If pressure-relief mattress is effective, patient generally experiences less discomfort.</p>
<p>4 Evaluate functioning of support surface periodically.</p>	<p>Regular inspection of mechanical components of mattress ensures proper functioning.</p>

Unexpected Outcomes

- 1 Patient develops localized areas of abnormal reactive hyperemia for longer than 30 minutes (WOCN, 2010), mottling, swelling, and tenderness with evidence of breakdown.
- 2 Existing pressure areas fail to heal or increase in size or depth.
- 3 Patient expresses discomfort while on support surface.
- 4 Bed or mattress develops leak (air, water, gel).

Related Interventions

- Modify skin care regimen.
- Increase frequency of skin assessment.
- Increase types of pressure-relief interventions.
- Check for proper inflation of support surface.
- Revise turning schedule.
- Consult with skin care expert.
- Notify health care provider.
- Modify skin care regimen.
- Revise turning schedule.
- Consult with skin care expert.
- Notify health care provider.
- Evaluate need for analgesia or mild sedation.
- Evaluate need to modify support surface.
- Reposition patient more frequently.
- Unless contraindicated, provide back massage. Do not massage reddened areas or bony prominences because massage to these areas contributes to skin breakdown (WOCN, 2010).
- Take corrective action according to agency or manufacturer policies/directions.

Recording and Reporting

- Record type of support surface applied, extent to which patient tolerated procedure, and condition of patient’s skin in nurses’ notes, electronic health record (EHR), and/or skin assessment flow sheet. Record any patient teaching and validation of understanding in nurses’ notes and EHR.
- Report evidence of pressure ulcer formation to nurse in charge or health care provider.

Special Considerations

Teaching

- Explain risks of immobility and pressure ulcer formation to patient and family members (see Chapter 18).
- Instruct in proper use of body mechanics, positioning, and pressure relief methods.
- Explain purpose and function of the pressure-redistribution surface. Include reminder that the surface augments care and

FIG 12-10 Cardiopulmonary resuscitation switch deflates low-air-loss bed to provide hard surface.

does not replace the need for turning and pressure-relief maneuvers.

- Explain precautions regarding sharp objects and fire hazard.

Pediatric

- Various pain assessment tools have been developed specifically for use in children (see [Chapter 15](#)).

- Parents can support children in being able to express their pain and treatment preferences ([Hockenberry and Wilson, 2011](#)).

Gerontologic

- Implement preventive measures because aging skin is drier, thinner, and less pressure sensitive, increasing the risk for skin breakdown.
- Adding mattress overlays changes the bed height. Use care when transferring and teaching family members to transfer a patient from bed to chair.

Home Care

- Most of the devices may be adapted for home use on a standard twin bed or hospital bed.
- Base selection on patient needs and environmental audit. For example, a patient on total bed rest who smokes is not an ideal candidate for a foam mattress because of the potential for fire; a patient with pets that sleep in the bed is not suited for an air-filled mattress because of the risk for puncture.
- Address concerns in the home setting related to need for a back-up generator or other plan to maintain the support surface during power outages.

SKILL 12-2 Placing a Patient on an Air-Suspension or Air-Fluidized Bed

Air-suspension beds are designed for patients who are immobile or confined to bed. The air-suspension bed supports a patient’s weight on air-filled cushions. There are two types of systems: low-air-loss and high-air-loss. A low-air-loss system minimizes pressure and reduces shear. If a patient has large stage III or IV pressure ulcers on multiple turning surfaces of the skin, a low-air-loss bed or air-fluidized bed may be indicated ([WOCN, 2010](#)).

High-air-loss beds provide for selective drying and do not have the effect of substantially increasing insensible fluid losses. For patients requiring high air loss under a body part (e.g., under the buttocks) you can substitute high-air-loss cushions. It is also possible to adapt the air-suspension beds to individual patient needs with specialty cushions for positioning, foot support, and lateral arm supports.

Another adaptation of the air-suspension bed is the kinetic low-air-loss bed ([Fig. 12-11](#)). This bed is used in intensive care areas and has the ability to provide a pressure-relief surface while rotating approximately 30 to 35 degrees continuously. Do not use this surface with a patient who has an unstable spine or who is in traction (see [Chapter 11](#)).

An air-fluidized bed is a powered device designed to distribute a patient’s weight evenly over its support surface ([Fig. 12-12](#)). The contact pressure of the patient’s body against the filter sheet stays at 11 to 16 mm Hg. The bed minimizes pressure and reduces shearing force and friction through the principle of fluidization. Fluidization is created by forcing a gentle flow of temperature-controlled air upward through a mass of fine ceramic microspheres. The microspheres fluidize and take on the appearance of boiling milk and all the properties of a fluid. The patient lies directly on a polyester filter sheet that allows air to pass through but does not allow the microspheres to escape. Patients feel as though they are floating on a surface such as a warm waterbed.

Air-fluidized beds are useful in the care of patients who require minimal movement to prevent skin damage by shearing force and

for patients who experience significant pain when being turned or positioned (e.g., burn patients, those who have undergone extensive skin grafts or have existing pressure ulcers, and victims of multiple trauma). Patients tend to perspire and lose body fluids while on the bed because the surface of the filter sheet warms. As patients perspire, moisture is quickly absorbed into the circulating microspheres. Diaphoresis often goes undetected; thus insensible fluid loss is not always evident until a patient develops fluid and electrolyte imbalances. Therefore you need to monitor the patient’s fluid balance status carefully.

FIG 12-11 Low-air-loss bed. (©2002 Hill-Rom Services. Reprinted with permission. All rights reserved.)

FIG 12-12 Combination air-fluidized, low-air-loss bed. (©2008 Hill-Rom Services. Reprinted with permission. All rights reserved.)

Conventional fluidized beds do not allow for head-of-bed position changes. Use foam wedges to elevate the head. Combinations of fluidized-low-air-loss beds that allow head-of-bed elevation are also available. These beds use air to lift the upper body while the lower body stays on a fluidized bed surface. The weight of the bed structure makes transport extremely difficult. A pediatric version of this bed is available.

Delegation and Collaboration

The skill of placing a patient on an air-suspension or air-fluidized bed can be delegated to nursing assistive personnel (NAP). However, first you complete the assessment, determine the need for a support surface, and select the specific surface. Some types of support surfaces require that the manufacturer representative set up and maintain the support system. The nurse directs the NAP to:

- Notify the nurse of any changes in the patient's skin.
- Continue to regularly turn and reposition the patient and seek assistance for patient position changes as necessary. This is not always necessary for patients who are placed on a lateral rotation air-suspension bed.
- Monitor the normal functioning of the air-suspension bed such as inflation and deflation cycles and report to the nurse any changes in these cycles.
- Notify the nurse if the patient becomes disoriented, restless, or complains of nausea.

Equipment

Air-suspension Bed

- Gore-Tex sheet (supplied by manufacturer)
- Disposable bed pads, if indicated
- Clean gloves (*optional*)

Air-fluidized Bed

- Foam positioning wedges if indicated
- Filter sheet (supplied by manufacturer)
- Clean gloves (*optional*)

STEP

RATIONALE

ASSESSMENT

- 1 Perform hand hygiene.
- 2 Determine patient's risk for pressure ulcer formation using a valid assessment tool (e.g., Braden Scale) and assess for risk factors for pressure ulcers, including nutritional deficits, shear stress, friction, alterations in mobility and sensory perception, moisture, and abnormal serum albumin and hemoglobin levels (see Chapter 18).
- 3 Identify patients who will benefit from air-suspension therapy or air-fluidized therapy (e.g., immobilized or burn patients).

Reduces transmission of microorganisms.
Risk assessment tools as suggested by the Agency for Healthcare Research and Quality (AHRQ) and WOCN (e.g., Braden Scale) provide an objective measure of risk consistent among nurse assessors over time (WOCN, 2010).

Beds effectively minimize pressure on fragile tissues and dependent body parts. Selected for patients who require pressure relief for treatment or prevention of pressure ulcers.

Clinical Decision Point Do not use this surface with a patient who has an unstable spine or who is in traction.

- 4 Inspect condition of skin, especially over dependent sites and bony prominences. Note appearance of existing ulcers and determine stage of ulcer (see Chapter 18).
- 5 Assess patient's level of comfort using a pain scale of 0 to 10.
- 6 Review health care provider orders.
- 7 Assess patient's level of orientation.
- 8 Assess patient's and family members' knowledge about therapy and understanding of purpose of bed.
- 9 Review patient's serum electrolyte levels if available.

Provides baseline to determine a change in skin integrity or in an existing pressure ulcer over time.

Provides baseline to determine patient's comfort needs. Nerve endings related to pressure, touch, temperature, and limb position are in the skin (WOCN, 2010). Patients usually require less analgesia while on the bed.

A health care provider's order is usually required to obtain third-party reimbursement for cost of bed.

Baseline used to detect change while patient is on bed. Some patients may become confused or disoriented from the flotation sensation of the bed (WOCN, 2010).

Blowers maintain bed inflation; they make a sound that creates anxiety for some patients.

Movement of air through the mattress increases patient's risk for dehydration (WOCN, 2010).

STEP	RATIONALE
<p>10 Determine if patient needs frequent weights.</p>	<p>Scales are available in some air-suspension beds and as underbed units for patients who need to be weighed frequently or those who cannot be moved for weighing.</p>
<p>11 Assess risk of complications from air-fluidized beds.</p> <ul style="list-style-type: none"> a Dehydration b Aspiration c Difficulty with patient positioning d Assess level of orientation 	<p>Patients may become dehydrated with use of this bed because of insensible fluid loss.</p> <p>Inability to elevate head of bed is limited to placing foam wedges under patient's head and shoulders.</p> <p>Repositioning is limited to use of foam wedges.</p> <p>Patients may be at risk for developing delirium from dehydration and floating sensation with air-fluidized bed.</p>

NURSING DIAGNOSES

- Anxiety
- Deficient fluid volume
- Deficient knowledge regarding use of support surface mattress
- Impaired physical mobility
- Impaired skin integrity
- Ineffective tissue perfusion
- Pain (acute, chronic)
- Risk for impaired skin integrity

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient's skin remains warm, clean, and intact or existing lesions show evidence of healing. • Existing pressure ulcers show evidence of healing by formulation of granulation tissue. • Patient expresses improved sense of comfort. • Patient experiences no complications from remaining on air-fluidized bed. <p>2 Review instructions provided by manufacturer.</p> <p>3 Explain procedure and purpose of bed to patient and caregiver.</p> <p>4 Obtain additional personnel needed to transfer patient to bed.</p> <p>5 For patients with moderate-to-severe pain, premedicate approximately 30 minutes before transfer to bed.</p> | <p>Skin is free from pressure effects of immobility.</p> <p>Low-pressure surface of bed facilitates healing of existing pressure ulcers.</p> <p>Surface of bed is soft, minimizing pain stimulation.</p> <p>Patient does not experience sensory perceptual changes or dehydration.</p> <p>Promotes safe and correct use of bed.</p> <p>Reduces anxiety and promotes patient's cooperation.</p> <p>Ensures safety by having sufficient personnel for transfer.</p> <p>Promotes patient's comfort and ability to cooperate during transfer to bed. |--|--|

STEP

RATIONALE

- c Specialty cushions for positioning, providing pressure relief, reducing moisture, preventing patient from sliding down in bed, or relieving weight from orthopedic devices

Reduces pressure, friction, and shearing forces.

Clinical Decision Point A patient should never be placed in prone position on an air-fluidized bed because of the chance of suffocation.

- d Lateral rotation (Fig. 12-13), which allows approximately 30 degrees of turning
- 9 Assess effectiveness of pressure-relief mattress or seat cushion by placing hand beneath support surface under a bony prominence.
- 10 Remove and dispose of gloves. Perform hand hygiene.

Helps to reduce risk and prevent pulmonary and urinary complications of reduced mobility (WOCN, 2010).

Underinflation or improper functioning of certain overlays may result in tissue damage. Likewise, overinflation can result in too firm a surface and create pressure damage.

Reduces transmission of microorganisms.

EVALUATION

- 1 Inspect condition of patient's skin periodically while patient is on bed, using the National Pressure Ulcer Advisory Panel (NPUAP) staging system.
- 2 Observe existing pressure ulcers for evidence of healing.
- 3 Ask patient to rate level of comfort on scale of 0 to 10.
- 4 Assess patient's level of orientation.

Determines if any new pressure areas are forming.

Evaluates healing progress of any existing pressure ulcers.

Flotation effects of bed minimize pain stimuli.

Determines onset of perceptual changes.

Unexpected Outcomes

- 1 Existing areas of skin breakdown or pressure areas fail to heal or increase in size or depth.
- 2 Patient is restless, confused, or agitated.
- 3 Patient becomes nauseated.
- 4 Bed malfunctions.

Related Interventions

- Modify skin care regimen.
- Revise turning schedule.
- Consult with skin care expert.
- Notify health care provider.
- Determine need for anti-anxiety medication and consult with physician.
- Evaluate alternative pressure-relief devices.
- Provide short-term antiemetic, such as Compazine. If using lateral rotation, obtain order to give Compazine around the clock.
- Notify health care provider.
- If using lateral rotation, decrease cycle frequency.
- Maintain patient safety.
- Follow agency or manufacturer policy.

FIG 12-13 Lateral rotation bed. (Tria Dyne™ Therapy System. Courtesy KCI Licensing, Inc., 2012.)

Recording and Reporting

- Record transfer of patient to bed, amount of assistance needed for transfer, tolerance of procedure, and condition of skin in nurses' notes, EHR, and/or skin assessment flow sheet. Record any patient teaching and validation of understanding in nurses' notes and EHR.
- Report changes in condition of skin, level of orientation, and electrolyte levels to health care provider.

Special Considerations

Teaching

- Explain function and purpose of air-suspension or air-fluidized bed.
- Explain the need to continue to change position at intervals to diminish the effects of immobility.
- Explain the need for adequate fluid intake because bed surface sometimes causes dehydration.

Pediatric

- The air-suspension bed is used commonly with older children and for children with significant burns. Make sure that instructions are age appropriate and include any restrictions such as raising the head of the bed.

SKILL 12-3 Placing a Patient on a Bariatric Bed

- Parents need to know that the child will have some dizziness or nausea when first placed on the air-fluidized bed. This is because of the flotation sensation and will disappear as the child becomes adjusted to the bed.

Gerontologic

- Some hospitalized older adults experience misperceptions of their environment that are intensified by the constant flotation of these types of beds. Proprioception abnormalities affecting older adults are the result of nervous system and muscle changes (WOCN, 2010).

Home Care

- The air-fluidized bed weighs between 1700 and 2100 pounds; therefore the company leasing the bed needs to inspect the home for accessibility and structural support.
- Consult with social worker or case manager to determine third-party reimbursement. Thorough documentation of skin condition is essential in obtaining reimbursement.

- A version of the air-fluidized bed is available for home use for rent or purchase; the bed rental company is responsible for proper cleaning.
- Instruct family in importance of maintaining patient hydration and skin care.
- Instruct family regarding steps to take in the event of a power failure. This may include purchasing a back-up generator for the home.

Long-Term Care

- Nurses and NAPs need to be instructed on proper use and inflation of the bed.
- Post signs and have protocols in place for procedures in the event of the need to perform cardiopulmonary resuscitation (CPR) (e.g., how to deflate the bed to provide a flat surface for compressions).

SKILL 12-3 Placing a Patient on a Bariatric Bed

A valuable resource in the care of a morbidly obese patient (a person who weighs more than 100 lbs above ideal weight) is the bariatric bed (Fig. 12-14). The bariatric bed is capable of allowing upright or sitting positions, patient transport, and in-bed scale use. It is equipped with hand controls that allow self-positioning and facilitate independence for an obese patient. The full-function hand controls also allow you to change the bed position and thus facilitate care while reducing risk for staff injury when moving a patient. The in-bed scale provides you with a means of obtaining accurate weights and thus improves health care and patient dignity. The bed is slightly wider than a standard hospital bed, yet it is within the guidelines for standard door width, which allows

movement into and out of a room without difficulty. Because the bariatric bed is capable of supporting weights up to 850 lbs, it provides a stable balanced surface that limits hospital liability should the standard bed frame collapse or the electric motor burn out.

A full- or double-wide bariatric bed can accommodate a patient up to 1000 lbs. However, when using this bed, you must assemble it in the patient's room and not use it for transfers because it is too large to fit through standard hospital doorways.

A limitation of this bed is the lack of pressure reduction or relief in the mattress. An at-risk obese patient needs to have some type of pressure-redistribution mattress placed on the bariatric bed. Choices for pressure redistribution include air or gel type of mattresses and low-air-loss replacement systems. These beds also have cardiopulmonary resuscitation (CPR) switches, which permit an immediate hard surface for chest compressions.

Delegation and Collaboration

The skill of placing a patient on a bariatric bed can be delegated to nursing assistive personnel (NAP). However, you must first complete the assessment, determine the need for a support surface, and select the specific surface. Some types of specialty beds require that the manufacturer's representative set up and maintain the system. The nurse directs the NAP to:

- Notify the nurse of any changes in patient's skin.
- Continue to regularly turn and reposition the patient and seek assistance for patient position changes as necessary.
- Monitor specifics on applying, cleaning, and maintaining support surface.

Equipment

- Bariatric bed
- Pressure-relief mattress overlay
- Sheets
- Overhead frame (*optional*)
- Heavy-duty lift
- Clean gloves

FIG 12-14 Bariatric bed with low-air-loss mattress replacement. (©2008 Hill-Rom Services. Reprinted with permission. All rights reserved.)

STEP

RATIONALE

ASSESSMENT

1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Determine patient's risk for pressure ulcer formation using a valid assessment tool (e.g., Braden Scale) and assess for risk factors for pressure ulcers, including nutritional deficits, shear stress, friction alterations in mobility and sensory perception, moisture, and abnormal serum albumin and hemoglobin levels (see Chapter 18).	Provides an objective measure of risk consistent among nurse assessors over time (WOCN, 2010).
3 Identify patients who will benefit from the bariatric bed system and assess their mobility status.	Selected for patients who are morbidly obese and have the potential to be independent in positioning with assistance of a stable surface.
4 Assess condition of patient's skin, paying particular attention to potential pressure sites and skinfolds. Assistance may be needed to turn patient to observe all skin surfaces. Determine need for patient to have pressure-redistribution mattress placed on bariatric bed.	Data provide baseline to determine any change in patient's condition while on the bed.
5 Assess patient's and family members' understanding of purpose of bed.	Improves patient and family cooperation.
6 Review health care provider's orders.	Health care provider's order is usually needed to obtain third-party reimbursement for cost of bed.
7 Assess need for patient to be weighed.	Scales are available in many bariatric beds or as underbed scales for beds without in-bed scales.
8 Determine the number of people needed to assist in safe patient transfer from regular bed to bariatric bed.	Reduced risk of injury by ensuring safe patient handling.

NURSING DIAGNOSES

- Deficient knowledge regarding use of support surface mattress
- Impaired physical mobility
- Impaired skin integrity
- Ineffective tissue perfusion
- Pain (acute, chronic)
- Risk for impaired skin integrity

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient is independent for position changes. • Patient's skin remains intact, or existing lesions show evidence of healing. • Patient remains free of injury. 	Bed surface is adaptable by hand-operated controls. Skin is free from pressure effects of immobility.
2 Explain procedure and purpose of bed to patient and family.	Bed is stable to allow for positioning without tipping or bending. Reduces anxiety and promotes patient's cooperation.
3 Review instructions supplied by bed manufacturer.	Promotes safe and correct use of bed.

Clinical Decision Point *Do not exceed weight limits indicated by the manufacturer and do not use with spinal cord-injured patients.*

4 For patients with moderate-to-severe pain, medicate approximately 30 minutes before transfer.	Promotes patient's comfort and ability to cooperate during transfer to bed. Decreases patient's energy expenditure (WOCN, 2010).
5 Obtain any additional personnel identified during assessment to transfer patient to bed.	Ensures safety of patient and staff by having sufficient personnel to assist in transferring.

IMPLEMENTATION

1 Close patient's room door or bedside curtain.	Maintains patient's privacy during transfer.
2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
3 Perform hand hygiene and put on clean gloves (if needed) before helping patient to bed using appropriate transfer techniques (see Chapter 9). Current safe patient-handling protocols mandate the use of a mechanical lift to move or transfer obese patients.	Appropriate transfer techniques maintain alignment and reduce risk for injury to patient and health care workers during the procedure. The recommended safe limit for nurses to lift in patient care is 35 lbs (Nelson et al., 2009). One nurse can safely logroll a patient weighing up to 78 lb; two caregivers are required if the patient weighs more than 78 lb but not more than 156 lb; and three caregivers are needed if the patient weighs more than 156 lb but not more than 234 lb (Gonzalez, 2009).

STEP	RATIONALE
4 Place pull sheet, slide board, hydraulic lifts, or other assistive devices under patient and transfer safely.	Reduces trauma from friction and shear to patient's skin.
5 Cover and position patient and place hand controls within reach. Be certain that out-of-bed alarm is on if needed. Attach overhead frame if needed.	Allows for maximal patient independence. Alarm alerts caregiver that patient has left bed surface.
6 Encourage patient to initiate frequent position changes and move in bed as much as possible.	Morbidly obese patients quickly increase pressure over bony prominences. Frequent removal (e.g., every 30 to 60 minutes) of pressure from these points helps to reduce risk for pressure ulcer formation.
7 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Inspect condition of patient's skin according to agency policy while patient is on bed.	Evaluates healing of any existing pressure ulcers. Determines if any new pressure areas are forming.
2 Ask patient to rate sense of comfort using pain scale of 0 to 10.	Identifies patient comfort or need for pain medication.
3 Evaluate patient's risk for injury.	Surface is balanced and allows maximal patient independence.
4 Evaluate patient's ability to move in bed.	Evaluates effectiveness of bed and education to promote independence.

Unexpected Outcomes

- Existing areas of skin breakdown or pressure areas fail to heal or increase in size or depth.
- Patient is unable to operate bed for position changes independently.

Related Interventions

- Modify skin care regimen.
- Consult with skin care expert.
- Notify health care provider.
- Reassess patient's level of independence and ability to understand instructions.
- Reinstruct patient and family in how to operate bed.
- Provide for return demonstration regarding bed operation.

Recording and Reporting

- Record transfer of patient to bed, tolerance of procedure, and condition of skin in nurses' notes, EHR, and/or skin assessment flow sheet. Record patient teaching and validation of understanding in nurses' notes and EHR.
- Report changes in condition of skin to nurse in charge or health care provider.

Special Considerations

Teaching

- Explain function and purpose of bariatric bed and pressure-relief mattress overlay.
- Explain the need to continue to change position at intervals to diminish effects of immobility.

SKILL 12-4 Placing a Patient on a Rotokinetic Bed

The Rotokinetic bed helps maintain skeletal alignment while providing constant rotation (Fig. 12-15). It is used in the care of patients with spinal cord injuries or multiple traumas. The support structure of the bed outlines the body parts and maintains proper alignment when secured properly. This bed improves skeletal alignment with constant side-to-side rotation up to 90 degrees. It rotates from side to side at a 60- to 90-degree angle every 7 minutes. You may adjust turning angles to meet a patient's needs. Constant rotation reduces pressure ulcer development and stimulates body systems. It is recommended that the bed stay in the rotation mode for at least 20 hours a day. There is an emergency lever that can quickly interrupt rotation when needed. To initiate cardiopulmonary resuscitation (CPR), return the bed to the horizontal position and lock in place.

The constant motion often leads to sensory distress for a patient, especially older adults. This is associated with the constant kinetic stimulation, the limited visual field, and inner ear disequilibrium. Be aware of these complications and provide necessary emotional support.

Delegation and Collaboration

The skill of placing a patient on a Rotokinetic bed cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Notify the nurse of any changes in the patient's skin while warning the NAP to not stop rotation, move, or reposition patient without the RN's assistance.
- Monitor the exact rotation frequency of the bed.
- Stop the rotation only for selected aspects of care determined by the nurse (e.g., bathing, oral hygiene, enemas).
- Immediately notify the nurse if the patient experiences confusion, nausea, and pain.

Equipment

- Rotokinetic bed with support packs, bolsters, and safety straps
- Top sheet
- Pillowcases for bolsters

FIG 12-15 Rotokinetic bed. (RotoRest, Courtesy Kinetic Concepts, San Antonio, Tex.)

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Prevents accidental rotation during transfer. Reduces transmission of microorganisms. Reduces risk for further tissue injury during transfer. Will need other health care providers to assist in transfer.</p> <p>Maintains proper alignment and prevents sliding during rotation.</p> <p>Prevents unnecessary exposure.</p> <p>Health care provider determines rotational angle based on patient’s overall condition and tolerance to constant motion. Reduces or prevents nausea, dizziness, and orthostatic hypotension.</p> <p>Allows opportunity to meet patient’s psychosocial needs.</p> <p>Allows nurse to easily access patient for any procedure.</p> <p>Informing patient of what to expect decreases anxiety.</p>
---	---

EVALUATION

<p>1 Inspect condition of skin (occipital region, ears, axillae, elbows, sacrum, groin, heels) and musculoskeletal alignment every 2 hours or more often if indicated by patient’s condition.</p>	<p>Evaluates healing process of any existing pressure ulcers and determines effectiveness of Rotokinetic therapy.</p>
--	---

STEP	RATIONALE
2 Inspect patient's pressure ulcers for evidence of healing.	Evaluates healing process.
3 Observe alignment and range of motion of all joints.	Determines if complications have developed.
4 Auscultate lung sounds every shift and compare with baseline.	Provides ongoing pulmonary assessment.
5 Determine patient's level of orientation once per shift while on bed or more often if patient's condition changes.	Evaluates if sensory overload has developed from excess kinetic stimulation.
6 Ask whether patient is experiencing nausea or dizziness.	Determines if patient is having inner ear disturbance.
7 Monitor blood pressure.	Determines if patient experiences orthostatic hypotension from position rotation.

Unexpected Outcomes

- 1 Existing areas of skin breakdown or pressure areas fail to heal or increase in size or depth.
- 2 Patient experiences hypotension.
- 3 Patient becomes disoriented, confused, nauseated, and anxious.
- 4 Patient develops abnormal lung sounds.
- 5 Bed fails to rotate.

Related Interventions

- Evaluate rotation schedule; bed needs to remain in rotation 20 hours per day to prevent skin breakdown.
- Modify skin care regimen.
- If severe drop in blood pressure, stop rotation, notify health care provider, remain with patient, and monitor vital signs every 5 minutes.
- For less severe blood pressure changes, decrease rotational angle. Gradually increase rotation angle as patient adjusts to rotation.
- Reorient patient to person, place, time.
- Provide audio stimulation via radio or tapes.
- Provide television adapted to Rotokinetic bed (available from manufacturer).
- Hang mirror on ceiling so patient is able to view surroundings.
- Provide symptomatic relief of motion sickness, and obtain order for antiemetic to be given around the clock.
- Increase frequency of pulmonary hygiene measures (e.g., cough and deep breathe, suctioning).
- Have patient use incentive spirometry.
- Provide for patient safety.
- Position bed flat.
- Follow manufacturer/agency policies.

Recording and Reporting

- Record transfer of patient to bed, time of transfer, degree of rotation, tolerance of procedure, and condition of skin before placement on bed in nurses' notes, EHR, and/or skin assessment flow sheet. Record patient teaching and validation of understanding in nurses' notes and EHR. Take a photograph to document skin condition and provide a baseline for later assessments for progress in healing.
- Record and report subjective data indicating response to the constant rotation and presence/absence of dizziness or nausea or blood pressure changes.
- Use a flow sheet to document routine assessment and care, including the length of time the bed rotation stopped. The bed needs to be rotating at least 20 hours out of every 24 hours and stopped for no more than 30 minutes at a time.
- Report changes in condition of skin to nurse in charge or health care provider.

Special Considerations

Teaching

- Explain function and purpose of Rotokinetic bed to patient and family members.
- Explain that patient will feel sensation of light-headedness or falling. However, patient will not fall because pads are positioned to prevent this.

Pediatric

- Provide age-appropriate education for the child. It is important that the child understand that he or she is secure in the bed and will not fall out as the bed turns.
- Distraction such as talking books, videos, and music help the older child adjust to the bed and the restricted mobility.

Gerontologic

- Older adults are at increased risk for sensation of light-headedness or dizziness.

Critical Thinking Exercises

You are assigned to admit Mr. Sachiko Hoji, a 48-year-old male who was involved in a motor vehicle accident that resulted in quadriplegia (causing loss of sensation and movement below the neck). The patient is unable to change positions or transfer without assistance. He also has a language barrier, and communicating instructions about his care is difficult. The nurse has arranged for the services of a qualified interpreter to assist in breaching the language barrier.

- 1 You anticipate that this patient will need a support surface. Before selecting this surface, what assessments will you make?
- 2 Which category of support surface will you select? What is your rationale for this selection?
- 3 Following consultation with physical therapy and social service, the health care provider orders an air-suspension bed with lateral rotation because Mr. Hoji has some blistering over bony prominences, and his impaired mobility and sensation increase his risk for developing pressure ulcers. Mr. Hoji begins experiencing a small amount of nausea and restlessness when initially placed on the air-suspension bed. He tells his wife, "I'm afraid that I'll fall out of this bed when it tilts. Will I?" Which actions should you implement for Mr. Hoji's nausea and anxiety?

REVIEW QUESTIONS

- 1 A patient at risk for pressure areas is placed on a specialty bed. Dehydration and/or electrolyte imbalances can occur with which type of specialty bed/mattress?
 - 1 Egg-crate mattress
 - 2 Air-suspension bed
 - 3 Aid-fluidized bed
 - 4 Bariatric bed
- 2 A nurse is caring for a patient on a Rotokinetic type of bed when he complains of sudden dizziness. The nurse checks his blood pressure and notes that on lateral rotation he develops orthostatic hypotension. What should the nurse's initial actions be?
 - 1 Have the nursing assistive personnel (NAP) notify the health care provider while the nurse assesses the patient
 - 2 Stop the rotation of the bed for a few minutes to further assess the patient
 - 3 Talk to the patient and assess for other factors that can make him hypotensive
 - 4 Increase his oral fluids and assess the patient again after he has been hydrated
- 3 A nurse is caring for a patient who can change position independently on an air-filled overlay on the mattress. While conducting a skin assessment, the nurse notices skin breakdown over the coccyx and left hip, even though this patient has received meticulous skin care and routine repositioning. What is the appropriate nursing action?
 - 1 Maintain the present mattress
 - 2 Increase repositioning frequency
 - 3 Check functioning and filling of the mattress
 - 4 Consider changing to a pressure-relief device
- 4 A patient needs to be placed on a bariatric bed. Which factor would be least considered when determining the need for the larger bed?
 - 1 The patient's ability to assist with transfer to the bed
 - 2 Availability of personnel to reposition the patient
 - 3 The ability of the environment to accommodate the bed
 - 4 The integrity of the skin on pressure areas and in skinfold regions
- 5 A patient on an air-fluidized bed needs to be turned. Which nursing intervention indicates that the nurse needs additional teaching about using this type of bed?
 - 1 The nurse prepares to place the patient in prone position on the bed.
 - 2 The nurse uses foam wedges to support the patient's head for comfort.
 - 3 The nurse asks the patient how much she can do before turning her.
 - 4 The nurse assesses visible skin areas before and after turning the patient.
- 6 A patient with paraplegia is sitting on a Roho cushion and self-adjusting the inflation during the day when he is up in his wheelchair. The home caregiver notes that the patient has small areas of continuing redness on his ischia. Which interventions are indicated? (Select all that apply.)
 - 1 The caregiver should report the situation to the nurse or case manager immediately.
 - 2 The caregiver should instruct the patient to not change the chair cushion inflation.
 - 3 The caregiver should check for proper inflation of the cushion.
 - 4 The caregiver should reinflate the cushion appropriately while the patient is sitting on it and wait to reevaluate the skin condition later.
 - 5 The caregiver should increase frequency of checking the patient's skin.
- 7 To check the inflation of a seat cushion in the wheelchair, the nurse should:
 - 1 Place a set of keys under the cushion and ask the patient if he can feel them.
 - 2 Visually inspect that the person's buttocks are not sitting directly on the seat.
 - 3 Manually check with a hand under the cushion to be sure that the person's ischia are cushioned appropriately.
 - 4 Avoid checking after inflating the cushion exactly according to the manufacturer's instructions.
- 8 In determining whether or not a mechanical lift should be used to transfer a person from a regular bed to a bariatric bed, which of the following statements reflects best practice? (Select all that apply.)
 - 1 All morbidly obese patients should be moved with a mechanical lift to prevent caregiver injury.
 - 2 Only patients weighing over 180 lbs who are completely dependent require the use of a mechanical lift.
 - 3 The appropriate use of mechanical lifts has been shown in numerous studies to reduce injury to nurses.
 - 4 The recommended safe limit for one nurse to logroll a patient is 156 lb.
 - 5 A lift team should be called to physically lift all patients from the bed to the chair.
- 9 The best guideline to use when selecting a pressure-relieving support surface for a patient is to:
 - 1 Consider the individual's specific risk factors when selecting a device.
 - 2 Choose the least expensive type of device.
 - 3 Consider staffing patterns and staff's current knowledge.
 - 4 Choose the most expensive type of device to ensure quality.
- 10 Place the following steps for applying an air mattress overlay in the correct order:
 - 1 Check air pumps to be sure that pressure cycle alternates.
 - 2 Bring any plastic strips or flaps around corners of bed mattress.
 - 3 Apply deflated mattress flat over surface of bed mattress.
 - 4 Place sheet over air mattress, being sure to eliminate all wrinkles.
 - 5 Attach connector on air mattress to inflation device and inflate to proper pressure.

KEY TERMS

Aspiration	Material safety data sheet (MSDS)	Mummy restraints	Seizure
Belt restraints	Mitten restraints	Physical restraint	Seizure precautions
Extremity restraints		Polypharmacy	Sentinel event

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe how safety principles are enhanced through a patient-centered care approach.
- Discuss current evidence in the area of fall prevention.
- Discuss the importance of a nursing assessment in providing for patient safety.
- Describe nursing interventions taken in the event of a fire and electrical shock.
- Describe nursing interventions specific for reducing patients' risks for falls.
- Describe steps in the design of a restraint-free environment.
- Discuss precautions used to prevent injury in patients who are restrained.
- Describe nursing interventions for a patient who experiences generalized seizures.
- Describe methods to evaluate safety interventions.
- Describe how to conduct a root cause analysis of a sentinel event.

Safety, often defined as freedom from psychological and physical injury, is a basic human need. Health care provided in a safe manner and a safe environment is essential for a patient's survival and well-being. A safe environment reduces the risk for illness and injury and contains the costs of health care by preventing extended lengths of treatment and/or hospitalization, improving or maintaining a patient's functional status, and increasing the patient's sense of well-being. The Institute of Medicine report "To Err Is Human: Building a Safer Health System" (IOM, 2000) was a pivotal publication that brought patient safety to the forefront of

health care in the United States. This report indicated that 44,000 to 98,000 people were dying each year as a result of preventable medical errors. Many health care organizations (e.g., The Joint Commission [TJC], The National Quality Forum [NQF], and The Centers for Medicaid and Medicare Services [CMS] now develop and monitor key health care safety initiatives and provide information to health care organizations and the public to promote patient safety. For example, the NQF (2011a) published "Safe Practices for Better Healthcare—2011 Update," which includes 29 safe practices and 12 new proposed safe practices that have been

demonstrated to be effective in reducing the occurrence of adverse events. Health care organizations foster a patient-centered safety culture by continually focusing on performance-improvement endeavors and risk-management findings and safety reports; providing current reliable technology; integrating evidence-based practice (EBP) into procedures; designing a safe work environment and atmosphere; and providing adequate staff educational opportunities.

As part of the health care team, a nurse is responsible to engage in activities that support a patient-centered safety culture. Patient-centered is defined by Quality and Safety Education for Nurses (QSEN) as recognizing a patient as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs (QSEN, 2011). There is an emphasis on improving the education of student nurses so they become more competent in promoting safe health care practices. The QSEN project was developed to meet the challenge of preparing future nurses who will have the knowledge, skills, and attitudes (KSAs) necessary to continuously improve the quality and safety of the health care systems within which they work (QSEN, 2011). The QSEN safety competency for nurses is defined as "Minimizes risk of harm to patients and providers through both system effectiveness and individual performance." The QSEN skills for safety competency include:

- Demonstrate effective use of technology and standardized practices that support safety and quality.
- Demonstrate effective use of strategies to reduce risk of harm to self or others.
- Use appropriate strategies to reduce reliance on memory.
- Communicate observations or concerns related to hazards and errors to patients, families, and the health care team.

As a nurse you are responsible for incorporating critical thinking skills when using the nursing process, assessing each patient and his or her environment for hazards that threaten safety, and planning and intervening appropriately to maintain a safe environment.

The Joint Commission requires hospitals to have a process for patients and their families to report concerns about safety such as asking caregivers if they have washed their hands. The Joint Commission launched a national campaign urging patients to "Know Your Rights," part of the Commission's Speak Up program (TJC, 2007). The program encourages people to take an active role in their own health care by speaking up if they have questions, paying attention to the care they receive, educating themselves about their diagnosis and treatment plan, and knowing and understanding their medications. In addition, TJC encourages patients to participate in all decisions about their treatment, making them partners in care (TJC, 2012a).

EVIDENCE-BASED PRACTICE

There continues to be significant research in the area of fall prevention, both in community and health care settings. In a review of studies designed to reduce the incidence of falls among community-living older adults, multifactorial programs were successful for older adults with a previous fall history (Costello and Edelstein, 2008). A multifactorial fall prevention program uses multiple interventions because individuals are at risk for falls for a variety of reasons. Research shows that medication and vision assessment, exercise, and home-hazard assessment with modifications may be beneficial in reducing falls in the home (Beer et al, 2011). Exercise alone is effective in reducing falls and should include a comprehensive program that combines muscle

strengthening, balance, and/or endurance training for at least 12 weeks. Tai chi shows improvements in body balance and ambulation (Bula et al., 2011). Improved balance confidence is important to avoid unnecessary, self-imposed restrictions of activity.

- Apply multifactorial interventions that match patients' risks and behaviors.
- Conduct a thorough medication assessment to identify polypharmacy (more than five medications).
- Determine potential withdrawal of certain at-risk medications such as psychotropics and sedatives.
- After a vision assessment, follow up with patients to determine their adherence in obtaining new glasses or other prescribed treatment.
- Provide educational information about fall risks and why modifications are beneficial following a home hazard assessment.
- Including an occupational therapist or physical therapist in a home-hazard assessment may have added benefit.

PATIENT-CENTERED CARE

Being hospitalized places patients at risk for injury in an unfamiliar and confusing environment. The experience is usually at least minimally frightening. Normal life cues such as a bed without side rails and the direction one usually takes to the bathroom are absent. Thought processes and coping mechanisms are affected by illness and its accompanying emotions. Thus patients are more vulnerable to injury. For patients of diverse cultural backgrounds, this vulnerability may be intensified. It is a nurse's responsibility to diligently protect all patients, regardless of their socio-economic status and cultural background. Most untoward events are related to failures of communication. Health care providers must be particularly attentive to communication during assessment. For example, nurses must use approaches that recognize a patient's cultural background so appropriate questions can be raised to clearly reveal health behaviors and risks. You enhance a patient's safety by considering him or her in light of the whole person and seeing each care situation through "the patient's eyes" and not just your perspective. Here are some specific patient-centered safety guidelines:

- When restraints are needed, clarify their meaning to the patient and the family. For example, some Asian families view the restraining of older adults as disrespectful. Similarly some survivors of war or persecution view restraints as imprisonment or punishment.
- Collaborate with family members in accommodating a patient's cultural perspectives regarding restraints. Removing the restraints when family members are present shows respect and caring for the patient.
- Be familiar with agency restraint protocol. Identify potential areas for negotiation with the patient's and family's preferences such as using a jacket versus arm restraints.
- When seizure precautions are necessary, explain and demonstrate the therapeutic regimen to the patient/family. Some cultures observe different caring practices for a person with seizures.

Safety Guidelines

- 1 Accurate patient identification is crucial to safety before any procedures (TJC, 2012b).
- 2 Safety begins with a patient's immediate environment. The call light/bed control system allows patients to adjust bed positions

- and signal caregivers. Explain to patients and visiting family members how to operate a call system correctly.
- 3 Always be alert to conditions within a patient's environment that pose risks for patient injury (e.g., hazards along walking paths, liquid spilled on the floor, poorly functioning equipment).
 - 4 Communicate clearly to other health care providers the plan of care, including procedures to be performed, procedures completed, and patient response. Communicate important test results to the right staff person in a timely manner (TJC, 2012b).

SKILL 13-1 Fall Prevention in a Health Care Agency

NSO Safety Module / Lessons 1 and 2

Patient falls are the most common type of inpatient accident, with approximately 1 million inpatient falls occurring in the United States each year (Oliver, Healey, and Haines, 2010). Between 1% and 3% of these falls result in fractures. A systematic review of studies examining the effectiveness of hospital fall prevention programs revealed no conclusive evidence that the programs can reduce the number of falls or fallers (Coussement et al., 2008). However, this is likely because falls are multifactorial and many studies focus on single interventions. Risk factors for falls among inpatients include a history of falling, muscle weakness, agitation and confusion, urinary incontinence or frequency, postural hypotension, and use of high-risk medications (e.g., benzodiazepine, opioids and antihistamines, and sedative hypnotics) (Chang et al., 2011; Oliver, Healey, and Haines, 2010).

Disease also plays a role in falls. For example, patients with cancer appear to have a higher fall rate compared with medicine and neurology patients and have the highest injury rate because of disease-related factors (e.g., osteoporosis, coagulation disorders) (Allan-Gibbs, 2010). Because a variety of factors create fall risks for patients, it is very important for nurses and other health care providers to perform thorough fall risk assessments and use fall prevention techniques individualized to the patients' risks and behaviors. The Centers for Medicare and Medicaid Services (CMS) have identified select serious adverse events as "Never Events" (i.e., adverse events that should never occur in a health care setting) (DHHS, 2008). One of these "Never Events" is hospital-acquired injury from external causes (e.g., fractures, head injury, crushing injury), as in the case of falls. The CMS denies hospitals higher payment for any hospital-acquired condition resulting from or complicated by the occurrence of a "Never Event."

Another area of risk includes wheelchair-related falls involving older adults and persons with disabilities. Patients are at risk for falls during transfer tasks and reaching while seated in a wheelchair. Wheelchair-related injuries from falls include fractures, concussions, dislocations, amputations, and serious head and spinal injuries (Opalek, Graymire, and Redd, 2009). An example of a wheelchair characteristic that increases risk for falls is having smaller and harder front wheels that cause a chair to tip when striking uneven terrain. Caregivers are also at risk for injury by not handling patients correctly or not asking for assistance. Injuries can occur while caregivers transfer patients who are agitated, fearful, unsteady, or too weak to transfer. Tripping over the front foot or leg rest and leaning over the back of the wheelchair to engage or disengage the wheel lock are common sources of injury.

The Joint Commission recommends that hospitals have formal fall-reduction programs, which include the evaluation of program effectiveness (TJC, 2012a). A fall-reduction program includes a fall risk assessment of every patient, which is usually conducted on

admission to a hospital and then routinely (see agency policy) until the patient's discharge. Most health care agencies use fall risk assessment tools designed to identify levels of risk such as low and high. A variety of tools are available, but not all have been well tested. The Hendrich II Fall Risk Model is one example of a fall assessment tool that has been shown to successfully identify high-risk patients (Ang et al., 2011).

It is important for nurses to identify patients' fall risks and communicate these risks to patients, their visiting family members, and members of the health care team. Patient-centered care is important, with nurses making patients their partners in recognizing fall risks and taking preventive action. Fall prevention strategies must be targeted to specific patient risks. For example, if a patient has postural hypotension, a nurse might choose a low bed and the practice of dangling the patient for 5 minutes on the side of the bed before trying to ambulate. Or a patient with a history of urinary incontinence might be given a bedside commode to use. Remember that patient situations change. Preventing falls and fall-related injuries requires diligent ongoing nursing assessment and engagement of the entire health care team in the implementation of patient-specific interventions (ICSI, 2010). The Joint Commission has a Speak Up campaign created for patients to follow in the home and hospital (Zhani, 2010). It offers tips and actions for helping people reduce their risk of falling, whether at home or in a medical facility.

Nurses are responsible for making a patient's bedside safe. Fig. 13-1 shows a variety of environmental interventions for patient safety. The call light/bed control system allows patients to adjust the position of a bed and signal caregivers for assistance. A full set of raised side rails (two to a bed or four to a bed) is a physical restraint. Traditionally health care providers used side rails for patient protection; however, patients have become entrapped or entangled in them. Raising only one of two, or three of four, side rails gives patients room to exit a bed safely and move around within the bed. It is also important to keep a bed in low position with wheels locked when stationary. Finally, always check a bed for structural risks (e.g., wobbly rails, damaged rails, or soft mattresses).

Electronic bed and chair alarms warn nursing staff when patients try to leave the bed or chair on their own. One type of alarm is a pressure-sensitive strip that is placed beneath a patient and under the buttocks on a bed or chair. As a patient rises off the sensor, an alarm sounds to alert staff. Another warning device is a tab alarm that connects to a patient in a chair or bed by a wire tether. When a patient moves beyond the length of the tether, the alarm sounds. An Ambularm is a device that a patient wears on a leg. The alarm signals when the leg is in a dependent position such as over a side rail or on the floor.

Additional devices to use at a patient's bedside are a gait belt, a bedside commode, a nonskid floor mat, an overhead trapeze, and a ceiling lift (see Fig. 13-1). All of these devices help patients either move in bed or transfer out of bed more safely.

Room well illuminated at all times

Call button within reach

Nonexit side rails up for support

Bed alarm

Bedside commode
placed alongside
bed if needed

Nonskid footwear available

FIG 13-1 Safe patient room environment with bed in low position, bed alarm activated, nonskid floor mat and call light in place, and bedside commode positioned along bedside.

Delegation and Collaboration

The skill of assessing and communicating a patient's fall risks cannot be delegated to nursing assistive personnel (NAP). However, the skills used to prevent falls can be delegated. The nurse directs the NAP by:

- Explaining a patient's mobility limitations and specific measures needed to minimize risks.
- Teaching specific environmental safety precautions to use (e.g., bed locked in low position, nonskid footwear).
- Explaining patient behaviors (e.g., disorientation, wandering, anxiety) that are precursors to falls and that should be reported immediately.

Equipment

- Fall risk assessment tool
- Hospital bed with side rails
- Wedge cushion
- Call light
- Seat belt
- Gait belt
- Wheelchair
- Bed alarm

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's fall risks using an agency fall risk assessment tool. Assess patient's age (over 65), number of co-morbidities, impaired memory and cognition (ability to cooperate), incontinence or urinary frequency/urgency, decreased hearing, decreased night vision, orthostatic hypotension or dizziness/vertigo, impaired gait, weak lower extremities, fatigue, need for transfer assistance, history of stroke, and decreased peripheral sensation (Kojima et al, 2011; Viera, Freund-Heritage, and da Costa, 2011).
- 2 Determine if patient has a history of recent falls (TJC, 2012a) or other injuries within the home. Assess previous falls; be specific and follow the acronym SPLATT (Meiner, 2011):
 - Symptoms at time of fall
 - Previous fall
 - Location of fall
 - Activity at time of fall
 - Time of fall
 - Trauma after fall

Certain physiologic factors predispose patients to fall (e.g., incontinence or urgency and the attempt to rush to a bathroom or find a urinal).

Key symptoms are often helpful in identifying cause for falls. Onset, location, and activity associated with a fall provide further details on causative factors and how to prevent future falls.

STEP	RATIONALE
<p>3 Review patient’s medication history, including over-the-counter (OTC) medications and herbal products and antidepressants, anticonvulsants, antihypertensives, antihistamines, anti-Parkinson drugs, antipsychotics, anxiolytics, corticosteroids, diuretics, histamine (H₂) receptors, hypnotics (especially benzodiazepines), hypoglycemics, and muscle relaxants. Also assess for polypharmacy (use of more than five medications).</p>	<p>Certain medications have been associated with patient falls (Chang et al., 2011; Gribbin et al., 2010; Kojima et al., 2011; Viera, Freund-Heritage, and da Costa, 2011). Multiple use of medications (polypharmacy) is also associated with falls, especially in older adults (Beer et al, 2011).</p>
<p>4 Assess patient for fear of falling; consider patients who are over 75 years of age, female, lower income, or single and have poor perceived general health and history of falling in last 3 months (Boyd and Stevens, 2009).</p>	<p>Fear and fear of falling are interrelated problems; each is a risk factor for the other (Scheffer et al., 2008).</p>
<p>5 Assess risk factors in health care agency (e.g., being attached to equipment such as sequential compression hose, intravenous [IV] or oxygen tubing, improperly lighted room, obstructed walkway to bathroom, clutter of supplies and equipment).</p>	<p>Environmental barriers pose risk for falls.</p>
<p>6 Assess condition of equipment.</p>	<p>Equipment in poor repair (e.g., uneven legs on bedside commode) increase fall risk.</p>
<p>7 Perform the timed “get up and go” (TGUG) test if patient is able to ambulate:</p> <ul style="list-style-type: none"> • Have patient rise from sitting position without using arms for support. • Instruct patient to walk 10 feet (3 m), turn around, and walk back to the chair. • Have patient return to chair and sit down without using arms for support. • Look for unsteadiness in patient’s gait. 	<p>Examination easily incorporated into clinical encounters with patient is measure of physical performance, with low scores associated with risk for falling (Khazzani et al., 2009). Patient taking less than 20 seconds to complete test is adequate for independent mobility. Patient who takes longer than 30 seconds is dependent and at risk for fall.</p>
<p>8 Assess patient for: osteoporosis, anticoagulant therapy, history of previous fracture, and recent chest or abdominal surgery.</p>	<p>Factors increase likelihood of injury from a fall.</p>
<p>9 Use patient-centered approach and determine what patient knows about risks for falling and steps that he or she takes to prevent falls.</p>	<p>Patient’s own knowledge of risks influences ability to take necessary precautions in reducing falls.</p>
<p>10 After assessment apply color-coded wristband (e.g., yellow) for patients at risk for falling. Some organizations institute fall risk signs on doors and special yellow labels on patient charts and assignment boards.</p>	<p>Color-coded bands are easily recognizable. National efforts in a majority of states have resulted in the standardization of yellow as a color for fall risk wrist bands.</p>

NURSING DIAGNOSES

- | | | |
|------------------------|--------------------------------|--------------------|
| • Activity intolerance | • Impaired physical mobility | • Impaired walking |
| • Deficient knowledge | • Impaired transfer ability | • Risk for falls |
| • Impaired memory | • Impaired urinary elimination | • Risk for injury |

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient’s environment is free of hazards. • Patient and/or family member is able to identify safety risks. 	<p>Environmental hazards predispose patient to potential injury. Patient awareness of risks promotes cooperation and understanding of treatment plan.</p>
<ul style="list-style-type: none"> • Patient and/or family member verbalizes understanding of fall prevention interventions. • Patient does not suffer a fall or injury. 	<p>Makes patient and family partners in prevention strategies. Fall precautions are successful in preventing a fall.</p>

IMPLEMENTATION

<p>1 Introduce yourself to patient, including both name and title or role.</p>	<p>Reduces patient uncertainty.</p>
<p>2 Explain plan of care. Specifically discuss reasons that patient is at risk for falling.</p>	<p>Promotes patient cooperation. Younger patients are very independent and often believe they are not likely to fall.</p>
<p>3 Gather equipment and perform hand hygiene.</p>	<p>Promotes organization and reduces transmission of microorganisms.</p>

STEP

RATIONALE

- 4 Provide privacy. Assign patient to bed that allows an exit toward his or her stronger side. Position and drape patient as needed.
- 5 Adjust bed to low position with wheels locked (see illustration). Place padded mats on floor at side of bed.
- 6 Encourage patient to wear properly fitted skid-proof footwear. *Option:* Place nonslip padded floor mat on exit side of bed.
- 7 Orient patient to surroundings and call light/bed control system:
 - a Provide patient's hearing aid and glasses.
 - b Explain and demonstrate how to turn call light/intercom system on and off at bedside and in bathroom (see illustration). Have patient perform return demonstration.

Maintains patient's self-esteem. Enhances patient's ability to move in bed and transfer out of bed.

Allows for proper body mechanics. Height of bed allows ambulatory patient to get in and out of bed easily and safely. Pads provide nonslippery surface on which to stand.

Prevents falls from slipping on floor.

Enables patient to remain alert to conditions in environment. Knowledge of location and use of call light is essential to patient safety.

Brake lock

STEP 5 Hospital bed should be kept in lowest position with wheels locked and side rails up (as appropriate).

- c Explain to patient and family when and why to use call system (e.g., report pain, get out of bed, go to bathroom).
 - d Consistently secure call light/bed control system to an accessible location within patient's reach.
- 8 Use of hospital side rails (acute care):**
- a Explain to patient and family the main reason for using side rails: moving and turning self in bed.
 - b Check agency policies regarding side rail use.
 - (1) Dependent, less mobile patients:
In a two-side rail bed, keep both rails up. (NOTE: Rails on newer hospital beds allow for room at foot of bed for patient to safely exit bed.) In a four-side rail bed, leave two upper rails up.
 - (2) Patient able to get out of bed independently: In a four-side rail bed, leave only one upper side rail up. In a two-side rail bed, keep only one rail up.

STEP 7b Nurse demonstrates use of call light to patient.

Increases likelihood of nurse being able to respond.

Ensures that patient is able to reach device immediately when needed.

Promotes patient and family cooperation.

Side rails are a restraint device if they immobilize or reduce ability of patient to move his or her arms, legs, body, or head freely (CMS, 2008).

Allows for safe exit from bed.

Clinical Decision Point Assess for excessive gaps and openings between mattress, bedframe, and side rails.

- 9 Provide environmental interventions:
 - a Remove excess equipment, supplies, and furniture from rooms and halls.

Reduces likelihood of falls from tripping.

STEP	RATIONALE
b Keep floors clutter and obstacle free, particularly path to bathroom. Coil and secure excess electrical, telephone, and other cords or tubing.	Reduces likelihood of falls from tripping.
c Clean all spills promptly. Post sign indicating wet floor. Remove sign when floor is dry.	Reduces falls from slipping on wet surface.
d Ensure adequate glare-free lighting: use night-light at night.	Reduces fall risk since glare is a problem for older adults because of normal visual changes.
e Have assistive devices (e.g., walker, cane, bedside commodes) located on exit side of bed.	Provides added support when transferring out of bed. Commode eliminates need to get up to walk to bathroom.
f Arrange necessary items (e.g., water pitcher, eyeglasses, dentures, telephone) within patient's easy reach.	Prevents patient from reaching and allows him or her to perform self-care activities safely.
g Secure locks on beds, stretchers, and wheelchairs.	Prevents accidental movement of devices during patient transfer.
10 Additional interventions for patients at high risk (based on fall risk assessment):	Level of risk defined by fall risk assessment tool.
a Prioritize call light responses to patients at high risk, using a team approach,	Ensures rapid response to calls from patients.
b Monitor and assist patients in following daily schedules.	Patients are less likely to try an activity on their own when they have a defined schedule.
c Establish elimination schedule, using bedside commode when appropriate.	Proactive toileting keeps patients from being unattended with sudden urge to use toilet.
d Stay with patient during toileting.	Designed to maintain alignment and comfort and makes it difficult to exit chair.
e Place patients in geri chair or wheelchair with wedge cushion. Use wheelchair only for transport, not for sitting an extended time.	Reduces fall-related injuries.
f Use low bed that has low height above floor and floor mats.	Gait belt gives you secure hold on patient during ambulation.
g Activate bed alarm for patient.	Use of hourly rounds has been shown to reduce incidence of falls (Halm, 2009).
11 When ambulating patient, have patient wear gait belt and walk along patient's strong side (see Chapter 10).	Promotes patient understanding and cooperation. Dangling provides adjustment to orthostatic hypotension, allowing blood pressure to stabilize before ambulating (see Chapter 10).
12 Explain to patient that hourly rounds will be conducted to reassess for fall risks, provide toileting needs, and attend to symptom management.	There is evidence that sustained exercise programs may reduce falls (Oliver, Healey, and Haines, 2010).
13 Explain to patient specific safety measures to prevent falls (e.g., wear well-fitting, flat footwear with nonskid soles; dangle feet for a few minutes before standing; walk slowly; ask for help if dizzy or weak).	Evidence shows that medication assessment with modification (e.g., eliminating unnecessary medications, adjusting dosages) can reduce incidence of falls in home setting (Costello and Edelstein, 2008). Drug interactions can also have effects that place patients at risk in an acute care setting.
14 Consult with physical therapist about possibility of gait training and muscle-strengthening exercises.	Facilitates patient's ability to assist in transfer to chair.
15 Discuss with health care provider and pharmacist possibility of adjusting patient's medications to reduce side effects and interactions.	Wedge cushion prevents patient from slipping out of chair.
16 Safe transport using a wheelchair:	
a During transfer position wheelchair on same side of bed as patient's strong or unaffected side (see Chapter 9).	
b Place wedge cushion in chair (see illustration).	

STEP

RATIONALE

STEP 16b Wheelchair with footplates raised and wedge cushion in place.

| <p>c Securely lock brakes on both wheels when transferring patient into or out of wheelchair.</p> <p>d Raise footplates before transfer (see illustration for Step b); lower footplates, placing patient's feet on them after he or she is seated.</p> <p>e Have patient sit with buttocks well back in seat. <i>Option:</i> Apply a quick-release seat belt.</p> <p>f Back wheelchair into and out of elevator or door, leading with large rear wheels first.</p> | <p>Keeps chair steady and secure.</p> <p>Prevents tripping over footplate.</p> <p>Prevents patient from sliding out of chair.</p> <p>Prevents smaller front wheels from catching in crack between elevator and floor, causing chair to tip.</p> |
|--|---|

EVALUATION

- | | |
|--|--|
| <p>1 Conduct hourly rounds.</p> <p>2 Observe patient's immediate environment for presence of hazards.</p> <p>3 Evaluate patient's ability to use assistive devices.</p> <p>4 Ask patient or family member to identify safety risks.</p> <p>5 Evaluate motor, sensory, and cognitive status and review if any falls or injuries have occurred.</p> | <p>Monitors patient for ongoing risks of falling.</p> <p>Ensures that there are no obstacles or barriers to patient's freedom of movement.</p> <p>Determines if instruction or clarification is needed.</p> <p>Determines extent of learning.</p> <p>Determines how effective nursing interventions are in reducing actual or potential threats to patient's safety.</p> |
|--|--|

Unexpected Outcomes

- 1 Patient/family member is unable to identify safety risks.
- 2 Patient starts to fall while ambulating with a caregiver.
- 3 Patient found after suffering a fall.

Related Interventions

- Reinforce identified risks with patient or review needed safety measures with family.
- Put both arms around patient's waist or grasp gait belt.
- Stand with feet apart to provide broad base of support.
- Extend one leg and let patient slide against it to the floor (Fig. 13-2, A).
- Bend knees and lower body as patient slides to floor (Fig. 13-2, B).
- Call for assistance.
- Assess patient for injury and stay with him or her until assistance arrives.
- Notify primary health care provider and family members.
- Follow agency occurrence or sentinel event reporting policy.
- Note pertinent events related to fall and treatment provided in medical record.
- Evaluate patient and environment; determine whether fall could have been prevented.
- Reinforce identified risks with patient and measures recommended to prevent fall recurrence.
- Monitor patient closely after fall to assess for possible injury.

FIG 13-2 A, Stand with feet apart to provide broad base of support; extend one leg against which patient can slide to floor. B, Bend knees and lower body as patient slides to floor.

Recording and Reporting

- Record fall risk assessment findings and specific interventions, including instructions, used to prevent falls in nurses' notes, electronic health record (EHR), and/or care plan.
- Report to health care personnel specific risks to patient's safety and measures taken to minimize risks.
- If patient suffers a fall, inform primary health care provider. Document what occurred, including description of the fall as given by patient or witness. Be sure to include baseline assessment, any injuries noted, tests or treatments given, follow-up care, and additional safety precautions taken after fall.

Special Considerations

Teaching

- Make available to patients and families the website for the Centers for Disease Control and Prevention (CDC), which has resources on fall prevention at <http://www.cdc.gov/HomeandRecreationalSafety/Falls/index.html>.
- Encourage patients to have annual vision and hearing examinations. Adaptive devices such as a hearing aid or glasses are sometimes necessary or need modification.
- Emphasize to patients the need to always look ahead when ambulating and use good posture.
- Instruct patients on how to use assistive devices and keep them in good repair.

Pediatric

- Falls are the leading cause of nonfatal injuries for all children ages 0 to 19 (CDC, 2009). Encourage parents to follow these CDC recommendations:

- *Play safely.* Be sure that playground equipment that a child uses is properly designed and maintained and that there is a safe, soft landing surface below.
- *Make home safety improvements.* Use home safety devices such as guards on windows that are above ground level, stair gates, and guard rails.
- *Keep sports safe.* Be sure that a child wears protective gear such as wrist guards, knee and elbow pads, and a helmet for biking or skating when playing active sports.
- *Supervision is key.* Supervise young children at all times around fall hazards, whether at home or out to play.
- Children's activity levels and curiosity increase risk for falls. Eliminate places for the child to climb. Consider using a crib hood if child is hospitalized.
- Keep side rails of hospital beds down to allow toddlers and preschoolers easy exit and to decrease the need to crawl over the rails (Hockenberry and Wilson, 2011).
- When caring for infants, keep a hand on a child when you turn away from the bedside.

Gerontologic

- Interventions to improve balance confidence has shown benefits, including multicomponent behavioral group interventions and exercise (including tai chi), which increases lower body strength and dynamic balance (Bula et al., 2011).

Home Care

- See Chapter 41.

SKILL 13-2 Designing a Restraint-Free Environment

NSO Safety Module / Lesson 1

Physical and chemical restraints restrict a patient's physical activity or normal access to the body and are not a usual part of treatment indicated by a patient's condition or symptoms. Serious and often fatal complications can develop from the use of restraints. Because of the risks associated with restraint use, current legislation emphasizes reducing their use. A restraint-free environment is the first goal of care for all patients.

Patients at risk for falls or wandering present special safety challenges when trying to create a restraint-free environment. Wandering is the meandering, aimless, or repetitive locomotion that exposes a patient to harm and is often in conflict with boundaries, limits, or obstacles (NANDA, 2012). This is a common problem in patients who are confused or disoriented. Interrupting a wandering patient can increase distress. The Department of Veterans Affairs has suggestions for managing wandering, most of which are environmental adaptations. Some of these include hobbies, social interaction, regular exercise, and circular design of a care unit (VA NCPS, 2010). Environmental modifications are effective alternatives to restraints. More frequent observation of patients, involvement of family during visitation, and frequent reorientation are also helpful measures. *There are many alternatives to the use of restraints. Use these alternatives before applying restraints.*

Delegation and Collaboration

The skills of assessing patient behaviors and orientation to the environment and determining the type of restraint-free interventions to use cannot be delegated to nursing assistive personnel (NAP). However, actions for promoting a safe environment can be delegated to NAP. The nurse instructs the NAP about:

- Using specific diversional or activity measures for making the environment safe.
- Applying appropriate alarm devices.
- Reporting patient behaviors and actions (e.g., confusion, getting out of bed unassisted, combativeness) to the nurse.

Equipment

- ❑ Visual or auditory stimuli (e.g., calendar, clock, radio, television, pictures)
- ❑ Diversional activities (e.g., puzzle, game, audio books, DVD)
- ❑ Wedge cushion
- ❑ Wrap-around belt (Fig. 13-3)
- ❑ Ambularm or pressure-sensitive bed or chair alarm
- ❑ Bed enclosure system

FIG 13-3 Wrap-around belt. (Courtesy Posey Company, Arcadia, Calif.)

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's medical history for dementia and depression.
- 2 Assess patient's behavior (e.g., orientation, level of consciousness, ability to understand and follow directions, combative behaviors, restlessness, agitation), balance, gait, vision, hearing, bowel/bladder routine, level of pain, electrolyte and blood count values, and presence of orthostatic hypotension.
- 3 Review over the counter (OTC) and prescribed medications (see Skill 13-1) for interactions and untoward effects.
- 4 Assess patient's knowledge of condition and prescribed treatments.
- 5 For patients who wander or have known dementia, assess for cognitive decline using the Mini-Mental State Examination (MMSE) (see Chapter 6).
- 6 Assess degree of wandering behavior using Revised Algate Wandering Scale (RAWS) (Nelson and Algate, 2007).
- 7 For patients with dementia, ask family or friends about his or her usual communication style and cues to indicate pain, fatigue, hunger, need to urinate or defecate (Evans and Cotter, 2008).

Wandering is associated with these common conditions (Futrell, Melillo, and Remington, 2008).

Accurate assessment identifies patients with safety risks and the physiologic causes for patient behaviors that prompt caregivers to use restraints. Ensures proper selection of nonrestraint interventions.

Medication interactions or side effects often contribute to falling or altered mental status.

Knowledge of treatment protocols and rationales increases patient's cooperation.

Determines cause and nature of wandering, which leads to effective intervention selection.

The RAWS provides a quantitative measure for wandering in several domains as reported by caregivers, including persistent walking, spatial disorientation, and eloping behavior (Futrell, Melillo, and Remington, 2008).

Enables you to use best method to determine patient needs, which often prompt wandering when need is unmet.

STEP

RATIONALE

NURSING DIAGNOSES

- | | | |
|---|--|---|
| <ul style="list-style-type: none"> • Deficient knowledge • Risk for falls | <ul style="list-style-type: none"> • Risk for injury • Risk for trauma | <ul style="list-style-type: none"> • Wandering |
|---|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient is injury free and/or does not inflict injury on others while in a restraint-free environment. | <p>Restraints and/or alternatives are successful in preventing injury.</p> |
|--|--|

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Orient patient and family to surroundings, introduce to staff, and explain all treatments and procedures. Be sure that patient is able to read your name badge.</p> | <p>Promotes patient understanding and cooperation.</p> |
| <p>2 Assign same staff to care for patient as often as possible. Encourage family and friends to stay with patient. In some agencies, volunteers are effective companions.</p> | <p>Increases familiarity with individuals in patient's environment, decreasing anxiety and restlessness. Companions are often helpful, preventing patient from being alone.</p> |
| <p>3 Place patient in room that is easily accessible to caregivers, close to nurses' station.</p> | <p>Allows for frequent observation to reduce falls in high-risk patients (VA NCPS, 2010).</p> |
| <p>4 Be sure that patient has glasses, hearing aid, or other sensory-aid devices on and that all are functioning.</p> | <p>Improves patient's level of orientation to environment.</p> |
| <p>5 Provide visual and auditory stimuli meaningful to patient (e.g., clock, calendar, radio/MP3 player [with patient's choice of music], television, and family pictures).</p> | <p>Orients patient to day, time, and physical surroundings. You must individualize stimuli for this to be effective.</p> |
| <p>6 Anticipate patient's basic needs (e.g., toileting, relief of pain, relief of hunger) as quickly as possible.</p> | <p>Basic needs provided in timely fashion decreases patient discomfort, anxiety, and restlessness.</p> |

Clinical Decision Point *Getting out of bed for toileting purposes is one of the most common events leading to a patient's fall (Tzeng, 2010), especially during evening or night hours, when rooms are often dark.*

- | | |
|--|---|
| <p>7 Provide scheduled ambulation, chair activity, and toileting (e.g., ask patient every hour about toileting needs). Organize treatments so a patient has uninterrupted periods throughout the day.</p> | <p>Regular opportunity to void avoids risk of patient trying to reach bathroom alone. Provides for sleep and rest periods. Constant activity overstimulates patients.</p> |
| <p>8 Position intravenous (IV) catheters, urinary catheters, and tubes/drains out of patient view. Use camouflage by wrapping IV site with bandage or stockinette. Place undergarments on patient with urinary catheter or cover abdominal feeding tubes/drains with loose abdominal binder.</p> | <p>Maintains medical treatment and reduces patient access to tubes/lines.</p> |
| <p>9 Decrease wandering by eliminating stressors from environment such as cold at night, changes in daily routines, and extra visitors (Futrell, Melillo, and Remington, 2008).</p> | <p>Reduced stress allows patient's energy to be channeled more appropriately.</p> |
| <p>10 Use stress-reduction techniques such as back rub, massage, and guided imagery (see Chapter 15).</p> | <p>Meaningful diversional activities provide distraction, help to reduce boredom, and provide tactile stimulation. Minimize occurrences of wandering.</p> |
| <p>11 Use diversional activities such as puzzles, games, music therapy, pet therapy, activity apron, performing purposeful activity (e.g., folding towels, drawing/coloring). Be sure that it is an activity in which patient has interest. Involve a family member in the activity.</p> | <p>Meaningful diversional activities provide distraction, help to reduce boredom, and provide tactile stimulation. Minimize occurrences of wandering.</p> |
| <p>12 Position patient on wedge cushion and apply wraparound belt.</p> | <p>Cushion prevents slipping in chair and makes it difficult for patient to get out of chair without assistance. Wraparound belt allows patient to lift flap for self-release.</p> |
| <p>13 Use pressure-sensitive bed or chair pad with alarms:</p> <ul style="list-style-type: none"> a Explain use of device to patient and family. b When in the bed, position device so that it is under the patient's mid-to-low back or under buttocks. c Test alarm by applying and releasing pressure. | <p>Alarms alert staff to patient who is standing or rising without assistance.</p> <p>Alarm activates sooner if placed under back. By the time buttocks are off the sensor, patient may be almost out of bed.</p> <p>Ensures that alarm is audible through call light system.</p> |

STEP

RATIONALE

- 14** Use an Ambularm monitoring device.
- Explain use of device to patient and family.
 - Measure patient's thigh circumference just above knee to determine appropriate size: leg circumference less than 18 inches (45 cm) requires regular size; 18 inches or greater requires large size.
 - Test battery and alarm by touching snaps to corresponding snaps on leg band.
 - Apply leg band just above knee and snap battery securely in place (see illustration).
 - Instruct patient that alarm will sound unless he or she keeps leg in horizontal position (see illustration).
 - Deactivate alarm to ambulate patient; unsnap device from leg band.
- 15** Place patient in bed enclosure system (see illustration).

Reinforces person's risk for falling or wandering.
Band that is too loose slips off; one that is too tight irritates skin or interferes with circulation.

Restraint alternative that allows patient freedom of movement within a protected environment.

STEP 14d Snap battery in place to activate alarm. (Courtesy Alert Care, Tiburon, Calif.)

STEP 14e Audio alarm sounds when patient approaches near-vertical position when getting out of bed. (Courtesy Alert Care, Tiburon, Calif.)

STEP 15 Bed enclosure system.

STEP

RATIONALE

- 16 Consult with physical, speech, and occupational therapy for activities that provide stimulation and exercise.
- 17 Minimize invasive treatments (e.g., tube feedings, blood sampling) as much as possible.

Involvement in meaningful and purposeful activities reduces tendency to wander. Exercise improves balance and coordination. Stimuli increase patients' restlessness.

EVALUATION

- 1 Observe patient for any injuries.
- 2 Observe patient's behavior toward staff, visitors, and other patients.
- 3 Determine need for continuation of invasive treatments and whether you can substitute less invasive treatment.

Patient should be injury free.
Ensures that patient's behavior does not cause injury to others.
Eliminates cause and reason for restraint.

Unexpected Outcomes

- 1 Patient displays behaviors that increase risk for injury to self or others.
- 2 Patient sustains injury or is out of control, placing others at risk for injury.

Related Interventions

- Review episodes for pattern (e.g., activity, time of day) that indicates alternatives that would eliminate behavior.
- Discuss with all caregivers and family alternative interventions.
- Notify health care provider and complete incident or occurrence report according to agency policy.
- Identify alternative measures for safety or behavioral control.
- Apply physical restraint (see Skill 13-3) only after all other interventions are unsuccessful.

Recording and Reporting

- Record restraint alternatives attempted, patient behaviors that relate to cognitive status, and interventions to mediate these behaviors in nurses' notes, EHR, and/or care plan.

Gerontologic

- Keep older adults active and ambulatory to increase endurance and function.
- Reminiscence helps older adults remain oriented.

Special Considerations

Teaching

- Teach family members ways to involve patient in their visits, keeping patient appropriately stimulated.
- Teach the family how to adapt the home environment (see Chapter 42) to minimize patient wandering.

Home Care

- Patients at risk for self-injury or violence to others need intensive supervision. Family and health care providers need to recognize this and take appropriate preventive measures.
- Have family members set up an area in the home where it is safe for an older adult to wander.

SKILL 13-3 Applying Physical Restraints

NSO Safety Module / Lesson 2

A physical restraint is any manual method, physical or mechanical device, material, or equipment that immobilizes or reduces the ability of a patient to move his or her extremities, body, or head freely (CMS, 2008). A drug may be considered a chemical restraint when it is given to manage behavior or restrict freedom of movement and is not part of the standard treatment for a patient's condition (NAPHS, 2007). Physical or chemical restraints should be the last resort and used only when reasonable alternatives fail (see Skill 13-2).

Restraints are most commonly used in hospitals to prevent the disruption of therapy, such as pulling out intravenous (IV) tubes or removing urinary catheters. Restraint use is more common in critical care settings, where nurses are concerned that disruption of therapy can significantly injure patients (Mion, 2008). The use of physical restraints is no longer a safe strategy, yet many nurses still believe that they are needed to control behavioral symptoms

and prevent falls in older adults with dementia (Evans and Cotter, 2008). The Centers for Medicare and Medicaid Services (CMS, 2008) and The Joint Commission (TJC, 2009a) have set standards for reducing the use of restraints in health care settings and using them only with extreme caution. In 2011 the National Quality Forum (NQF) released its National Voluntary Consensus Standards for Public Reporting of Patient Safety Events (NQF, 2011b). The report provides a framework for publicly reporting patient safety information, including adverse events, about health care organizations to consumers. The NQF has endorsed a select list of serious reportable events, one of which is patient death or serious disability associated with the use of restraints or bedrails while being cared for in a health care agency.

The CMS (2008) released revisions to the Medicare conditions of participation, outlining standards for the safe use of restraints

in hospitals and defining patients' rights and choices regarding restraints. It requires that a restraint be used only under the following circumstances: (1) to ensure the immediate physical safety of the patient, a staff member, or others; (2) when less restrictive interventions have been ineffective; (3) in accordance with a written modification to the patient's plan of care; (4) when it is the least restrictive intervention that will be effective to protect the patient, staff member, or others from harm; (5) in accordance with safe and appropriate restraint techniques as determined by hospital policies; and (6) it is discontinued at the earliest possible time.

Restraints are a temporary means to maintain patient safety. However, there is no evidence that they prevent falls, reduce wandering, or prevent medical devices from being pulled out (Ebersole et al., 2008). Research has shown that patients suffer fewer injuries if left unrestrained (Knox and Holloman, 2012). The use of mechanical or physical restraints requires a licensed health care provider's order and must be based on a face-to-face patient assessment. The order must be current, specifying the type of restraint and the duration and circumstances or patient behaviors under which the restraint is to be used. Orders should be renewed according to agency policy (usually every calendar day) and based on reassessment and reevaluation of the restrained patient. A patient's or family member's informed consent is necessary in the long-term care setting.

The use of restraints is associated with serious complications, including pressure ulcers, hypostatic pneumonia, constipation, incontinence, and death. The Food and Drug Administration

(FDA) regulates restraints as medical devices and requires manufacturers to label them "prescription only." Most patient deaths in the past have resulted from strangulation from a vest or jacket restraint. Numerous agencies no longer use vest restraints. For these reasons this text does not describe their use.

Delegation and Collaboration

The skills of assessing a patient's behavior and level of orientation, the need for restraints, the appropriate restraint type, and the ongoing assessments required while a restraint is in place cannot be delegated to nursing assistive personnel (NAP). Applying and routinely checking a restraint can be delegated to NAP. The Joint Commission (2009a) requires training on first aid for anyone who monitors patients in restraints. The nurse directs the NAP by:

- Reviewing correct placement of the restraint and how to routinely check the patient's circulation, skin condition, and breathing.
- Reviewing when and how to change a patient's position and provide range-of-motion (ROM) exercises, toileting, and skin care.
- Instructing NAP to notify nurse immediately if there is a change in level of patient agitation, skin integrity, circulation of extremities, or patient's breathing.

Equipment

- ☐ Proper restraint (e.g., belt, wrist, mitten)
- ☐ Padding (if needed)

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's behavior (e.g., confusion, disorientation, agitation, restlessness, combativeness, repeated removal of tubing or other therapeutic devices, and inability to follow directions).
- 2 Follow agency policies regarding restraints. Check health care provider's order for purpose, type, location, and time or duration of restraint. Determine if signed consent for restraint use is needed.

If patient's behavior continues despite treatment or restraint alternatives, use of restraint is indicated.

In acute care settings a licensed health care provider who is responsible for care of patient must order least restrictive type of restraint. Each original restraint order is limited to 4 hours for adults 18 years of age and older, 2 hours for children ages 9 through 17, and 1 hour for children under age 9 (TJC, 2009a). Original orders may be renewed up to maximum of 24 hours (CMS, 2008).

Clinical Decision Point *If a nurse or qualified health provider (see agency policy) restrains a patient in an emergency situation because of violent or aggressive behavior that presents an immediate danger, a face-to-face health care provider assessment within 1 hour is necessary (TJC, 2012a).*

- 3 Review manufacturer instructions for correct restraint application and determine most appropriate size of restraint.
- 4 Inspect area where restraint is to be placed. Note if there is any nearby tubing or devices. Assess condition of skin, sensation, adequacy of circulation, and ROM.

You need to be familiar with all devices used for patient care and protection. Incorrect application of restraint device can result in patient injury or death.

Provides baseline to monitor patient's response to restraint. Provides baseline data to monitor patient's skin integrity.

NURSING DIAGNOSES

- Anxiety
- Risk for impaired skin integrity
- Risk for impaired physical mobility.
- Risk for injury
- Risk for peripheral neurovascular dysfunction
- Risk for self-directed or other-directed violence

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- Expected outcomes following completion of procedure:
 - Patient maintains intact skin integrity, pulses, temperature, color, and sensation of restrained body part.
 - Patient is free from injury.
 - Patient's therapy (e.g., IV tube, catheters) is uninterrupted.
 - Patient maintains self-esteem and sense of dignity.
 - Restraint is discontinued as soon as possible.

Restraints applied and monitored correctly.

Restraints removed in timely manner.

Disruption of therapy causes patient injury, pain, or discomfort and increases risk for infection.

Physical restraints have detrimental effect on psychosocial well-being of patient.

Limits period of time patient is at risk for injury.

IMPLEMENTATION

- Gather equipment and perform hand hygiene.
- Use calm approach and introduce yourself to patient, including both name and title or role.
- Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.
- Provide privacy. Explain to patient and family purpose of restraint. Be sure that patient is comfortable and in correct anatomic position.
- Adjust bed to proper height and lower side rail on side of patient contact.
- Pad skin and bony prominences (as necessary) that will be covered by restraint.
- Apply proper-size restraint: *Follow manufacturer directions.*

Promotes organization and reduces transmission of microorganisms.

Reduces patient anxiety and uncertainty.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012b).

May promote cooperation. Positioning prevents contractures and neurovascular impairment.

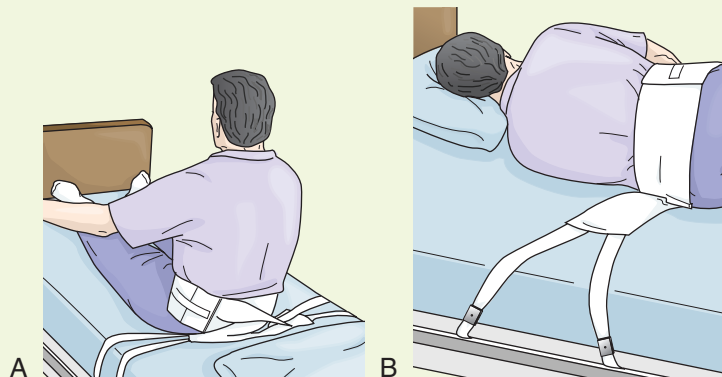

Allows you to use proper body mechanics and prevent injury.

Reduces friction and pressure from restraint to skin and underlying tissue.

a Belt restraint:

Have patient in sitting position. Apply belt over clothes, gown, or pajamas. Make sure to place restraint at waist, not chest or abdomen. Remove wrinkles or creases in clothing. Bring ties through slots in belt. Help patient lie down if in bed. Avoid applying belt too tightly (see illustrations).

Restrains center of gravity and prevents patient from rolling off stretcher, sitting up while on stretcher, or falling out of bed. Tight application or misplacement can interfere with ventilation. This type of restraint may be contraindicated in patient who had abdominal surgery.

STEP 7a A, Apply belt restraint with patient sitting. B, Properly applied belt restraint allows patient to turn in bed. (A from Sorrentino SA: *Mosby's textbook for nursing assistants, ed 7, St Louis, 2008, Mosby.*)

b Extremity (ankle or wrist) restraint:

Commercially available limb restraints are made of sheepskin with foam padding. Wrap limb restraint around wrist or ankle with soft part toward skin and secure snugly (not tightly) in place by Velcro straps. Insert two fingers under secured restraint (see illustration).

Restraint immobilizes one or all extremities to protect patient from fall or accidental removal of therapeutic device (e.g., IV tube, Foley catheter).

Tight application interferes with circulation and causes neurovascular injury.

STEP

RATIONALE

STEP 7b Securing an extremity restraint. Check restraint for constriction by inserting two fingers under restraint. (From Sorrentino SA: Mosby's textbook for nursing assistants, ed 7, St Louis, 2008, Mosby.)

Clinical Decision Point Patient with extremity restraints is at risk for aspiration if placed in supine position. Place patient in lateral position or with head of bed elevated rather than supine.

c Mitten restraint:

Thumbless mitten device restrains patient's hands. Place hand in mitten, being sure that Velcro strap(s) are around wrist and not forearm (see illustration).

Prevents patients from dislodging invasive equipment, removing dressings, or scratching; yet allows greater movement than wrist restraint.

d Elbow restraint (freedom splint):

Restraint consists of rigidly padded fabric that wraps around arm and is closed with Velcro. Upper end has a clamp that hooks to patient's gown sleeve (see illustration). Insert patient's arm so elbow joint rests against padded area, keeping joint rigid.

Commonly used with infants and children to prevent elbow flexion (e.g., when IV line placed in antecubital fossa). May also be used for adults.

STEP 7c Mitten restraint. (Courtesy Posey Company, Arcadia, Calif.)

STEP 7d Elbow restraint. (Courtesy Posey Company, Arcadia, Calif.)

- 8 Attach restraint straps to portion of bedframe that moves when raising or lowering head of bed. Be sure that straps are secure. *Do not attach to side rails.* Restraints can be attached to frame of chair or wheelchair as long as ties are out of patient's reach.
- 9 Secure restraints with quick-release tie (see illustrations), buckle, or adjustable seat belt–like locking device. *Do not tie in a knot.*
- 10 Double-check and insert two fingers under secured restraint.

Patient will be injured if restraint is secured to side rail and bed is then lowered.

Allows for quick release in emergency.

Checking for constriction prevents neurovascular injury.

STEP

RATIONALE

STEP 9 Posey quick-release tie. (Courtesy Posey Company, Arcadia, Calif.)

Clinical Decision Point Restraint should not interfere with equipment such as an IV line or be placed over other types of access devices such as an arteriovenous shunt.

- | | |
|--|---|
| <p>11 Assess proper placement of restraint, including skin integrity, pulses, temperature, color, and sensation of restrained body part.</p> <p>12 Remove restraints at least every 2 hours (TJC, 2012a) or according to agency policy and assess patient each time. If patient is violent or noncompliant, remove one restraint at a time and/or have staff assist while removing restraints.</p> | <p>Provides baseline to later evaluate if injury develops from restraint use.</p> <p>Removal provides opportunity to change patient's position, offer nutrients, perform full ROM, toilet and exercise patient.</p> |
|--|---|

Clinical Decision Point Do not leave violent or aggressive patient unattended while restraints are off.

- | | |
|---|--|
| <p>13 Secure call light or intercom system within reach.</p> <p>14 Leave bed or chair with wheels locked. Keep bed in lowest position.</p> <p>15 Perform hand hygiene.</p> | <p>Allows patient, family, or caregiver to obtain assistance quickly.</p> <p>Locked wheels prevent bed or chair from moving if patient tries to get out. Placing bed in lowest position reduces chance of injury if patient falls out of bed.</p> <p>Reduces transmission of microorganisms.</p> |
|---|--|

EVALUATION

- | | |
|---|---|
| <p>1 Following application, evaluate patient's condition for signs of injury every 15 minutes (e.g., circulation, nutrition and hydration, ROM in extremities, vital signs, hygiene and elimination, physical and psychological status, and readiness for discontinuation). Visual checks can be performed if patient is too agitated to approach (TJC, 2012a).</p> <p>2 Evaluate patient for any complications of immobility.</p> <p>3 Observe IV catheters, urinary catheters, and drainage tubes routinely.</p> <p>4 Evaluate patient's need for restraints on an ongoing basis (see agency policy). When restraint is used for violent or self-destructive behavior, licensed health care provider must evaluate patient in person within 1 hour of initiation of restraints.</p> | <p>Frequent assessments prevent injury to patient and allows for removal of restraint at earliest possible time.</p> <p>Limitation in movement can result in complications (e.g., pressure ulcers, ventilation impairments).</p> <p>Determines if therapeutic devices are positioned correctly and that therapy remains uninterrupted.</p> <p>Ensures that restraint application continues to be medically appropriate. Orders may be renewed within these limits: 4 hours for adults 18 and over, 2 hours for children ages 9 through 17, and 1 hour for children under 9 years of age (TJC, 2009a). Original orders may be renewed up to a maximum of 24 hours (CMS, 2008).</p> |
|---|---|

Unexpected Outcomes

- 1 Patient experiences impaired skin integrity.
- 2 Patient has altered neurovascular status of an extremity (e.g., cyanosis, pallor and coldness of skin) or complaints of tingling, pain, or numbness.
- 3 Patient has increased confusion, disorientation, and agitation.
- 4 Patient releases restraint and suffers a fall or other traumatic injury.

Related Interventions

- Reassess need for continued use of restraint and if you can use alternative measures. If restraint is necessary to protect patient or others from injury, ensure that you applied it correctly and provided adequate padding.
- Check skin under restraint for abrasions and remove restraints more frequently.
- Institute appropriate skin/wound care.
- Change wet or soiled restraints to prevent skin breakdown.
- Remove restraint immediately and notify health care provider.
- Evaluate cause for altered behavior and attempt to eliminate cause.
- Provide appropriate sensory stimulation, reorient as needed, attempt restraint alternatives, involve family.
- Attend to patient's immediate physical needs, inform health care provider of fall or injury, and reassess type of restraint and its correct application.

Recording and Reporting

- Record patient's behavior before and after restraints were applied, level of orientation, and patient's or family member's statement of understanding of purpose of restraint and consent (when required).
- Record restraint alternatives tried and patient's response in nurses' notes and EHR.
- Record reason for restraint, the type and location, the time applied, the time ending the restraints, and the routine observations made every 15 minutes (e.g., skin color, pulses, sensation, vital signs, behavior) in the nurses' notes and EHR and flow sheets.

Special Considerations

Teaching

- Explain thoroughly the use of restraints. Caution family against removing, repositioning, or retying restraint.

Pediatric

- Limit the use of restraints to clinically appropriate and adequately justified situations (e.g., examination or treatment that involves the head and neck) after using all appropriate alternatives. Remain with infant while restrained and remove restraint immediately after treatment is completed.

- When a child needs to be restrained for a procedure, it is best if the person applying the restraint is not the child's parent or guardian.
- When an infant or small child requires a restraint, a papoose board with straps or a mummy wrap using a blanket or sheet effectively controls his or her movements (Hockenberry and Wilson, 2011).

Gerontologic

- Restrained older adults often respond with anger, fear, depression, humiliation, demoralization, discomfort, and resignation.
- Consider the risks associated with restraints (e.g., pressure ulcers, impaired strength and balance) for older adults (Meiner, 2011). All of the complications of immobility are amplified, leading to greater risk for functional decline.

Home Care

- A health care provider's order is needed for use of a restraint in the home. Provide clear, detailed instructions to the family caregiver, with a return demonstration of restraint application. Do not send a restraint home with family unless device is necessary to protect patient from injury. Carefully assess the family caregiver for competency and understanding of intent for using restraint.

PROCEDURAL GUIDELINE 13-1 Fire, Electrical, and Chemical Safety

Fires in health care settings are typically electrical or anesthetic related. Although smoking is not allowed in health care agencies, smoking-related fires still pose a significant risk because of unauthorized smoking in beds or bathrooms. In the home setting oxygen-related fires are a risk for patients requiring continuous oxygen therapy (see [Chapter 23](#)). Health care agencies need to routinely check and maintain all electrical devices. Every biomedical device (e.g., suction machine, infusion pump) must have a safety inspection sticker with an expiration date applied to it. Electrical equipment in good working order requires a three-prong electrical plug for proper grounding. If a patient brings an electrical device to the hospital, an engineer must inspect the device for safe wiring and function before use. Always discourage patients from

bringing nonessential electrical devices (e.g., hair dryers or electric toothbrushes) into a health care agency. Many patients with disabilities use battery chargers for mobility equipment function. These devices need to be inspected by hospital engineers as well.

Prevention is the key to fire safety. Nursing measures include complying with agency smoking policies, using equipment correctly, and keeping combustible materials away from heat sources. If a fire occurs, health care personnel report the exact location of the fire, contain it, and extinguish it only if it is safe and possible. All personnel are then mobilized to evacuate patients if needed. Most agencies have fire doors that are held open by magnets and close automatically when a fire alarm sounds. Fire doors should *never* be blocked.

PROCEDURAL GUIDELINE 13-1 Fire, Electrical, and Chemical Safety—cont'd

Chemicals in many medications (e.g., chemotherapy drugs), anesthetic gases, cleaning solutions, and disinfectants are potentially toxic. They injure the body after skin or mucous membrane (e.g., eyes) contact, ingestion, or vapor inhalation. Health care agencies provide employees access to a material safety data sheet (MSDS) for each hazardous chemical in the workplace. An MSDS form contains information about the properties of the particular chemical and information for handling the substance in a safe manner (e.g., storage, disposal, protective equipment, and spill-handling procedures).

Delegation and Collaboration

The skill of protecting patients from fire, electrical, and chemical hazards can be delegated to nursing assistive personnel (NAP). When an event occurs, a nurse leads the health care team in an emergency response. In the event of fire the health care team collaborates with the local fire department. In the event of an electrical or chemical event the team collaborates with the safety officer of the agency. The nurse directs the NAP to:

- Identify patients requiring the most assistance to evacuate or protect.
- Alert the nurse to any risk for chemical exposure.

Equipment**Fire**

- Appropriate fire extinguisher for fire: type A, B, C, or ABC

Chemical

- Appropriate personal protective equipment: clean gloves, mask, gown
- MSDS form

Procedural Steps

- 1 Review agency guidelines for rapid response to fire, electrical, and chemical emergency. Know your responsibilities such as initiating fire alarm and patient evacuation.
- 2 Know the location of fire alarms, emergency equipment (e.g., fire extinguishers), MSDS forms, emergency eyewash stations, and emergency exit routes.
- 3 Assess patient's mental status and ability to ambulate, transfer, or move to anticipate the procedures that will be needed to evacuate him or her.
- 4 Be alert to situations that increase the risk of fire (e.g., a patient on oxygen charging a cell phone while in the bed).
- 5 Know which patients are on oxygen. Oxygen delivery may be shut off in the event of a severe fire.
- 6 Inspect equipment for current maintenance sticker. Check electrical equipment for basic safety features (i.e., intact cords and plugs, intact casing). Know agency process for tagging and reporting broken or unsafe equipment.
- 7 Fire safety:
 - a Follow the acronym RACE.
 - (1) Rescue patient from immediate injury by removing from area or shielding from fire to avoid burns.
 - (2) Activate fire alarm immediately. Follow agency policy for alerting staff to respond. (In many situations perform Steps (1) and (2) simultaneously by using call system to alert staff while you help patients at risk.)
 - (3) Contain the fire by:
 - (a) Closing all doors and windows.
 - (b) Turning off oxygen and electrical equipment.
 - (c) Placing wet towels along base of doors.

- (4) Evacuate patients:
 - (a) Direct ambulatory patients to walk by themselves to a safe area. Know the fire exits and emergency evacuation route.
 - (b) If patient is on life support, maintain respiratory status manually until you remove him or her from fire area.
 - (c) Move bedridden patients by stretcher, bed, or wheelchair.
 - (d) For patients who cannot walk or ambulate (*Options*):
 - i Place on blanket and drag patient out of area of danger.
 - ii Use *two-person swing*: Place patient in sitting position and have two staff members form a seat by clasping forearms together. Lift patient into "seat" and carry out of area of danger (see illustrations A and B).

STEP 7a(4)(d)ii **A**, Hands positioned to form two-person evacuation swing. **B**, Patient seated firmly on swing and holding shoulders of nurses for evacuation.

- iii Use *"back-strap"* method: Stand in front of patient and place his or her arms around your neck. Grasp patient's wrists firmly against your chest. Pull patient onto your back and carry out of danger.

PROCEDURAL GUIDELINE 13-1 Fire, Electrical, and Chemical Safety—cont'd

- (5) If fire department personnel are on the scene, they will help with evacuation of patients.

Clinical Decision Point Know the weight and size of patients and their self-help ability when choosing an evacuation carry. Use safe patient-handling techniques. Use of a two-person carry versus trying to carry patient independently reduces risk for injury.

- b Extinguish fire using appropriate fire extinguisher: type A for ordinary combustibles (e.g., wood, cloth, paper, most plastics), type B for flammable liquids (e.g., gasoline, grease, paint, anesthetic gas), type C for electrical equipment, type ABC for any type of fire (most common extinguisher in use).
- (1) To use an extinguisher, follow the acronym PASS:
- Pull the pin (see illustration A).
 - Aim nozzle at base of fire (see illustration B).
 - Squeeze extinguisher handles (see illustration C).
 - Sweep from side to side to coat area evenly.
- 8 Electrical safety:
- If patient receives an electrical shock, immediately unplug the electrical source and assess for presence of a pulse. *Caution:* When disengaging electrical source, check for presence of water on floor.

Clinical Decision Point Do not touch a person who is being shocked while he or she is still engaged with the electrical source. If unable to disconnect source, call emergency number for assistance.

- Once the source of electricity is disconnected, provide appropriate interventions. If patient is pulseless, institute emergency resuscitation (see Chapter 27).
 - Notify emergency personnel and patient's health care provider.
 - If patient has a pulse and remains alert and oriented, obtain vital signs and assess the skin for signs of thermal injury.
- 9 Chemical safety:
- Attend to any person exposed to a chemical. Treat chemical splashes to the eyes immediately; flush eyes with water. Use clean, lukewarm tap water for 15 to 20 minutes; stand under a shower, or place head under running faucet. Remove contact lenses if flushing does not remove them (see Chapter 19).
 - Notify persons in the immediate area of the spill and evacuate all nonessential personnel from area.
 - Refer to MSDS; if spilled material is flammable, turn off electrical and heat sources.
 - Avoid breathing vapors of spilled material; apply appropriate respirator.
 - Use appropriate personal protective equipment (refer to MSDS) to clean up a spill.
 - Dispose of any materials used in cleanup as hazardous waste.
- 10 Regularly inspect patient's room for fire or electrical hazards.
- 11 Follow agency policy for reporting a sentinel event (Procedural Guideline 13-2). Documentation will likely be made as a sentinel event report and not in nurses' notes or EHR.

STEP 7b(1)(a-c) A, Pull safety pin from fire extinguisher. B, Aim nozzle of hose at base of fire. C, Squeeze handle while sweeping side to side with nozzle.

SKILL 13-4 Seizure Precautions

Seizures are sudden, abnormal, and excessive electrical discharges from the brain that change motor or autonomic function, consciousness, or sensation. Seizures are epileptic and nonepileptic. Epileptic seizures result from epilepsy, a neurologic condition in which a brain abnormality causes recurrent seizure activity. Nonepileptic seizures are a response to a stimulus outside of the central nervous system such as alcohol withdrawal, high fever, drug toxicity, and poisoning. The two basic types of seizures are partial (simple and complex) and generalized. A partial seizure starts in a specific part of the brain. In a simple seizure a patient does not lose consciousness. In a partial complex seizure a patient loses consciousness. Generalized seizures, of which there are several types, affect the whole brain and cause both nonconvulsive and convulsive seizures. Status epilepticus, characterized by prolonged seizures lasting more than 10 minutes or a series of seizures that occur in rapid succession over 30 minutes, is a medical emergency (Eliahu et al., 2008).

Your role as a nurse is to protect patients who have a seizure disorder from harm. The most immediate risks from a generalized seizure are traumatic injury and choking, requiring you to protect the patient physically and assist with airway management as needed. After that you assess cardiopulmonary effects and administer ordered antiseizure medications. Because each type of seizure has a unique combination of clinical features, it is important to assess a patient carefully if you witness a seizure. Careful observation may help to determine the type of seizure. For example, a generalized seizure lasts from 1 to 2 minutes. A cry, loss of consciousness, tonic (muscle rigidity), clonic (rhythmic muscle jerking), and incontinence are all characteristics. Following the seizure there is a postictal phase, which lasts for up to an hour.

During a seizure perform interventions to keep the patient's airway open. Traditionally nurses have used oral airways to

maintain the patient's airway. However, forcing an object into a patient's mouth can injure the jaw, tongue, or teeth and cause stimulation of the gag reflex, causing vomiting, aspiration, and respiratory distress (NINDS, 2011). Forcing an airway or tongue blade into a patient's mouth is no longer recommended. Insert an airway only when there is clear access for insertion, possibly after the seizure resolves and there is a need for airway support.

Delegation and Collaboration

The skill of assessing a patient on seizure precautions cannot be delegated to nursing assistive personnel (NAP). However, the skills for making a patient's environment safe can be delegated. The nurse directs NAP by:

- Explaining the patient's prior seizure history and factors that may trigger a seizure.
- Instructing to inform the registered nurse immediately when seizure activity develops.
- Explaining how to protect the patient in the event of a seizure.
- Emphasizing not to try to restrain the patient or place anything in the patient's mouth during a seizure.

Equipment

- Suction machine
- Oral airway
- Oral Yankauer suction catheter
- Oxygen via nasal cannula or face mask
- Equipment for vital signs (see Chapter 5)
- Equipment for intravenous access (see Chapter 31)
- Emergency medications (e.g., IV diazepam, lorazepam, valproate [Depacon], phenytoin [Dilantin])
- Clean gloves

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <p>1 Assess patient's seizure history (e.g., new diagnosis, frequent seizures, seizure within last year) and knowledge of precipitating factors. Ask patient to describe frequency of past seizures, presence and type of aura (e.g., metallic taste, perception of breeze blowing on face, or noxious odor), and body parts affected if known. Use family as resource if necessary.</p> | <p>Knowledge about seizure history enables nurse to anticipate onset of seizure activity and take appropriate safety measures.</p> |
| <p>2 Assess for medical and surgical conditions, including history of head trauma, electrolyte disturbances (e.g., hypoglycemia, hyperkalemia), heart disease, excess fatigue, alcohol or caffeine consumption.</p> | <p>Common conditions lead to seizures or worsen existing seizure condition.</p> |
| <p>3 Assess medication history (e.g., antidepressants and antipsychotics). Assess for patient's adherence to anticonvulsants and therapeutic drug levels if test results available.</p> | <p>Certain medications lower seizure threshold.
If patient does not take seizure medications as prescribed and stops them suddenly, this often precipitates seizure activity.</p> |
| <p>4 Inspect patient's environment for potential safety hazards (e.g., extra furniture) if seizure occurs. Keep bed in low position, side rails up at head of bed, patient in side-lying position when possible.</p> | <p>Protects patient from injury sustained by striking head or body on furniture or equipment.</p> |
| <p>5 Assess patient's individual and cultural perspective about the meaning of seizures and their treatment.</p> | <p>Some cultures follow different caring practices for a person with seizures.</p> |

STEP

RATIONALE

NURSING DIAGNOSES

- Deficient knowledge
- Noncompliance
- Risk for aspiration
- Risk for ineffective airway clearance
- Situational low self-esteem

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Patient remains free of traumatic injury while experiencing seizure.
- Patient's airway remains patent during seizure activity.
- Patient does not experience lowered sense of self-esteem following seizure episode.

Seizure precautions prevent patients from incurring injury from a fall or generalized seizure activity.

Airway occlusion and aspiration are potential complications of seizure activity.

Loss of bowel or bladder control is common in generalized seizures, causing patient to feel embarrassment or shame.

IMPLEMENTATION

1 For patients with a history of seizures, keep bed in lowest position with side rails up (see agency policy). Pad rails if patient is at risk for head injury. Have oral suction and oxygen equipment ready for use.

2 Patient with history of seizures should be in room close to nurse's station or room with video monitor.

3 Seizure response:

a Position patient safely

(1) If standing or sitting, guide patient to floor and protect head in your lap or place pillow under head. Turn patient onto side with head tilted slightly forward. Do not lift patient from floor to bed during seizure.

(2) If patient is in bed, turn him or her onto side and raise side rails.

b Note time seizure began and call for help. Track duration of seizure. Have health care provider notified immediately. Have staff member bring emergency cart to bedside and clear surrounding area of furniture.

c Keep patient in side-lying position, supporting head and keeping it flexed slightly forward.

d If possible, provide privacy. Have staff control flow of visitors in area.

e Do not restrain patient; if patient is flailing limbs, hold them loosely. Loosen restrictive clothing/gown.

f *Never force any object into patient's mouth* such as fingers, medicine, tongue depressor, or airway when teeth are clenched.

Reduces risk of fall and injury. Equipment ensures prompt intervention directed toward maintaining a patent airway. Padded side rails are used only when patient is at risk for head injury (Clore, 2010; Lewis et al., 2011).

Improves likelihood of quick response with emergency equipment.

Position protects patient from aspiration and traumatic injury, especially head injury.

Reduces exposure to injury. Description of seizure may help in ultimate identification of type of seizure.

Position prevents tongue from blocking airway and promotes drainage of secretions, reducing risk of aspiration.

Embarrassment is common after a seizure, especially if others witnessed it.

Prevents musculoskeletal injury. Promotes free ventilatory movement of chest and abdomen.

Prevents injury to mouth and possible aspiration.

Clinical Decision Point *Injury can result from forcible insertion of a hard object into the mouth. Soft objects break and become aspirated. Insert a bite block or oral airway in advance if you recognize the possibility of a generalized seizure.*

g Maintain patient's airway; suction orally as needed. Check patient's level of consciousness and oxygen saturation. Provide oxygen by nasal cannula or mask if ordered. *Use oral airway only if you can easily access oral cavity* (see Chapter 27).

Prevents hypoxia during seizure activity.

h Observe sequence and timing of seizure activity. Note type of seizure activity (tonic, clonic, staring, blinking); whether more than one type of seizure occurs; sequence of seizure progression; level of consciousness; character of breathing; presence of incontinence; presence of autonomic signs of lip smacking, mastication, or grimacing; rolling of eyes.

Continued observation helps to document, diagnose, and treat seizure disorder.

STEP

RATIONALE

- i As patient regains consciousness, assess vital signs and reorient and reassure him or her. Explain what happened and answer patient's questions. Stay with patient until fully awake.
- 4 Status epilepticus is a medical emergency.
 - a Call health care provider and response team immediately.
 - b Insert oral airway (see Chapter 27) when jaw is relaxed (between seizure activity).
 - c Access oxygen and suction equipment; keep airway patent.
 - d Prepare for IV insertion (if one is not in place) and administration of IV antiseizure medications.
- 5 After seizure assist patient to side-lying position in bed with padded side rails (if needed) up and bed in lowest position (see illustration). Place call light or intercom system within reach and provide quiet, nonstimulating environment. Instruct patient not to get out of bed without assistance.

Informing patients of type of seizure activity experienced helps them to participate knowledgeably in their care. Some patients remain confused for a period of time after the seizure or become violent.

Medical emergency requires rapid response. Provides route for intravenous (IV) medication.

Provides for continued safety. Patients are often confused and lethargic following a seizure (postictal).

STEP 5 Position of patient following seizure and when on seizure precautions.

- 6 As patient regains consciousness, reorient and reassure. Explain what happened and provide time for him or her to express feelings and concerns.
- 7 Perform hand hygiene.

Patients may be confused postictal. Patients who understand disease are better prepared to manage their seizure activity and have higher self-esteem.

Reduces transmission of microorganisms.

EVALUATION

- 1 Check vital signs and oxygen saturation every 15 minutes during postictal phase and maintain patent airway.
- 2 Examine patient for injury, including oral cavity (broken teeth, laceration of tongue or mucosa) and extremities.

Determines patient's cardiopulmonary status and response to seizure episode.

Determines presence of any traumatic injuries resulting from seizure activity.

Clinical Decision Point *If onset of seizure was not witnessed and you suspect that patient fell and struck head, treat as a closed head injury or spinal injury. Place a cervical collar on patient before attempting to turn or reposition.*

- 3 Evaluate patient's mental status after seizure (level of consciousness, confusion, hallucinations). Encourage him or her to verbalize feelings.

Temporary mental status changes are common following a seizure. Therapeutic interaction enables patient to recognize feelings associated with having a seizure disorder.

STEP

RATIONALE

Unexpected Outcomes

- 1 Patient suffers traumatic injury.
- 2 Patient aspirates.

Related Interventions

- Attend to patient's immediate physical needs.
- Administer prescribed treatments.
- Inform health care provider
- Reassess patient's environment to ensure that environment is free of safety hazards.
- Turn onto side, insert oral airway (if possible; see [Chapter 27](#)), and apply suction to remove material in oral pharynx and maintain patent airway.
- Administer oxygen as needed.

Recording and Reporting

- Record in nurses' notes and EHR what you observed before, during, and after seizure. Provide detailed description of the type of seizure activity and sequence of events (e.g., presence of aura [if any], level of consciousness, color, movement of extremities, incontinence, patient's status immediately following seizure, and time frame of events).
- Alert primary health care provider immediately as seizure begins. Status epilepticus is an emergency situation requiring immediate medical therapy.

Special Considerations**Teaching**

- Instruct patient to avoid seizure triggers such as caffeine.
- Patients need to know that antiseizure medications help control epilepsy. Warn them to take prescribed medications regularly. They should never stop medications suddenly because this precipitates seizures.
- Advise patient to avoid alcohol, which is often incompatible with anticonvulsive medications and intensifies central nervous system depression.
- Proper oral hygiene and frequent dental care are necessary when patient takes phenytoin (Dilantin) long term, since gingival hyperplasia is a side effect.
- Encourage patient to wear a medical alert bracelet or carry identification card noting presence of seizure disorder and listing medications taken.
- Fatigue, stress, and illness can potentiate seizures. Teach patients to eat a balanced diet at regular intervals, get adequate sleep, and consult their health care provider promptly when ill.
- A seizure disorder usually imposes driving limitations. It is recommended that a waiting period of 1 seizure-free year elapse before patient attempts to drive or operate dangerous equipment (see state law).

Pediatric

- Teach parents for what to observe in seizures because many times they are present at the onset.
- Child should wear a medical alert bracelet noting presence of a seizure disorder.
- Encourage children with severe atonic seizures to wear helmets to protect them when they fall. A child with generalized seizures should have side rails padded and suction and oxygen available to manage respiratory secretions for airway maintenance.

Gerontologic

- Older adults often have symptoms that make it difficult to recognize a seizure disorder. Confusion lasting several days, receptive and expressive speech problems, and unusual behaviors are often the result of a seizure.
- Older adults metabolize antiseizure medications more slowly, allowing drugs to accumulate and possibly result in toxicity.
- If patient has dentures, do not try to remove them during a seizure. If they loosen, tilt head slightly forward and remove after seizure.

Home Care

- Instruct family members about steps to take when patient experiences a seizure.
- Assess patient's home for environmental hazards that could increase the risk of injury in the event of a fall.
- Until a seizure condition is well controlled (usually for at least 1 year), make sure that patient does not take a tub bath or engage in activities such as swimming unless a knowledgeable family member is present.
- Refer patient to the Epilepsy Foundation or a similar community resource for support groups.

PROCEDURAL GUIDELINE 13-2 Conducting a Root Cause Analysis

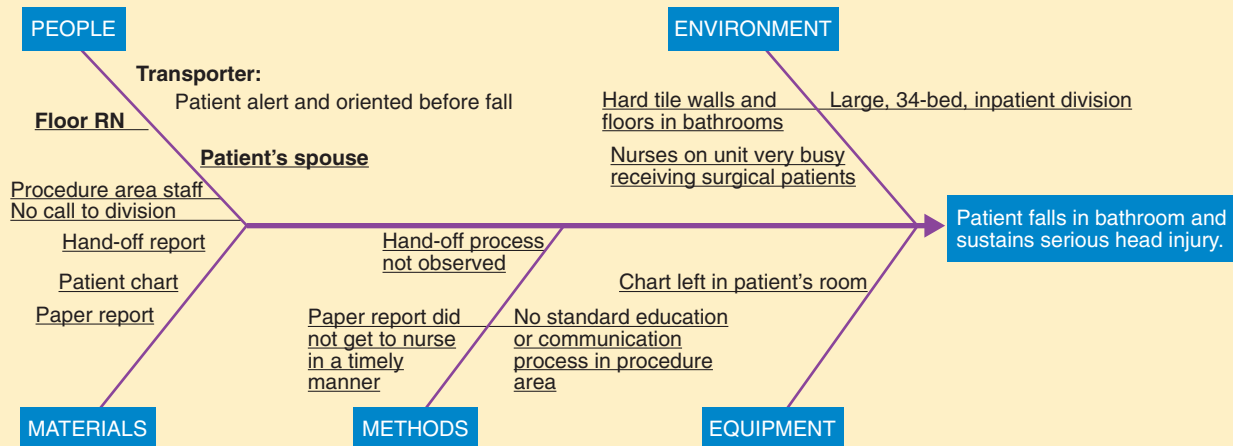

Root cause analysis (RCA) is a process of responding to sentinel events with the purpose of discovering the causes of the event and developing an effective plan for preventing future events (e.g., falls, injuries, and medication errors). The Joint Commission requires an RCA of sentinel events with a resultant action plan (TJC, 2009b). An RCA needs to be relevant and thorough. It is not about placing blame or relieving accountability; it is about looking at all the details that may have contributed to an error. Most health care agencies have a safety department that includes a specially trained team to lead all RCAs. The people closest to an error and the people close to any system processes that may have contributed to the error must participate in the RCA. The process is valuable for genuine practice improvement and the prevention of similar events in the future.

Delegation

The skill of conducting an RCA is the responsibility of a multidisciplinary team.

Procedural Steps

- 1 In response to a sentinel event (e.g., injury from a restraint, patient fall) ensure that immediate needs of patient/family are met. Report the event according to agency policy.
- 2 The designated safety team reviews the event, identifies the professionals involved, and ensures that all professional groups are represented in the analysis.
- 3 The team analyzes factors leading to and associated with the sentinel event by asking these questions:
 - a What happened? Describe details of event, when it occurred, and area within agency affected.
 - b Why did it happen? Describe process or activity in which the event occurred. Use a flow chart to show steps in the process.
 - c What factors contributed to the event? Describe steps contributing to the event, the people involved, equipment performance, environmental factors, and factors beyond organization control.
- 4 For each question the team decides if any element was a root cause and if action is needed.
- 5 Further analysis asks why the event happened in more detail and the proximate factors contributing to it. Examples are:
 - a Human Resource issues—Staffing, competence, staff performance
 - b Educational issues—Can orientation and training improve?
 - c Information management issues—To what degree was all necessary information available, accurate, and complete?
 - d Leadership issues—Does the work unit culture support risk identification and reduction? What barriers exist for communicating need to prevent adverse events?
- 6 Here are examples of approaches for analyzing data in an RCA:
 - a Six Sigma (Smith and Erwin, 2011)
 - (1) Define problem.
 - (2) Map process.
 - (3) Gather data.
 - (4) Conduct cause/effect analysis seeking root cause.
 - (5) Verify root cause with data.
 - (6) Identify solutions and prevention steps.
 - (7) Create pilot of implementation (with evaluation).
 - (8) Implement.
 - (9) Control/monitor plan.
 - (10) Lessons learned
 - b Fish Diagram (see illustration) (Gano, 2007)
 - (1) Arrange a list of causal factors in a fish diagram. Depending on the model used, there are predetermined categories (e.g., People, Equipment, Environment) into which causes for events should be able to be identified.
- 7 Develop an action plan for risk reduction—For each factor in the analysis that needs an action, develop a plan.
- 8 Implement the plan—Consider if pilot testing the planned improvement is needed.
- 9 Evaluate results.

STEP 6b Root cause analysis for patient fall. (Adapted from the Institute for Healthcare Improvement, IHI, 2004.)

Critical Thinking Exercises

Daniel Werneck is a 78-year-old patient who entered the hospital for lower gastrointestinal bleeding. During the morning nurses administered a series of enemas to Mr. Werneck before diagnostic tests of the colon. He has a history of high blood pressure, which is well controlled on medications. He has some weakness in his left leg as a result of an old back injury. As the evening nurse you assess Mr. Werneck and find that he is having diarrhea and abdominal cramping. His wife stays with him until visiting hours conclude. He is alert and tells you, "I'm fine. I just feel a bit worn out from the testing today."

- 1 Which factors in Mr. Werneck's case place him at risk for falling?
- 2 Which interventions can you implement for fall prevention?
- 3 At 11 PM you enter Mr. Werneck's room and find him lying on the floor. What are your first two actions?

REVIEW QUESTIONS

- 1 A nurse is providing information to nursing assistive personnel (NAP) regarding a patient who is having frequent seizures. Which instructions are most important for the nurse to include?
 - 1 If a seizure occurs, turn the patient on his side and insert an oral airway.
 - 2 Hold the patient firmly during the seizure so he does not bump his head.
 - 3 If a seizure occurs, be sure to lower the bed side rails.
 - 4 If a seizure occurs, stay with him while watching his ability to breathe.
- 2 An elderly patient with a seizure disorder wears dentures. If the patient has a seizure, when should the nurse remove the dentures?
 - 1 When the patient experiences an aura, right before the seizure begins
 - 2 During the most active part of the seizure so the airway stays open
 - 3 As soon as the seizure is over
 - 4 During the postictal period if the dentures are loose
- 3 A patient is found unconscious on the floor and may have sustained a head injury. Which immediate action should the nurse implement to prevent further injury?
 - 1 Perform a complete head-to-toe assessment
 - 2 Place a cervical collar on the patient
 - 3 Use at least three people to put him back in bed
 - 4 Contact the health care provider for further orders
- 4 A nurse restrains a violent patient following agency policy. Which activity must occur within 1 hour after the restraints have been applied to meet national standards?
 - 1 The patient will receive a detailed explanation.
 - 2 The patient's next-of-kin will be notified.
 - 3 A health care provider will assess the patient.
 - 4 The nurse will document the situation.
- 5 A patient with a head injury and unpredictable behavior has soft restraints applied to each extremity after having pulled out an intravenous (IV) line repeatedly. Which method by the nurse is most appropriate when removing the restraints for assessment and skin care?
 - 1 Remove one hand and one leg restraint at the same time.
 - 2 Remove the upper-extremity restraints at the same time and then the lower ones.
 - 3 Remove one restraint at a time with another staff member present.
 - 4 Remove all of the restraints at the same time with another staff member present.
- 6 How would you demonstrate Quality and Safety Education for Nurses (QSEN) skills for safety competency in which of the following behaviors? (Select all that apply.)
 - 1 During rounds on three different patients you use your memory to recall which patient needs to get an analgesic in the next 30 minutes.
 - 2 You place a patient on a new bed alarm system without having attended an in-service on the system.
 - 3 You follow evidence guidelines in your assessment of a patient's fall risk.
 - 4 During a change of shift report you include a fall occurrence involving a patient for whom you cared.
- 7 A nurse working in a home health agency is collaborating with other nurses to develop a fall prevention program for patients in the community. Using evidence from the literature on fall prevention, the nurses would likely include which of the following strategies?
 - 1 Developing a recommended set of diversional activities for patients to use in the home
 - 2 Conducting a standard vision assessment when visiting patients the first time
 - 3 Developing guidelines for using restraints for persons with dementia
 - 4 Instituting the use of the Revised Algae Wandering Scale (RAWS)
- 8 A fire is discovered in a trash can in a patient's room. Which action by the nurse should be questioned?
 - 1 Turning off the oxygen sources
 - 2 Getting the patient out of the room
 - 3 Asking the patient to place her blanket over the trash can
 - 4 Calling for help
- 9 A nurse enters a patient's room, finds the patient asleep, and notices sparks and fire coming from an electrical outlet. The patient is in traction for fractures to the legs. Place the following steps for the nurse's response to the fire in their correct order.
 - _____ 1 Contain the fire by turning off all oxygen in the room.
 - _____ 2 Rescue the patient by moving the bed away from the outlet.
 - _____ 3 Alert a staff member to activate the fire alarm.
 - _____ 4 Evacuate the patient from the room.
- 10 A nurse uses a patient-centered approach for any safety interventions to minimize a patient's vulnerability and diligently protect the patient from injury. Which of the following approaches are patient-centered when applying a restraint? (Select all that apply.)
 - 1 Determining the meaning of restraints to the patient's family
 - 2 Using a standard assessment guide that is evidence based before restraining the patient
 - 3 Collaborating with family members in accommodating a patient's cultural perspectives about restraints
 - 4 Identifying a patient's preferences for using an extremity restraint or mitten restraint

KEY TERMS

Biologic agent	Detection and surveillance	International Nursing	Pandemic
Biologic disaster	Disaster response	Coalition for Mass	Shelter-in-place
Bioterrorism/bioterrorist attack	Epidemic	Casualty Education (INCMCE)	Strategic national stockpile (SNS)
Chemical warfare agent	Field triage tag	Manmade disaster	Triage
Decontamination	First responders	Mutual aid agreement	Weapons of mass destruction (WMD)
Department of Homeland Security (DHS)	Hazard/hazard identification	Natural disaster	
	Incident Command System (ICS)	Nuclear event	

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe elements of the Centers for Disease Control and Prevention strategic plan for disasters.
- Discuss the characteristics of different types of disasters.
- Identify actions to take in the event of biologic, chemical, and radiation exposure.
- Discuss guidelines for patient care in the event of a mass casualty incident.
- Describe psychosocial effects of disasters on patients.

Although disaster preparedness and the possibility of terrorist attacks has been a subject of discussion and research for over 20 years, the attacks on the World Trade Center and Pentagon on September 11, 2001, forever changed the reality and sense of security felt by citizens of the United States. They demonstrated the vulnerabilities, including the lack of preparedness of the health care community, in the event of a mass casualty incident (MCI). The attacks increased public awareness of not only probable future terrorist attacks but also the more common natural or environmental disasters affecting individuals on a more regular basis. National preparedness has progressed considerably during the last decade. Hospitals have plans and disaster drills for internal and external disasters (Veenema, 2011). Medical and public health professionals have joined the disaster preparedness community; the U.S. Federal government increased investment in preparedness; and community partners and participants are involved in disaster

preparedness (Inglesby, 2011). In addition, The Institute of Medicine (IOM) issued a report, *Guidance for Establishing Crises Standards of Care for Use in Disaster Situations*, designed to assist schools, hospitals, health care and emergency systems, and community agencies in developing policies and protocols for standards of care in disasters, where resources are scarce (IOM, 2009).

Throughout history nurses have played a role in the multidisciplinary approach in preparing for and responding to disasters. Information gathered from post-disaster evaluations have provided a considerable body of knowledge and experience to improve the response of an entire health care team and the many agencies/individuals involved (e.g., police, firefighters, administrators, and paramedics) in a disaster response. The Department of Homeland Security has identified preparedness and education of the nation as an essential component to national security against domestic and foreign threats (DHS, 2008).

DISASTER DEFINED

A disaster is any unexpected event the effect of which leads to significant destruction and/or adverse consequences. More specifically, a disaster is any event in which needs exceed available resources. [Box 14-1](#) provides common disaster terminology definitions. Although these definitions standardize the events of an MCI, it is important to understand that each disaster is unique in the way it affects individuals, families, and communities.

When most Americans hear the term *disaster*, they immediately think terrorist attack. In reality the most common forms of disaster are natural or manmade (e.g., major fires, hurricanes, tornadoes, and floods). If the public is not adequately protected, the spread of natural-borne disease can create a natural disaster.

An **epidemic** is an infectious disease or condition that attacks many people at the same time in the same geographic area. A **pandemic** is an epidemic that occurs in many parts of the world. History tells us that there are approximately three influenza pandemics every 100 years that result in the death of millions of people. Experts believe that the world is due for another pandemic influenza virus to which virtually no one is immune. A pandemic flu is highly contagious from person to person ([CDC, 2011a](#)). Surveillance by the World Health Organization continues for such infections as severe acute respiratory syndrome (SARS) and avian influenza (bird flu) for indications of mutations and increased transmission ([Boxes 14-2 and 14-3](#)). If a pandemic flu occurs, it will take months for a vaccine to be developed and, once manufactured, doses would first be rationed to persons with a compromised immune system, older adults, and health care workers ([CDC, 2011b](#); [WHO 2011a](#)). To be adequately prepared, citizens need education on preventing the spread of influenza (see [Chapter 7](#)).

HOMELAND SECURITY

The National Strategy for Homeland Security and the Homeland Security Act (HSA) of 2002 were enacted to secure the homeland

from terrorist attack. Since the development of the HSA, the Department of Homeland Security (DHS) has evolved and strengthened their mission, vision, and core values to provide a unifying core as the basis for efforts to prevent and discourage terrorist attacks. This governmental agency coordinates the efforts of multiple organizations to secure and maintain the safety of the United States.

BOX 14-2 Severe Acute Respiratory Syndrome (SARS)

- A viral respiratory illness caused by a coronavirus (SARS-CoV).
- Spread by close person-to-person contact through respiratory droplets. Strict adherence to contact and droplet precautions, along with eye protection, seems to prevent SARS-CoV transmission in most instances.
- In 2003 8098 people worldwide became sick with SARS; of these 774 died.
- Onset of a high fever; other symptoms include headache and body aches.
- About 10% to 20% have diarrhea. After 2 to 7 days SARS patients may develop a dry cough.
- Most SARS patients develop pneumonia.
- Treatment may consist of various therapies, including antibiotics, antivirals, corticosteroids, alternative medicine (i.e., glycyrrhizin), and assisted ventilation.
- Research for vaccine development is ongoing.

Data from Centers for Disease Control and Prevention: *Severe, acute respiratory syndrome (SARS)*, 2011, available at <http://www.cdc.gov/sars/index.html>, accessed February 12, 2012.

BOX 14-3 Avian Influenza (“Bird Flu”)

- It is an infectious disease of birds that is highly contagious among poultry; it has also been documented in pigs, tigers, leopards, ferrets, domestic cats, and the stone marten (a weasel-like animal).
- More than 200 cases among humans have been reported worldwide; approximately half of the people reported as infected have died.
- It is believed to be transmitted primarily through close contact with live or dead diseased birds or contaminated surfaces; person-to-person transmission is rare. No evidence of disease is spread through poorly cooked food.
- Incubation period is 2 to 8 days, possibly as long as 17 days.
- Initial symptoms include a high fever and flulike symptoms (i.e., fever, cough, sore throat, and muscle aches). Watery diarrhea and vomiting have also been reported as early symptoms. Eye infection (conjunctivitis) and pneumonia may occur. Clinical deterioration is rapid, with respiratory distress and multi-organ dysfunction.
- Antiviral drugs (e.g., oseltamivir phosphate [Tamiflu]) can improve survival when administered within 48 hours of symptom onset.
- On April 17, 2007 the U.S. Food and Drug Administration announced approval of a vaccine against one strain of the avian flu H5N1 virus. The vaccine has been purchased by the federal government and is being held in the strategic national stockpile. Research continues for vaccines against other strains of the H5N1 virus.
- Concern is that the virus could start a pandemic; however, currently the virus does not spread easily from person to person and is not sustainable among humans.

Data from World Health Organization (WHO): *Avian influenza fact sheet*, 2011, available at http://www.who.int/mediacentre/factsheets/avian_influenza/en/, February 12, 2012.

BOX 14-1 Disaster Definitions and Types

- **Disaster:** A catastrophic and/or destructive event that disrupts normal functioning; it may include any anticipated or unexpected event, the effects of which lead to significant destruction and/or adverse consequences
- **Mass casualty incident or event (MCI):** Any event or situation that results in multiple casualties and/or deaths; an MCI exists when health care needs exceed health care resources
- **All-hazards event:** Multiple manmade or natural events with destructive capacity to cause multiple casualties
- **All-hazards preparedness:** The comprehensive preparedness necessary to manage casualties resulting from a disaster, regardless of etiology
- **Casualty:** Any individual who is ill, injured, missing, or killed as a result of an MCI
- **Medical disasters:** Catastrophic events that result in human casualties that overwhelm the available health care resources
- **Natural/environmental disasters:** Catastrophic events that result from an ecologic event that exceeds the capacity of the community (e.g., the impact of hurricanes or tornados on a community)
- **Manmade disasters:** Catastrophic events the principal direct cause of which is attributable to human action
- **Technologic disasters:** Catastrophic events in which people, property, community infrastructure, and economic welfare are adversely affected by the disruption of technology (e.g., industrial accidents, unplanned release of nuclear waste)

Terrorism Preparedness

In addition to the activities of the DHS, the Centers for Disease Control and Prevention (CDC) is a leading federal agency designed to protect the health and safety of people at home and abroad. The mission of the CDC Coordinating Office for Terrorism Preparedness and Emergency Response (COTPER) is to protect the health and life of all people related to community emergency preparedness and response (CDC, 2009). The CDC strategic plan in the event of a disaster first focuses on preparedness, which is key to the impact that any disaster has on the individuals or communities involved. Preparedness requires that nurses have a basic understanding of the science of a disaster and an understanding of the key components of any plan to deal with an MCI (CDC, 2010a,b).

In the event of a biologic, chemical, or radiation attack, the CDC strategic plan includes the following:

- **Preparedness and prevention:** The comprehensive preparedness required to manage self, family, and/or the community when an event occurs that is likely to result from a catastrophic and or destructive event that disrupts normal functioning
- **Detection and surveillance:** Awareness of the environment, recognizing what is unusual or different and knowing what these differences possibly mean for purpose of mitigation or prevention (DHS, 2011a)
- **Diagnosis and characterization of biologic, chemical, and radiologic agents:** The ability of an individual to recognize or identify clusters of data indicating that a biologic, chemical, or radiologic MCI event has occurred
- **Response:** The systematic, coordinated, and effective delivery of services when disaster strikes
- **Communication:** The establishment of protocols and standing orders in the event of a disaster to successfully manage health care and use the media for communicating information to the public (e.g., directions to treatment facilities, evacuation routes) (Traditional modes of communication will likely be interrupted in the event of an MCI; therefore part of disaster preparedness involves backup plans for maintaining public and intraagency/interagency communication [e.g., use of two-way radios and satellite phones].)

Although the CDC plan is for mass casualty disaster events or community-wide incidents, the plan clearly applies to any disaster event. The CDC and the American Red Cross advocate preparedness and coordination of prompt, effective emergency efforts. This preparedness coordination includes outreach to other agencies or

groups through mutual aid agreements. These agreements might include the willingness of one agency to provide shelter (e.g., a church, school, or recreation center) and other agencies to provide clothing (e.g., department stores, the Salvation Army, or Goodwill). Some agreements might include identifying and caring for the deceased (e.g., funeral homes); still other agencies agree to provide vehicular support in the time of a disaster. Disaster planning is not only a multidisciplinary task but also a multiagency task. Although the average citizen, government agency, and other health care workers play a vital role in disaster preparedness, nurses will always have unique responsibilities within this multidisciplinary and multiagency coalition.

Disaster Preparedness

To further support the need for health care providers to increase their preparedness, some states are enacting new laws that require disaster training as part of the continuing education requirement for licensure. However, only disaster planning, education, training, and drills on a local, national, and global level will effectively prepare health care providers, volunteers, and other individuals needed in the event of an MCI. Nurses need to influence, develop, and practice policies that will improve the safety and quality of health care at the time of an MCI (USDHHS, 2010).

It is essential that, in addition to the preparation of government officials and first responders for disasters, the public must also be aware of and prepared for them. To facilitate public awareness of disasters the DHS established The National Terrorism Advisory System (NTAS) to provide government officials, first responders, and public citizens with information regarding the nature and degree of terrorist threat (Fig. 14-1) (DHS, 2011b).

The D-I-S-A-S-T-E-R Paradigm

A series of National Disaster Life Support (NDLS) courses provide coordinated training with an all-hazards approach to MCIs (AMA, 2011). The D-I-S-A-S-T-E-R model put forth in the training program standardizes methods for recognizing a disaster, managing the scene, and providing care to disaster victims.

Detection

Detection is the first goal in an MCI and includes (a) determining the presence of an MCI or public health emergency (PHE), (b) recognizing the cause of the incident, and (c) becoming aware of the environment or more specifically changes in the environment (e.g., an unusual pattern of patient presentation, unusual smells, or suspicious individuals). Although many events have a clear cause,

Alert Is Issued		
Elevated Threat Alert Warns of a credible terrorist threat against the United States	Imminent Threat Alert Warns of a credible, specific, and impending terrorist threat against the United States	
Information Included in Alert		
Summary	Details, including affected areas	Duration of alert
How you can help	Steps to stay prepared	How to stay informed
Sunset Provision An individual threat alert is issued for a specific time period and then automatically expires. It may be extended if new information becomes available or the threat evolves.		

FIG 14-1 National Terrorism Advisory System overview. (Department of Homeland Security—Adapted from data available at <http://www.dhs.gov/xlibrary/assets/ntas/ntas-public-guide.pdf>.)

others have an insidious onset. For example, if a large number of otherwise healthy young adults start showing up in an emergency department (ED) with similar but unexplained symptoms, nurses and other health care providers should suspect that something is not right. Detection is sometimes simply the awareness of an unusual health care situation.

Remember, to be able to provide care, you first need to ensure personal safety. It is essential that rescue and health care workers avoid becoming victims, which may go against your initial instinct to help others. When the scene of a disaster is in a clearly designated area outside the health care agency, you need to determine the security of the scene. Always consider external scenes of disasters such as sites of explosions or severe storm damage unsafe until trained professionals arrive and determine that the scene is safe.

The use of biologic agents is a considerable terrorist threat because they are easy to disperse and affect large numbers of people at a relatively low cost (Box 14-4). Incubation periods and common initial clinical symptoms make detection of a biologic attack difficult.

Another form of MCI is the dissemination, or spreading, of a toxic chemical agent. There are a number of methods for spreading toxic chemical agents (e.g., fire or explosion). Health care providers are often at risk for becoming secondary victims when chemical agents create an MCI. Chemical agents are categorized based on their mechanism of injury (CDC, 2006a). These include pulmonary agents, blistering agents, blood agents, and nerve agents.

The thought of nuclear and radiologic incidents creates considerable fear for many individuals. Most often the cause for disseminating radioactive material is generally known. A fire or an

explosion is often associated with nuclear attacks; however, devices designed to disseminate radioactive material are not always obvious (e.g., a “dirty bomb”). The effects of nuclear and radiologic events depend on the amount of radiation exposure. Most victims will have delayed onset of symptoms (including nausea, vomiting, and diarrhea), but some will have obvious burns. Generally the sooner symptoms appear, the greater the exposure to radioactive material.

Incident Command

Incident command is the need for the emergency system to be activated when a threat or hazard is suspected. For most individuals this means activating the 9-1-1 system so emergency responders can be brought in to assume command. Emergency responders initially remain outside the possible contaminated area. Therefore the impact of the disaster on roads, traffic, and availability of resources can delay or prevent their arrival. An Incident Command System (ICS), also referred to as an incident management system (IMS), provides a standard approach to managing emergencies when multiple agencies are involved. ICSs are used by all forms of government and the private sector during an emergency situation and help guide five major functions: (1) command, (2) operations, (3) planning, (4) logistics, and (5) finance/administration (DHS, 2011c). Fig. 14-2 offers an example of a general chain of command in an MCI.

Scene Security and Safety

Nurses are not responsible for determining the security and safety of a disaster scene. This task is the responsibility of trained emergency personnel (e.g., firefighters and police). When a health care agency is the scene of the disaster or a secondary site for a disaster, trained personnel determine scene security and safety. A health care agency becomes a secondary disaster site when contaminated by the agent from the original disaster scene. For example, a patient has been exposed to mustard gas, an oily chemical that is difficult to remove from a patient’s body. If not properly decontaminated, the victim contaminated by the mustard gas will inadvertently contaminate health care providers and others (CDC, 2010a). The same is true for many biologic agents. The first priority at any disaster scene is to protect yourself and other team members. The second priority is to protect the public, patients, and the environment (Box 14-5).

Knowing which personal protective equipment (PPE) to use minimizes the risk for contact with contaminated materials or individuals. Proper use of many advanced forms of PPE requires training, fitting, and an understanding that not all PPE protects against all potential hazards. When used inappropriately, PPE becomes a hazard (e.g., dehydration, decreased vision, mobility,

BOX 14-4 Potential Organisms for Bioterrorism by CDC Category

Category A—Greatest Threat

- Can be easily disseminated or transmitted person to person
- Cause high mortality with a potential for major public health impact, including:
 - Anthrax (*Bacillus anthracis*)
 - Botulism (*Clostridium botulinum* toxin)
 - Plague (*Yersinia pestis*)
 - Smallpox (*variola major*)
 - Viral hemorrhagic fevers (Ebola, Marburg, Lassa, Machupo)

Category B—High Risk

- Moderately easy to disseminate
- Cause moderate morbidity and low mortality, including:
 - Brucellosis (*Brucella* species)
 - Epsilon toxin of *Clostridium perfringens*
 - Food safety threats (e.g., *Salmonella*, *Escherichia coli*, *Shigella*)
 - Ricin toxin from *Ricinus communis* (castor beans)
 - Staphylococcal enterotoxin B
 - Water safety threats (e.g., *Vibrio cholerae*, *Cryptosporidium parvum*)

Category C—Emerging Biologic Weapons for Terrorist Use

- Pathogens that could be engineered for mass dissemination, including:
 - Nipah virus
 - Hantavirus

Data from Centers for Disease Control and Prevention (CDC): Bioterrorism agents/diseases, 2012, available at <http://www.bt.cdc.gov/agent/agentlist.asp>, accessed August 19, 2012.

BOX 14-5 The Do’s and Don’ts of Scene Safety and Security

DO

- Stay out of a disaster scene unless well trained and invited.
- Call 9-1-1.

DON’T

- Don’t enter the scene unless invited.
- Don’t needlessly disturb the scene; important evidence could be lost or contaminated by an eager but untrained helper.
- Don’t interfere with the services of other emergency personnel when uninvited or untrained.
- Don’t open suspicious packages.

HOSPITAL EMERGENCY INCIDENT COMMAND SYSTEM

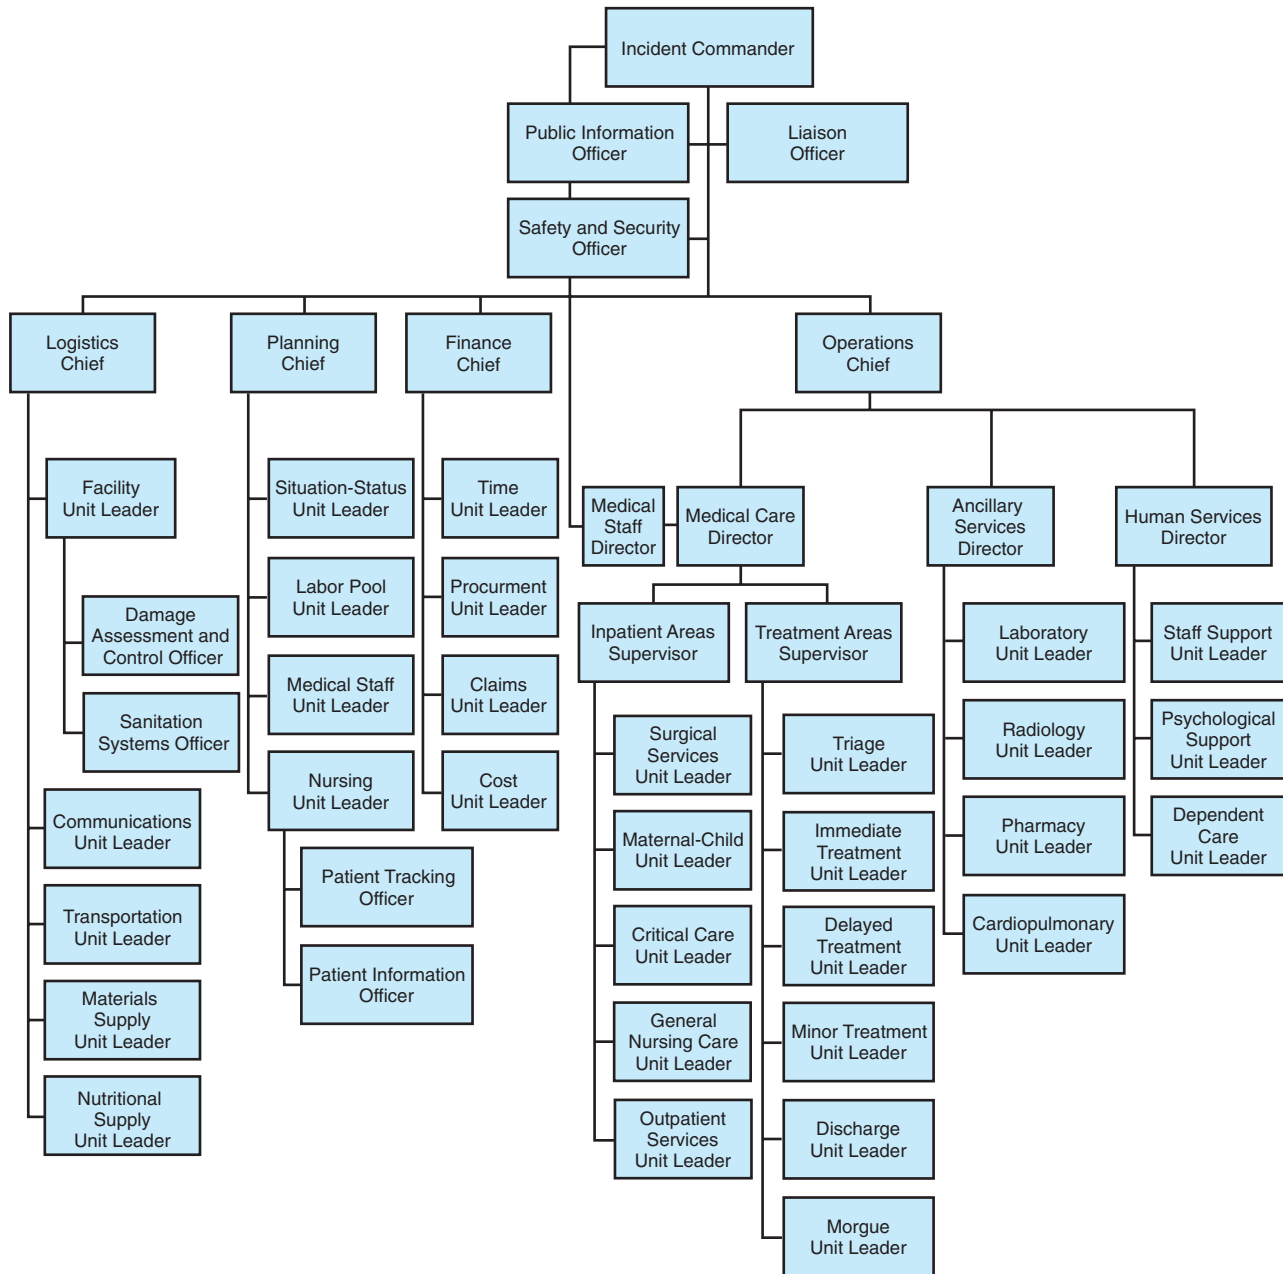

FIG 14-2 The Hospital Emergency Incident Command System prepares all response teams to work smoothly in a disaster situation.

and ability to communicate). Some of these hazards result because, while using advanced forms of PPE, the user is unable to eat, drink, or go to the bathroom.

PPEs are categorized by levels A to D for the level of safety provided. Level A is selected when the greatest level of skin, respiratory, and eye protection is required. It provides maximum protection because it offers a self-contained breathing apparatus, total encapsulating chemical-protective suit, coveralls, undergarments, chemical-resistant boots and gloves, hard hat, and disposable protective suit worn over the encapsulating suit (Fig. 14-3). Highly trained personnel use level A protection in heavily contaminated areas. If you are not wearing this type of protection and you are near an area where level A PPE is being used, the general rule is to get out or do not enter. Level B provides the highest level of

respiratory protection but less skin protection. Used by trained responders, this PPE includes a self-contained breathing apparatus; hooded chemical-resistant suit; and face, boot, and glove protection. Level B protection also requires training and fitting. First responders (emergency personnel first on the scene) and hospital personnel are trained and fitted to use level C protection, which involves knowing the concentration and type of airborne substance(s) and the criteria for using air-purifying respirators. Level C constitutes the use of full-face or half-mask, air-purifying respirators (National Institute for Occupational Safety and Health [NIOSH] approved), hooded chemical resistant clothing, and protective gloves and boots. Because of the garment protection worn with levels A, B and C, the user is at risk for dehydration and hyperthermia.

PPE Protection Equipment			
Level A	Level B	Level C	Level D
 <p>Airtight seals with SCUBA or airline</p>	 <p>No airtight seals</p>	 <p>Half-mask acceptable; hard hat optional</p>	 <p>Standard precautions appropriate to the circumstances</p>

FIG 14-3 The Occupational Safety and Health Administration (OSHA) defines personal protective equipment for the four levels of hazardous exposure. PPE, Personal protective equipment; SCUBA, self-contained underwater breathing apparatus.

For level D protection standard work uniform or work clothes are appropriate and used for nuisance contamination only. The users must wear coveralls and chemical resistant shoes; and, depending on the contaminant, gloves, goggles, mask, face shield, and hard hats may also be worn. There is no respiratory protection. It is important to take standard precautions when using level D protection. Depending on the circumstances, some health care providers also choose to use a fluid-impermeable gown, cap, eye protection, mask, gloves, and shoe covers (OSHA, 2011).

The most recently labeled level of protection is BioPPE. BioPPE requires the use of standard work clothes along with contact and respiratory protection. Double gloving and an N95 mask (see Chapter 7) or better respirator are recommended. Hand hygiene that includes washing with soap and water followed by use of an alcohol gel is important not only at this level but also at all other levels. BioPPE protection is not adequate when caring for patients exposed to toxic chemicals; however, it provides adequate protection against radiologic and biologic agents.

Assessment

Assessing hazards is more important than knowing the exact cause of a disaster. By allowing trained individuals to assess a disaster scene, you will avoid becoming a victim. Health care providers and volunteers need to learn to shift thinking and realize that the MCI can result in secondary hazards that come in many forms (Box 14-6).

Support

In terms of a disaster, *support* means, “Give me what I need to get the job done.” The earlier you ask for support, the better. Support varies with the situation and task at hand. Support resources necessary during a disaster include human resources, agencies, facilities, supplies, and vehicles. For example, although there are not enough hospitals to accommodate all victims, a school or recreation center could easily be turned into a makeshift hospital if there has been preparation for unforeseen disasters.

BOX 14-6 Potential Hazards at the Scene of a Disaster

- Downed power lines
- Smoke/toxic gases
- Debris that can result in trauma
- Fractured/leaking gas lines
- Fire resulting in burns
- Structural collapse
- Blood and other body fluids
- Inclement weather
- Hazardous materials
- Nuclear, biologic, or chemical exposure
- Flooding and the threat of drowning
- Radiation exposure
- Explosion, particularly secondary explosions
- Snipers
- Darkness
- Infection
- High-velocity projectiles and the pressure wave after an explosion
- Becoming incapacitated and unable to protect yourself or your patient

The CDC has developed a strategic national stockpile (SNS) that contains large amounts of medical equipment in the event of a disaster (CDC, 2011c). Most local communities will be prepared to provide essential resources for up to 72 hours (via hospitals, pharmacies) to support local needs. Once local and federal authorities confirm the need for the SNS and on request of the governor’s office of the affected state, the 12-hour push package is flown or transported within 12 hours to any state in the United States. The 12-hour push package contains approximately 100 steel containers that hold pharmaceuticals (prepackaged 10-day supplies of antibiotics, antidotes, narcotics, epinephrine, albuterol, prednisone, and other medications), intravenous (IV) fluids and IV supplies,

BOX 14-7 ID-ME—Assess, Treat, and Send

ventilators, suction equipment, airway supplies, tablet-counting machines, and other emergency provisions (CDC, 2011c).

Chaos is common in every disaster. It is manageable, but it is difficult to control. In the event of a disaster many “worried well” (injured individuals who are able to transport themselves to a health care agency or even frightened individuals who fear contamination) will leave a disaster scene. Within 30 minutes these individuals will overrun the hospital nearest the disaster scene, leaving the most highly injured individuals at the site of the disaster. Adding to the chaos at the health care agency is the responsibility to care for sick and injured individuals already admitted to the hospital or ED.

First responders must quickly distinguish between actual victims with exposure to the weapon of mass destruction (chemical, biologic, or nuclear) that led to the MCI and the worried well. Regardless of the lethality of any biologic, nuclear, or chemical terrorist attack, the “shock” to the community and society often serves the intended purpose of the terrorist. You need to recognize the worried well as victims because they are obviously suffering fear and anxiety. However, do not let them distract you from the job of rescuing as many potential survivors as possible. Quickly differentiating worried well from actual injured patients prevents wasting valuable time.

Also consider the security of a health care agency in disaster planning. Health care providers offer a valuable resource and cannot spend time maintaining the security of the health care agency. The local police in collaboration with agency administration and security personnel are responsible to maximize the protection of lives and assets of the health care agency. Keep security officers informed about the incident history, current status, and potential problems. As part of this protection, roadblocks, checkpoints, and agency lockdown procedures are often put in place.

Triage, Treat, and Evacuate

Triage is the sorting of individuals by the seriousness of their condition and the likelihood of their survival (Box 14-7). There are many different modern triage systems to classify, tag, and treat victims of MCI. These systems use a variety of symbols, colors, and other devices to classify individuals as to the need for treatment. Mass casualty triage is an initial sorting of victims into groups. The disaster triage model described in this section is the SALT (Sort-Assess-Lifesaving Interventions-Triage/Treatment) triage system.

The SALT triage system was developed by a workgroup of emergency medical services (EMS) physicians who were funded by the

CDC and tasked with reviewing current triage systems and making recommendations for a national standard (Lerner et al, 2011). The group could not find a model that had enough research evidence or all the elements of a system that they deemed necessary to recommend as a national standard. They developed the SALT triage system instead, using the best features of several widely accepted models. All victims are first sorted into groups based on mobility. They are then individually assessed, sorted into categories, and evacuated for treatment as needed (Fig. 14-4). The ultimate goal is to sort, assess, and perform lifesaving measures as quickly as possible to large numbers of victims.

At a disaster, Step One in the SALT triage model is to “sort” individuals into one of three categories before they are assessed individually. Category one consists of persons who are not moving and have obvious life-threatening injuries. Category two consists of persons who can wave or have purposeful movements. Category three consists of persons who can walk. Step Two of the SALT triage system involves individual assessment and further sorting of patients into categories. These categories include (1) those minimally injured, (2) people who will survive even with delayed treatment, (3) those who need immediate intervention, and (4) people expected to die. Lifesaving interventions will be administered according to which category the person is labeled. Step Three involves treatment and/or transport of victims. As with any emergency, reassessment is always necessary. During reassessment rescue workers need to consider patient conditions, resources, and scene safety.

EVIDENCE-BASED PRACTICE

When disaster strikes, unexpected problems may occur. Because there are many types of disasters, the American Nurses Association recommends that nurses need to know their disasters because the type of disaster has a direct impact on nursing actions (ANA, 2010). When the first plane hit the World Trade Center in 2001, calls overwhelmed hospital telephone systems. After the Madrid, Spain terrorist bombing in 2004, the CDC developed a disaster plan for nursing care. Working with the assumption that aid will not come for at least 72 hours, the plan was designed to treat 300 injured patients for up to 72 hours (CDC, 2010b). This plan includes the following recommended actions:

- Be able to rapidly increase nursing staff.
- Maintain a list of employees with their proximity to the hospital.

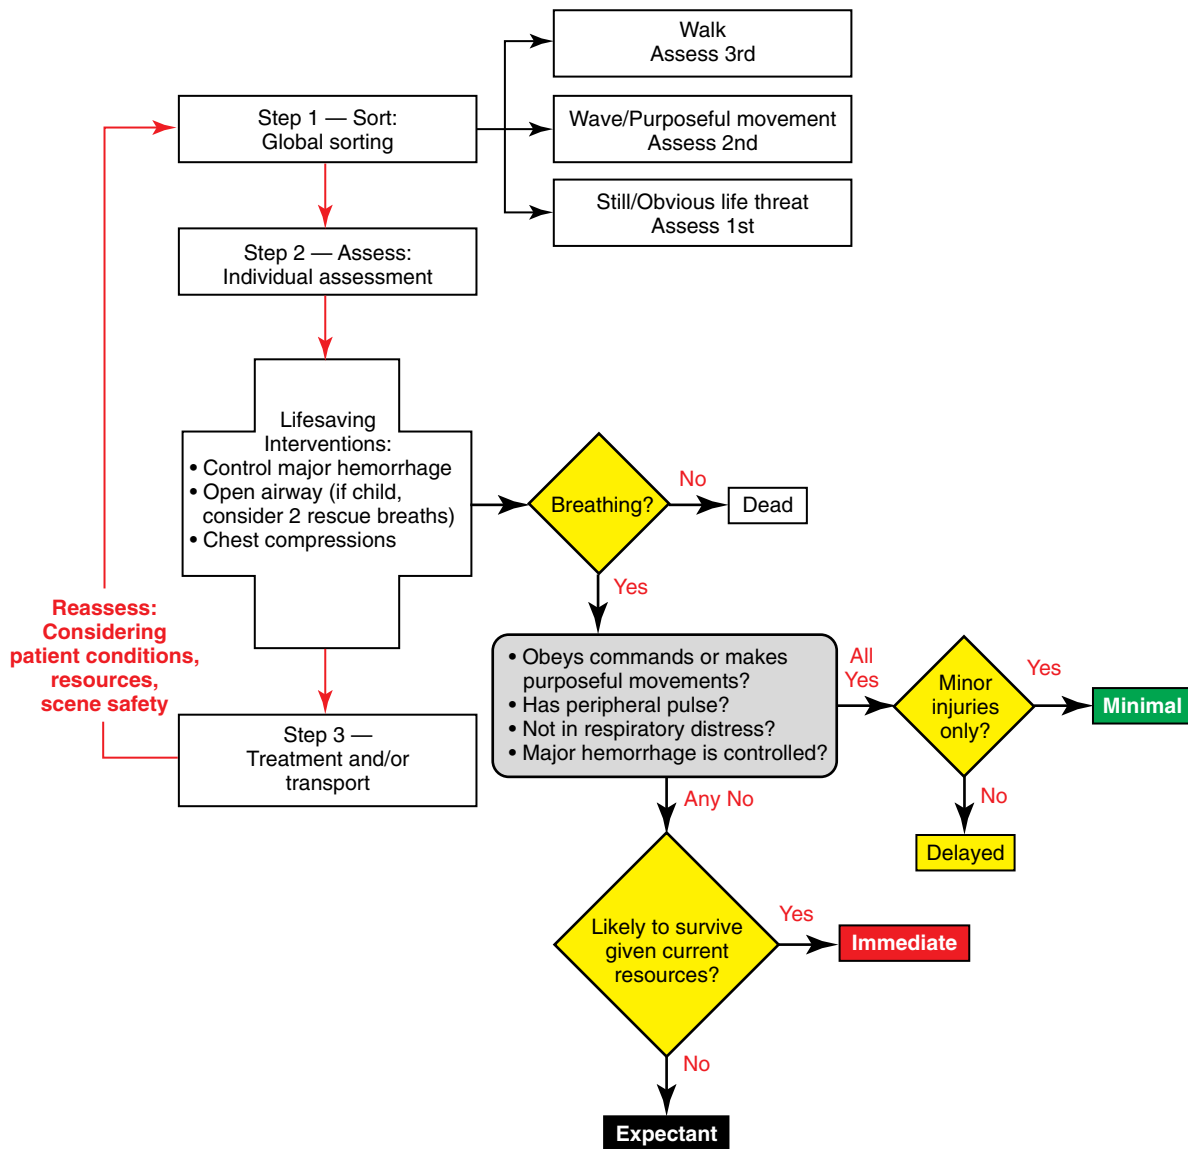

FIG 14-4 SALT Mass casualty triage algorithm (Sort, Assess, Lifesaving interventions, Treatment/transport). (US Department of Health and Human Services: Adapted from Lerner EB et al: *Mass casualty triage: an evaluation of the science and refinement of a national guideline*, Disaster Med Public Health Prep 5(2):129, 2011.)

- Consider using a rapid response model for accessing nursing staff.
- Have protocols in place for tiered staffing.
- Have just-in-time nursing training about bomb blast injuries and treating pediatric bomb injuries available. Have a plan to deploy pediatric nurses quickly.
- Provide nurse training for the rapid influx and treatment of patients (Tillman, 2011).
- Implement rapid discharge procedures.
- Maintain a centralized database with staff competencies (Strangeland, 2010).
- Have a plan for hospitals to implement a drill with EMS at least once a year to prepare for an MCI.
- Quickly critique and share the information with participants.

Many lessons have been learned from previous disasters, and failure of communication systems is identified as a major issue. Communication is essential, and preparing for interruptions during disasters is recommended by both the Federal Emergency Management

Agency (FEMA) and the Federal Communications Commission (FCC, 2011). Other lessons learned include the following:

- When it becomes necessary to evacuate patients, the Agency for Healthcare Research and Quality (AHRQ) recommends that a discharge summary go with the patient. The discharge summary should include current medications, allergies, current orders, and a brief history (USDHHS, 2010).
- Some staff had difficulty passing through roadblocks in previous disasters; thus it is now recommended that all staff keep their hospital identification with them.
- The need for diversional activities to reduce stress deserves important consideration. Staff could share items such as musical instruments or a DVD player and movies.

PATIENT-CENTERED CARE

To provide the highest standard of care while in a disaster situation it is essential to acknowledge the cultural diversity of all individuals involved. A lack of cultural considerations of victims leads to the

impression of insensitivity and biases toward patients who are different racially, sexually, or ethnically. Regardless of cultural differences and perhaps language difficulties, it is important to convey compassion and work closely with people within the community for disaster recovery. As noted with bereavement counseling, existing support networks are often more effective. Emergency responders need to support rather than further disrupt these networks (Mendez, 2010). Some disaster events result in a changed culture for individuals, families, and communities.

Safety Guidelines

When considering all forms of disaster, there are basic safety guidelines for a nurse or other health care provider to follow:

- 1 Rapid response is crucial. Know your agency policies for disaster response and the specific role that each member must perform.

- 2 Health care providers are responsible for ensuring that the contaminated, the injured, and those concerned about potential exposure to a hazardous agent are medically treated in an efficient manner.
- 3 The potential for public alarm and major disruption of everyday life is enormous because of widespread fear of the unknown. Know crisis intervention and stress-management techniques.
- 4 A health care agency such as a hospital is part of a community. Hospitals and other agencies need to work with their communities in developing and instituting plans for notification and communication.
- 5 In an MCI the majority of people, whether contaminated, exposed, or not, will self-triage and go directly to a local hospital, bypassing triage and treatment. Plans are needed to transfer patients to other medical facilities.

SKILL 14-1 Care of a Patient After Biologic Exposure

Bioterrorism or a biologic attack is the result of the release of a biologic agent into a specified environment (CDC, 2007). Some biologic attacks are unannounced or covert, and the onset of symptoms is delayed by an incubation period (i.e., the time between exposure and onset of symptoms). Differing biologic agents have incubation periods from 1 or 2 days to several weeks, during which some of these agents may be transmitted as an infected patient exposes others. The mode of transmission of the biologic agent determines the severity of the disaster. Recognition of bioterrorism is a challenge because early signs and symptoms mimic the flu or produce a rash mistaken for a viral illness (Fig. 14-5, A and B). Sometimes several biologic agents are disseminated at the same time, further confusing the issue. To understand how to protect yourself from becoming a victim, you need to understand the mode of transmission and precautions to take for biosafety (Table 14-1).

- N95 mask
- Face shield
- Equipment for physical examination
- Oxygen therapy
- Airway maintenance supplies
- Intravenous therapy supplies

Delegation and Collaboration

The skill of assessment of a patient exposed to a biologic agent cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Use appropriate personal equipment (PPE) to prevent exposure during care activities.
- Use proper techniques for handling a body after death to prevent contamination.

Equipment

Choice of equipment depends on the route of transmission of the infecting agent. The following is a general list of supplies needed in the event of release of the most contagious biologic agents. Not all equipment is needed in all situations.

- Biohazard bags with label
- Soap and water
- 0.5% diluted bleach or Environmental Protection Agency (EPA)-approved germicidal agent
- Negative-pressure room (high-efficiency particulate air [HEPA] filtration may be required) with anteroom
- Clean gloves
- Gown
- Shoe covers
- Head covers
- Mask
- Standard face mask

FIG 14-5 Differences in distribution of smallpox versus chickenpox. **A**, Man with smallpox. Courtesy CDC/NIP/Barbara Rice. **B**, Chickenpox covering patient torso. Courtesy David Efron, MD.

TABLE 14-1 Summary of Selected Class A Biologic Warfare Agents

Disease/Infectious Agent	Form and Incubation/Onset of Symptoms	Untreated Course of Disease		Probable Route of Contamination for Use as a Biologic Warfare Agent	Treatment of Mass Casualties	Prophylaxis/Vaccine
		Early-Onset Symptoms	Late-Onset Symptoms			
Bacterial Biologic Agents						
Anthrax <i>Bacillus anthracis</i> , a gram-positive bacillus that can remain stable in spore form	Inhalation or pulmonary (usually within 48 hours but may incubate for up to 60 days)	Febrile flulike symptoms (malaise, low-grade fever, dry cough, and headache)	Severe respiratory distress, hemodynamic failure, and death	Aerosol; no person-to-person transmission	Ciprofloxacin or doxycycline	Ciprofloxacin (Cipro) or, if susceptible, doxycycline; vaccine available but in short supply
	Cutaneous (1-12 days)	Local urticaria; painless papular lesions usually located on head, forearms, or hands	Papular lesions become vesicular, later developing black eschar and edema	Person-to-person transmission with direct contact with skin lesions		
	Gastrointestinal (1-7 days)	Abdominal pain, nausea, vomiting, and diarrhea	Gastrointestinal bleeding, fever; usually followed by toxic sepsis and death		Contaminated food and/or water	
Plague Acute, severe bacterial infection secondary to a gram-negative bacillus, <i>Yersinia pestis</i>	Bubonic Onset of symptoms dependent on route of transmission (1-6 days)	Swollen, tender lymph nodes (most notable femoral and inguinal), high fever, rapid pulse	Hypotension, extreme exhaustion, death	Aerosol and then human-to-human by droplet inhalation	Ciprofloxacin or doxycycline	Ciprofloxacin or doxycycline; no vaccine available at the present time
	Pneumonic (1-6 days)	High fever, chills, tachycardia, headache	Fulminate pneumonia (foamy hemoptysis, tachypnea, and dyspnea), sepsis, and death			
Botulism Anaerobic gram-positive bacillus that produces a potent muscle-paralyzing neurotoxin	Foodborne (12-36 hours)	Nausea, vomiting, diarrhea	Symmetric cranial nerve paralysis, descending flaccid paralysis (progressive paralysis of arms, respiratory muscles, and legs), and death	Contaminated food	Passive immunization (antitoxin); supportive care	Passive immunization (antitoxin); antitoxin available in short supply
	Inhalational (2 hours-8 days)	No fever, no changes in mental status	Symmetric cranial nerve paralysis, descending flaccid paralysis (progressive paralysis of arms, respiratory muscles, and legs), and death	Inhalation of aerosolized toxin		

Continued

TABLE 14-1 Summary of Selected Class A Biologic Warfare Agents—cont'd

Disease/Infectious Agent	Form and Incubation/Onset of Symptoms	Untreated Course of Disease		Probable Route of Contamination for Use as a Biologic Warfare Agent	Treatment of Mass Casualties	Prophylaxis/Vaccine
		Early-Onset Symptoms	Late-Onset Symptoms			
Typhoidal tularemia <i>Francisella tularensis</i> , an extremely infectious bacteria	Contaminated water or food or via aerosol distribution (1-14 days)	Flulike symptoms (headache, cough, fever and chills, malaise)	Pharyngeal ulcers, pleuritic chest pain, pneumonia, pericarditis, respiratory failure, sepsis, and death	Inhalation of aerosolized bacteria	Ciprofloxacin or doxycycline	Ciprofloxacin or doxycycline; vaccine available, only limited supply; vaccine offers incomplete protection
Major Viral Biological Agent of Concern—Smallpox						
Smallpox variola virus	Distribution via airborne droplets, aerosols, and fomites (7-17 days; weaponized smallpox when delivered aerosolized has an incubation period of only 3-5 days)	Acute viral symptoms (high fever, myalgia, headache, and backache)	Continued viral symptoms, high fever, prostration, synchronous onset of rash progressing from macules to papules to vesicles, and eschar formation Vesicles more abundant on extremities and face, and all develop at the same time; pustules appear on palms of hands and soles of feet (unlike chickenpox)	Transmitted person to person by large droplets; therefore spread may be by inhalation of aerosolized virus, oral secretions, infected human vector exposure, or exposure to contaminated objects	Supportive therapy only (ventilator)	None; vaccine available in short supply

STEP**RATIONALE****ASSESSMENT**

- | | |
|---|--|
| <ol style="list-style-type: none"> 1 Perform hand hygiene. Don proper personal protective equipment (PPE). 2 Conduct a focused health history and physical examination (e.g., pulmonary assessment—oxygen saturation, lung sounds, sputum character; cardiac—heart sounds; neurologic—Glasgow Coma Scale, reflexes). Review history of patient's presenting symptoms and determine if pattern exists. 3 Measure patient's vital signs and include assessment of pain on a scale of 0 to 10. 4 Review results of diagnostic tests and consult with health care provider. 5 Assess patient for health risks (e.g., history of heart disease, pulmonary disease, cancer) that complicate effects of exposure to biologic agent. | <p>Proper PPE provides safety to personnel and helps prevent spread of infectious agent to health care provider.</p> <p>Symptom identification and clustering of data assist in accurately determining exposure to type of biologic agent and patient's response.</p> <p>Provides baseline to later evaluate patient's response to therapy.</p> <p>Initial signs and symptoms of exposure to biologic agent suggest common disorders (e.g., flu). Further review of diagnostic findings helps to rule out other common disorders.</p> <p>Patients with preexisting medical conditions often require additional treatment or are at greater risk for death.</p> |
|---|--|

STEP

RATIONALE

- | | |
|---|---|
| <p>6 Stay calm and assess patient's immediate psychological response after exposure. Some patients present with dissociative symptoms (e.g., feeling as though "not there" or sensing that everything is outside of the person): disorientation, depression, anxiety, psychosis, and an inability to care for self. Even without direct exposure to a biologic agent, many individuals, spurred by feelings of fear and doom, will present for emergency services.</p> <p>7 Identify all patient contacts (names, addresses, and phone numbers) in the emergency department (ED) waiting room.</p> <p>8 Identify resources available (e.g., critical incident stress debriefing teams, counselors, psychiatric/mental health nurse practitioners).</p> | <p>Aids in providing appropriate crisis intervention and stress management. Remaining calm and projecting confidence while assessing individuals for clinical symptoms help to reduce anxiety of the ill and worried well as they experience the general sense of panic associated with a biologic event.</p> <p>All patient contacts need to be identified for proper follow-up by the public health department. Often patients will self-triage and transport to the ED.</p> <p>Expert resources help to assess extent of psychological impact of disaster.</p> |
|---|---|

Clinical Decision Point *You should consider a biologic event when large numbers of ill persons present who have unexplained yet similar symptoms; when there are unexplained deaths, particularly among young and healthy populations; when there is an unusual pattern associated with the symptoms (e.g., geographic, seasonal, patient population); when a patient fails to respond to traditional therapy; when a single patient presents with symptoms suggestive of an uncommon agent (e.g., anthrax or smallpox). Once you suspect a biologic event, notify incident command immediately.*

NURSING DIAGNOSES

- | | | |
|---|--|---|
| <ul style="list-style-type: none"> • Acute confusion • Acute pain • Anxiety/fear • Decreased cardiac output • Impaired gas exchange • Impaired oral mucous membrane | <ul style="list-style-type: none"> • Impaired skin integrity • Impaired swallowing • Ineffective airway clearance • Nausea • Post-trauma syndrome | <ul style="list-style-type: none"> • Risk for imbalanced body temperature • Risk for imbalanced fluid volume • Risk for peripheral neurovascular dysfunction |
|---|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient is comforted. • Patient's vital signs return to baseline. • Patient's work of breathing decreases. • Patient's skin integrity returns to baseline. • Patient's level of consciousness (LOC) returns to baseline. • Patient's mental health status returns to a pre-trauma level of functioning. <p>2 Dispense timely and accurate information, including an accurate description of agent to which patient is exposed and implications to patient and family.</p> | <p>In some cases care is only palliative, with comfort as the focus. Do not underestimate the value of <i>comfort</i> as <i>care</i>.</p> <p>When there are no underlying medical conditions and <i>if</i> the patient's disease process is responsive to treatment (when available), vital signs will return to normal, taking days or weeks.</p> <p>Indicates improved gas exchange and cardiac output. Antibiotic and antitoxin therapy will aid in resolution/healing of lesions over time.</p> <p>Treatment measures restore neurologic function and oxygenation status.</p> <p>Crisis intervention is successful in reducing patient's anxiety, fear, and dissociative symptoms.</p> <p>Information helps to relieve anxiety and fear.</p> |
|--|--|

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Perform hand hygiene.</p> <p>2 Institute transmission-based isolation precautions (see Chapter 7). (See Table 14-1 for mode of transmission of category A biologic agents.) Use strict isolation with smallpox because of its communicability from person to person. Use airborne precautions, contact precautions, and a negative pressure room for patients suspected of having smallpox.</p> | <p>Reduces transmission of microorganisms.</p> <p>Reduces transmission of microorganisms and the likelihood of additional secondary sites of contamination.</p> |
|--|---|

STEP	RATIONALE
3 Decontaminate as instructed by health care provider. If you suspect anthrax, have patient remove clothing and place in labeled plastic biohazard bag. <i>CAUTION: Do not pull over patient's head; instead cut garments off.</i> Instruct patient to shower thoroughly using soap and water.	Handle clothing minimally to avoid agitation. Showering with soap and water aids in decontaminating and reducing exposure (CDC, 2006 a,b).
4 Administer appropriate antibiotics and/or antitoxins.	Various biologic agents are commonly treated with ciprofloxacin (Cipro) and/or doxycycline (e.g., anthrax, plague, typhoidal tularemia). Botulism requires supportive care and use of an antitoxin. For some viral pathogens treatment is only supportive.
5 Administer immunizations (e.g., smallpox).	In the event that smallpox is the biologic weapon, the best treatment is prevention by immunization with vaccine before the onset of symptoms. Vaccination within 3 days of exposure completely prevents the disease or significantly reduces its effect. Vaccination 4 to 7 days after exposure offers some protection from disease or decreases its severity (CDC, 2011c).
6 Administer fluid and nutrition therapy.	Biologic agents commonly cause gastrointestinal (GI) disturbances that sometimes result in dehydration.
7 Administer oxygen therapy.	Various biologic agents (e.g., pulmonary anthrax) commonly cause respiratory symptoms that will result in an altered gas exchange.
8 Provide supportive care (e.g., comfort measures, including pain management).	Some victims of a biologic attack will not survive; palliative care is essential (see Chapter 16).
9 Counsel patient and family on acute and potential long-term psychological effects of exposure. Offer access to trained counselors. Support survivors of a disaster by identifying resources available.	Reaction of patients will include shock, fear, and immobilization. Long-term psychological effects can arise without proper counseling. Social support networks foster coping in the days following a disaster event.

Clinical Decision Point Collaborate with the health care provider and other rescue workers for an ongoing plan for managing patients exposed to a biologic agent. You will need to do this while caring for other patients who are already present in the health care agency seeking care for illness unrelated to the current MCI.

EVALUATION

1 Observe for improved airway maintenance, breathing, circulation, LOC, and neurologic functioning.	Evaluates patient's response to available treatment and/or supportive care.
2 Evaluate vital signs and level of pain.	Evaluates patient's response to treatment.
3 Inspect condition of patient's skin; note character of remaining lesions.	Evaluates patient's response to antibiotic therapy.
4 Query patient, "Tell me how you feel right now." Check level of orientation and ability to conduct conversation.	Evaluates patient for changes that suggest either improvement or deterioration of psychological status.

Unexpected Outcomes

- 1 Patient's physical symptoms progress despite appropriate treatment.
- 2 Patient becomes more anxious or delusional or develops suicidal ideations.
- 3 Patient death occurs.
- 4 Secondary contamination of rescue workers.

Related Interventions

- Notify health care provider.
- Continue to provide comfort care.
- Notify mental health treatment team.
- Remain calm, offer reassurance, and protect self and others from physical harm.
- Continue to provide comfort measures.
- When handling bodies, take into account continued risk for contamination; make sure that everyone is fully informed regarding proper procedure.
- Rescue workers immediately report symptoms to a health care provider or nursing supervisor.

Recording and Reporting

- Report suspected cases of a biologic incident to health care provider or ED officer. In the event of an ED exposure to a communicable disease, the department will be locked down immediately. Public health officials (e.g., the emergency officer) will determine if the hospital should be locked down.
- Create checklists that can be used quickly and use them in a disaster event to record specific data regarding patient status,

treatment administered, and response to treatment and/or comfort measures.

- Report any unexpected outcome to health care provider in charge.

Special Considerations

Teaching

- Preparation for an MCI goes a long way toward preventing casualties and chaos. Public education of the likelihood of a

mass casualty biologic event is necessary and includes information about types of biologic agents, mode of transmission, symptoms, treatment, and locations of shelters and disaster treatment sites.

- Encourage families to prepare for the unexpected (see Home Care Considerations).

Pediatric

- Children are one of the most vulnerable populations, and many facets influence the impact of disaster on children. These facets often include age, sex, family dynamics, and the level of and direct exposure to disaster (Hockenberry and Wilson, 2011).
- Children often have both physical and emotional needs during disasters. They often show fear and may have temporary changes in behavior after the disaster. These changes are usually related to stress (Hockenberry and Wilson, 2011).
- Many disasters result in the need to relocate, which creates stress and unique challenges in children. Stress may be increased by changes in children's cultural, psychological, and social environment. Reactions of their parents and other family members contribute to how well the child will cope with relocation and whether or not he or she will be able to stay connected with friends and familiar activities (Hockenberry and Wilson, 2011).
- Children are particularly vulnerable to the adverse effects of environmental chemicals and toxins because (1) pound for pound children take in larger doses of toxins through food, water, and air; (2) their organ systems are less mature and unable to remove some of the toxins; and (3) their life expectancy is longer, and long-term effects of exposure to toxins is unknown (Hockenberry and Wilson, 2011).
- Disasters disrupt infrastructure and may cause large-scale displacement, leading to unsafe water, lack of access to health care, and decreases in vector control and infectious agents (WHO, 2011b). Outbreaks of communicable diseases have been reported after natural disasters, and children are more likely to develop infections secondary to immature immune systems (Hockenberry and Wilson, 2011).
- It is important to keep the family together after a disaster. Family togetherness provides reassurance to a child and alleviates fears of being abandoned and unprotected (Hockenberry and Wilson, 2011).
- Media has an enormous influence over children and may impact development and behavior. Encourage parents to limit their children's exposure to media reports of the disaster and to watch television with them whenever possible to clarify information and answer questions (Hockenberry and Wilson, 2011).
- The death of a child, regardless of the situation, is always traumatic; parents may have a compelling need to be present during pediatric resuscitation and at the time of death; ideally you should allow it. It is important for a nurse to be present to explain to the parent what is happening and facilitate the grieving process (Hockenberry and Wilson, 2011).

Gerontologic

- Under disaster conditions triage older adults according to injuries, not age.
- Because the older adult often has several concurrent illnesses, possible exposure to a biologic agent often worsens these conditions and results in the need for more immediate care than an initial triage may suggest.

Home Care

- Assemble a disaster kit before disaster strikes. FEMA and the American Red Cross offer free literature on establishing home care preparedness (Boxes 14-8 and 14-9).

BOX 14-8 Basic Disaster Supply Kit

- Water: 1 gallon of water per person per day (minimum of 3-day supply)
- Food: minimum of 3-day supply for evacuation/2-week supply for home
- Manual can opener
- Plastic resealable bags
- Utility knife
- Disposable cups, plates, and utensils
- Several flashlights
- Battery-powered radio or television
- Fresh batteries
- Matches in waterproof container
- First-aid kit
- Medications (7-day supply)
- One complete change of clothing and footwear for each person
- Blankets
- Sanitation and hygiene items (e.g., hand sanitizer, toilet paper)
- Small fire extinguisher
- Shut-off valve wrench

Additional Considerations

- Items for infants, seniors, or disabled persons
- Pet-care items
- Entertainment items for small children
- Extra set of keys and identification
- Copies of medical prescriptions in plastic sealable bags

Additional Supplies for Sheltering-in-Place (in the Event of a Chemical or Radiologic Hazard)

- Roll of duct tape and scissors
- Plastic sheeting precut to fit shelter-in-place room openings (10 square feet per person will provide sufficient air to prevent carbon dioxide buildup for up to 5 hours)
- Additional supplies in preparation for a pandemic flu (Have a 2-week supply of basic items so you can survive without outside help or going out in public.)
- Thermometer, nonaspirin pain reliever, prescription medication
- Household-cleaning supplies (e.g., disinfectant sprays, bleach)
- Extra bath and hand soap

Data from American Red Cross (ARC) and Centers for Disease Control and Prevention (CDC): Emergency preparedness and response, 2011, available at <http://www.emergency.cdc.gov/preparedness/kit/disasters/>, accessed August 19, 2012.

BOX 14-9 Suggested Foods for a Disaster Supply Kit

- Ready-to-eat canned meats, fruits, and vegetables
- Protein or fruit bars
- Peanut butter
- Dry cereal or granola
- Nuts
- Dried fruit
- Canned juices
- Nonperishable pasteurized milk
- Comfort/stress foods

Data from American Red Cross (ARC) and Centers for Disease Control and Prevention (CDC): Emergency preparedness and response, 2011, available at <http://www.emergency.cdc.gov/preparedness/kit/disasters/>, accessed August 19, 2012.

- Individuals with special needs (e.g., hearing impairment, impaired mobility, individuals without vehicles, and individuals with special diets) require additional planning to be prepared in the event of a disaster.
- In case of a disaster many schools and employers have disaster plans; individuals need to familiarize themselves with these plans along with their own home disaster plan.
- Post emergency telephone numbers by the telephone and teach children how and when to call 9-1-1.
- Family members need to have a mechanism in place to ensure that they are able to stay in contact in case they are separated (e.g., a designated meeting place, a friend to call to notify when separated from the family).
- An individual of the family needs to know how to turn off water, gas, and electricity in case of a disaster because emergency management personnel often make this request of civilians in the event of a disaster.
- Install a high-efficiency particulate air (HEPA) filter in the return duct of the furnace. These filters will filter out most biologic agents but not chemical agents.
- Have as many members of the family as possible take a first aid class to reduce the risk of complications from a biologic infectious agent during a disaster. Individuals need to maintain a first-aid kit in an accessible location in the home and know which type of PPE will protect the family from secondary exposure.
- Listen to the radio or television for instructions when a biologic disaster becomes a reality. However, limit media exposure to reduce reliving the event and further traumatization. Children and older adults are prone to the emotional stressors of such continuous reporting, which leads to a sense of helplessness.
- Remain isolated and advise friends and relatives not to visit if family members are symptomatic.
- Use the appropriate PPE needed to protect the family; this can include sheltering-in-place.
- Maintain strict hand hygiene for both well and symptomatic family members after using the bathroom, before eating and drinking, and after contact with pets.
- Have family caregivers wear gloves (vinyl or latex) when in contact with a sick individual's blood or body fluids.
- When a sick individual's symptoms worsen, transport to the nearest designated hospital.
- Change the sick person's clothing and bed linens frequently; wash them separately from those of other family members, using any commercial detergent.
- Disinfect any surfaces with which the symptomatic person comes in contact, using an appropriate disinfectant (e.g., Lysol), especially when soiled by blood or other body fluids.
- Family caregiver's highest priority is to avoid becoming a victim. This individual needs to get plenty of rest, drink fluids frequently, and eat a healthy diet. If the caregiver develops symptoms, obtain appropriate medical care immediately.

SKILL 14-2 Care of a Patient After Chemical Exposure

A chemical disaster is the dispersal of a toxic chemical agent into the environment. The mechanism of dispersal is not always known. In fact, the dispersal mechanism such as an explosion or fire can be a secondary terrorist attack designed to create greater fatalities. Explosions spread a toxic chemical in uncontrolled directions, creating more victims. Symptoms from chemical exposure are usually apparent within minutes, but some are delayed up to 24 hours. Early recognition of a chemical event is a priority because you will need to administer many chemical antidotes quickly. Toxic chemical incidents such as biologic events are often unannounced or overt. Terrorists often intend for chemical agents to cause mass casualties and induce fear and/or mass hysteria.

Chemical events are generally confined to small areas, although larger dispersal of these agents may occur (e.g., via a crop duster). The nature and scale of contamination depends on the state of the agent used (e.g., gas versus liquid), characteristics of the chemical used (e.g., heavy or lighter than air), and where the event occurs (e.g., indoors, where ventilation systems affect dispersal, or outdoors, where wind and velocity affect speed and direction of dispersal). For safety reasons, rescue workers should be upwind and uphill from a toxic chemical disaster scene to avoid exposure. The exception is when cyanide gas has been released. Cyanide is lighter than air and thus will travel uphill. It has the unique smell of bitter almonds. If you detect the smell, evacuate the area immediately, although exposure may have already occurred (CDC, 2008).

Because symptoms are almost immediate, it is important to evacuate victims as quickly as possible from the contaminated zone to a decontamination zone. Special respiratory and skin personal protective equipment (PPE) prevent contamination of rescue workers. Before decontamination victims are a potential source of contamination for rescue workers. It is imperative that a nurse protect against toxic chemical contamination when in contact with a contaminated patient. Secondary contamination is high

with toxic chemical incidents. Table 14-2 summarizes common chemical warfare agents, presenting symptoms, and untreated course of exposure.

The rapid chemical decontamination of victims of a toxic chemical incident is more important than determining the exact

TABLE 14-2 Summary of Selected Chemical Warfare Agents

Chemical Agent	Onset of Symptoms	Untreated Course of Chemical Exposure
“Lethal” agents —nerve agents (tabun, sarin, soman, and VX)	Symptoms are generally immediate.	Pinpoint pupils and shortly thereafter salivation, runny nose, dyspnea, chest tightness, nausea, muscle twitching, coma, seizures, and death
“Blood” agents —hydrogen cyanide	Rapid onset of symptoms though cyanide poisoning is often associated with the smell of bitter almonds	Death caused by asphyxiation
“Blister” agents —mustard and lewisite	Symptoms may be immediate or delayed.	Skin irritation and blistering
“Choking” agents— phosgene and chlorine	Symptoms can be immediate or delayed up to 24 hours.	Coughing, choking, and disruption in pulmonary function that can lead to death

toxic chemical. When decontamination is necessary, trained personnel are required. Decontamination is either gross or technical, which generally occurs at the scene. The hospital also provides decontamination when a contaminated individual presents for treatment. A nurse and all other health care personnel need to use appropriate precautions to avoid becoming victims.

Delegation and Collaboration

The skill of assessing a patient exposed to a chemical agent cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Use appropriate PPE to prevent chemical exposure.
- Use techniques for handling a body after death to prevent contamination.

Equipment

The following is a general list of supplies needed in the event of release of the most toxic chemical agents:

- Decontamination room or area (adult decontamination rooms may not meet the needs of children requiring decontamination; decontamination areas for ambulatory victims will not meet the needs of those who are not ambulatory)
- Scissors or a tool to cut off clothing
- Biohazard bags with labels
- Large volumes of water, decontamination shower (Fig. 14-6)
- Appropriate PPE
- Equipment for physical examination

FIG 14-6 Inflatable decontamination shower for ambulatory victims. (Courtesy Professional Protection Systems, Ltd.)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|--|
| <p>1 Perform hand hygiene. Don proper personal protective equipment (PPE).</p> | Proper PPE provides safety to personnel and helps prevent spread of infectious agent to health care provider. |
| <p>2 Assess patient's symptoms and level of pain (on a scale of 0 to 10). Perform appropriate focused physical examination (see Skill 14-1).</p> | Symptom identification and clustering of data accurately identify patient's problem and response. |
| <p>3 Observe for presence of liquid on patient's skin or clothing and odor (e.g., chlorine). Note condition of skin.</p> | Common conditions present when chemical exposure has occurred. |
| <p>4 Assess patient for preexisting medical conditions that will complicate the effects of the toxic chemical exposure.</p> | Patients with preexisting medical conditions will likely require additional treatment and sometimes are at greater risk for death. |

Clinical Decision Point Consider a toxic chemical event when large numbers of ill persons present who have unexplained yet similar symptoms. The primary objective for initial care is decontamination, the process used to remove harmful contaminants from the surface of the skin. You achieve this by removing clothing; scrubbing the skin; and hydrolysis, a process of chemical dilution using large volumes of water.

- | | |
|--|--|
| <p>5 Calmly assess patient's immediate psychological response following exposure. Some patients present with dissociative symptoms, disorientation, depression, anxiety, psychosis, and inability to care for self. Even without direct exposure to a chemical agent, many individuals, spurred by feelings of fear and doom, will present for emergency services and quickly overwhelm available emergency services.</p> | Aids in being able to provide appropriate crisis intervention and stress management. Remaining calm and projecting confidence reduces the anxiety of the ill and worried well as they experience the general sense of panic associated with chemical exposure. |
| <p>6 Identify resources available (e.g., critical incident stress debriefing teams, counselors, psychiatric/mental health nurse practitioners).</p> | Expert resources assess extent of psychological impact of disorders. |

STEP

RATIONALE

NURSING DIAGNOSES

- | | | |
|--|--|---|
| <ul style="list-style-type: none"> • Acute confusion • Acute pain • Anxiety/fear • Decreased cardiac output • Impaired gas exchange | <ul style="list-style-type: none"> • Impaired oral mucous membrane • Impaired skin integrity • Impaired swallowing • Impaired verbal communication • Ineffective airway clearance | <ul style="list-style-type: none"> • Nausea • Post-trauma syndrome • Risk for imbalanced fluid volume • Risk for peripheral neurovascular dysfunction |
|--|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Patient is comforted.
- Patient's vital signs return to baseline.
- Patient's work of breathing decreases.
- Patient's skin integrity returns to baseline.
- Patient's level of consciousness (LOC) returns to baseline.
- Patient's mental health status returns to a pre-trauma level of functioning.

2 Explain care to patient and family, including decontamination and treatment. Explain your role, orient to location and activities to perform, explain what patient has experienced, and ask, "How are you feeling right now?" Assure them that a medical professional will see them shortly.

Because of the fatal nature of many chemical agents, the only care available is palliative.

When there are no underlying medical conditions and *if* the patient's condition is responsive to treatment (when available), vital signs will return to normal within days or weeks.

Indicates improved gas exchange and cardiac output.

Minimizing exposure of skin to chemical agent reduces severity and extent of skin lesions.

Neurologic stability is achieved by minimizing exposure to chemical and giving antitoxin quickly.

Crisis intervention is successful in reducing patient's anxiety, fear, and dissociative symptoms.

Information helps to calm anxiety and fear.

IMPLEMENTATION

1 Perform hand hygiene.

2 Prepare for decontamination. Only trained personnel using required PPE may decontaminate patients with toxic chemical contamination.

Reduces transmission of and injury from toxic chemicals.

Reduces likelihood of secondary toxic chemical contamination to untrained personnel attempting decontamination.

Clinical Decision Point Hold victim outside decontamination area until preparations are completed for decontamination procedure. If patient is grossly contaminated, consider decontamination before entry into building.

3 Provide for patient privacy by closing room curtains or door.

Prevents discomfort and embarrassment when clothing is removed.

4 Decontaminate patient:

a Act quickly; avoid touching contaminated parts of clothing as much as possible.

b Remove all of patient's clothing. *CAUTION: Do not pull over patient's head; instead cut garments off.*

Cutting off clothing prevents contamination of head and hair.

c Use large amounts of soap and water to wash patient thoroughly.

Will lead to chemical dilution and in some cases will prevent patient death.

d If eyes are burning or vision is blurred, rinse eyes with plain water for 10 to 15 minutes. If patient wears contacts, remove and place with contaminated clothing; do not reinsert in eyes. Wash eyeglasses with soap and water; reapply when completed.

Flushes toxins from the eye.

5 Dispose of patient's contaminated clothing in an appropriate biohazard bag and seal. Place bag in another plastic bag and seal (see agency policy).

Reduces likelihood of secondary chemical contamination.

6 Initiate treatment for chemical agent using appropriate chemical agent protocol.

Appropriate chemical agent protocol varies with patient exposure (e.g., linesterase, nerve agent, chlorine, and lewisite) (Box 14-10).

7 Establish airway if needed; administer oxygen therapy.

Various chemical agents commonly cause respiratory problems that will result in altered gas exchange.

STEP	RATIONALE
8 Control bleeding.	Various chemical agents cause extensive bleeding.
9 Administer fluid and nutrition therapy.	Various chemical agents commonly cause gastrointestinal disturbances that can result in dehydration.
10 Provide supportive care (e.g., comfort measures, including pain management).	Some victims will not survive; it is essential for a nurse to provide palliative symptom control.
11 Counsel patient and family on both acute and potential long-term psychological effects of exposure. Offer access to trained counselors.	Reaction of patients to exposure includes shock, immobilization, and fear. Long-term psychological effects can arise without proper counseling.

Clinical Decision Point Collaborate with the health care provider and other rescue workers for an ongoing plan to manage patients exposed to a toxic chemical agent. You will need to do this while also caring for other patients who are already present in the health care agency seeking care for illness unrelated to the current MCI.

EVALUATION

1 Observe status of airway maintenance, breathing, circulation, LOC, and neurologic functioning. Assess vital signs.	Evaluates patient’s physical response to available treatment and/or supportive care.
2 Ask patient to rate pain level on a 0-to-10 scale.	Determines if comfort measures are effective.
3 Inspect condition of skin; note extent of blistering.	Determines extent of healing.
4 Evaluate patient’s level of orientation, ability to problem solve, and perception of condition.	Evaluates patient’s psychological status and ability to make decisions.

Unexpected Outcomes

- Secondary contamination of rescue workers occurs.
- Patient’s physical symptoms progress despite appropriate treatment.
- Patient’s psychological symptoms progress despite appropriate treatment. Patient exhibits anxiety, disorientation, and suicidal ideation.
- Patient death occurs.

Related Interventions

- Rescue workers immediately remove their clothing, scrub their bodies, and use copious amounts of soap and water.
- Contain clothes in appropriate biohazard bags.
- Provide clean clothes.
- Notify health care provider in charge.
- Continue to provide comfort care.
- Notify mental health treatment team.
- Remain calm, offer reassurance, and protect self and others from physical harm.
- Continue to provide comfort measures.
- When handling bodies, take into account continued risk for contamination; make sure that everyone is fully informed regarding proper procedures. When delegating preparation of the deceased, always take into account the level of training of those managing the body.

BOX 14-10 Examples of Chemical Exposure Protocols

CHLORINE PROTOCOL

- Dyspnea?
 - Try bronchodilators
 - Admit to hospital
 - Oxygen by mask
 - Chest x-ray examination
- Treat other problems and reevaluate (consider phosgene)
- Respiratory system OK?
 - Yes—Go to 5
- Is phosgene poisoning possible?
 - Yes—Go to Phosgene Protocol on the CDC website
- Give supportive therapy: treat other problems or discharge

MUSTARD PROTOCOL

- Airway obstruction?
 - Yes—Tracheostomy
- If there are large burns:
 - Establish IV line—Do not push fluids as for thermal burns
 - Drain vesicles—Unroof large blisters and irrigate area with topical antibiotics
- Treat other symptoms appropriately:
 - Antibiotic eye ointment
 - Sterile precautions prn
 - Morphine prn

CDC, Centers for Disease Control and Prevention; IV, intravenous; prn, as needed.

Modified from Centers for Disease Control and Prevention: *Emergency room procedures in chemical hazard emergencies: a job aid*, 2010, available at <http://www.cdc.gov/nceh/demil/articles/initialtreat.htm>, accessed February 12, 2012.

Recording and Reporting

- Report suspected cases of a toxic chemical event to health care provider or emergency officer.
- Record in nurses' notes and electronic health record (EHR) patient's status, decontamination and treatment procedures, and response to treatment and/or comfort measures.
- Report any unexpected outcome to health care provider in charge.

Special Considerations

Teaching

- Preparation for an MCI goes a long way toward preventing casualties and chaos. Public education about the likelihood of a mass casualty chemical event is necessary. This education needs to include information regarding types of chemical agents, mode of dissemination, symptoms, and treatment.
- Education of the public needs to include locations of shelters and disaster treatment sites.
- See *Skill 14-1* for family disaster plan and preparation.

Pediatric

- To avoid becoming a secondary victim, emergency responders need to consider potential contamination of children before

picking them up and holding them. Often decontamination consists of providing fresh air and a large volume of low-pressure warm water. Observe children for potential hypothermia because they are more susceptible.

- Adult decontamination facilities are not always appropriate to meet the needs of children. The special protective equipment worn by rescue workers may frighten young children. The cleaning process and possible separation from uncontaminated parents will likely cause considerable stress and anxiety. Additional health care workers are often necessary to ensure that adequate decontamination has taken place. Verbal encouragement and praise will be effective in facilitating the process.
- See *Skill 14-1* for further pediatric considerations.

Gerontologic

- See *Skill 14-1* for gerontologic considerations.

Home Care

- Keep upwind and uphill from the release of the toxic chemical unless it is cyanide.
- Use appropriate PPE needed to protect the family; this includes sheltering-in-place.
- See *Skill 14-1* for further home care considerations.

SKILL 14-3 Care of a Patient After Radiation Exposure

Radiologic events differ from nuclear events. A radiologic event is the dispersal of radioactive material via a “dirty bomb,” by deliberate contamination of food or water supplies, or over the terrain. A nuclear event involves a device that releases nuclear energy in an explosive manner as a result of a nuclear chain reaction. Early symptoms of radiation exposure are similar to those experienced by anxious individuals. Thus, once radiation release becomes publicly recognized, an enormous number of worried well will compromise incident management, scene security, and triage (CDC, 2011b).

Radiation comes in a variety of forms. Alpha particles are the least dangerous, traveling only a few centimeters. They do not penetrate materials easily and are harmful only if ingested. An individual's clothing block alpha particles from reaching the skin. Beta particles penetrate a short distance into the skin. Protective clothing is necessary for protection. Gamma rays pose the greatest health risk because the waves penetrate deeply, causing severe burns and internal injury. Lead shielding protects against gamma rays. Blasts caused by a nuclear explosion cause not only injury from radiation exposure but also traumatic injuries and burns. Some victims will present with many combined forms of injury requiring treatment. The sooner symptoms begin to appear, the greater the patient's exposure to the radiation. Early symptoms, within a few hours, suggest that the individual has received a lethal dose of radiation. They include nausea, vomiting, diarrhea, and a possible burn. For some, hair begins to fall out, and the victim quickly becomes immunocompromised.

Nuclear incidents usually result in wide destruction requiring specialized equipment and resources at the scene to assess structural damage and levels of radioactivity. Radiologic events usually cover much smaller areas, but they are often difficult to define. *Table 14-3* presents characteristic differences between a nuclear event and a radiologic event. Specialized equipment and training are required to assess the source of radioactivity, determine the scope of contamination, and perform decontamination. Decontamination is

important with radiation exposure; however, it needs to occur in an area where there is not continued radiologic release (CDC, 2011d,e). The principles to follow to protect individuals from exposure involve distance, time, and shielding.

Delegation and Collaboration

The skill of assessment of a patient exposed to a radiologic agent cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Use appropriate personal protective equipment (PPE) to prevent exposure.
- Use techniques for handling a body after death to prevent contamination.

Equipment

The following is a general list of supplies needed in the event of release of the most radiologic exposure:

- ❑ Decontamination room or area (adult decontamination rooms do not always meet the needs of children requiring

TABLE 14-3 Characteristics of a Nuclear Event and a Radiologic Event

Characteristics	Nuclear Event	Radiologic Event
Event recognition	Obvious	Not obvious
Thermonuclear explosion	Yes	No
Casualties	Large	Small
Amount of radiation release and contamination	Large	Small
Likelihood of terrorism	No	Yes

From American Medical Association: *Core Disaster Life Support: provider manual*, version 1.01, Chicago, 2002, The Association. Used with permission of the American Medical Association.

- decontamination; decontamination of ambulatory victims will not meet the needs of those who are not ambulatory)
- ❑ Scissors or some other tool to cut off clothing
- ❑ Clothing containers; type depends on the kind of radiologic exposure
- ❑ Appropriate personal protective equipment (PPE) for use by personnel in area of radiation release
- ❑ Appropriate PPE for health care workers in hospital setting (i.e., surgical masks, N95 masks, recommended if available)
- ❑ Radiation meter available to survey hands and clothing at frequent intervals (CDC, 2011d)
- ❑ Equipment for select specimen collection
- ❑ Equipment for physical examination

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| <p>1 Assess patient's symptoms by performing a focused physical examination (see Skill 14-1).</p> | <p>Symptom identification and clustering of data are the first steps to determining patient's condition and response.</p> |
|--|---|

Clinical Decision Point Before assessment, a specially trained technician conducts a radiation survey of the patient, initially conducting a scan of the face, hands, and feet with a radiation survey instrument. If meter results are positive, a thorough survey (5 to 8 minutes per person) is conducted.

- | | |
|--|--|
| <p>2 Assess patient for secondary traumatic wounds: location, drainage, size, appearance.</p> | <p>Radioactive fragments are sometimes embedded in a wound. Very high localized levels of internal contamination indicate radioactive fragments.</p> |
|--|--|

Clinical Decision Point Do not touch the wound if you suspect that radioactive fragments are present.

- | | |
|---|---|
| <p>3 Assess patient for preexisting medical conditions that will complicate effects of the radiologic exposure.</p> | <p>Patients with preexisting medical conditions can require additional treatment or are at greater risk for death.</p> |
| <p>4 Determine patient's allergies, specifically allergy for iodine sensitivity.</p> | <p>Patients with iodine sensitivity need to avoid taking potassium iodide, the treatment of choice for radioactive iodine exposure.</p> |
| <p>5 Assess individual psychological response to radiologic event. Some patients present with dissociative symptoms (e.g., feeling as though "not there," sensing that experiences are outside the person), disorientation, depression, anxiety, psychosis, and an inability to care for self. Ask patient, "How do you feel now?" Determine level of orientation, ability to follow conversation.</p> | <p>Aids a nurse in being able to provide appropriate crisis intervention and stress management. Remaining calm and projecting confidence while assessing individuals for clinical symptoms versus feelings of panic goes a long way toward reducing the anxiety of the ill and worried well as they experience the general sense of panic associated with a radiologic event.</p> |
| <p>6 Identify resources available (e.g., critical incident stress debriefing teams, counselors, psychiatric/mental health nurse practitioners).</p> | <p>Expert resources assess extent of psychological impact of disaster.</p> |

Clinical Decision Point A radiologic event is the event most feared by most individuals. Many are uneducated regarding the dangers of and differences among radiation materials. Health care agencies will likely have many anxious, frightened individuals who can potentially create a danger to the environment.

NURSING DIAGNOSES

- | | | |
|---|---|--|
| <ul style="list-style-type: none"> • Acute pain • Anxiety • Deficient fluid volume | <ul style="list-style-type: none"> • Diarrhea • Fear • Impaired tissue integrity | <ul style="list-style-type: none"> • Nausea • Post-trauma syndrome • Risk for infection |
|---|---|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient is comforted. • Patient is successfully decontaminated. • Patient's vital signs return to baseline. • Patient is free of nausea and diarrhea. • Patient's skin integrity returns to baseline. | <p>In some cases the only care that is available is palliative. Decontamination procedures remove radioactive materials from patient's skin. When there are no underlying medical conditions and if the patient's disease process is responsive to treatment (when available), vital signs will return to normal within days or weeks. Gastrointestinal alterations following radiation exposure typically respond to antidiarrheal and antiemetic medications. Radiologic burns are minimized through successful decontamination procedures.</p> |
|--|---|

STEP	RATIONALE
<ul style="list-style-type: none"> • Patient's immune system (e.g., complete blood count [CBC]) returns to baseline. • Patient's work of breathing decreases. 	Exposure to radiation is successfully minimized.
2 Explain care to patient and family. Explain your role, orient to location and activities to perform, explain what patient has experienced, and ask, "How are you feeling right now?" Assure them that medical personnel will see them shortly.	Indicates improved gas exchange and cardiac output. Crisis intervention reestablishes patient's orientation and sense of reality.

IMPLEMENTATION

1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Only trained personnel use required PPE to decontaminate patients with radiologic contamination.	Reduces likelihood of secondary radiologic contamination to untrained personnel attempting decontamination.
3 Provide for patient privacy by closing room curtains or door.	Prevents anxiety or embarrassment when clothes are removed.
4 Decontaminate patient: <ol style="list-style-type: none"> Remove patient's clothing. Wash patient's skin thoroughly with water and soap, taking care not to abrade or irritate the skin. Do not allow radioactive material to be incorporated into any wounds. Have radiation technician resurvey patient after washing. Rewash as necessary. Isolate and cover any area of the skin that is still positive for radiation by using a plastic bag or wrap. 	Normally eliminates up to 90% of contamination. Use of large amounts of water is critical in decontamination.
5 Bag and tag patient's contaminated clothing for further evaluation and place in appropriate biohazard container.	Determines if radiation residual is present. The area is washed until no further reduction in contamination is achieved (verified by survey instrumentation) and then covered to reduce exposure of health care workers. Reduces likelihood of secondary contamination when you use containers designed to contain the radiologic particle.
Clinical Decision Point Collaborate with the health care provider and other rescue workers for an ongoing plan to manage patients exposed to radiologic materials. You will need to do this while also caring for other patients who are already present in the health care agency seeking care for illness unrelated to the current nuclear or radiologic event.	
6 Prepare for possibly obtaining a CBC, urinalysis, fecal specimen, and swabs of body orifices (see Chapter 43).	CBC establishes baseline to determine patient's immunologic status over time. A health care provider who suspects internal contamination will order collection of urine, feces, and body orifice swabs to analyze for radionuclides.
7 Treat symptoms according to ordinary treatment practices: provide intravenous fluid support, antidiarrheal therapies, antiemetic medications, and potassium iodide tablets (CDC, 2011d,e).	Patient exposed to radiation is at risk for gastrointestinal (GI) alterations and fluid imbalance. Potassium iodide reduces risk for thyroid cancer from radioactive iodine exposure.

EVALUATION

1 Observe skin integrity, fluid balance, respiratory and GI status, level of consciousness, and neurologic functioning. Look for improvement of other radiologic agent-specific symptoms. Evaluate vital signs.	Evaluates patient's physical response to available treatment and/or supportive care.
2 Monitor CBC and other laboratory tests.	Determines patient's immune response.
3 Evaluate patient's level of consciousness, orientation, and ability to relate events. Ask if patient remembers what has occurred; observe affect.	Determines if psychological status has improved.

Unexpected Outcomes

- Secondary contamination of rescue workers occurs.
- Patient's symptoms progress despite appropriate treatment.
- Patient's psychological state deteriorates with development of disorientation, suicidal ideation, violence toward others.
- Patient death occurs.

Related Interventions

- Institute appropriate decontamination of worker.
- Notify health care provider in charge.
- Continue to provide comfort care.
- Notify mental health treatment team.
- Remain calm, offer reassurance, and protect self and others from physical harm.
- Continue to provide comfort care.
- When handling bodies, take into account continued risk for contamination; make sure that everyone is fully informed about proper procedure. When delegating preparation of the deceased, take into account the level of training of those managing the body.

Recording and Reporting

- Record in nurses' notes and EHR patient's status and response to treatment and/or comfort measures.
- Report presence of open wound and any suspected radioactive fragment to health care provider in charge.
- Report any unexpected outcomes to health care provider.

Special Considerations

Teaching

- See Skill 14-1.

Pediatric

- Children are vulnerable to radiation because (1) their organ systems are more sensitive than those of adults, and (2) they have more years of life expectancy over which to develop complications from the radiologic exposure.
- See Skills 14-1 and 14-2 for further pediatric considerations.

Gerontologic

- Because some older adults have many concurrent illnesses, it is possible that radiologic agents will worsen these conditions and result in the older adult needing more immediate care than an initial triage had indicated.
- See Skill 14-1 for further gerontologic considerations.

Home Care

- When a radiologic or nuclear event becomes reality, listen to the radio or television for special instructions, including appropriate means for maintaining a safe shelter.
- Keep upwind and uphill from the release of the radioactive materials.
- See Skill 14-1 for further home care considerations.

Critical Thinking Exercises

Victims of an explosion involving a chemical are arriving in the emergency department (ED). Authorities state that the substance is unknown at this time, but there were reports by people in the area of a “funny smell” earlier in the day.

- 1 What are some safety measures that a rescue worker should take to avoid exposure?
- 2 Victims on the scene are triaged. How would the following patients be color coded, and which would receive the highest priority? A 22-year-old with cyanosis, a respiratory rate of 35, and confusion; a 14-year-old with a diffuse red rash on the extremities; a 56-year-old with controlled bleeding of deep lacerations received from falling debris; a 41-year-old with burns on 50% of the body.
- 3 What should the nurse working in the ED expect the initial care to be, and how is it achieved?
- 4 Yvette is an 18-year-old patient who arrived in the ED for treatment. Her clothing appears to be saturated with the unknown chemical. How should Yvette's clothing be handled?
- 5 Among the victims to be treated is a 3-year-old. What special considerations need to be taken when decontaminating children?

- 1 A nurse who has been delegated to care for the community patients currently admitted to the ED
 - 2 A nurse assigned to triage disaster victims transported to the ED but able to walk in to the triage area
 - 3 A nurse who is assigned to care for patients on an as-needed basis
 - 4 A nurse who must inform a mother that her three children did not survive
- 3 Four victims from a disaster arrive at the ED at the same time. Which victim should receive the highest level of priority for care?
 - 1 A disaster victim who arrives at the ED without a pulse
 - 2 A disaster victim who arrives at the ED with labored respirations, cool skin, a pulse of 120 beats/min, and a blood pressure of 90/60 mm Hg
 - 3 A disaster victim who is a noted politician with an open fracture of his left arm
 - 4 A disaster victim who is under the age of 6 years, regardless of the extent of his injuries
 - 4 A patient arrives at the ED with suspected cutaneous anthrax. Which type of precautions should be used with this patient?
 - 1 Standard
 - 2 Contact
 - 3 Respiratory
 - 4 Airborne
 - 5 A practice emergency drill is being held in the ED. The drill would be considered successful if which group of people were initially protected at the disaster scene?
 - 1 The health care workers
 - 2 The patient(s)
 - 3 The news crews reporting the event
 - 4 The family members of the victim(s)
 - 6 In the case of a biologic exposure, delegation and collaboration are important. Which of the following tasks may be delegated to the nursing assistive personnel (NAP)?
 - 1 Conducting a focused health history
 - 2 Assessing the patient for health risk
 - 3 Reviewing diagnostic test results
 - 4 Gathering appropriate personal protective equipment (PPE)
 - 7 A patient exposed to toxic chemical agents arrives at the ED. When caring for the patient, which action is most important?
 - 1 Determining what the toxic chemical agent is
 - 2 Decontaminating the patient
 - 3 Assessing the patient's immediate psychological response to exposure
 - 4 Assessing the patient for preexisting medical conditions

REVIEW QUESTIONS

- 1 A hospital committee formed to work on an emergency response plan is meeting initially to discuss how to proceed with the process. Why is a clearly defined, executable, and practiced emergency response plan the best indicator that an agency will be successful in a disaster situation?
 - 1 Practice makes staff more familiar with disaster protocols in the event of a true disaster.
 - 2 Practice of protocols helps to meet all of the regulatory agency guidelines.
 - 3 Practice prevents the likelihood of acute traumatic stress disorder in the staff.
 - 4 Practice is cost-effective in the long term because fewer staff will be required to handle the disaster as a result of the preparation of the staff members.
- 2 A major traffic accident involving multiple vehicles and an explosion has sent numerous patients to the local ED. Which experienced nurse has the most difficult assignment and a greater chance for demonstrating signs and symptoms of acute traumatic stress disorder?

- 8 Understanding the levels of personal protective equipment is important to both rescue workers and health care providers. Most hospital personnel are trained and fitted to use which level of protection?
- 1 Level A
 - 2 Level B
 - 3 Level C
 - 4 Level D
- 9 During a radiologic event the treatment of choice is:
- 1 Potassium iodide.
 - 2 Potassium chloride.
 - 3 Potassium hypochlorite.
 - 4 Potassium carbonate.
- 10 In the event that smallpox is the biologic weapon, which is the best treatment to reduce the effects of exposure?
- 1 Administering antibiotics
 - 2 Decontaminating the person
 - 3 Providing supportive care
 - 4 Immunizing with vaccine

 - Audio Glossary

KEY TERMS

Acute pain	Effleurage	Opioid Naïve	Physical dependence
Addiction	Epidural analgesia	Oversedation	Preemptive analgesia
Analgesia	Guided imagery	Pain intensity	Pseudoaddiction
Anaphylaxis	Massage	Pain rating scales	Rational polypharmacy
Chronic pain/persistent pain	Multimodal analgesia	Patient-controlled analgesia (PCA)	Sedation scale
Cutaneous stimulation	Nonopioids	Pétrissage	Sleep apnea
Drug tolerance	Opioids		Splinting

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Assess a patient's level of comfort.
- Assess a patient's level of pain.
- Assess a patient's level of sedation.
- Identify skills appropriate for relieving a patient's reported pain.
- Plan care based on a patient's history, including pain history and physical assessment.
- Describe delivery of medication through a patient-controlled analgesia (PCA) device.
- Teach a patient to use a PCA device.
- Monitor and manage a patient receiving epidural analgesia.
- Monitor and manage a patient receiving a local anesthetic infusion pump.
- Identify and discuss various nonpharmacologic pain-relief measures.
- Monitor and manage a patient receiving nonpharmacologic measures to relieve pain.
- Evaluate the effectiveness of pain-management techniques.

Pain is a complex problem that is physical and/or mental in nature while being subjective and highly individualized. It is tiring and demands a person's physical, emotional, and mental energy. It interferes with personal relationships and even influences the meaning of life. Although certain types of pain create predictable signs and symptoms, you primarily assess it by relying on a patient's self-report. The patient is the only one who knows whether pain is present and what the experience is like. The International Association for the Study of Pain (IASP) defines pain as an unpleasant subjective sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage (IASP, 2010).

The Joint Commission requires that a patient's reports of pain are to be addressed and appropriately treated (Box 15-1). Optimal pain management is considered the right of every patient. Many people receive inadequate pain relief for conditions that could be treated or managed (IOM, 2011; Pasero and McCaffery, 2011). When you care for a patient with cognitive impairments, pain management represents a special challenge. It is important that you carefully observe a patient's behavior and nonverbal responses to pain when he or she is unable to self-report (Box 15-2) (Herr et al., 2011).

Pain is difficult to categorize, but the literature commonly identifies three types: acute, chronic/persistent, and cancer

BOX 15-1 The Joint Commission Pain Standards

The Joint Commission calls on health care organizations to do the following:

- Recognize the right of patients to appropriate assessment and management of pain
- Assess pain in all patients
- Record the assessment in a way that facilitates regular reassessment and follow-up
- Educate providers/patients and families
- Establish policies that support appropriate prescription or ordering of pain medicines
- Include patient needs for symptom control in discharge planning
- Collect data to monitor effectiveness and appropriateness of pain management

From The Joint Commission: *Comprehensive accreditation manual for hospitals: the official handbook*, Oak Brook Terrace, Ill, 2012, The Joint Commission.

BOX 15-2 Pain Assessment in a Nonverbal Patient**Recommended Assessment Approaches**

- Attempt a self-report of pain using simple yes/no responses or vocalizations or a numeric rating scale.
- Explain why a self-report cannot be used.
- Search for the potential cause of pain by using physical examination techniques (e.g., palpation).
- Assume that pain is present after ruling out other causes (infection or constipation).
- Identify pathologic conditions or procedures that may cause pain.
- Observe patient behaviors (e.g., confusion, pacing, facial expressions, vocalizations, body movements such as guarding) that indicate pain. These vary based on patient's developmental level.
- Ask family members, parents, and caregivers for a proxy report of patient's pain.
- Attempt an analgesic trial if pathologic conditions or procedures that may induce pain are present.

Using a Behavioral Pain Assessment Tool

- Use reliable and valid tools to ensure that appropriate criteria are used in assessment (e.g., the NOPPAIN for older adults).
- Select an appropriate scale for each patient (e.g., visual analog scale or FACES scale); no one scale is required for all specific groups of patients.
- Vital signs are not sensitive indicators for the presence of pain.

NOPPAIN: Noncommunicative Patient's Pain Assessment Instrument. Modified from Bell L: Pain assessment in the adult nonverbal or sedated patients, *Am J Crit Care* 19:356, 2010; Herr K et al: *Pain in the nonverbal patient: position statement with clinical practice recommendations*, The American Society for Pain Management Nursing, 2011, ASPMN.

pain (APS, 2009). Because cancer pain differs from chronic non-cancer pain in significant ways (time frame, pathology, treatment strategies), currently it is in a different category (Box 15-3).

The most effective pain management combines pharmacologic and nonpharmacologic strategies with the administration of pharmacologic agents. There are three types of analgesics: (1) non-opioids, including acetaminophen (Tylenol) and nonsteroidal antiinflammatory drugs (NSAIDs); (2) opioids (traditionally called *narcotics*); and (3) adjuvants or coanalgesics (e.g., antidepressants and muscle relaxants) that enhance analgesics or have analgesic properties. Timely administration before a patient's pain becomes

BOX 15-3 Pain Categories**Acute/Transient Pain**

- Protective and has an identifiable cause
- Has a rapid onset
- Varies in intensity
- Is of short duration
- Generally disappears with healing (Mackey, 2011)

Chronic/Persistent Pain

- Extends beyond the period of healing, eventually becoming a disease in its own right, not a symptom
- Often lacks identified pathology
- Rarely has autonomic signs; vital signs no longer indicate pain (Drew and St. Marie, 2011)
- Does not provide a protective function
- Disrupts sleep and other activities of daily living (ADLs)
- Degrades health and function of the individual

Cancer Pain

- May be acute, chronic, or intermittent (More cancer patients are living longer with chronic pain.) (APS, 2009)
- Usually related to tumor recurrences or treatments

BOX 15-4 Terminology Related to the Use of Opioids in Pain Treatment**Physical Dependence**

A state of adaptation that is manifested by a drug class-specific withdrawal syndrome produced by abrupt cessation, rapid dose reduction, decreasing blood level of an opioid, and/or administration of a drug that can act as an antagonist.

Addiction

A primary, chronic, neurobiologic disease, with genetic, psychosocial, and environmental factors influencing its development and manifestations. Addictive behaviors include one or more of the following: impaired control over drug use, compulsive use, continued use despite harm, and craving.

Drug Tolerance

A state of adaptation in which exposure to a drug induces changes that result in a diminution of one or more of the effects of the drug over time.

Approved by the Boards of Directors of the American Academy of Pain Medicine, The American Pain Society and American Society of Addiction Medicine, February 2011, American Pain Society, 2011.

severe is crucial for optimal relief. Pain is easier to prevent than to treat. In most situations administration of pharmacologic agents "around-the-clock" rather than on an "as-needed" (prn) basis is preferable. This approach alleviates pain before it becomes severe and facilitates an earlier recovery. Although nonpharmacologic strategies are sometimes omitted in the acute care setting because of time constraints, you should make every effort to include complementary/integrative methods, which generally do not require a health care provider's order (check agency policy). Complementary strategies for pain relief provide an opportunity for a patient to assume an active role in achieving a higher level of comfort and in some instances freedom from pain (NIH, 2011).

Knowing and understanding the terms related to opioid use (Box 15-4), teaching your patient and his or her family about pain treatment, and having an attitude of dignity and caring will allow

you to individualize a patient's pain control plan. Using an integrated approach that considers both pharmacologic and nonpharmacologic therapies in managing pain is recommended (Baird et al., 2010).

EVIDENCE-BASED PRACTICE

Pain is considered a co-morbid medical condition and not simply a symptom of a pathologic state. The current trend in health care is to prevent it. Preemptive analgesia is a method of preventing pain while reducing overall opioid use. Understanding the influence of genes (Young and Plenge, 2010) and gender and age (deTovar et al., 2010; Herr, 2011) on pain management is essential. In addition, nonpharmacologic interventions to pain management help to control acute and chronic pain (Allred et al., 2010; Baird et al., 2010). The goal is to develop an individualized pain-management plan to provide optimum pain relief with minimal adverse effects.

- Assess for causes of pain or conditions that intensify or moderate it.
- When possible, talk with family caregivers to identify behavioral changes associated with pain in patients who are unable to effectively report their level of pain (e.g., young children, critically ill patients, patients with cognitive impairments) (Herr et al., 2011).
- Post any behavioral changes in a patient's care plan to alert other caregivers.
- Premedicate with analgesia when therapy or a painful procedure is to be performed (e.g., dressing change, diagnostic testing).
- Cautiously use nonopioids, which may have more dangerous side effects than opioids, especially for the elderly. For example, acetaminophen and NSAIDs have some very serious side effects (e.g., liver damage, gastrointestinal bleeding), even when given in recommended dosages (Rahme and Bernatsky, 2010; USFDA, 2009).
- Your primary goal should be pain relief and whatever measures it takes accomplish the goal. Some patients may need opioids the rest of their lives, just as some patients need insulin the remainder of their lives (APS and AAPM, 2009; Gloth, 2011).
- Individualize patient care and avoid misconceptions regarding pain control (Table 15-1). All health care professionals need to consider common misconceptions about pain when planning patient care.
- A method of using smaller doses of more medications is a new practice called *rational polypharmacy* or *multimodal dosing*. When these are combined, there are fewer side effects and greater analgesia (Pasero and McCaffery, 2011).

PATIENT-CENTERED CARE

Pain is unique to each individual, and it is important to recognize all factors influencing a patient's pain and integrate them into an individualized plan for pain management. To effectively design this plan, carefully assess a patient's coping style, physical status, past experiences with pain, culture and ethnicity, expectations for pain relief, and emotional health. A timely, factual, and accurate pain assessment requires you to work closely with patients and their families. You need to learn and understand what pain means in the eyes of the patient. Be objective, listen carefully, and explore any symptoms that a patient expresses. Effective communication and caring are keys to gathering all the information needed to

TABLE 15-1 Misconceptions: Barriers to the Assessment and Treatment of Pain

Misconception	Correction
<ul style="list-style-type: none"> • The best judge of the existence and severity of a patient's pain is the health care provider or nurse caring for the patient. 	<ul style="list-style-type: none"> • The patient's self-report is the most reliable indicator of the existence and intensity of pain.
<ul style="list-style-type: none"> • Clinicians should use their personal opinions and beliefs about the truthfulness of a patient to determine a patient's true pain status. 	<ul style="list-style-type: none"> • Allowing each clinician to act on personal beliefs presents the potential for different pain assessments by different clinicians, leading to different interventions from each clinician. This results in inconsistent and often inadequate pain management. It is essential to establish a patient's self-report of pain as the standard for pain assessment.
<ul style="list-style-type: none"> • Visible signs, either physiologic or behavioral, always accompany pain and can be used to verify its existence and severity. 	<ul style="list-style-type: none"> • Even with severe pain, periods of physiologic and behavioral adaptation occur, leading to periods of minimal or no observable signs of pain. Lack of pain expression does not necessarily mean lack of pain.
<ul style="list-style-type: none"> • The pain rating scale preferred for use in daily clinical practice is the visual analog scale (VAS). 	<ul style="list-style-type: none"> • The preferred pain rating scale depends on a patient's cognitive and physical ability, culture, developmental level, and availability.
<ul style="list-style-type: none"> • Cognitively impaired older adults are unable to use pain rating scales. 	<ul style="list-style-type: none"> • When an appropriate pain rating scale is used and a patient is given sufficient time to process information and respond, many cognitively impaired older adults can use a pain rating scale.
<ul style="list-style-type: none"> • If patients hurt enough, they will tell you. 	<ul style="list-style-type: none"> • Patients are often hesitant to report pain for fear of being labeled as complainers, hypochondriacs, or addicts.
<ul style="list-style-type: none"> • Psychosocial interventions alone will reduce or alleviate pain. 	<ul style="list-style-type: none"> • Nonpharmacologic interventions are synergistic with medications but are not a substitute for pharmacologic management of pain.

Modified from Pasero C, McCaffery M: *Pain: assessment and pharmacological management*, St Louis, 2011, Mosby.

accurately determine a patient's pain and its impact. Knowing these factors will help you intervene effectively to manage your patient's pain.

Pain assessment tools, along with explanations of how to use them, are now available in many different languages (Pasero and McCaffery, 2011). Cultures vary in recognition of pain, expression of pain, when to seek treatment, and what treatments are desirable. For example, some cultures tend to be stoic, whereas others tend to be more expressive (Finley et al., 2009; Giordano et al., 2010).

Be sure to assess for cultural, ethnic, and genetic variations in tolerance and metabolism of analgesics and other medications (Manouagian, 2010; Tennant, 2010). Be aware of cultural variables

that may influence the operation of equipment such as PCA pumps. For example, Orthodox Jews may not use electrical equipment during the Sabbath and Holy Days; thus alternative methods of pain relief are needed during these times (Spector, 2008).

Explore a patient's beliefs about pain/discomfort. For example, cultures with a holistic worldview of health and illness mix religious/spiritual, natural (hot and cold), and the supernatural in their belief systems. When necessary use an interpreter to explain the pain tools and help a patient report the pain.

Safety Guidelines

- 1 Know a patient's medical history, type of therapies used, and medications, including over-the-counter (OTC) products. Many patients do not mention using these for fear of being criticized or because they do not want them taken away.
- 2 Patients currently receiving opioids for chronic pain often require higher doses of analgesics to alleviate new or increased pain; this is tolerance, not an early sign of addiction (see Box 15-4). Be aware of individualized dosages and ensure that all caregivers are aware of this individualization.
- 3 Drug-drug interactions, including enhanced or reduced effects or side effects, often occur with the multiple drug use required by people with chronic pain. This practice is termed *rational polypharmacy* or *multimodal analgesia* (Manouagian, 2010; Pasero and McCaffery, 2011).
- 4 While 0 is an ideal goal for a pain level, in some chronic/persistent pain situations it is not realistic. Many patients are able to do most of the things they desire at a pain intensity of 1 or 2, even 3. If a patient's goal is above 3, reassess understanding of the pain scale.

BOX 15-5 Sedation Scale*

- S = Sleep, easy to arouse
- 1 = Awake and alert
- 2 = Slightly drowsy, easily aroused
- 3 = Frequently drowsy, arousable, drifts off to sleep during conversation
- 4 = Somnolent, minimal-or-no response to physical stimulation

Remember—sedation precedes respiratory depression.

*Many institutional sedation scales include nursing actions to be taken for each level of sedation.

From Pasero C, McCaffery M: *Pain assessment and pharmacologic management*, St Louis, 2011, Mosby.

- 5 Communicate to the health care provider any significant changes in a patient's comfort level and need for changes in the pain-management regimen.
- 6 Know your agency policy for frequency of pain assessment and timing for follow-up assessments. The first 24 hours on opioids requires frequent assessment, at least every 4 hours.
- 7 Determine the safety of the equipment used for pain management. Correct programming of the PCA pump and correct functioning of any pump is vital for patient safety.
- 8 When using a PCA pump, the patient is the only person who should press the button to administer pain medication.
- 9 Respiratory depression can be a side effect of opioids, whether oral, intravenous, or epidural, and especially with opioid-naïve patients. Using a standard sedation scale can prevent respiratory depression by observing for and intervening for oversedation (Box 15-5).

SKILL 15-1 Providing Pain Relief

The assessment of pain aims to find the cause of a person's pain, identify his or her perception of pain, and determine the effect of pain on the individual. Accurate and factual pain assessment is necessary for determining a patient's response, arriving at a proper nursing diagnoses, and selecting appropriate therapies. A comprehensive pain assessment helps you understand the impact of pain on a patient's life (Hadjistavropoulos et al., 2009). Effectively managing a patient's pain does not necessarily mean eliminating it, but it does mean getting it to an acceptable level for him or her. Pain management requires you to work with a patient and family to prevent pain whenever possible and identify an acceptable intensity of pain and level of other factors, especially sleep, that allows maximum patient function.

The nursing process offers a systematic method for pain management that results in improved pain relief for most patients. This process recognizes distinct and unique differences in patient perceptions and responses to pain. The nursing process guides you in learning to know a patient and develop an individualized plan of care. The American Society for Pain Management Nursing (ASPMN) developed clinical practice guidelines for pain assessment and associated treatment principles (Herr et al., 2011).

Delegation and Collaboration

Assessment of a patient's pain cannot be delegated to nursing assistive personnel (NAP). The NAP may screen patients for pain and

provide selected nonpharmacologic strategies (e.g., back rubs, heat, cold, elevation) as instructed by the nurse. The nurse directs the NAP to:

- Eliminate environmental conditions that aggravate pain (e.g., an excessively warm, noisy room).
- Provide maximum rest periods; a written schedule for all to follow is ideal.
- Turn and place patients in a position of comfort at least every 2 hours or remind patients to turn themselves. Encourages patient to use a pillow for splinting if needed.
- Observe for behavioral signs of pain for a patient who is unable to self-report (see Box 15-2).
- Ask patient to report pain using the pain-intensity scale chosen by patient and nurse.
- Report in a timely manner any patient reports of pain intensity above predetermined goal and nonverbal behaviors suggestive of pain.
- Screen for pain during patient transfer or other activity that might provoke pain.

Equipment

- ❑ Pain rating scale (check agency policy)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <p>1 Assess patient's risk for pain (e.g., those undergoing invasive procedures, anxious patients, those unable to communicate).</p> <p>2 Ask patients if they are in pain.
Older adults and patients from various cultures may not admit to having pain. Try using other terms such as <i>hurt</i> or <i>discomfort</i>.</p> <p>3 Assess patient's response to previous pharmacologic interventions, especially ability to function (e.g., sleeping, eating, and other activities of daily living [ADLs]).
Determine if any analgesic side effects are likely based on medication and patient's previous responses (e.g., itching or nausea).</p> <p>4 Examine site of patient's pain or discomfort when possible. Inspect (discoloration, swelling, drainage), palpate (change in temperature, area of altered sensation, painful area, areas that trigger pain), and assess range of motion of involved joints. Percussion and auscultation can help to identify abnormalities (e.g., underlying mass or lung crackles) and determine cause of pain (Chapter 6). When assessing abdomen, always auscultate first and then inspect and palpate.</p> <p>5 Assess physical, behavioral, and emotional signs and symptoms of pain:</p> <ul style="list-style-type: none"> a Moaning, crying, whimpering, groaning, vocalizations b Decreased activity c Facial expressions (e.g., grimace, clenched teeth) d Change in usual behavior (e.g., less active, irritable) e Abnormal gait (e.g., shuffling) and posture (e.g., bent, leaning) f Guarding a body part g Diaphoresis h Increased blood glucose level reflecting stress of unrelieved pain i Decreased gastrointestinal (GI) motility, constipation, nausea, and vomiting j Insomnia, anorexia, and fatigue k Depression, hopelessness, anger, fear, social withdrawal <p>l Concomitant symptoms: Symptoms that often occur with pain (e.g., headache, constipation). Note: constipation can also develop from opioids.</p> | <p>Allows you to anticipate patient's needs and intervene in a timely manner, possibly preventing pain.</p> <p>There is no objective test to measure pain.</p> <p>Accept patient's self-report of pain (APS, 2009; Pasero and McCaffery, 2011). Observe for nonverbal indicators of pain; ask significant others if they believe patient is in pain (Herr et al., 2011).</p> <p>Determines extent to which therapies have or have not been successful in the past (Gloth, 2011).</p> <p>Some side effects, especially the itching that can occur with morphine, are often poorly tolerated by the patient and indicate a need to identify another analgesic.</p> <p>Reveals the nature of the pain and directs you toward appropriate interventions.</p> <p>Signs and symptoms may reveal source and nature of pain. Nonverbal responses to pain are useful in assessing pain in patients who are cognitively impaired or nonverbal.</p> <p>The stress of unrelieved pain causes the endocrine system to release excessive amounts of hormones (especially cortisol) and decreased levels of insulin (Pasero and McCaffery, 2011).</p> <p>Signs and symptoms of pain originate from involvement of visceral organs with stimulation of the parasympathetic nervous system, which decreases GI tract activity (Drew and St. Marie, 2011).</p> <p>Depression frequently occurs in patients with chronic pain and increases perception and intensity of pain (Drew and St. Marie, 2011).</p> <p>Multiple symptoms increase complexity in care of patient.</p> |
| <p>Clinical Decision Point Physiologic responses (e.g., tachycardia, hypertension) to acute pain are of short duration and return to normal within minutes. Be aware that with persistent pain a patient does not usually exhibit physical signs and symptoms. Never use physiologic responses alone to determine pain therapy selected, even with acute pain (Pasero and McCaffery, 2011).</p> | |
| <p>6 Assess characteristics of pain. Follow agency policy regarding frequency of assessment. Use the PQRSTU pain assessment.</p> <ul style="list-style-type: none"> a Provocative/Palliative factors (e.g., "What makes your pain better or worse?"): Consider patient's experience with over-the-counter (OTC) drugs (including herbals and topicals) that have helped to reduce pain in the past. b Quality: Use open-ended questions such as "Tell me what your pain feels like." | <p>Guides clinician in collecting complete information about patient's pain experience.</p> <p>Identifies the nature and source of pain and what patient uses to reduce discomfort. A combination of interventions is often the most effective approach to pain relief (APS, 2009).</p> <p>Assists in determining underlying pain mechanism (e.g., somatic versus neuropathic pain).</p> |

STEP

RATIONALE

- | | |
|--|---|
| <ul style="list-style-type: none"> c Region/Radiation (e.g., “Show me everywhere your pain is.”). Have patient use finger (if possible) to point out areas of pain. d Severity: Use a valid pain rating scale appropriate to patient’s age, developmental level, and comprehension (see illustrations). Ask patient to rate pain before any intervention. Also assess patient’s pain when he or she is moving, not just lying in bed or sitting in a chair. e Timing: Ask patient if pain is constant, intermittent, continuous, or a combination. Does pain increase during specific times of the day, with particular activities, or in specific locations? f How is pain affecting <i>U</i> (patient) regarding ADLs, work, relationships, and enjoyment of life? | <p>Identify location of pain and possible causative factors for acute/transient pain.</p> <p>An appropriate pain rating scale is reliable, easily understood, and reflects changes in pain intensity (Herr, 2011).</p> <p>Environmental stimuli such as loud noises, bright lights, strong odors, or temperature extremes sometimes alter patient’s response to pain.</p> <p>Provides important baseline information to later gauge effectiveness of interventions.</p> |
|--|---|

NURSING DIAGNOSES

- | | | |
|--|--|--|
| <ul style="list-style-type: none"> • Activity intolerance • Anxiety • Deficient knowledge • Disturbed sleep pattern • Fatigue | <ul style="list-style-type: none"> • Fear • Ineffective coping • Chronic pain • Impaired physical mobility | <ul style="list-style-type: none"> • Acute pain • Powerlessness • Readiness for enhanced comfort • Risk for constipation |
|--|--|--|

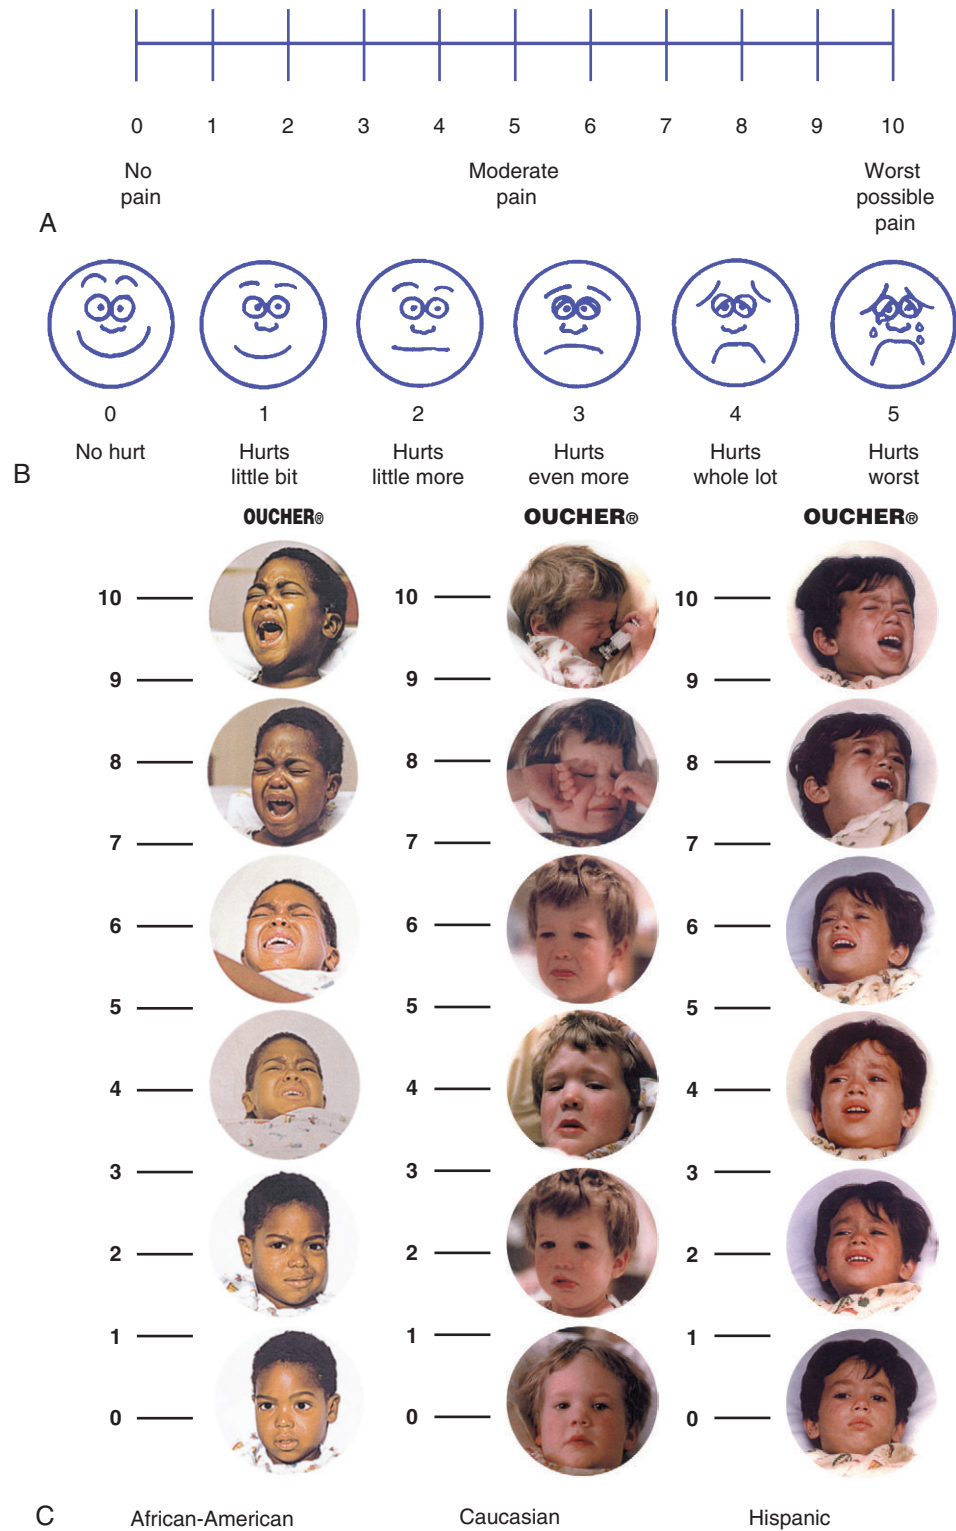

Related factors are individualized based on patient’s condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient verbalizes full or partial relief from pain. • Patient displays nonverbal behaviors such as relaxed face and absence of squinting. • Patient’s sleep, nutrition, physical activity, and personal relationships improve. | <p>Patient’s self-report of pain is single most reliable indicator of pain (Pasero and McCaffery, 2011).</p> <p>Nonverbal behaviors can be valid and reliable indicators of pain and pain relief in the cognitively impaired (Herr et al., 2011).</p> <p>Adequate pain relief usually permits patient to participate in usual ADLs.</p> |
|--|---|

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Perform hand hygiene and apply clean gloves if indicated.</p> <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient’s identification bracelet and/or ask patient to state name.</p> <p>3 Prepare patient’s environment.</p> <ul style="list-style-type: none"> • Temperature suited to patient • Lighting • Sound • Eliminate unnecessary interruptions and coordinate care activities; allow for rest. <p>4 Teach patient how to use pain rating scale. STEP 6d **A**, Pain rating scale. From McCaffery M, Pasero C: Pain: clinical manual, ed 2, St Louis, 1999, Mosby. **B**, Wong-Baker FACES pain rating scale. From Wong DL et al.: Whaley and Wong's nursing care of infants and children, ed 7, St Louis, 2003, Mosby. **C(1)**, African-American version of Oucher pain scale. Developed and copyrighted in 1990 by Mary J. Denyes, PhD, RN, Wayne State University and Antonia M. Villarruel, PhD, RN, University of Michigan. Cornelia P. Porter, PhD, RN, and Charlotta Marshall, RN, MSN, contributed to the development. **C(2)**, Caucasian version of Oucher pain scale. Developed and copyrighted in 1983 by Judith E. Beyer, PhD, RN, University of Missouri-Kansas City School of Nursing, Kansas City, Mo. **C(3)**, Hispanic version of Oucher pain scale. Developed and copyrighted in 1990 by Antonia M. Villarruel, PhD, University of Michigan, and Mary J. Denyes, PhD, RN, Wayne State University.

STEP

RATIONALE

- 8 Teach patient how to splint over the site of pain using either a pillow or hand.
- Explain purpose of splinting.
 - Place pillow or blanket over site of discomfort and help patient place hands firmly over area of discomfort (see illustration).

Splinting reduces pain by minimizing muscle movement.

Promotes patient's cooperation.

Splinting immobilizes painful area.

STEP 8b Patient splinting painful area.

- Have patient hold area firmly while coughing, deep breathing, and turning.
- 9 Reduce or eliminate emotional factors that increase pain experiences.
- Offer information that reduces anxiety (e.g., explaining the cause of pain if known).
 - Offer patient opportunity to pray (if appropriate).
 - Spend time to allow patient to talk about pain.
- 10 If used, remove and dispose of gloves. Perform hand hygiene.

Splinting decreases movement and subsequent pain during activity.

Helps patients relax. Thoughts influence feelings, which change perception and behaviors, including a perception of pain relief (Baird et al., 2010).

Reduces transmission of microorganisms.

EVALUATION

- Within 1 hour of an intervention (e.g., when the drug used is at its peak effect), ask patient to describe level of relief using a scale of 0 to 10.
- Compare patient's current pain with personally set pain-intensity goal.
- Compare patient's ability to function and perform ADLs before and after pain interventions.
- Observe patient's nonverbal behaviors.
- Evaluate for analgesic side effects.

Evaluates effectiveness of pain-relieving interventions in a timely manner (Pasero and McCaffery, 2011).

Assists in determining appropriate changes to the pain-management plan.

Contributes to determining effectiveness of pain-relieving interventions, especially in nonverbal patients (APS, 2009; Gloth, 2011; Herr et al., 2011).

Determines effectiveness of pain-relieving interventions (Herr et al., 2011).

Side effects of analgesics may be controlled by reducing the dose, increasing time intervals, or administering other medications (D'Arcy, 2008).

Unexpected Outcomes

- Patient verbalizes continued pain that exceeds pain-intensity goal or displays nonverbal behavior reflecting worsening pain.
- Patient experiences unexpected or adverse reaction to medication.

Related Interventions

- Perform a complete pain assessment.
- Implement nonpharmacologic pain relief measures.
- Ask family members what might be helpful.
- Notify health care provider.
- Assess unexpected effects on patient.
- Notify health care provider immediately.
- Be prepared to administer antidote if indicated (e.g., antiemetic, antihistamine, opioid-reversing agent such as naloxone [Narcan]).
- Monitor for effectiveness of antidote; antidote may have a shorter half-life than the opioid; a repeat dose of antidote may be needed.
- Complete adverse reaction documentation according to agency policy.

Recording and Reporting

- Record and report character of pain before intervention, therapies used, and patient response to interventions in nurses' notes and electronic health record (EHR).
- Record inadequate pain relief (not reaching goal), a reduction in patient function, adverse effects from pain interventions (pharmacologic and nonpharmacologic), and any patient or family education given.
- Report continued inadequate pain relief to health care provider.

Special Considerations

Teaching

- Review patient's and family's understanding of the pain rating scale used and how to use it when providing pain therapies.
- Explain to patient and family about behavioral changes that may result from pain (Elhoaris and Resnik, 2010).
- Ask patient and family about fear of addiction, a common primary concern, or other misconceptions that could undermine the patient's pain relief (see Table 15-1).

Pediatric

- Although validity and reliability scores of pain rating scales generally increase with age, you can use some rating scales with a child as young as 3 years of age (deTovar et al., 2010; Finley et al., 2009).
- Some children are reluctant to report pain because they have misconceptions about the cause of their pain or they fear the consequences (e.g., another painful procedure or an injection).
- Infants and children experience pain but respond to it differently than adults. For example, they cry and thrash about, have sleep disturbances, have a shortened attention span, suck or

rock, refuse to eat or play, or are quiet and withdrawn. Variations in pain response are related to the child's personality, developmental level, and previous pain experiences (Hockenberry and Wilson, 2011).

- Parents are a helpful source of information when assessing a child's pain and planning pain-relief therapies. Most parents know how their child exhibits pain and which pain relief interventions have been successful (Riddell and Racine, 2009).
- Children with verbal skills can rate their level of pain on the Wong-Baker FACES pain rating scale or the Oucher pain scale (deTovar et al., 2010).

Gerontologic

- Many geriatric patients understand a categorical pain scale such as none, mild, moderate, severe more than they do a numeric scale (Deane and Smith, 2008; Pasero and McCaffery, 2011).
- Some older adults may require more time for you to explain the pain assessment scale that you select.
- Pain is not a natural occurrence of aging, although older adults are at risk for experiencing more pain-producing conditions.
- Nonverbal older adults experiencing pain typically receive fewer analgesics than similar patients who are able to report their pain (Hadjistavropoulos et al., 2009; Herr et al., 2011). Thus be sure your assessment is thorough and evaluate a patient's response critically.

Home Care

- Consider home conditions such as type of bed, stairs, and environmental stimuli. A supportive bed and quiet environment enhance sleep and promote pain management.
- Assess the pain-management attitudes of the primary home care provider (significant other) and provide necessary education to achieve successful pain control (Viclop et al., 2009).

SKILL 15-2 Patient-Controlled Analgesia

Video Clip

Patient-controlled analgesia (PCA) is an interactive method of pain management that permits a patient control over pain through self-administration of analgesics (D'Arcy, 2008; Wells et al., 2008). It is a safe method of analgesic administration for acute and chronic pain, including conditions such as postoperative pain, cancer, and end-of-life pain. Commonly prescribed medications delivered via PCA include morphine sulfate, hydromorphone (Dilaudid), and fentanyl. PCA devices are individually programmed to automatically deliver a specific health care provider-prescribed continuous infusion (basal rate) of medication, a bolus dose (patient initiated), or both. PCA prevents overdosing by having a preprogrammed delay time or "lockout" (usually 6 to 16 minutes) between patient-initiated doses. In addition, the health care provider may limit the total amount of opioid that a patient receives in 1 to 4 hours. A patient depresses the button on a PCA device to deliver a regulated dose of analgesic. It is crucial that candidates for PCA be able to understand how, why, and when to self-administer the medication (APS and AAPM, 2009). Available routes of PCA administration include subcutaneous, intravenous (IV) (the most common), and epidural. Monitoring levels of sedation are essential with the use of PCA. This is especially true for patients who are "opioid naïve" (i.e., those who have never taken any opioids for any reason or who have not taken opioids in the past 5 weeks) (Pasero and McCaffery, 2011). In addition, oversedation is a risk in patients with sleep apnea (brief cessation of respirations during sleep) or

obese patients with short, thick, necks who commonly have undiagnosed sleep apnea (see Box 15-5).

PCA has several advantages. It allows more constant serum levels of an opioid and avoids peaks and troughs of a large bolus. Patients receive better pain relief and fewer side effects from opioids because blood levels are maintained at a level of minimum effective analgesia concentration. Increased patient control and independence are other advantages for patients. Because PCA provides medication on demand, the total amount of opioid use can be reduced.

Concerns involving PCA use are patient related, pump failure, or health care provider errors. Patients may misunderstand how PCA therapy works, mistake the PCA button for a nurse call button, or have family members operate the demand button (Wells et al., 2008). A pump may fail to deliver a drug on demand, have a faulty alarm or low battery, or lack free-flow protection. Health care providers may incorrectly program a dose, concentration, or rate. Incorrect programming is the most common type of error. Other errors include failing to clamp or unclamp tubing, improperly loading syringe or cartridge, failing to monitor for side effects/overdose, and not responding to alarms (D'Arcy, 2008). PCA requires careful monitoring; never try to operate it without fully understanding the particular model in use.

Delegation and Collaboration

The skill of administration of PCA cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Immediately report any new symptom or change in patient status, including unrelieved pain or oversedation, to the nurse.
- Never administer a PCA dose for the patient.

Equipment

- PCA system and tubing
- Identification label and time tape (may come attached and completed by pharmacy)

- Needleless connector
- Alcohol swab
- Adhesive tape
- Clean gloves (when applicable)
- Equipment for vital signs and pulse oximeter, capnography (CO₂) monitoring equipment

STEP

RATIONALE

ASSESSMENT

- 1** Check accuracy and completeness of each MAR or computer printout with the health care provider's order for name of medication, dosage, frequency of medication (continuous or demand or both), and lockout settings. Verify that patient is not allergic to medication.

Requires health care provider's order required for opioid medication. Ensures that patient receives right medication. *This is the first check for accuracy.*

Clinical Decision Point Nausea is not an allergic reaction and can be treated. Itching alone is not an allergic reaction but is a common side effect of opioids. Itching is also treatable and should not preclude use of PCA.

- 2** Assess patient's cognitive and physical ability to press device button.

Determines if patient is able to use PCA for pain management.

- 3** Assess character of patient's pain, including physical, behavioral, and emotional signs and symptoms (see [Skill 15-1](#)).

Establishes baseline to determine patient's response to analgesia.

- 4** Obtain pulse oximetry or capnography reading.

Provides baseline of patient's oxygenation status for later determination of patient's response to analgesic.

- 5** Assess environment for factors that could contribute to pain (e.g., noise, temperature of room).

Elimination of irritating stimuli may be effective in reducing pain perception.

- 6** If patient has had surgery, apply clean gloves and inspect incision. Gently palpate around the area for tenderness. Use sterile gloves if placing hand directly on the incision.

Reveals evidence of tissue trauma or damage, which stimulates peripheral pain receptors to transmit impulses to cortex to create conscious awareness of pain ([Drew and St. Marie, 2011](#)).

- 7** When giving an IV, assess existing IV infusion line (peripheral or central) and surrounding tissue for patency and condition of site for infiltration or inflammation (see [Chapter 28](#)).

IV line must be patent with fluid infusing for medication to reach venous circulation safely and effectively. Never attach PCA to an IV line with blood running or to IV lines with incompatible drugs infusing. If necessary, start another IV site.

- 8** Assess patient's knowledge and effectiveness of previous pain-management strategies, especially previous PCA use.

Response to pain-control strategies helps to identify learning needs and affects patient's willingness to try therapy.

NURSING DIAGNOSES

- Activity intolerance
- Acute pain
- Anxiety
- Chronic pain
- Deficient knowledge regarding use of PCA
- Fear
- Ineffective coping
- Impaired physical mobility

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1** Expected outcomes following completion of procedure:
- Patient verbalizes pain relief
 - Patient exhibits a relaxed facial expression and body position.
 - Patient remains alert and oriented.

Drug is given safely and is effective in providing pain control. Supports successful pain relief.

Nonverbal cues of pain relief

Indicates freedom from overly sedating effects of opioids. Sleepiness is usually from fatigue and not necessarily a sign of oversedation.

Suggests successful pain relief.

Demonstrates safe and appropriate use of PCA device.

- Patient increasingly participates in self-care activities.
- Patient correctly operates PCA device.

- 2** Explain purpose and demonstrate function of PCA to patient and family:

Effective explanations allow patient participation in care and independence in pain control ([Pasero and McCaffery, 2011](#)).

STEP

RATIONALE

IMPLEMENTATION

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Perform hand hygiene. 2 Prepare analgesic while following the “six rights” for administration of medication (see Chapter 20). NOTE: Pharmacy prepares medication cartridge. 3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient’s identification bracelet and/or ask patient to state name. 4 At the bedside compare the MAR or computer printout with the name of medication on the drug cartridge. Have a second registered nurse (RN) confirm the health care provider’s order and the correct setup of the PCA. The second RN should check the health care provider’s order and the device independently and not just look at the existing setup. 5 Before initiating analgesia, explain purpose of PCA and demonstrate its function to patient and family, as follows: <ol style="list-style-type: none"> a Explain type of medication in PCA device. b Explain that the device safely administers self-initiated small but frequent amounts of medication prn to provide comfort and minimize side effects from analgesia. Tell patient that self-dosing before repositioning, walking, or coughing and deep breathing will help in performing activities. c Explain that device is programmed to deliver ordered type and dose of pain medication, lockout interval, and 1- to 4-hour dosage limits. Explain how lockout time prevents overdose. d Demonstrate to patient how to push medication demand button on PCA device. e Instruct patient to notify a nurse for possible side effects, problems in attaining pain relief, changes in severity or location of pain, alarms sounding, or questions. 6 Check infuser and patient-control module for accurate labeling or evidence of leaking. 7 Program computerized PCA pump as ordered to deliver prescribed medication dose and lockout interval. 8 Insert drug cartridge into infusion device (see illustration) and prime tubing. 9 Apply clean gloves. Attach needleless adapter to tubing adapter of PCA module. 10 Wipe injection port of main IV line with alcohol. | <p>Reduces transmission of microorganisms and possible infection. Ensures safe and appropriate medication administration. <i>This is the second check for accuracy.</i></p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Ensures that the correct patient receives the right medication. <i>This is the third check for accuracy.</i></p> <p>Thorough explanation allows patient participation in care and independence in pain control. Preoperative education about PCA improves postoperative pain relief (D’Arcy, 2011).</p> <p>Helps patient understand how to control pain effectively. Small, frequent dosing with PCA produces a constant serum drug level with minimal fluctuation (Lehne, 2011).</p> <p>Confirms with patient the safety of the PCA device.</p> <p>Gives patient control of pain.</p> <p>Ensures that you respond to problems that arise.</p> <p>Avoids medication error and injury to patient.</p> <p>Ensures safe, therapeutic drug administration.</p> <p>Locks system and prevents air from infusing into IV tubing.</p> <p>Prevents transmission of microorganisms. Connects device with IV line.</p> <p>Alcohol is a topical antiseptic that minimizes entry of surface microorganisms during needle insertion.</p> |

| <p>1 Have patient use pain rating scale to evaluate pain intensity following treatments, procedures, and according to agency policy.</p> <p>2 Monitor patient's level of sedation, vital signs, and pulse oximetry or capnography every 1 to 2 hours for the first 12 hours (APS and AAPM, 2009).</p> <p>3 Observe patient for adverse reactions, especially excessive sedation.</p> <p>4 Have patient demonstrate dose delivery.</p> <p>5 Evaluate number of attempts (number of times patient pushed button); delivery of demand doses (number of times drug actually given); and basal dose, if ordered, according to agency policy (usually every 4 to 8 hours).</p> | <p>Determines response to PCA dosing.</p> <p>Oversedation precedes respiratory depression.</p> <p>Serious problems require immediate action; oversedation can lead to life-threatening respiratory depression and must be treated.</p> <p>Evaluates skill in use of PCA.</p> <p>Assists in evaluating effectiveness of PCA dose and frequency in relieving pain.</p> <p>Maintains compliance with Federal Controlled Substances Act.</p> |
|---|--|

Unexpected Outcomes

- 1 Patient verbalizes continued or worsening discomfort or displays nonverbal behaviors indicative of pain.

- 2 Patient is sedated and not easily aroused.

- 3 Patient unable to manipulate PCA device to maintain pain control.

Related Interventions

- Perform complete pain reassessment.
- Assess for possible complications other than pain.
- Inspect IV site for possible catheter occlusion or infiltration.
- Evaluate number of attempts and deliveries initiated by patient.
- Check that maintenance IV fluid is running continuously.
- Evaluate pump for operational problems.
- Consult with health care provider.

- Stop PCA.
- Notify health care provider.
- Elevate head of bed 30 degrees unless contraindicated.
- Instruct patient to take deep breaths.
- Apply oxygen at 2 L/min per nasal cannula (if ordered).
- Assess vital signs.
- Evaluate amount of opioid delivered within past 4 to 8 hours.
- Ask family members if they pressed the button without patient's knowledge.
- Review MAR for other possible sedating drugs.
- Prepare to administer an opioid-reversing agent.
- Observe patient frequently (APS, 2009).

- Consult with health care provider regarding alternative medication route or possibly a basal (continuous dose).
- If agency allows, assess patient support system for significant other who can responsibly manipulate PCA device (Pasero and McCaffery, 2011).

Recording and Reporting

- Record drug, concentration, dose (basal and/or demand), time started, lockout time, and amount of IV solution infused and remaining solution. Many agencies have special PCA documentation forms.
- Record regular assessment of patient response to analgesia on PCA medication form, in nurses' notes and EHR, on pain assessment flow sheet, or on other documentation according to agency policy. This includes vital signs, oximetry or capnography, sedation status, pain rating, status of vascular access site.

Teaching Considerations

- Give instructions during pain-free or pain-reduced states and before initiating therapy. Instruct surgical patients before surgery.
- Encourage patients to push button on timing unit at the earliest indication of pain. Teach preemptive pain management.
- Explain regimen to family so they can support and help patient (but not push button for patient).
- Inform patient of nonpharmacologic pain-management strategies that supplement or enhance pharmacologic intervention (see Skill 15-5).
- Inform patient and family that patient will not overdose with PCA if only the patient pushes the button.

Pediatric Considerations

- PCA is an effective means of pain control in children who can understand the concept. When selecting children for PCA use, consider a patient's developmental level, cognitive level, and motor skills. Ordinarily PCA use is safe and effective for patients

as young as 5 years old (deTovar et al., 2010). From a developmental perspective, use of PCA is particularly effective with adolescents because it leads to feelings of control.

- Some agencies have provided specific guidelines and training to allow parents to push the button for children too young or unable to use the device on their own.
- Pharmacologic pain support is safe and effective in pediatric patients when dose is calibrated according to child's weight (Klieber et al., 2011).
- There are no reports of addiction secondary to the use of PCA in pediatric patients (APS and AAPM, 2009). Untreated pain in children may also become chronic.

Gerontologic Considerations

- Older patients sometimes appear more sensitive to analgesics and experience more opioid side effects (D'Arcy, 2009; Deane and Smith, 2008; Gloth, 2011). Older adults' reduced renal and liver function slows opioid metabolism and excretion. This causes a faster peak effect and a longer duration of action of the opioid. Dosages should be started low and titrated upward slowly until pain relief is achieved (Drew and St. Marie, 2011; Gloth, 2011).
- If patient confusion occurs while using PCA, call to get orders to lower the dose, lengthen the lockout, or add a nonopioid analgesic to reduce the opioid dose; nurse-activated around-the-clock dosing is another alternative; refusing to medicate is not the answer; confusion may be caused by pain, not the medications (D'Arcy, 2009; Pasero & McCaffery, 2011).

SKILL 15-3 Epidural Analgesia

Administration of analgesics into the epidural space is an efficient intervention to manage acute pain during labor; following surgery; and for chronic pain, especially for patients with cancer (D'Arcy, 2011). Epidural analgesia is effective during labor and does not result in any adverse effects or increased frequency of cesarean delivery (Gerli et al., 2011; James, 2011). Patient-controlled epidural analgesia (PCEA) has been shown to provide excellent post-operative pain control when compared with intravenous (IV) patient-controlled analgesia (PCA) (Ferguson et al., 2009). Use of PCEA is safe and efficient, and complications from this technique are rare. Epidural opioids reduce the total amount of opioid medication required to control pain and thus produce fewer opioid-related side effects (D'Arcy, 2011).

The epidural space is a potential space that contains a network of vessels, nerves, and fat located between the vertebral column and the dura mater, the outermost meninges covering the spinal cord (Fig. 15-1). Analgesics delivered into this space distribute by (1) diffusion through the dura mater into the cerebrospinal fluid (CSF), where they act directly on the receptors in the dorsal horn of the spinal cord; (2) blood vessels in the epidural space and deliver systemically; and/or (3) absorption by fat in the epidural space, creating a depot where the analgesia is slowly released systemically. An analgesic acts by binding to opiate receptors in the dorsal horn of the spinal column, thus blocking pain impulse transmission to the cerebral cortex.

Opioids and local anesthetics, separately or in combination, are often used in epidural analgesia. Opioids are delivered close to their site of action (central nervous system) and thus require much smaller doses to achieve the same pain relief (D'Arcy, 2009; D'Arcy, 2011). Common opioids administered epidurally include morphine, hydromorphone (Dilaudid), fentanyl, and sufentanil. These opioids differ by their lipophilic “fat-loving” and hydrophilic “water-loving” properties, which affect absorption rate and duration of action. Fentanyl and sufentanil are fat-loving, causing them to have a quicker onset and shorter duration of action (2 hours). Morphine and hydromorphone are water-loving, resulting in longer onset and duration of action (24 hours).

A patient should be placed in the lateral side-lying or sitting position with the shoulders and hips in alignment and the hips and head flexed during insertion of an epidural catheter. An anesthesia provider places a catheter into the epidural space below the second lumbar vertebra, where the spinal cord ends (Fig. 15-2). However, epidurals may also be placed at the thoracic level of the spinal cord. Catheters intended for temporary or short-term use are not sutured in place and exit from the insertion site on the back. A catheter intended for permanent or long-term use is “tunneled” subcutaneously and exits on the side of the body (Fig. 15-3) or on the abdomen. Tunneling reduces infection and catheter dislodgement. A sterile occlusive dressing covers the catheter exit site and is secured to the patient. An x-ray film is the only way to confirm epidural catheter placement.

A health care provider administers epidural medication intermittently via a bolus injection, or a patient can inject on demand (PCEA). An epidural infusion can also be given continuously via a controlled delivery system such as an implanted infusion pump (Fig. 15-4) (D'Arcy, 2011). The use of epidural opioids requires astute nursing observation and care. The catheter poses a threat to patient safety because of its anatomic location, its potential for migration through the dura, and its proximity to spinal nerves and vessels (Pasero and McCaffery, 2011). Catheter migration into the subarachnoid space can produce dangerously high medication levels. Monitor a patient's motor and sensory function, including any onset of urinary retention. You should not administer other supplemental opioids or sedatives when patients are on an epidural because the combined effect may cause respiratory depression. In many health care agencies anesthesiologists and nurse anesthetists are the only health care providers who may initiate epidural opioid infusions or administer a medication bolus.

Delegation and Collaboration

The skill of epidural analgesia administration cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

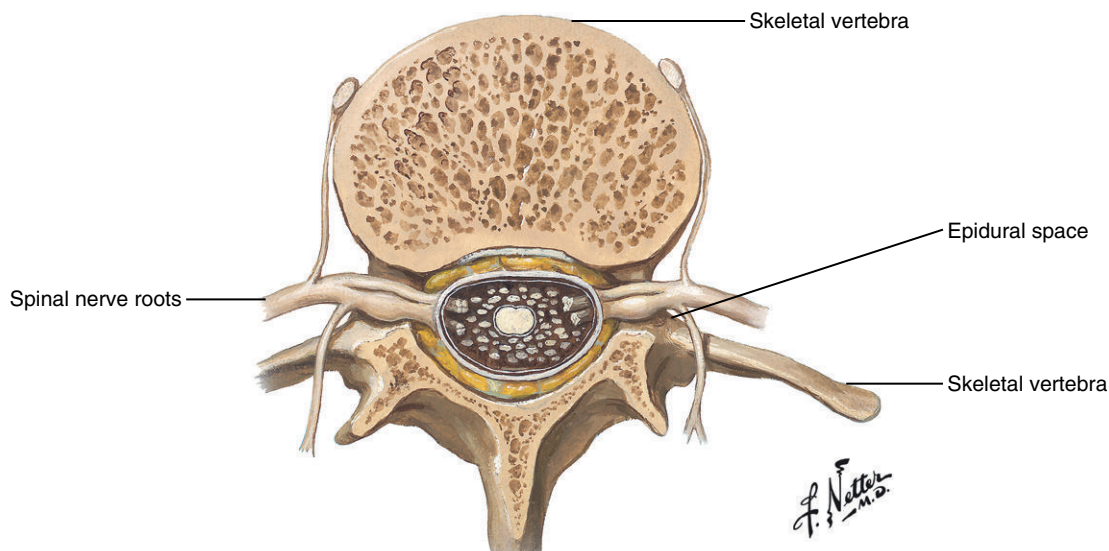

FIG 15-1 Anatomic drawing of epidural space. (Reprinted from www.netterimages.com © Elsevier, Inc. All rights reserved.)

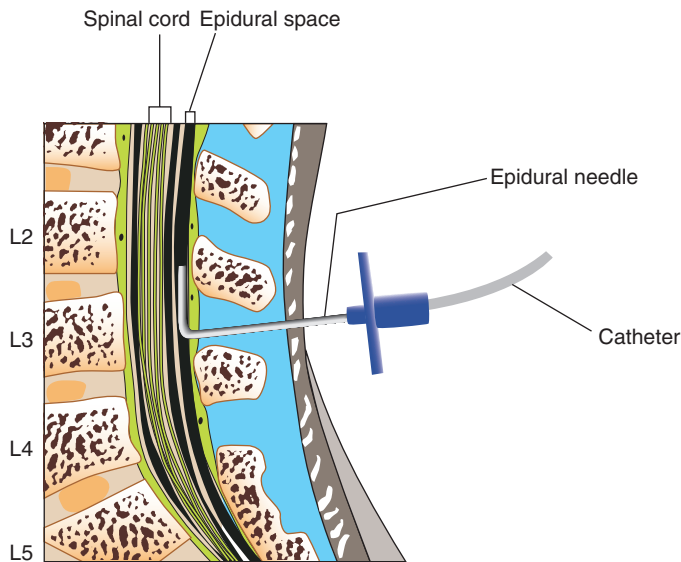

FIG 15-2 Placement of epidural catheter.

FIG 15-3 Epidural catheter attached to ambulatory infusion pump. (Image courtesy Astra Zeneca Pharmaceuticals, Wilmington, Del. All rights reserved.)

FIG 15-4 SynchroMed implantable pump. (Courtesy Medtronic, Inc., Columbia Heights, Minn. All rights reserved.)

- Pay particular attention to the insertion site when repositioning or ambulating patients to prevent catheter disruption.
- Avoid pulling patient up in bed while he or she is lying flat on the back, which can dislodge the epidural catheter.
- Immediately report to the nurse any change in level of consciousness.
- Report any catheter disconnection immediately.
- Immediately report to the nurse any change in patient status or comfort level.

Equipment

- Clean gloves
- Sterile gloves (if removing epidural dressing)
- Prediluted preservative-free opioid as prescribed by health care provider for use in IV infusion pump (usually prepared by pharmacy)
- Infusion pump and compatible tubing (Do not use Y-ports for continuous infusion; some infusion pumps have color-coded tubing for intraspinal use)
- 20-gauge needleless adapter
- Filter needle (per agency policy)
- Syringe
- Antiseptic swab
- Sterile gauze pad
- Tape
- Label (for injection port)
- Equipment for vital signs and pulse oximetry

STEP

RATIONALE

ASSESSMENT

- 1 Assess level of patient's comfort and character of patient's pain (see Skill 15-1).
- 2 Assess presenting medical/surgical condition and appropriateness for epidural analgesia (e.g., major abdominal or thoracic surgery, women in labor, advanced cancer, and patients predisposed to cardiopulmonary complications from preexisting medical conditions or surgery). Consult with health care provider on findings.

Establishes baseline pain level.

Certain conditions make epidural analgesia the treatment of choice.

STEP	RATIONALE
3 For cognitively impaired or non-English-speaking patients, assess nonverbal pain responses.	Cognitively impaired patients or patients for whom English is a second language may have difficulty understanding the therapy, especially if PCEA is used. Nonverbal responses provide baseline pain assessment.
4 Check to see if patient recently received anticoagulants.	Recent anticoagulation may contraindicate the placement of epidural catheter because of risk for epidural site hematoma (Pasero and McCaffery, 2011).
5 Assess if patient routinely takes herbal medications; document the complete list.	Some herbal medications interfere with the clotting mechanism (e.g., ginkgo biloba, ginseng, ginger). Currently there is no contraindication to their use (NIH, 2011).

Clinical Decision Point Contraindications to epidural analgesia include coagulopathies, abnormal clotting test results, history of multiple abscesses, and sepsis. Additional contraindications include skeletal or spinal abnormalities (Pasero and McCaffery, 2011).

6 Assess for history of drug allergies.	Avoids placing patient at risk for allergic reaction.
7 Assess patient's sedation level by assessing level of wakefulness or alertness, ability to follow commands, and drowsiness (see Box 15-5).	Establishes a baseline before first dose. Sedation always precedes respiratory depression from opioids.
8 Assess rate, pattern, and depth of respirations; pulse oximetry; and blood pressure (see Chapter 5).	Establishes baseline. Vasodilation can occur, causing hypotension, including orthostatic hypotension. Respiratory depression may also occur.
9 Assess initial motor and sensory function of lower extremities (see Chapter 6). Test sensation in lower extremities. Have patient flex both feet and knees and raise each leg off the bed. Pay special attention to patients with preexisting sensory or motor abnormalities.	Establishes a baseline. Monitoring of motor and sensory function ensures that neural blockage does not affect motor function (D'Arcy, 2011).

Clinical Decision Point For all patients on PECA assess for muscle impairment (e.g., sensation or strength) before ambulation or transfer (D'Arcy, 2011).

10 Verify that catheter is secured to patient's skin from the back, side, or front.	Prevents catheter dislodgement or migration.
11 Assess catheter insertion site for redness, warmth, tenderness, swelling, and drainage. Apply sterile gloves when removing occlusive dressing.	Catheter sites are at risk for local infections. Purulent drainage is a sign of infection. Clear drainage may indicate CSF leaking from punctured dura. Bloody drainage may indicate that catheter entered blood vessel.
12 Verify health care provider's order against MAR for name of medication, dosage, route, infusion method (bolus, continuous, or demand), and lockout settings.	Ensures that right drug is administered to patient. <i>This is the first check for accuracy.</i>
13 For continuous infusion check patency of IV tubing and check infusion pump for proper calibration and operation. Keep IV line patent for 24 hours after epidural analgesia is completed.	Kinked or clamped tubing will interrupt analgesic infusion; may cause clotting at end of IV catheter and require replacement. Patent IV line allows IV access in case medications are needed to counteract adverse reactions.

NURSING DIAGNOSES

- | | | |
|--|------------------------------|----------------------|
| • Activity intolerance | • Acute pain | • Risk for infection |
| • Anxiety | • Chronic pain | • Risk for injury |
| • Deficient knowledge regarding epidural analgesia | • Impaired physical mobility | |

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:	
• Patient verbalizes pain relief within 30 to 60 minutes of initiating epidural infusion.	Indicates that drug and dose are effective in relieving pain, catheter is intact, and equipment is functioning properly in compliance with health care provider's order.
• Patient has no headache during epidural infusion or after discontinuation.	Indicates that catheter is in epidural space. No CSF leakage.
• Patient remains normotensive, and heart rate remains at or above baseline.	Indicates absence of some of the side effects of epidural opioids.

STEP	RATIONALE
<ul style="list-style-type: none"> • Patient is alert, oriented, and easily aroused. • Patient's respirations are regular, of adequate depth, and equal to or greater than 8 breaths/min. Pulse oximetry is within normal range. • Patient voids without difficulty; averages a minimum of 30 mL/hr. • Patient has no or minimal pruritus and no paresthesias of lower extremities. • Epidural system remains intact and functioning. 	<p>Indicates absence of excessive sedation/oversedation (see Box 15-5).</p> <p>Indicates adequate ventilation and reduced risk for respiratory depression from opioids (Maddox et al., 2008).</p> <p>Indicates absence of urinary retention (a potential side effect of opioid medications).</p> <p>Indicates absence of potential side effect of epidural medications.</p> <p>Infusion system is patent; no interruption in medication delivery to epidural space.</p>
<p>2 Explain purpose and function of epidural analgesia and expectations of patient during procedure (e.g., ask patient to call for assistance before getting out of bed).</p>	<p>Proper explanation enhances patient cooperation and assists with effective results (Elhoaris and Resnik, 2010).</p>

IMPLEMENTATION

- 1** Prepare analgesic, following “six rights” of medication administration (see [Chapter 20](#)). **NOTE:** Pharmacy prepares medication for pump. In the case of a bolus injection, draw up prediluted, preservative-free opioid solution through the filter needle into syringe.
- 2** Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 3** Attach “epidural line” label to the epidural infusion tubing. Be sure that there are *no Y-ports* for continuous or demand infusions.
- 4** At bedside compare the MAR or computer printout with the name of medication on the drug container.
- 5** Perform hand hygiene and apply clean gloves.
- 6** Administer epidural analgesic.
 - a** Administer dose on demand. Refer to [Skill 15-2](#) for preparation of patient on self-dosing, and explain the epidural method of delivery.
 - b** Administer continuous infusion.
 - (1) Attach container of diluted preservative-free medication to infusion pump tubing and prime tubing (see [Chapter 22](#)).
 - (2) Insert tubing into infusion pump; attach distal end of tubing to epidural catheter.
 - (3) Check infusion pump for proper calibration and operation. Many agencies have two registered nurses check settings.
 - (4) Tape all tubing connections. Give ordered bolus or start infusion (see [Chapter 22](#)).
 - c** Administer bolus dose of analgesic.
 - (1) Take prepared syringe and change filter needle to regular 20-gauge needleless adapter.
 - (2) Clean injection cap of epidural catheter with anti-infective swab. (*Do not use alcohol.*)
 - (3) Dry injection cap with sterile gauze.
 - (4) Insert needleless adapter of syringe into injection cap. Aspirate.

RATIONALE

- Ensures safe and appropriate medication administration. *This is the second check for accuracy.*
- Ensures correct patient. Complies with The Joint Commission standards and improves patient safety ([TJC, 2012](#)).
- Labeling helps to ensure that medication analgesic is administered into correct line and epidural space. Labeling of high-risk catheters prevents connection with an inappropriate tube or catheter ([TJC, 2012](#)). Using tubing without Y-ports prevents accidental injection or infusion of other medications. *This is the third check for accuracy* and ensures that the right patient receives the right medication.
- Gives patient control over administration of analgesic.
- Tubing should be filled with solution and free of air bubbles to avoid air embolus.
- Infusion pump propels fluid through tubing.
- Ensures that patient is receiving proper dose and pain relief.
- Taping maintains a secure closed system to help prevent infection. Sometimes a filter is necessary in the tubing (see agency policy).
- Prevents infusion of microscopic glass particles and allows medication to be injected.
- Cleaning agent prevents introduction of microorganisms into the central nervous system. Alcohol causes pain and is toxic to neural tissue.
- Reduces possible injection of antiseptic.
- Aspiration determines position of catheter. Should aspirate less than 1 mL of clear fluid.

STEP

RATIONALE

Clinical Decision Point *If you aspirate more than 1 mL of clear fluid or bloody return, it means that catheter may have migrated into subarachnoid space or into a vessel. Do not inject drug. Notify anesthesia provider immediately.*

- | | |
|---|---|
| <p>(5) Inject opioid at a rate of 1 mL over 30 seconds.</p> <p>(6) Remove syringe from injection cap. There is no need to flush with saline.</p> <p>7 Explain that you will monitor patient's response to epidural analgesia routinely. Instruct patient on signs and problems to report.</p> <p>8 Remove and dispose of gloves. Perform hand hygiene.</p> <p>9 Before removal of epidural catheter, check for presence of therapeutic anticoagulation. Check agency policy for removal while patient is receiving anticoagulation therapy.</p> | <p>Slow injection prevents discomfort by lowering the pressure exerted by fluid as it enters the epidural space.</p> <p>The catheter is in a space, not a blood vessel; thus flushing with saline is not required (Pasero and McCaffery, 2011).</p> <p>Reassures patient and reduces anxiety.</p> <p>Reduces transmission of microorganisms.</p> <p>Removal of epidural catheter while patient is anticoagulated increases risk for spinal hematoma because of anticoagulation and inability to compress vessels.</p> |
|---|---|

EVALUATION

- | | |
|--|--|
| <p>1 Evaluate patient's comfort level using a pain rating scale of 0 to 10.</p> <p>2 Observe sedation level; respiratory rate, rhythm, and pattern; and pulse oximetry every 1 to 2 hours for 12 to 24 hours and every 4 hours after an epidural bolus of opioid is given to an "opioid-naïve" patient (someone who has <i>not</i> received opioids on an around-the-clock basis for more than 5 to 7 days). Closely monitor a patient who is not opioid naïve (see agency policy), is receiving a larger dose of opioid than usual, or has other risk factors (e.g., sleep apnea) (Pasero and McCaffery, 2011).</p> <p>3 Monitor blood pressure and pulse. Assist patient when changing positions to avoid postural hypotension.</p> <p>4 Monitor intake and output. Assess for bladder distention. Observe for frequency or urgency of urination.</p> <p>5 Observe for pruritus, especially of face, head, neck, and torso. Inform patient that this is a side effect but is often not an allergic response.</p> <p>6 Observe for nausea and vomiting and presence of headache.</p> <p>7 Evaluate catheter insertion site every 2 to 4 hours for redness, warmth, tenderness, swelling, or drainage. Note character of drainage (e.g., bloody, clear, or purulent).</p> <p>8 Evaluate for motor weakness or numbness and tingling of lower extremities (paresthesias).</p> | <p>Evaluates effectiveness of epidural infusion.</p> <p>Oversedation occurs before respiratory depression and should be closely monitored to prevent respiratory depression (Maddox et al., 2008; Pasero and McCaffery, 2011).</p> <p>Postural hypotension, vasodilation, and heart rate changes may occur from pain or medication side effects (Pasero and McCaffery, 2011).</p> <p>Urinary retention may occur as a result of effects of medication on spinal nerves innervating the bladder.</p> <p>Pruritus <i>alone</i> is rarely an allergy to opioids (Pasero and McCaffery, 2011).</p> <p>Nausea from epidural analgesia worsens by movement. Headache and CSF fluid leakage may occur from a dural puncture.</p> <p>Bloody drainage may occur if catheter has migrated into a vessel. Report immediately and treat as an emergency (Pasero and McCaffery, 2011).</p> <p>Reducing epidural dose may help eliminate unwanted motor and sensory deficits (Pasero and McCaffery, 2011).</p> |
|--|--|

Unexpected Outcomes

- 1 Patient states that pain is still present or has increased. Primary causes are insufficient drug dose or catheter blockage, breakage, or improper position.
- 2 Patient is sedated or not easily aroused.
- 3 Patient experiences periods of apnea; or respirations are less than 8 breaths/min, shallow, or irregular.

Related Interventions

- Check all tubing, connections, medication doses, and pump settings.
- Report to health care provider adequacy of medication dose.
- Stop epidural infusion and elevate patient's head of bed 30 degrees (unless contraindicated).
- Prepare to administer opioid-reversing agent per health care provider's order.
- Monitor all vital signs, pulse oximetry, and sedation level continuously until patient is easily aroused.
- Instruct patient to take deep breaths.
- Notify health care provider.
- Prepare to administer opioid-reversing agent such as naloxone (Narcan) per health care provider's order (agency procedure manual may have protocol).
- Monitor at least every 30 minutes until respirations are at least 8 or more per minute and of adequate depth for 2 hours.

- | | |
|--|---|
| <p>4 Patient reports sudden headache. Clear drainage is present on epidural dressing, or more than 1 mL of fluid is aspirated from catheter. Possible indication that catheter has migrated into the subarachnoid space.</p> <p>5 Blood is present on epidural dressing or aspirated from the catheter. Probable indication that catheter has punctured a blood vessel.</p> <p>6 Redness, warmth, tenderness, swelling, exudate is noted at catheter insertion site. Patient is febrile. These are signs and symptoms of infection.</p> <p>7 Patient experiences minimal urinary output, urinary frequency or urgency, bladder distention, pruritus, or nausea and vomiting.</p> | <ul style="list-style-type: none"> • Stop infusion. • Notify health care provider.
<ul style="list-style-type: none"> • Stop infusion. • Notify health care provider.
<ul style="list-style-type: none"> • Notify health care provider.
<ul style="list-style-type: none"> • Consult with health care provider about reducing the dose of opioid and discuss treatment for side effects. |
|--|---|

Reporting and Recording

- Record drug, dose, method (bolus, demand, or continuous), and time given (if injection) or time begun and ended (if demand or continuous) on appropriate medication record. Specify concentration and diluent.
- With continuous or demand infusion, obtain and record pump readout hourly for first 24 hours after infusion begins and then every 4 hours. Review pump settings and usage together with staff coming on the next shift.
- Record regular periodic assessments of patient’s status in nurses’ notes, in EHR, and/or on appropriate flow sheet, including vital signs, pulse oximetry, intake and output (I&O), sedation level, pain severity score, neurologic status, appearance of epidural site, presence or absence of adverse reactions to medication, and presence or absence of complications resulting from placement and maintenance of epidural catheter (Pasero and McCaffery, 2011).
- Report any adverse reactions or complications to health care provider immediately.

Teaching Considerations

- Describe catheter placement and use to patient as appropriate. Drawing or showing pictures often helps.
- Teach patient and family members the purpose, action, and signs and symptoms of adverse reactions to opioid or local anesthetic. Teach when and which signs and symptoms to report to a nurse.
- Teach patient to report pain level with acceptable (to patient) pain scale.
- Inform patient of other pain-management strategies that supplement or enhance pharmacologic intervention (e.g., imagery, distraction, relaxation) (Allred et al., 2010; NIH, 2011).
- Some patients may attempt to ambulate without assistance or overdo other activities. Caution them to begin slowly to avoid injury and to always call for nurse to assist with any activity.

Explain that the first attempt to ambulate may feel strange secondary to decreased sensation, but motor (leg) function should be unaffected.

Pediatric Considerations

- Apply EMLA cream to the epidural site a minimum of 60 minutes before catheter insertion.
- Epidural analgesia can be used in selected situations (Hockenberry and Wilson, 2011).

Gerontologic Considerations

- Older adults are at the same risk for complications and medication adverse effects as other adult patients (Deane and Smith, 2008).

Home Care Considerations

- Patients needing long-term therapy are discharged with a tunneled catheter. Before considering catheter placement and care in the home, assess patient’s fine-motor skills, cognitive ability, stage of disease and prognosis, and degree of involvement of family caregiver.
- Teach patient and caregiver proper dosage and administration of medication. Evaluating patient’s technique for catheter care, administering medication, and reinforcing instructions are priorities.
- Teach patient and caregiver aseptic technique for medication administration as needed and for all catheter care procedures, including dressing changes. Instruct patient to change dressing every week (policy varies with home care agency). Teach signs and symptoms of infection and instruct patient to report to nurse or health care provider immediately should signs and symptoms appear.
- Teach patient and caregiver about signs and symptoms of adverse reactions to medication being used and interventions to alleviate mild side effects in the home.
- Give patient and family phone numbers of health care providers to contact in emergency and resources in the community.

SKILL 15-4 Local Anesthetic Infusion Pump for Analgesia

During surgery for joint replacement some surgeons insert a one-way catheter into the surgical site and attach it to an infusion pump (Fig. 15-5). The pump delivers a local anesthetic (e.g., bupivacaine [Marcaine], lidocaine, ropivacaine [Naropin], or mepivacaine [Carbocaine]) directly into the wound bed to provide pain relief to the surgical site. Patients may still require oral analgesics, but the total dosage is often reduced (ISMP, 2011). The pump has a demand (4 to 6 mL/bolus) and a continuous (basal) rate (2 to 4 mL/hr) feature. Continuous flow reservoirs hold 100 mL, whereas patient-controlled units have a 60-mL reservoir. The device is one-time use only and usually remains in place for about 48 hours.

Rarely is the pump removed during hospitalization. Patients learn how to remove the catheter at home. Nursing care focuses on assessment of catheter site and connections, evaluation of local anesthetic side effects, and patient teaching.

Delegation and Collaboration

The skill of managing local anesthetic infusion pump analgesia cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Pay close attention to the insertion site when providing care to avoid dislocation.

FIG 15-5 Local anesthetic infusion pump in use after shoulder surgery. Image courtesy Breg, Inc, Vista, Calif. All rights reserved.

- Report if the dressing becomes moist; report any catheter disconnection immediately.
- Notify nurse immediately of a change in patient's status or level of comfort.

Equipment

- Pump in place from surgery

Home Catheter Removal

- Clean gloves
- Sterile 4 × 4-inch gauze pads
- Tape
- Plastic bag

STEP

RATIONALE

ASSESSMENT

- 1 Perform hand hygiene, apply clean gloves, and assess surgical dressing and site of catheter insertion. Dressing should be dry and intact.
- 2 Assess catheter connections. If connections become detached, do not reattach; instead notify surgeon immediately.
- 3 Perform a complete pain assessment (see Skill 15-1).
- 4 Review surgeon's operative report for position of catheter.
- 5 Read label on device and compare to MAR or health care provider's order.
- 6 Assess for presence of blood backing up in tubing. If blood is present, stop infusion and notify health care provider.
- 7 Determine the level of extremity activity that patient can perform per health care provider's orders.
- 8 Assess for signs of local anesthetic toxicity: hypotension, dizziness, tremor, severe itching, swelling of the skin or throat, irregular heartbeat, palpitations, confusion, ringing in the ears, muscle twitching, numbness around the mouth, metallic taste, seizures.
- 9 Assess patient's and family caregiver's knowledge of infusion pump.

Determines if catheter is placed properly.

Reattachment could lead to infection. Misconnections could lead to infusion of inappropriate agents into joint site.

Provides baseline to determine efficacy of analgesia.

Confirms catheter location.

Provides information regarding type of anesthetic, concentration, volume, flow rate, date and time prepared.

Indicates possible displacement of catheter into blood vessel.

Excessive activity can cause catheter displacement.

Early identification of toxicity prevents or lessens the possibility of complications.

Local anesthetics can have serious systemic effects (ISMP, 2011).

Assesses level of teaching and support required.

NURSING DIAGNOSES

- Acute pain
- Anxiety
- Risk for infection
- Deficient knowledge regarding purpose of infusion pump
- Impaired physical mobility

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient verbalizes full or partial relief from pain.
 - Patient achieves reduction of nonverbal behaviors indicative of pain such as grimacing, clenching teeth, rocking.
 - Patient is free of adverse drug reactions.
 - Patient moves about in bed, sleeps and eats better, is more active, and communicates easily with family and friends.
 - Catheter is removed correctly without injury to patient.

Patient's self-report of pain is the single most reliable indicator of pain.

Nonverbal behaviors are valid and reliable indicators of pain in the absence of self-report (Herr et al., 2011).

Adequate pain relief allows patient to participate in activities of daily living (ADLs).

Patient and family caregiver are able to follow instructions for catheter removal.

STEP	RATIONALE
------	-----------

IMPLEMENTATION

<p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on the patient's identification bracelet and/or ask patient to state name.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p>
<p>2 When repositioning or ambulating patient, use caution to avoid catheter dislodgement.</p>	<p>Decreases transmission of microorganisms.</p>
<p>3 Teach patient or family caregiver how to remove catheter (may also be done by home health nurse).</p> <p>a Teach patient or family caregiver how to perform hand hygiene and apply clean gloves.</p> <p>b Have patient assume a relaxed position in bed or chair with lower extremity in normal alignment.</p> <p>c Gently remove surgical dressing.</p> <p>d Explain to patient what he or she will feel when removing the catheter.</p> <p>e Place a 4 × 4–inch gauze over site. Grasp catheter firmly and pull outward from skin with steady motion. If resistance occurs, stop pulling. Reposition extremity and try again. If tubing continues to stretch and demonstrates resistance, stop pulling, cover area with sterile dressing, and notify surgeon.</p> <p>f Observe for mark on end of catheter tip.</p> <p>g After catheter is removed, place a new sterile dressing over the area and apply pressure for at least 2 minutes.</p> <p>h Place catheter in bag using standard precautions. Remove gloves and perform hand hygiene.</p>	<p>Relaxes joint muscles, reducing traction from muscle tension, and provides distraction.</p> <p>Provides access to infusion catheter.</p> <p>Helps patient anticipate procedure and reduces anxiety.</p> <p>Approach designed to minimize tissue trauma.</p>
<p>4 Remind patient or family caregiver of follow-up appointment with surgeon.</p>	<p>Indicates complete removal of catheter; retaining a part of catheter could lead to inflammation, infection, and/or an embolus (Pasero and McCaffery, 2011).</p> <p>Prevents hematoma formation.</p> <p>Patient is to bring catheter to surgeon's office on first visit. Reduces transmission of microorganisms and helps prevent infection.</p> <p>Increases patient adherence.</p>

EVALUATION

<p>1 Ask patient to rate pain intensity using appropriate scale at both rest and with activity.</p>	<p>Determines patient response to local infusion of medication.</p>
<p>2 Observe for signs of adverse drug reaction and report any signs immediately.</p>	<p>Local analgesics can result in systemic adverse effects if absorbed by veins (Pasero and McCaffery, 2011).</p>
<p>3 Observe patient's position, mobility, relaxation, participation in activities of daily living, and any nonverbal behaviors.</p>	<p>Indicates successful pain management.</p>
<p>4 Inspect condition of surgical dressing.</p>	<p>A wet dressing indicates possible catheter migration out of wound, especially if drainage is clear.</p>
<p>5 During follow-up visit inspect catheter exit site.</p>	<p>Determines if area has healed without infection.</p>

Unexpected Outcomes

- 1 Patient verbalizes pain intensity greater than previously determined goal or demonstrates nonverbal behaviors indicative of pain. Catheter may be displaced or clogged, or surgical site may be developing complications.
- 2 Patient reports symptoms of local anesthetic adverse reaction. Possible hypersensitivity to local anesthetic, displacement of catheter into vein, or pump failure (releasing too much drug into site).

Related Interventions

- Check reservoir for presence of medication.
- Check patency of tubing.
- Notify health care provider.
- Stop infusion (ISMP, 2011).
- Notify health care provider.

Reporting and Recording

- Record drug, concentration, date inserted, and type of demand feature (continuous or demand) in medication record.
- Record location of catheter, patient's pain rating, response to anesthetic, and additional comfort measures given in nurses' notes and EHR.

- Record additional analgesics necessary to control pain.
- Record any adverse reactions to local anesthetic (ISMP, 2011).
- Report damp dressing and/or displaced catheter to surgeon.

Teaching Considerations

- Provide preoperative teaching because device is placed in operating room.

- If device is on demand (not continuous), instruct patient to depress button every 6 hours.
- Instruct patient to inform nurse if pain exceeds pain-intensity goal because additional oral and/or intravenous analgesics are available for breakthrough pain.

Pediatric Considerations

- Local continuous infusion pumps have been used for children undergoing orthopedic surgery. Instruct parents and the child as described under Home Care Considerations. Explain special precautions not to dislodge the catheter.

Gerontologic Considerations

- Continuous dosing is sometimes administered, but demand doses require a mentally competent adult (Herr et al., 2011). In addition, take special precautions to protect the catheter.

Home Care Considerations

- Instruct patient to notify health care provider if excessive fluid or bleeding on the dressing occurs.
- Provide written instructions regarding any possible adverse reactions and reporting them to the health care provider immediately.
- Provide verbal and written instructions regarding how and when to discontinue device when at home. Remind patient to place catheter in a plastic bag and bring it to first follow-up visit with health care provider.
- Provide instructions regarding extremity movement.
- Home-health nurse may be ordered to remove pump via surgeon's order.

SKILL 15-5 Nonpharmacologic Pain Management

Video Clip

Effective pain management does not always mean the elimination of pain. A variety of nonpharmacologic interventions are available to lessen a patient's pain in any health care setting. Some of these interventions are also classified as complimentary or alternative therapies, and there is evidence to support pain relief (NIH, 2011). Use these interventions in combination with pharmacologic interventions, not in place of them. Nonpharmacologic techniques diminish the physical effects of pain, alter a patient's perception of pain, and provide a patient with a greater sense of control. Distraction, relaxation, guided imagery, and cutaneous stimulation such as massage and acupressure are a few examples of effective nonpharmacologic measures.

Many nonpharmacologic techniques trigger a relaxation response by stimulating the parasympathetic nervous system (PNS). Because pain often causes muscle tension and anxiety, PNS stimulation relieves these disturbing responses (Baird et al., 2010; Drew and St. Marie, 2011). Nonpharmacologic interventions are appropriate for patients who find such interventions appealing, express anxiety or fear, may benefit from avoiding or reducing drug therapy, and have incomplete pain relief with pharmacologic interventions alone. You will have an excellent opportunity to help patients control their pain by teaching them to add a variety of nonpharmacologic techniques (Box 15-6). Patients and families today are more aware of complementary techniques and should be encouraged to continue whatever has worked for them. Because everyone responds differently, finding new methods that work for a patient may take more time than finding pharmacologic techniques.

CUTANEOUS STIMULATION

Massage

A gentle massage, a form of cutaneous stimulation, is the application of touch and movement to muscles, tendons, and ligaments without manipulation of the joints. A proper massage not only blocks perception of pain impulses but also helps relax muscle tension and spasm that otherwise might increase pain. Massage hastens the elimination of wastes stored in muscles, improves oxygenation of tissues, and stimulates the relaxation response in the

nervous system. A superficial massage of the back, shoulders, and lower part of the neck is sometimes referred to as a backrub. Offering a backrub after a bath or before a patient prepares for sleep promotes relaxation and comfort. An effective backrub takes 3 to 6 minutes and is an important intervention for decreasing pain and improving sense of well-being. Massage also involves the feet and hands (Asadzker et al., 2011). Do not perform massage over bruised, swollen, or inflamed areas or bones of spine.

BOX 15-6 Nonpharmacologic Strategies for Pain Management*

Relaxation and Power of the Mind

- Self-comfort
- Progressive muscle relaxation
- Autogenics training
- Breathing exercises
- Music relaxation
- Visual imagery
- Yoga

Put Your Body to Work

- Exercise
- Pacing
- Energy conservation
- Body mechanics

Spirituality and Reflection

- Engaging in religious practices
- Humor
- Setting aside time to focus on what is
- Sharing your stress with others
- Journaling
- Praying

What To Do When Pain Flares

- Cold and hot therapies
- Ball therapy
- Contrast baths
- Hand massage
- Herbs[†]

*Should be used along with analgesia medications.

†Contact health care provider before using herbs, which could interact with prescribed analgesics.

Heat and Cold

Heat and cold applications relieve pain and promote healing. The selection of heat versus cold varies with a patient's preference and condition. The application of heat or cold in a health care agency or home health environment requires a health care provider's order. Although the physiologic responses to heat and cold differ, superficial heat or cold applications provide comfort in similar conditions such as muscle spasms, strains, and localized joint pain (see [Chapter 40](#) for a review of warm and cold therapy).

Relaxation

Relaxation is a cognitive and/or physical strategy that provides pain relief or reduces pain to an acceptable level, usually in conjunction with pharmacologic methods when pain is severe. A patient's full participation and cooperation are necessary for relaxation techniques to be effective. The techniques are particularly useful for chronic pain, labor pain, and relief of procedure-related pain. Relaxation interventions involve progressive muscle relaxation, massage, quiet breathing, deep breathing, guided imagery, or a combination ([Chen and Francis, 2009](#); [Gloth, 2011](#); [NIH, 2011](#)).

Guided Imagery

Guided imagery is a creative sensory experience that effectively reduces pain perception and minimizes reaction to pain. It draws on internal experience of memories, dreams, fantasies, and visions; explores the inner world of experience; protects the privacy of a patient; and fosters the imagination. The goal of imagery is to have a patient use one or several of the senses to create an image of a desired result. This image creates a positive psychophysiologic response. Focus of the imagination helps patients change their perceptions about their disease, treatment, and healing ability, which helps relieve pain, tension, or stress. Choosing images that patients find pleasant requires a careful assessment. Otherwise you may mistakenly describe images of objects or things that a patient fears or dislikes. For example, a scene of rolling waves at the seashore is restful to one patient but may be frightening to another ([Baird et al., 2010](#)).

Distraction

Distraction is a technique that diverts an individual's attention away from mild or even moderate pain sensation. By introducing meaningful stimuli, you help a patient refocus attention. Some believe that a person can consciously attend to only one stimulus, thus diverting the attention away from pain. Distraction strategies you can offer a patient include changing activity, listening to music ([Allred et al., 2010](#); [Leibovici et al., 2009](#)), reading, focusing on another person, walking, napping, writing, concentrating on a mental and physical activity simultaneously (playing a musical instrument), learning something new (completing a crossword puzzle), and listening to or watching a comedy program ([NIH, 2011](#)). Therapeutic communication with a nurse is another example of distraction. When the distraction is removed, a patient may have a heightened awareness of pain.

Delegation and Collaboration

Assessment of a patient's pain cannot be delegated to nursing assistive personnel (NAP). The skill of nonpharmacologic pain management strategies can be delegated to NAP. The nurse directs the NAP to:

- Identify and explain which nonpharmacologic measures work best for the patient.
- Explain the importance of eliminating environmental conditions that enhance pain.
- Identify the need to adapt strategies to patient restrictions (e.g., massage in side-lying versus prone position).

Equipment

- Pain rating scale
- Massage:* Lotion or oil (consider aroma therapy lotion), folded sheet, bath towel
- Relaxation:* Patient's music preference, radio or CD player, relaxation tape and tape player
- Distraction:* Based on patient preference (e.g., reading material, puzzles, video games)

STEP **RATIONALE**

ASSESSMENT

<p>1 Using pain rating scale, have patient identify pain intensity or discomfort.</p> <p>2 Assess physiologic, behavioral, and emotional signs and symptoms of pain, including patient self-report (see Skill 15-1).</p> <p>3 Assess characteristics of pain and possible underlying cause (see Skill 15-1).</p>	<p>Pain score establishes baseline to determine effects of intervention.</p> <p>Responses serve as means to evaluate effectiveness of pain-relief measures.</p> <p>Overt signs and symptoms are usually not present with chronic pain. Physical signs and symptoms indicate change in comfort level.</p> <p>Establishes baseline to determine if nonpharmacologic approaches are appropriate.</p>
---	---

Clinical Decision Point *It helps to administer an analgesic before implementing a nonpharmacologic strategy so a patient is able to gain a level of comfort needed to practice these approaches.*

<p>4 Examine the site of patient's pain or discomfort. Include inspection (discoloration, swelling, drainage), palpation (change in temperature, area of altered sensation, painful area, areas that trigger pain), and range of motion of involved joints (if applicable).</p> <p>5 Review health care provider's orders for pain relief.</p>	<p>Clinical observations may clarify information from patient. Site of discomfort may direct you to specific types of pain-relief measures.</p> <p>In some acute care settings a medical order is necessary to perform nonpharmacologic therapies.</p>
--	--

STEP	RATIONALE
6 Assess patient's understanding of pain and willingness to receive nonpharmacologic pain-relief measures.	Participation increases effectiveness of pain-relief measure. If patient is reluctant to try activity, provide information about suggested therapy.
7 Assess preferred patient activities (e.g., puzzles, crocheting or knitting, board games, music, imagery, and relaxation tapes).	Doing these activities in health care setting increases patient participation.
8 Assess patient's language level and identify descriptive terms to use when providing nonpharmacologic pain-relieving strategies.	Provides clarification of information.

NURSING DIAGNOSES

- Activity intolerance
- Acute pain
- Anxiety
- Chronic pain
- Deficient knowledge regarding nonpharmacologic methods of pain control
- Ineffective coping
- Powerlessness

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedures: <ul style="list-style-type: none"> • Patient demonstrates and describes pain-relief measures. • Patient is relaxed and comfortable after technique as evidenced by slow, deep respirations; calm facial expressions; calm tone of voice; relaxed muscles; relaxed posture. • Patient verbalizes pain relief. 	Demonstrates patient understanding and learning. Nonpharmacologic strategies help patient relax and experience less discomfort. Physiologic response to relaxation procedures and massage is deep relaxation. Patient's subjective expression is the most reliable indicator of the presence of pain.
2 Explain purpose of technique and what you expect of patient during activity.	Proper explanation of activity enhances patient participation.
3 Plan time to perform technique when patient is able to concentrate (e.g., after voiding, awakening from a nap).	Increases opportunity for success.
4 Administer an analgesic 30 minutes before implementing a nonpharmacologic strategy.	Patient is able to gain a level of comfort needed to perform these approaches.

IMPLEMENTATION

1 Prepare patient's environment. <ul style="list-style-type: none"> • Temperature suited to patient • Lighting • Sound • Eliminate unnecessary interruptions and coordinate care activities; allow for rest. 	Temperature and sound extremes can enhance patient's perception of pain. Bright or very dim lighting can aggravate pain sensation.
2 Massage	

Clinical Decision Point *Massage is contraindicated in cases of muscle, bone, or joint injury.*

a Perform hand hygiene.	Reduces transmission of microorganisms.
b Place patient in comfortable position such as prone or side-lying. Have patients with difficulty breathing lie on side of bed with head of bed elevated.	Enhances relaxation and exposes areas to be massaged.
c Adjust bed to comfortable position for you; lower upper side rail on side where you are standing.	Ensures proper body mechanics and prevents strain on back.
d Turn on music to patient's preference.	Promotes relaxation.
e Ensure that patient is not allergic to lotion; warm lotion in hands or in basin of warm water. NOTE: If you massage the head and scalp, delay use of lotion until completed.	Warm lotion is soothing, and warmth helps to produce local muscle relaxation.
f Choose stroke technique based on desired effect or body part. <ol style="list-style-type: none"> (1) Effleurage: Massaging upward and outward from vertebral column and back again (see illustration). 	Ensures fuller relaxation of body part. A light, gliding stroke used without manipulating deep muscles smooths and extends muscles, increases nutrient absorption, and improves lymphatic and venous circulation.

STEP	RATIONALE
(2) Pétrissage (see illustration).	Kneading tense muscle groups promotes relaxation and stimulates local circulation.
(3) Friction	Strong circular strokes bring blood to surface of skin, increasing local circulation and loosening tight muscle groups.
g Encourage patient to breathe deeply and relax during massage.	Potentiates effects of massage.
h Standing behind patient, stimulate scalp and temples.	
i Supporting patient's head, use friction to rub muscles at base of head.	Strong circular strokes (friction) stimulate local circulation and relaxation.
j With patient in supine position, massage hands and arms as appropriate:	Releases tension in hands and arms. Studies indicate that anxious behaviors may be significantly reduced with hand massage (Asadizker et al., 2011).
(1) Support hand and apply friction to palm using both thumbs.	
(2) Support base of finger and work each finger in corkscrew-like motion.	
(3) Complete hand massage using effleurage strokes from fingertips to wrist.	
(4) Knead muscles of forearm and upper arm between thumb and forefinger.	Encourages relaxation; enhances circulation and venous return.
k After determining that patient has no neck injury or condition that contraindicates neck manipulation, massage neck as appropriate:	
(1) Place patient prone unless contraindicated.	Provides access to neck muscles.
(2) Knead each neck muscle between thumb and forefinger.	Reduces tension that often localizes in neck muscles.
(3) Gently stretch neck by placing one hand on top of shoulders and other at base of head. Gently move hands away from one another.	Helps relax muscle body.
l Massage back as appropriate:	Patient with back injury, surgery, or epidural infusion should not receive back massage.
(1) Keep patient in prone position unless contraindicated; side-lying position is an option.	Provides access to muscle groups in back.
(2) Do not allow hands to leave patient's skin.	Continuous contact with surface of skin is soothing and stimulates circulation to tissues.
	Breaking contact with skin can startle patient.
(3) Apply hands first to sacral area; massage in circular motion. Stroke upward from buttocks to shoulders. Massage over scapulas with smooth, firm stroke. Continue in one smooth stroke to upper arms and laterally along sides of back down to iliac crest (see illustration). Continue massage pattern for 3 minutes.	General, firm pressure applied to all muscle groups promotes relaxation.

STEP 2f(1) Effleurage.

STEP 2f(2) Pétrissage.

STEP

RATIONALE

STEP 2I(3) Circular massage.

- | | |
|---|---|
| (4) Use effleurage along muscles of spine in upward and outward motion. | Massage follows distribution of major muscle groups. |
| (5) Use pétrissage on muscles of each shoulder toward front of patient. | Area often tightens because of tension. |
| (6) Use palms in upward and outward circular motion from lower buttocks to neck. | Brings blood to surface of skin. |
| (7) Knead muscles of upper back and shoulder between thumb and forefinger. | These muscles are thick and can be massaged vigorously. |
| (8) Use both hands to knead muscles up one side of back and then the other. | |
| (9) End massage with long, stroking effleurage movements. | Most soothing of massage movements. |
| m Massage feet as appropriate: | |
| (1) Place patient in supine position. | Returns patient to comfortable anatomic position. |
| (2) Hold foot firmly. Support ankle with one hand or support sides of foot with each hand while performing massage. | Maintains joint stability during massage (<i>Asadziker et al., 2011</i>). |
| (3) Make circular motions with thumb and fingers around bones of ankle and top of foot. | All massage strokes help to relax muscles. |
| (4) Trace space between tendons with firm finger pressure, moving from toe to ankle. | |
| (5) Massage sides and top of each toe. | |
| (6) Use top of fist to make circular motions on bottom of foot. | |
| (7) Knead sides of foot between index finger and thumb. | |
| (8) Conclude with firm, sweeping motions over top and bottom of foot. | Too light strokes may tickle. |
| n Tell patient that you are ending massage. | Informs and prepares patient for inhalation and exhalation. |
| o When procedure is complete, instruct patient to inhale deeply and exhale. Caution him or her to move slowly after resting a few minutes. | Returns patient to more awake and alert state.
When deeply relaxed, patient may experience dizziness on arising too rapidly, need time for vessels to redistribute blood supply. |
| p Wipe excess lotion or oil from patient's body with bath towel. | Excess lotion or oil can irritate skin and lead to breakdown. |
| q Return bed to low position and raise side rails as appropriate when massage is finished. Perform hand hygiene. | Side rails cannot be used as a restraint. |
| 3 Progressive relaxation | |
| a Instruct patient to take several slow, deep, diaphragmatic breaths. | Increased oxygen lessens anxiety and prevents shortness of breath with relaxation breathing technique. Avoids hyperventilation. |
| b Have patient close eyes if desired. | Helps patient maintain focus. |
| c Have patient alternate tightening for 3 to 4 seconds and then relaxing all muscle groups for 6 to 7 seconds, beginning at feet and working upward toward head. | Alternating tension and relaxation in muscle groups allows patient to feel the difference. |

STEP	RATIONALE
(1) Instruct patient to tighten muscles during inhalation and relax muscles during exhalation.	Relaxation is an integrated response associated with diminished sympathetic nervous system arousal; decreased muscle tension is desired outcome.
(2) As each muscle group relaxes, ask patient to enjoy relaxed feeling and allow mind to drift and think how nice it is to be relaxed. Have patient breathe deeply.	Relaxation decreases pulse and respiration rates, and blood pressure and helps reduce anxiety (Baird et al., 2010).
d Calmly explain that patient will feel sensations of tingling, heaviness, floating, or warmth as relaxation occurs.	Distracts patient from perceiving pain.
e Ask patient to continue slow, deep breaths.	Enhances relaxation response.
f When exercise is complete, instruct patient to inhale deeply, exhale, and then initially move about slowly after resting a few minutes.	Breathing deeply prevents the Valsalva maneuver, which increases intrathoracic pressure and compromises cardiac function.
4 Deep breathing	Prevents anxiety if sensation occurs without warning.
a Instruct patient to sit comfortably with feet uncrossed. If patient is unable to sit, move to supine position with small pillow under head.	Allows opportunity to enjoy feelings of relaxation.
b Have patient place one hand on chest and the other on abdomen.	Returns patient to more awake and alert state.
c Coach patient to inhale deeply through the nose, allowing the abdomen to rise and the hand to move outward.	Rising too rapidly can cause dizziness.
d When the abdomen is partially expanded, tell patient to continue to breathe and allow chest to expand, moving the upper hand outward.	Encourages relaxation.
e Pause for a few seconds. Then have the patient exhale slowly through pursed lips to ensure slow, controlled release of air. Repeat for 4 to 6 minutes.	Allows patient to focus on chest and then abdomen.
5 Guided imagery	Provides steady timing of inhalation and focuses the patient on stretching abdominal muscles.
a Direct patient through guided imagery exercise.	Affords maximal inhalation.
(1) Instruct patient to imagine that inhaled air is ball of healing energy.	Permits optimal exchange of oxygen and carbon dioxide.
(2) Imagine that inhaled air travels to area of pain.	Developing specific images helps to remove pain perception.
b Alternatively you may direct imagery.	Patient's ability to concentrate decreases pain perception.
(1) Ask patient to imagine a pleasant place such as beach or mountains. Choose an image peaceful for the patient.	Directs imagery after selection of restful place.
(2) Direct patient to experience all sensory aspects of restful place (e.g., for beach: warm breeze, warm sand between toes, warmth of sunshine, rhythmic sound of waves, smell of salt air, gulls gliding and swooping in air).	Helps patient concentrate and relax through stimulation of numerous senses (Baird et al., 2010). Make sure that it is something in their experience, not just yours.
(3) Direct patient to continue deep, slow, rhythmic breathing.	Promotes relaxation through muscle relaxation.
(4) Direct patient to count to three, inhale, and open eyes. Suggest that patient move about slowly initially.	Guided imagery requires an intense level of concentration that takes time to achieve. Practice relaxation tapes are available almost everywhere; libraries are an excellent source.
c Provide patient time to practice exercise without interruption.	Redirection of attention can alter emotional or cognitive aspects of pain (Allred et al., 2010).
6 Distraction	Directs attention inward and protects patient from external distraction.
a Direct patient's attention away from pain with distraction techniques.	Promotes relaxation by concentrating on kinesthetic action, thus reducing ability to concentrate on pain (Leibovici et al., 2009).
b Ask patient to close eyes or to focus on single object in room.	Focusing on an activity helps divert attention from painful sensation.
c Instruct patient to concentrate on slow, rhythmic breathing. Guide breathing or instruct patient to control and concentrate on breathing by thinking: "in, one, two; out, one, two."	
d Continue distraction using patient preferred technique.	
(1) Use music of patient's choosing. Emphasize listening to rhythm and adjust volume as pain increases or decreases.	

STEP

- (2) Direct patient to give detailed account of an event or story.
- (3) Engage patient in conversation; encourage participation of family members and visitors.

RATIONALE

Stress details of event to enhance distraction from painful stimulus.

Visitors can help direct attention away from mild-to-moderate pain. Rarely is someone in severe pain able to use distraction.

EVALUATION

- 1 Observe character of respirations, body position, facial expression, tone of voice, mood, mannerisms, verbalization of discomfort.
- 2 Ask patient to use a pain rating scale to rate comfort level.
- 3 Observe patient perform pain-control measures.

Determines effectiveness of procedure, level of relaxation, degree of pain relief achieved, and which procedures were the most effective.

Measures change in pain intensity.
Confirms learning.

Unexpected Outcomes

- 1 Patient is not able to concentrate on technique because pain intensity is unchanged or escalating or demonstrates nonverbal behaviors indicative of pain.

Related Interventions

- Reassess character of pain and determine if further analgesia is necessary.
- Ensure that environment is conducive to learning and using technique.
- Consult with health care provider on an increase in dose or alternate medication.
- Consider a different technique or a combination of complementary strategies.

Recording and Reporting

- Record in nurses' notes and EHR patient's assessment findings, procedure and technique(s) used, preparation given to patient, patient's response to procedure or technique, change in overall condition, and further comfort needs related to event. Incorporate pain-relief technique into nursing care plan.
- Report patient's response to nonpharmacologic interventions to the staff at change of shift or in a care plan meeting.
- Report any unusual responses to techniques (e.g., uncontrolled or aggravated pain, or muscle spasms) to nurse in charge or health care provider.

Teaching Considerations

- Provide patient information about each nonpharmacologic therapy, including purpose, rationale for how pain is relieved, how patient can maximize benefits. If NAP performs massage, you still need to provide patient education.
- Some techniques require more practice before patients achieve results. Pharmacologic intervention is sometimes required to lessen pain so patient can relax.
- Teach patient to rest between periods of activity at home and hospital because fatigue increases pain perception.
- Teach family member how to perform massage (if not contraindicated) as part of home care.

Pediatric Considerations

- You can use nonpharmacologic pain-management therapies successfully with children. Adapt distraction and relaxation

strategies to the developmental level of the child (e.g., use a pacifier for an infant, offer reading or playing a recording of a favorite story for a preschooler, encourage a teenager to listen to music on a CD player with headphones) (Allred et al., 2010; Finley et al., 2009; Hockenberry and Wilson, 2011). Play therapists are usually available at large pediatric hospitals and are good resources for appropriate distraction techniques.

- Because children usually have an active imagination, relaxation is often a powerful adjuvant in pain control.
- Parents are very helpful in providing pain relief. For example, they provide comfort by their presence, conversation, and holding and cuddling their child.

Gerontologic Considerations

- Visual, hearing, cognitive, and motor impairments make it difficult for older adults to be able to effectively use procedures such as distraction, relaxation, or guided imagery. Make certain that glasses, hearing aids, and other assistive devices are in place. Do not assume that complementary techniques will not work on the elderly (NIH, 2011).

Home Care Considerations

- Family members need to collaborate on planning time to reduce noise and other stimuli in the home to promote patient's relaxation.

Critical Thinking Exercises

Mrs. Silver is an 85-year-old newly admitted widow. She has a history of stroke, pulmonary emboli (blood clots in the lungs), a myocardial infarction (heart attack), heart failure, and a broken right hip over the past 8 years. In the past 3 years she was declared legally blind as a result of macular degeneration in both eyes. She is confined to a wheelchair, unable to stand or walk, and is very depressed because she can no longer read, her favorite pastime.

When you do a pain assessment on Mrs. Silver, you discover that she has difficulty using the numeric rating scale of 0 to 10 and becomes frustrated when people ask her to use it. She asks you to decide the number for her because she “just doesn’t understand.” She describes her pain to you as deep, aching pain in her right leg, hip, and shoulder that keeps her awake at night and makes it very difficult to turn on her right side.

Mrs. Silver has an order for morphine 10 mg by mouth every 3 hours as needed; she had been taking this at home for several months. She tells you that, when she requested the pain pill at 4 AM this morning, the night nurse told her that she has to be very careful because she could become a drug addict if she takes morphine. She says that she is in pain right now but is afraid to take anything. Her vital signs are BP 98/70, P76, R16, and T97. Her bowel sounds are slightly hypoactive. She reports she has not had a bowel movement for 3 days.

- 1 How often will you assess this patient’s pain, and which pain assessment tool will you use?
- 2 Which nonpharmacologic pain control approaches are appropriate for Mrs. Silver? Provide rationale.
- 3 The patient says to her nurse, “do you think my pain medicine is causing my constipation”? What should be the nurse’s answer?

REVIEW QUESTIONS

- 1 What should you do if a postoperative patient activates (pushes the button) the patient-controlled analgesia (PCA) three times as frequently as the medication is ordered?
 - 1 Realize that this is normal and there is no need for any nursing action
 - 2 Explain that pain is to be expected after surgery
 - 3 Thoroughly reassess patient’s pain and call the health care provider who prescribed the PCA to request orders to increase the dose or change or add a medication
 - 4 Tell the patient that he is only allowed to push the button three times an hour
- 2 Which patient is the BEST candidate for use of a PCA pump?
 - 1 A very confused older adult having minor surgery
 - 2 An obese adult with sleep apnea
 - 3 An older teenager having an appendectomy
 - 4 A middle-age adult having major surgery who requires an interpreter
- 3 Which patient is the *worst* candidate for use of a PCA pump?
 - 1 A very confused older adult having minor surgery
 - 2 An obese adult with sleep apnea
 - 3 An older teenager having an appendectomy
 - 4 A middle-age adult having major surgery who requires an interpreter
- 4 What is the most common health care provider error associated with PCA therapy?
 - 1 Giving the wrong medication
 - 2 Using a wrong concentration of a medication (e.g., Dilaudid 1 mg/mL is ordered; Dilaudid 2 mg/mL is placed in the machine)
 - 3 Presence of a faulty alarm
 - 4 Programming the PCA machine incorrectly

- 5 Which nursing measure is key to preventing oversedation with opioids?
 - 1 Awaken a patient at least once a shift
 - 2 Frequently monitoring a patient using a standard sedation scale
 - 3 Assessing the quality of respirations once a shift
 - 4 Medicating as ordered, even if a patient is extremely sleepy
- 6 On a patient’s medical record you discover that a prior pain assessment was made using a behavioral pain scale for nonverbal patients. According to the nurse the patient was unable to use a numeric scale for pain intensity. Prioritize the nursing actions by marking 1 next to the highest priority; 2 next to the second priority; 3 next to the third priority, and 4 next to the lowest priority.
 - _____ Look at the chart for any indication that the patient was nonverbal at one time and see when it (the behavioral scale) was last used.
 - _____ Administer the appropriate pain medication based on your patient’s self-report.
 - _____ Educate the patient on the 0-to-10 scale and assess his or her pain intensity using it. Document the number of the pain intensity and the reason for the change in assessment tool.
 - _____ Assist the patient in repositioning, turn room lights low, and administer a backrub.
- 7 Vital signs are always reliable indicators of the intensity of a patient’s pain.
 - 1 True
 - 2 False
- 8 Older patients should not be given opioids for pain because they are too potent, even at low doses.
 - 1 True
 - 2 False
- 9 The best approach for giving analgesics for postoperative pain involves:
 - 1 Around-the-clock (ATC) on a fixed schedule
 - 2 Only when a patient requests it
 - 3 Only when the nurse decides that a patient has moderate-or-greater pain intensity
 - 4 Every hour while awake unless a patient refuses it
- 10 Why would a patient request an increased dose of pain medication?
 - 1 The patient is experiencing increased anxiety.
 - 2 The patient is requiring more staff and/or family attention.
 - 3 The patient is experiencing increased pain.
 - 4 The patient is experiencing beginning symptoms of addiction.

KEY TERMS

Advance directives	Brain death	Hospice	Palliative care
Autopsy	Grief	Organ/tissue donation	Postmortem care

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify a nurse's role in assisting patients and families in grief and at the end of life.
- Discuss principles of palliative care.
- Describe hospice care.
- Describe approaches to symptom management at the end of life.
- Discuss a nurse's role in facilitating autopsy and organ and tissue donation requests.
- Describe physiologic changes in impending death.
- Describe elements of postmortem care.

Nurses have historically played a vital role in the care of patients and families facing serious, life-limiting illness and death. They continue to expand their knowledge, leading the way in the development of compassionate, evidence-based palliative care (Ferrell and Coyle, 2010). The World Health Organization (2011) defines palliative care as an “approach that improves the quality of life of individuals and their families facing life-threatening illness, through the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychological and spiritual.” When patients receive relief from the symptoms caused by disease or treatment, they have a higher quality of life and are better able to participate in making health care decisions. Although this chapter focuses on end-of-life care, patients of all ages with any diagnosis receive palliative care, even as they seek treatment and cure for their illness.

At the end of life palliative care interventions help patients experience a “good death,” often through hospice care. Hospice, an interdisciplinary, patient- and family-centered program of total palliative care, helps people live as well as possible through the dying process. Patients are eligible for

hospice care as a Medicare or Medicaid benefit during the final phase of a terminal illness, usually the last 6 to 12 months of life. Because hospice is a philosophy of care, not necessarily a place, the services can be provided at home; in freestanding hospice facilities; or in nursing home, extended care, or acute care settings.

To receive hospice care at home, a family caregiver must be available to provide care when a patient is no longer able to function alone. Hospice team members offer 24-hour accessibility and coordinate care between the home and inpatient settings. As the time of a patient's death comes closer, the hospice team provides intensive support to the patient and family. Hospice benefits include respite for family caregivers, limited hospitalization for acute symptom management, and bereavement care after death (Hospice Foundation of America, 2010). Unfortunately many patients enter hospice care only a few days or weeks before death, limiting the amount of time they have to benefit from the nurses, physicians, social workers, volunteers, and spiritual care providers who make up the interdisciplinary team. Be familiar with the scope of hospice services qualifying criteria and educate patients and family members about this option for end-of-life care.

FIG 16-1 The nurse collaborates to develop an effective approach to symptom management.

Grief experiences in situations of serious illness and at the end of life have profound physical, psychological, social, and spiritual effects on dying persons, family members, friends, and caregivers. The grief associated with serious illness or death arises from many sources: fear of the unknown, pain, sadness about leaving loved ones behind, loss of control, or unresolved guilt. A nurse listens carefully to understand the significance of the loss to the patient or family members, identifies concerns, and assesses their ability to sustain hope and move forward in life.

Many symptoms that patients and families experience are caused by grief, illness, or medical treatments at the end of life. Examples of a patient's physical symptoms include pain, alterations in bowel and bladder elimination, nausea, loss of appetite, fatigue, shortness of breath, and mental status changes. Patients or family members also experience psychological symptoms such as anxiety, depression, or uncertainty because of lack of understanding of the disease, prognosis, or treatment plan. Spiritual distress often heightens a patient's perceptions of discomfort. Assess a patient's or family member's needs and strengths and initiate a plan of care for symptom management (Fig. 16-1).

At the time of death nurses provide compassionate care to patients and family members by offering information, guidance, and support and facilitating communication. As described in Skill 16-3, nurses provide postmortem care (i.e., care of the body after death) in a dignified manner, consistent with a patient's religious and cultural beliefs.

EVIDENCE-BASED PRACTICE

An extensive body of research supports the development of evidence-based palliative care. Research continues on the type and prevalence of symptoms, symptom management, pharmacologic interventions, use of advance directives, caregiver and nurse coping, and family decision making (Aoun et al., 2011; Benzein and Saveman, 2008; Daaleman et al., 2008; Johnstone and Kanit-saki, 2009).

Above all, nurses strive for positive patient-centered outcomes at the end of life. Researchers are studying what patients and family members perceive as important at the end of life, helping caregivers focus on behaviors that bring about the highest degree of patient and family satisfaction.

A systematic review of research literature focused on caregiver interventions that patients and family members described as satisfying care. The dominant themes of satisfaction that surfaced in

the research studies include accessibility, coordination of care, competence, communication and relationships, education, emotional support, personalization of care, and support for patient decision making (Dy et al., 2008). Research supports the use of the following strategies for expert palliative care nursing:

- Patients and family members are most satisfied when they receive attentive, compassionate care. Novice nurses who are grounded in authentic, openhearted, holistic nursing care practices are capable of providing valuable care to patients at the end of life.
- Personalize your plan of care. Discuss priorities and preferences for care with patients and family members regularly as changes in a patient's condition may shift care preferences and needs.
- Develop competence in providing symptom management, comfort care, emotional support, and caring personal interactions.
- Give as much time as needed to discuss a sensitive topic, maintain contact, and respond to requests promptly.
- Use teamwork and interdisciplinary communication to ensure coordination of care.
- Support patients' decision making and provide assistance with advance care planning to help them maintain a sense of control.

PATIENT-CENTERED CARE

Nurses caring for patients receiving palliative and hospice care maintain a patient-centered focus by developing a plan of care that gives highest priority to patient's values, quality of life, and care preferences. Because patients near the end of life depend on family caregivers to maintain a high quality of life and death, a nurse's care extends to family members and the patient. Patients and family caregivers know their needs and preferences and should be encouraged to share their care priorities and be given as many options as possible in making decisions (Wasserman, 2008).

Patients with life-limiting chronic illness often want to determine their own approaches to living with illness and symptom management and participate in self-care activities as long as possible (Johnston, 2010). Patient-centered care focuses on encouraging patients to set realistic goals and helps them identify ways to achieve them so they can maintain their usual routines and a sense of normalcy.

When patients with advanced illness are no longer able to participate in making decisions, they can communicate their values and preferences in an advance directive. Advance directives specify medical interventions such as mechanical ventilation that a patient does not want in certain situations and are also used to communicate the care a patient wants (e.g., pain relief) to the fullest extent possible (Mahon, 2010).

Patients describe their life values orally or in writing, indicating which types of treatments are acceptable or unacceptable to them should they lose their capacity to make health care decisions. There are many forms available to help guide patients and their family caregivers through the advance directive process (Five Wishes, 2011). Patients may also designate a person, a durable power of attorney (DPOA) for health care decisions who knows a patient's values well enough to make decisions when they are no longer able to do so. The Patient Self-Determination Act of 1991 requires that all health care agencies serving Medicaid and Medicare patients provide patients with information regarding advance directives.

Nurses facilitate the optimal use of advance directives. As helpful as advance directives are, many people do not have one or need help understanding their usefulness and how to prepare one

(Johnstone and Kanitsaki, 2009). Discussions about advance directives and goals of care involve the patient, DPOA, family members, and the interdisciplinary health care team. Communicate to the health care team a patient's desire to complete an advance directive and help the patient access the appropriate resources. If a patient has an advance directive, make sure to place a copy in the medical record and instruct him or her to give copies to their health care provider and family members. Be familiar with agency policies and state laws because they often differ from place to place.

Cardiopulmonary resuscitation (CPR), an emergency procedure providing artificial ventilation and manual external cardiac massage, is used in cases of cardiac and/or pulmonary arrest. CPR is performed on a patient who has a cardiopulmonary arrest unless the patient's health care provider has written and signed a "do not resuscitate" (DNR) or "no CPR" order. Adults in consultation with the health care team may consent to a DNR status verbally or in writing. Assure patients who choose not to be resuscitated that they will continue to receive full palliative care and symptom relief. Patients who are receiving hospice care in an agency must also specifically designate their DNR status to agency personnel.

Patient-centered care respects patients' cultural heritage. Human responses to illness, death, and grief are transmitted from generation to generation through family and culture. Cultural norms influence family, gender, and community roles at the time of death. Culture also affects the meaning of pain and suffering, how one expresses grief and emotion, and ideas about an afterlife. Given the wide range of cultural beliefs, first engage in self-reflection on your own cultural and personal beliefs regarding loss and death. Gather knowledge on common end-of-life cultural or religious practices and then validate through nurse-patient discussions the relevance of those practices for a particular patient of that culture or religion (Giger, 2013).

Cultural differences influence communication at the end of life. For some people discussing death is taboo. Some people believe in the authority of the healer or the power of words. They fear that informing a patient that he or she has a serious disease brings about a poor outcome. Contrast this belief with Western cultural practices of full disclosure, honesty, informed consent, and the belief that "talking through" things helps with emotional adjustment (Erichsen et al., 2010). Caregivers who rely on biomedical interventions in the face of serious illness or impending death feel conflict with patients and families who rely mainly on spiritual interventions or afterlife considerations.

Cultural differences also influence processes such as obtaining informed consent or making life-support decisions. Research shows that ethnicity and culture are strongly related to attitudes toward life-sustaining treatments during terminal illness and the use of hospice services (Washington et al., 2008). Religious and cultural practices also govern how to care for a body near or after death (Pattison, 2008). An overview of selected religious and cultural considerations in the care of the body near or after death can be found in Box 16-1.

Safety Guidelines

1 Patients receiving palliative or hospice care are particularly vulnerable and need nurse advocates.

BOX 16-1 Religious and Cultural Considerations in Care of the Body Near and After Death

Buddhism—People prefer a quiet place for death. A Buddhist monk may chant to promote a peaceful, accepting mind in the dying person. Incense may be used. When the person has died, the body should be covered with a cotton sheet. Others should not touch the body, and the deceased's mouth and eyes are left open. Maintain strict silence after death. Autopsy and organ donation are permitted.

Christianity—Christianity has many denominations with varying practices, as do other world religions. Bible texts may be read near or at the time of death. Protestant Christians receive the sacraments of Holy Communion or sometimes baptism. Christians in the Roman Catholic tradition often request sacraments of Penance, Anointing of the Sick, and Holy Communion at the end of life. Many Christian groups offer prayers and anointing and view death as "going home" to Jesus. There are no prescribed rituals for body preparation, and autopsy and organ donation are usually permissible.

Hinduism—Persons prefer to die at home or in a quiet setting. Because of a belief in reincarnation, efforts are made to resolve relationships before death. The head of a person nearing death should face the east with a lamp placed near the head. If the dying person is unable to chant his mantra, a family member can chant it into the right ear. Passages from the Bhagavad Gita are recited. Family members prefer to wash the body after death and are present to chant, pray, and use incense. Hindus prefer cremation of the body.

Islam—A Muslim reader recites verses from the Qur'an when the person is near death. Family members prepare the body, and non-Muslims should not touch it. After death the person's eyes should be closed, and arms and legs straightened. Autopsy or organ donation is generally not permissible, except as required by law.

Judaism—Deathbed confessional, blessings, and readings from the Torah are traditional in Orthodox Judaism. A family member remains with the body until burial, which takes place within 24 hours, not on the Sabbath. A family member closes the deceased's eyes on death. Synagogue burial societies may prepare the body, which is wrapped in white linen. Organ donation prohibitions may exist in Orthodox Judaism, but not for all Jews. Autopsies may be considered if organs are not removed.

- 2 Patients at the end of life frequently receive potent medications for symptom management, are often weak or frail, and have limited reserves. Medication errors can cause an earlier-than-anticipated death or may postpone the time of death or cause prolonged suffering (Dietz et al., 2010).
- 3 Patients at the end of life or with cognitive deficits lose their capacity to report side effects, evaluate treatments, or participate in decision making. Caregivers must make frequent assessments and carefully observe patient behaviors and responses.
- 4 Proper patient identification, especially in communicating the patients' DNR or CPR status, ensures that caregivers will not initiate unwanted and unhelpful medical interventions. Know your agency's methods for designating a patient's resuscitation status.

SKILL 16-1 Supporting Patients and Families in Grief

People suffer losses and experience grief throughout life. Losses are described in several ways: necessary, actual, perceived, maturational, and situational. Necessary losses such as leaving friends after high school graduation are a natural part of life. Such losses are usually replaced by something different or better. Some necessary losses such as the death of a loved one are more difficult and never seem acceptable. A person experiences an actual loss when an object or person can no longer be felt, heard, or experienced. Examples include the loss of a person or a destroyed home. Perceived losses are uniquely interpreted by an individual and are often not obvious to others. For example, one person perceives a failure to get into a specific college as a lost opportunity, whereas for another person that event is a relief. Maturational losses occur as a part of normal life development. For instance, a parent feels loss when a child moves away from home. Situational losses include loss from sudden, unpredictable external events such as natural disasters. All types of loss can cause grief and a need for adjustment.

Hospitalization, chronic illness, and disability involve multiple losses. Hospitalized patients lose privacy and control over normal routines. With chronic illness a person's body no longer functions as it once did, leading to a loss of self-esteem and social roles. Disability creates financial insecurity and often threatens interpersonal relationships. Death separates people from the physical presence of a person in their lives.

Grief

Grief is the emotional response to a loss, manifested in ways unique to an individual and based on personal experiences, cultural expectations, and spiritual beliefs (Walter and McCoyd, 2009). Coping with grief involves a period of mourning (i.e., the outward, social expressions of grief and the behavior associated with loss). Mourning behaviors and rituals help grieving individuals adapt to loss, receive social support, adjust expectations, and go forward in life. Most mourning rituals are culturally influenced, learned behaviors. Bereavement includes grief and mourning (i.e., the inner emotional responses and outward behaviors in response to loss) (ELNEC, 2008). A person's psychological makeup, personal experiences, family, cultural expectations, and spiritual beliefs influence how he or she grieves (Hooyman and Kramer, 2008). The depth and duration of grief (i.e., one's inner emotional response to loss) depends on the type of loss and the person's perception of the loss.

As a nurse help patients by understanding types of grief. Normal or uncomplicated grief is evidenced by feelings, behaviors, and reactions associated with loss such as sadness, anger, crying, resentment, and loneliness. Families may feel the presence of the lost

person and yearn for his or her return. They may find it difficult to resume life as it was before their loss. An uncomplicated grief experience often helps a person mature and develop life perspective. Anticipatory grief occurs before an actual loss or death and involves gradual disengagement from what is being lost. For example, if the dying process extends over a long period of time, the patient and family prepare for death before it occurs and sometimes, but not always, display fewer common grief responses at the time of death (Simon, 2008). Complicated grief occurs when a person has difficulty moving through the grief experience (Field and Filanosky, 2010). Grief may be chronic (lasting over long periods of time), delayed (suppressed until a much later and unexpected time), exaggerated (overwhelming grief that is expressed in self-destructive behaviors), or masked (unaware that disruptions in normal functions are a result of the loss).

Remember that people do not experience grief in the same way. Some people do not report feeling distressed or depressed, and others feel distressed for a lifetime without negative consequences. Not all people want to process the emotional experience of grief and focus instead on resilience, growth, or positive outcomes after a loss (Holman et al., 2010).

Use basic knowledge of grief responses to support patients and their families and to address other common psychosocial and spiritual symptoms at the end of life such as fear and loneliness. Personality type and culture influence the extent to which individuals share emotions or find it helpful to talk about their grief. Some patients talk openly about their approaching death, and others choose not to acknowledge it. Health care providers, depending on their own personal and cultural understandings of grief and death, often avoid initiating conversations on these difficult topics. Provide opportunities for discussion, paying close attention to a patient's response and indications of a desire to talk further (Wittenberg-Lyles, 2010).

Delegation and Collaboration

The skills of assessing patient's or family member's grief reactions and designing appropriate interventions cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Inform the nurse when a patient or family member exhibits behavior commonly associated with grief (e.g., crying, anger, withdrawal).
- Form supportive relationships with patients and families and inform the nurse when patients or family members have questions or concerns.
- Alert the nurse to the arrival of family members so the nurse can discuss the plan of care and offer support.

STEP

RATIONALE

ASSESSMENT

- 1 Sit near patient in a quiet, private location. Center yourself and establish a quiet presence. Establish eye contact. Be aware that use of eye contact in some cultures conveys disrespect or discomfort.
- 2 Consider the influence of patient's age, gender, race, language, religion, culture, and socioeconomic status on communication.
- 3 Listen carefully, observing patient responses. Use open communication to develop a genuine, caring nurse-patient relationship.

Presence expresses caring and creates healing moments (Gauthier, 2008; Newman, 2008). Privacy protects confidentiality and promotes a sense of safety for patient when expressing thoughts and emotions.

Individual differences influence patient's grief response and communication style (Hooyman and Kramer, 2008).

A nurse establishes trust in a caring relationship, listens to the patient, and demonstrates a desire for communication (Galvin and Todres, 2009; Lowey, 2008).

STEP	RATIONALE
<p>4 Determine meaning of the loss to patient and its type, suddenness, and when it occurred. Use open-ended questions such as:</p> <ul style="list-style-type: none"> • “Tell me about your family.” • “What concerns do you have about how your illness will affect your family?” 	<p>The type, meaning, suddenness, and time elapsed since the loss influence the grief experience and coping methods.</p>
<p>5 Combine knowledge of grief theory with observation of patient behaviors. Validate observations by sharing them with patient; paraphrase, clarify, or summarize, as in the following examples:</p> <ul style="list-style-type: none"> • “You’ve mentioned several times that you feel hopeless.” • “It seems that this is hard for you to talk about.” • “You look sad. Is there something in particular that brought on your tears?” 	<p>Use information about type and stage of grief to guide discussion, not to judge patient’s responses. Confirms accuracy of your observations and validates patient’s feelings. Prompts patient to continue.</p>
<p>6 Encourage patient to describe the loss and its impact on daily life (e.g., “You said your diagnosis changed your life forever. Tell me more.”).</p>	<p>Listening to patient’s description helps to minimize assumptions.</p>
<p>7 Ask patient to describe the coping strategies that he or she uses most often in difficult times (e.g., “What or who helps you in times of crisis?”).</p>	<p>Familiar, effective coping strategies are often helpful in the current crisis, loss, or grief experience.</p>
<p>8 Assess family caregivers’ unique needs and resources. Note if patient receives care at home and who gives the care.</p>	<p>Illness significantly affects family relationships. Although family members experience similar issues, their needs may differ.</p>
<p>9 Assess patient’s spiritual needs and resources, focusing on aspects likely to be involved (e.g., trust, life purpose, faith/belief, and hope).</p>	<p>Situations of loss and grief often challenge or strengthen spiritual concepts such as meaning, hope, community, and a sense of God’s presence (Daaleman, 2008; Penman et al., 2009).</p>

NURSING DIAGNOSES

- | | | |
|---|---|---|
| <ul style="list-style-type: none"> • Caregiver role strain • Complicated grieving • Compromised family coping • Death anxiety • Fear | <ul style="list-style-type: none"> • Grieving • Ineffective coping • Ineffective denial • Readiness for enhanced family coping • Readiness for enhanced hope | <ul style="list-style-type: none"> • Readiness for enhanced spiritual well-being • Risk for caregiver role strain • Risk for complicated grieving • Risk for spiritual distress |
|---|---|---|

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedures:</p> <ul style="list-style-type: none"> • Patient maintains relationships with significant people. • Patient expresses grief in keeping with his or her cultural and religious practices. • Patient uses effective coping strategies. • Patient maintains normal life routines. 	<p>Patient in grief or loss retains connections with social network. Patient receives support necessary to retain cherished values and ways of being. Patient identifies a sense of relief. Patient adjusts to life-changing circumstances and maintains a sense of control.</p>
---	--

IMPLEMENTATION

<p>1 Show an empathic understanding of patient’s strengths and needs.</p>	<p>Promotes nurse-patient trust, caring, and reciprocity (Betcher, 2010; Wright et al., 2009).</p>
<p>2 Offer information about patient’s illness and clarify misunderstandings or misinformation.</p>	<p>Misunderstanding adds to patient’s uncertainty, anxiety, and suffering.</p>
<p>3 Encourage patient to sustain relationships with others to help maintain independence and receive necessary help. Include patient-identified support persons in discussions.</p>	<p>Affiliation with others offers support and helps patient stay engaged in life.</p>
<p>4 Help patient achieve short-term goals (e.g., symptom relief, completion of tasks, resolution of relational problems).</p>	<p>Helping patients identify and meet their personal goals contributes to their quality of life.</p>
<p>5 Provide frequent opportunities for patient and family members to express their fears and concerns. Be attentive to expressions of intense emotions.</p>	<p>Emotions change quickly and frequently at stressful times and complicate communication for nurses and patients (Hultman et al., 2008).</p>
<p>6 Help patients and family caregivers identify and solve problems. Encourage use of available resources (e.g., hospice, respite care, palliative care team, and support groups).</p>	<p>Facilitates family grief resolution and reduces caregiving stress. Solving caregiving problems results in better patient care (Spichiger, 2008).</p>

STEP

- 7 Instruct patient in relaxation strategies, guided imagery, meditation, hand massage, healing touch, or acupressure.
- 8 Encourage visits with loved ones, life review with stories or photographs, or projects such as organizing photo albums or journal writing.
- 9 Address patient's spiritual needs by facilitating religious/spiritual practices and connections with religious community, prayer, music, and providing a listening presence. Make a referral to a spiritual care provider.

RATIONALE

Complementary therapies effectively reduce stress and provide useful coping strategies (Mariano, 2010; Osaka et al., 2009). Patient sees that life still has meaning and dignity and creates a legacy (Butler, 2009; McSherry, 2011).

Spiritual interventions help patients maintain hope and connect with the things at the core of their identity. Caregivers who connect meaningfully with patient need to initiate interventions (Benzein and Saveman, 2008; Daaleman, 2008).

EVALUATION

- 1 Note patient descriptions of relationships and activities with others.
- 2 Observe patient's behaviors during ongoing interactions.
- 3 Elicit patient perceptions of benefit gained from use of coping interventions.
- 4 Discuss progress toward performing routine activities at home.

Provides information on the extent to which patient retains relational ties.

Demonstrates patient's ability to express grief and coping. Evaluates efficacy of interventions.

Evaluates patient's achievement of desired goals or need for goal revision.

Unexpected Outcomes

- 1 Patient does not acknowledge loss and shows signs of extreme sorrow, anger, withdrawal, or denial.
- 2 Family and patient relationships do not give patient needed support.

Related Interventions

- Consider referral to a grief specialist professional (e.g., nurse practitioner, psychologist, spiritual care provider).
- Share and validate observations of family strain or patient concern over family interactions.
- Consider a family-patient discussion with health care team.

Recording and Reporting

- Record interventions used to support patient coping and note patient's verbal and nonverbal responses in nurses' notes and electronic health record (EHR).
- Report patient's grief reactions to members of the interdisciplinary team, noting behaviors that affect health outcomes such as treatment refusals or prolonged inactivity.

Special Considerations

Teaching

- Give family caregivers basic information about common grief responses and how to offer support. Coach them on ways to provide emotional and spiritual support to patient and one another (e.g., listening attentively, avoiding false reassurances, allowing for the expression of difficult emotions, talking about normal family activities).

Pediatric

- Children's understanding of death, influenced by age and developmental level, differs from that of adults. Respect parents' wishes about when and what to tell children about illness or

death. When discussing sensitive topics with children, encourage parents to offer caring explanations at a level a child is able to understand.

- Play therapy or drawing helps children express thoughts, emotions, or fears about illness or death.
- Be alert to all family members' grief reactions because they may feel guilt, resentment, or helplessness with the illness or death of a sibling, child, or grandchild. Facilitate communication with family members who must be separated from the child.
- Surrogate decision makers, usually the parents, need to make health care decisions for infants and young children. Some decisions are difficult because outcomes in children are often unpredictable.

Gerontologic

- Many older adults have coexisting medical conditions that add to their symptom burden. They have also lived long enough to have experienced cumulative losses, including members of their family and support group, which complicates their grief experience (Derby et al., 2010).

SKILL 16-2 Symptom Management at the End of Life

Quality palliative care centers on vigilant symptom management. Patients living with life-limiting illness often experience multiple, complex physical, emotional, and spiritual symptoms (Aoun et al., 2011). Managing patients' symptoms at the end of life begins by understanding the impact that these symptoms have on patients' lives from their point of view (Fig. 16-2). Assess all symptoms thoroughly because a patient's fear of not being heard or believed compounds the magnitude of symptoms. Patients identify pain

as their most common and severe symptom (see Chapter 15). In addition to the psychological and spiritual interventions discussed in Skill 16-1, nurses manage physiologic symptoms at the end of life.

Delegation and Collaboration

The skill of symptom management can be delegated to nursing assistive personnel (NAP). The nurse must conduct the initial

FIG 16-2 Nurses use their presence and therapeutic communication to assess how symptoms affect a patient's life.

assessments of symptoms, but the NAP can assist with supportive care. The nurse directs the NAP to:

- Notify the nurse if patient reports new symptoms or if existing symptoms worsen or change.
- Provide basic comfort care such as positioning, room temperature control, hygiene, and mouth care.
- Report possible adverse effects of drug therapy as instructed by the nurse.
- Speak to unconscious or dying patients because hearing is the last sense to diminish.

STEP

RATIONALE

ASSESSMENT

<p>1 Ask patients to describe symptoms in their own words. Use open-ended prompts such as “Describe your leg pain to me,” or “Tell me about how you are sleeping since you started taking this medication.”</p> <p>2 Allow sufficient time for patients to describe their symptoms and encourage them to say more:</p> <ul style="list-style-type: none"> • “Is there anything else bothering you?” • “You’ve told me about your ____ pain. Do you have pain anywhere else?” <p>3 Assess patient’s pain severity on a scale of 0 to 10 and assess other characteristics of pain routinely with all new reports (see Chapter 15).</p> <p>4 Perform hand hygiene.</p> <p>5 Assess respiratory rate, breathing patterns, and lung sounds. Ask if patient feels that he or she is getting enough air. Assess for presence of airway secretions.</p> <p>6 Observe condition of skin, especially back, heels, and buttocks (see Chapter 6).</p> <p>7 Inspect patient’s oral cavity, including mucosa, tongue, and teeth (see Chapter 6).</p> <p>8 Assess bowel function (see Chapter 34):</p> <ul style="list-style-type: none"> a Determine usual bowel elimination pattern (frequency, character, usual time of day) and effectiveness of usual bowel-management routines. b If patient is passing liquid stool, assess for presence of a fecal impaction (see agency policy). c Review medication regimens, prescription and over-the-counter drugs known to cause constipation (e.g., opioids, antacids). d Identify typical food and fluid intake over 1 week and activity levels. <p>9 Assess urinary elimination (see Chapter 33) and ability to control urination. If incontinent, assess for potential complications (e.g., skin breakdown or patient discomfort).</p>	<p>Allows patients to describe their personal perceptions and experiences of symptoms.</p> <p>Ensures a more complete assessment. Prevents you from making assumptions about patient’s symptoms, prematurely stopping the assessment process.</p> <p>Consistent use of a standard pain scale helps assess changes in patient pain levels and evaluate effectiveness of pain interventions (Paice, 2010).</p> <p>Reduces transmission of microorganisms.</p> <p>Dyspnea, air hunger, or shortness of breath results from metabolic or respiratory changes. Near the end of life, Cheyne-Stokes respirations are common and are characterized by alternating periods of apnea and hyperpnea.</p> <p>Decreased peripheral circulation and activity level contribute to skin breakdown.</p> <p>Dehydration, difficulty swallowing, and inflammation of the mouth are common. Bacterial colonization of the mouth increases with age, reduced salivary flow, medications, and immunosuppression (Rohr et al., 2010).</p> <p>Patients experience constipation because of decreased intestinal motility, fluid intake, and activity and increased anal sphincter tone from pain medications, especially opioids (Kyle, 2010).</p> <p>Diarrhea results from infections, diseases, or medications (e.g., antibiotics or chemotherapy).</p> <p>Watery stool leaking around blockage indicates fecal impaction.</p> <p>Medications can alter bowel elimination patterns.</p> <p>Bowel elimination patterns are influenced by oral intake and activity levels.</p> <p>Urinary incontinence results from progressive disease (e.g., spinal cord involvement and reduced level of consciousness) (Kyle, 2010).</p>
--	--

STEP	RATIONALE
10 Assess patient's appetite and for presence of nausea or vomiting.	Medications, pain, depression, disease progression, or decreased blood flow to digestive organs near death often contribute to nausea, vomiting, and decreased appetite.
11 Assess daily food and fluid intake in relation to patient's condition and preferences.	Intake affects fluid balance.
12 Assess fatigue using a general scale in patients near the end of life (none, moderate, severe). Ask if fatigue limits patient's ability to perform desired activities (see Chapter 10).	Metabolic demands of a disease and treatments cause weakness and fatigue.
13 Assess for excessive restlessness in patient near death.	Terminal restlessness (delirium) causes significant patient and caregiver stress (Heidrick and English, 2010).
a Assess for pain, nausea, dyspnea, full bladder or bowel, poor sleep patterns, anxiety, or joint pain from immobility.	Determines presence of common physical problems that need to be treated or ruled out as causative factors.
b Review medical record for hypercalcemia, hypoglycemia, hyponatremia, or dehydration.	Metabolic imbalances cause restlessness or delirium.
c Review patient's medications.	Unintended responses to medications result in changed activity states.
d Determine if patient has unresolved emotional or spiritual issues.	Spiritual distress contributes to restlessness or increased pain.

NURSING DIAGNOSES

- | | | |
|--------------------------|---------------------------------|---------------------------------|
| • Acute pain | • Diarrhea | • Ineffective breathing pattern |
| • Anxiety | • Fatigue | • Ineffective tissue perfusion |
| • Chronic pain | • Nausea | • Risk for constipation |
| • Constipation | • Impaired oral mucous membrane | • Total urinary incontinence |
| • Deficient fluid volume | • Impaired swallowing | |

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:	
• Patient reports acceptable level of pain.	Indicates pain control.
• Patient reports feeling warm and comfortable.	Warming interventions help reverse effects of reduced peripheral circulation.
• Patient reports comfortable eating and drinking patterns.	Optimal food and fluid intake are based on patient preferences and comfort.
• Patient has soft, formed bowel movements.	Indicates adequate bowel function and peristaltic activity.
• Skin remains free of irritation or breakdown.	Interventions to protect the skin from bowel or urinary incontinence are effective.
• Patient is not restless.	Therapies have a calming effect.
• Patient reports less distress from fatigue.	Energy conservation methods are effective; patient adjusts to changes in activity level.
• Patient experiences less respiratory distress.	Patient is less apprehensive and breathes easily.

IMPLEMENTATION

1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Administer medications and initiate nonpharmacologic pain management interventions (see Chapter 15):	Well-timed interventions keep pain from escalating. Pain decreases patient's sense of well-being and activity.
a Provide patient education on causes and patterns of pain and explain interventions.	Patient's knowledge of pain and interventions allows him or her to maintain some control (Paice, 2010).
3 Provide general comfort measures:	
a Provide bath and skin care based on patient's preferences and hygiene needs (see Chapters 17 and 18).	Daily baths are not always desired or necessary at end of life if they cause discomfort, fatigue, or increased pain.
b Provide eye care and use artificial tears in patients with decreased consciousness (see Chapter 19).	Eye irritation causes pain. Blink reflex diminishes near death, causing drying of cornea.
c Reposition frequently; do not position on tubes or other objects.	Prolonged, even slight pressure from weight of patient's body or objects causes skin injury.

STEP	RATIONALE
<p>4 Provide oral hygiene after meals and at bedtime while awake and more frequently in mouth-breathing or unconscious patients (see Chapter 17).</p>	<p>Mouth rinses are effective in removing oral debris and cleaning the mouth. Dehydration develops as patient experiences metabolic changes and fluid intake declines.</p>
<p>a Use antifungal oral rinses as prescribed or sodium bicarbonate or normal saline rinses.</p>	<p>Patients near death breathe through the mouth, drying oral mucosa.</p>
<p>b Moisten lips with nonpetroleum balm.</p>	
<p>5 Initiate bowel-management regimen to reduce risk for constipation:</p>	<p>Interventions improve peristalsis and soften fecal mass (Enck, 2009).</p>
<p>a Increase fluid intake if medically tolerated and preferred by patient.</p>	
<p>b Encourage physical activity (e.g., walking) if tolerated.</p>	
<p>c Administer daily stool softener or laxative, especially in patients using opioids for pain management; give enemas as needed.</p>	
<p>6 Provide low-residue diet for diarrhea; treat infections or discontinue medications if possible. Administer antidiarrheal medications.</p>	<p>Patients with chronic diarrhea require rigorous skin care to promote comfort. They are also at risk for dehydration and thirst (Kyle, 2010).</p>
<p>7 Address urinary incontinence with intervention appropriate for patient's conditions (e.g., condom catheter, indwelling urinary catheter, adult incontinence pads [see Chapter 33]).</p>	<p>Urinary output declines near death, making it possible to manage incontinence without an indwelling catheter. Consider an indwelling catheter if skin integrity, patient preference, or fatigue from bed changes becomes an issue.</p>
<p>8 Offer patient favorite foods in amount and at time patient desires. Do not overly encourage patients to eat.</p>	<p>Near-death patients have little desire for food and water as body functions slow. Little evidence exists that anorexia or dehydration causes patient discomfort (Acreman, 2009).</p>
<p>a Treat nausea by administering antiemetics rectally as prescribed. As nausea subsides, offer clear liquids and ice chips. Avoid caffeinated liquids, milk, and fruit juices.</p>	<p>Gastrointestinal (GI) mucosa tolerates clear liquids more readily. Certain liquids increase stomach acidity.</p>
<p>b Consider presence of nausea in patients receiving enteral feedings.</p>	<p>Patients who have decreased consciousness are unable to report nausea.</p>
<p>9 Manage fatigue.</p>	<p>Strategies to conserve energy and reduce fatigue allow for completion of desired activities. Conserve patient energy by modifying environment (Kehl, 2008).</p>
<p>a Balance activity and rest periods according to patient's priorities, energy level, and preferred time of day. Eliminate extra steps in activities.</p>	
<p>b Explain care activities before performing and include patient in setting daily schedule.</p>	<p>Minimizes anxiety and maintains patient's autonomy and involvement</p>
<p>c Assist ambulatory patients with physical activity.</p>	<p>Fatigued patients may need assistance and monitoring to ensure patient safety.</p>
<p>d Incorporate safe exercise (e.g., walking, yoga) in activity plan for patients with advanced stage cancer.</p>	<p>Research has shown that, even for people with advanced stage cancer, exercise decreases anxiety, stress, and fatigue (Albrecht and Taylor, 2012).</p>
<p>10 Support patient's ventilatory efforts.</p>	<p>Promotes maximal ventilation, lung expansion, and drainage of secretions.</p>
<p>a Position for comfort in semi-Fowler's or Fowler's position.</p>	<p>Deep airway suctioning causes discomfort and is not effective in reducing airway noise or secretion clearance (Hipp and Letizia, 2009).</p>
<p>b Position patient near death on side to decrease noisy respirations. Elevate head to facilitate postural drainage. Turn from side to side to mobilize and drain secretions. Suction only if necessary.</p>	
<p>c Provide ordered anticholinergic medications.</p>	<p>Medications reduce saliva and excessive secretions.</p>
<p>d Stay with patients experiencing dyspnea or air hunger. Use interventions that patients perceive as relieving their shortness of breath (choice of oxygen delivery modes, fan near face, body position). Administer opioids or anxiolytics as prescribed. Keep room cool with low humidity.</p>	<p>Sharing control with patients reduces anxiety that contributes to feelings of air hunger. Morphine relieves perception of dyspnea and dries secretions. Air movement stimulates trigeminal nerve in cheek, which decreases dyspneic sensation. Use of oxygen has little benefit unless patient feels better using it (Balkstra, 2010).</p>
<p>11 Manage restlessness.</p>	<p>Reduces unnecessary external stimulation and provides a comforting space.</p>
<p>a Keep patient's room quiet with soft lighting and at comfortable temperature. Offer family members opportunities to maintain close contact. Encourage use of soft music, prayer, or reading from patient's favorite book.</p>	<p>Privacy allows family members chance to provide verbal assurances and touch. The presence of a family member to hold a hand provides a calming effect (Pasacreta et al., 2010).</p>

STEP

- b** Use least-sedating pharmacologic means possible to control restlessness. Consult with interdisciplinary team for titration of medication (haloperidol or lorazepam). Discontinue all nonessential medication. Use subcutaneous, transdermal, sublingual, or rectal medication delivery routes.

RATIONALE

Reduce delirium without making patient unconscious. Control of restlessness relieves family's concern that patient is in pain or distress. Discontinuation of unnecessary medications makes drug interactions less likely. Use least-invasive route for patient comfort (Balkstra, 2010).

EVALUATION

- 1 Ask patient to rate pain on scale of 0 to 10 (see Chapter 15) and evaluate pain characteristics. Assess behavior in nonverbal patients.
- 2 Ask patient to describe mouth comfort and inspect oral cavity.
- 3 After patient defecates inspect feces.
- 4 Observe skin condition.
- 5 Ask patient to rate fatigue (scale of 0 to 10). Observe for fatigue or shortness of breath when patient performs activities.
- 6 Observe patient's respiratory patterns and ask him or her if breathing is easy and comfortable.
- 7 Observe patient's behavior or ask family to report on it. Note level of restlessness.

Determines extent of pain relief.

Evaluates condition of oral cavity and ability to chew or swallow. Determines character of stool.

Determine if skin tears or areas of pressure are present. Determines if patient is less distressed with activity.

Determines if respiratory distress is relieved.

Determines level of comfort and extent of restlessness.

Unexpected Outcomes

- 1 One or several symptoms remain unresolved, with patient reporting little or no relief.
- 2 Patient becomes anxious, fearful, or exhausted as a result of continued symptoms.

Related Interventions

- Increase frequency of or change an intervention. Try combination therapies.
- Give patients therapy choices and try different interventions. Explain goals of therapies and possible reasons for symptoms.
- Answer call lights quickly and explain plan of care throughout the day.

Recording and Reporting

- Record detailed description of patient symptoms in nurses' notes, EHR, and/or appropriate flow sheets. Use consistent descriptors for comparison over time.
- Record type of interventions used and patient's response in nurses' notes and EHR. Note successful interventions in the care plan.
- Report unexpected new symptoms or uncontrolled existing symptoms to health care provider.

Special Considerations

Teaching

- Involve family members in the patient's care (Fig. 16-3). With proper instruction they can perform most symptom

FIG 16-3 Involve family in patient's care.

management interventions, deliver personal care (e.g., bathing, oral hygiene), and administer medications in the home setting.

Pediatric

- Allow young children to visit a dying parent or grandparent if desired. Encourage parents to express their concerns about how to talk about death and loss with their child.
- Teach parents how to recognize and assess pain in a nonverbal child.
- Encourage involvement of siblings of a child who is dying, based on their needs and readiness.

Gerontologic

- Include older adults in conversations and accommodate communication limits (e.g., hearing deficits).
- Older adults need companionship and maintenance of self-esteem. Detached caregiver behaviors such as being slow to respond to physical discomforts, failing to keep room odor free, and speaking in hushed tones of voice are often perceived by the person as abandonment. Encourage a family member, friend, sitter, or hospice volunteer to stay with the patient during the night. Some older adults who have developed a lifestyle around aloneness prefer solitude. Be sensitive to patient's preferences (Ebersole et al., 2008).
- Assessing and addressing pain in an older adult who is cognitively impaired or nonverbal is sometimes difficult and involves proactive symptom management.

Home Care

- Recommend that family members monitor their own energy levels and request respite care when they need relief. Suggest resources for help with meals, shopping, or staying with the patient while family goes out.

SKILL 16-3 Care of a Body After Death

Nurses provide postmortem care in home and institutional settings, caring for a deceased person's body with sensitivity and in a manner consistent with a patient's religious or cultural beliefs. Maintaining the integrity of rituals and mourning practices gives families a sense of some familiarity and control in the face of death. Individual variations exist within cultural and religious groups (see [Box 16-1](#)).

Two legal considerations arise at the time of death. First, the 1986 Omnibus Budget Reconciliation Act (OBRA) legally requires that a patient's survivors be made aware of the option of organ and tissue donation. In most states citizens can sign the back of their driver's license if they wish to be an organ or tissue donor. However, a family member still usually gives consent for donation at the time of death. Patients may indicate their wish to donate organs and tissue in an advance directive.

In the case of vital organ donation (e.g., heart, lungs, liver, pancreas, or kidneys), a patient must remain on life support until the organs are surgically removed. A nurse's role in organ procurement includes helping to identify potential organ donors, providing care for the donor's body, and caring for the family throughout the donation process ([Matzo and Hill, 2010](#)). Family members often need help understanding what "brain death" (i.e., the irreversible absence of all brain function, including the brainstem) means for a person who has died. Patients appear to still be alive because life support keeps the deceased's organs functioning until they can be retrieved. Tissues such as eyes, bone, and skin are retrieved from deceased patients not on life support. Because of the sensitive nature of making requests for organ donation, professionals educated in organ procurement often assume that responsibility. They inform family members of their options for donation, provide information about costs (no cost to the family), and inform them that donation does not delay funeral arrangements.

Nurses also play a role in the donation request process. Facilitate the conversation by providing a private place and helping to identify the surrogate to be involved in the request. Sometimes you notify the local donor registry to determine if a patient qualifies for organ donation because certain medical conditions prohibit donation. Reinforce explanations of the procedure and inform the family about how you will care for the deceased's body. Above all, honor the family's cultural and religious practices concerning organ and tissue donation and support their final decision. Donor families often report that donating organs helped them in their grief and that they felt positive about the experience.

The second procedure of legal and medical significance often performed after a death is an autopsy, or postmortem examination. An autopsy, the surgical dissection of a body after death, helps

determine the exact cause and circumstances of a death, discover the pathway of a disease, or provide data for research purposes. It is not performed in every death. State laws determine when autopsies are required, but they are usually performed in circumstances of unusual death (e.g., violent trauma; unattended, unexpected death in the home) and when death occurs within 24 hours of hospital admission ([Matzo and Hill, 2010](#)). Be available to answer questions and support the family's choices. Autopsies normally do not delay burial or change the appearance of the deceased, but there may be a cost to families. The patient's legal representative and the health care provider or designated requester must sign a consent form. If appropriate, explain the value that autopsies have for advancing medical knowledge.

After death the body undergoes many physical changes, including loss of skin elasticity and change in body temperature (algor mortis), purple discoloration of the skin (livor mortis), and a stiffening of the body (rigor mortis). Provide postmortem care as soon as possible to prevent tissue damage or disfigurement. To prevent livor mortis of the face, elevate the head of the bed 30 degrees immediately after death and before beginning other activities.

Delegation and Collaboration

The skill of care of a body after death can be delegated to nursing assistive personnel (NAP). However, it is often best for the nurse and NAP to work together in providing postmortem care. The nurse directs the NAP to:

- Follow agency policy in cases of autopsy or organ and tissue donation.
- Honor family cultural or religious rituals when performing postmortem care.
- Handle the body with dignity and respect for privacy.

Equipment

- Clean gloves and isolation gown
- Plastic bag for hazardous waste disposal
- Washbasin, washcloth, warm water, and bath towel
- Clean gown or disposable gown for body as indicated by agency policy
- Shroud kit with name tags
- Syringes for removing urinary catheter
- Scissors
- Small pillow or towel
- Paper tape, gauze dressings
- Paper bag, plastic bag, or other suitable receptacle for patient's belongings to be returned to family members
- Valuables envelope

STEP

RATIONALE

ASSESSMENT

- 1 Ask health care provider to establish time of death and determine if he or she has requested an autopsy. If an autopsy is planned or a possible crime is involved, use special precautions to preserve evidence (see agency policy).
- 2 Determine if family members or significant others are present and if they have been informed of the death. Identify patient's surrogate (next of kin or durable power of attorney [DPOA]).

Certifies patient's death. Autopsy requested to determine cause of death and learn more about a disease.

Verifies that family has been notified of patient's death to avoid inappropriate communication of this sensitive information.

STEP	RATIONALE
3 Determine if patient's surrogate has been asked about organ and tissue donation and validate that donation request form has been signed. Notify organ request team per policy.	Federal guidelines require documentation that request has been made.
4 Provide family members and friends a private place to gather. Allow them time to ask questions or discuss grief.	Creates safe environment for grieving family. Questions provide information about how they are coping with loss and their needs.
5 Ask family members if they have requests for preparation or viewing of the body (e.g., position of body, special clothing, shaving). Determine if they wish to be present or assist with care of the body.	Respects individuality of patient and family and supports their right to having cultural or religious values and beliefs upheld. Provides closure for those who wish to help with body preparation.
6 Contact a support person (spiritual care provider or staff member) to stay with family members not helping to prepare the body.	Provides family support during an emotional time.
7 Consult health care providers' orders for special care directives or specimens that are to be collected.	Specimens may be used in determining cause of death.
8 Perform hand hygiene; apply clean gloves, gown, or protective barriers.	Reduces transmission of microorganisms.
9 Assess general condition of the body and note presence of dressings, tubes, and medical equipment. (If leaving room at this time, remove personal protective equipment and perform hand hygiene.)	Validates if tissue damage was present before postmortem care.

NURSING DIAGNOSES

For patients:

- Risk for impaired skin integrity

For family members and significant others:

- Compromised family coping
- Ineffective coping
- Deficient knowledge regarding organ donation
- Grieving
- Powerlessness

Related factors are individualized based on the patient's, family's, and significant others' needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Body is free of new skin damage.
- Significant others express grief.

Careful handling of body prevents lacerations, bruises, or abrasions during postmortem care.

Significant others feel supported through their loss.

Clinical Decision Point *Immediately after death and before proceeding with other activities, place body in supine position and elevate head of bed 30 degrees to decrease livor mortis.*

2 Place body in a private room if possible. If patient has a roommate, explain and move roommate to another location temporarily.

Provides staff with larger area for postmortem care and for family members to gather in a private setting.

3 Direct NAP to gather needed equipment and arrange at bedside.

Because this is often an emotional time for family members, organized care is important.

IMPLEMENTATION

1 Help family members notify others of the death. Promptly notify the mortuary, as chosen by the family, and discuss plans for postmortem care.

Following a death, grieving persons have difficulty focusing on details and often need guidance. Being informed increases a sense of control.

2 If patient has made tissue donation, consult agency policy for care of the body guidelines.

Retrieval of tissues (e.g., eyes, bone, skin) may require special procedures.

3 Perform hand hygiene; apply clean gloves, gown, or protective barriers.

Reduces transmission of microorganisms.

Clinical Decision Point *If family caregivers are assisting in postmortem care, have them wear a gown and gloves to protect them from body fluids.*

4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. Tag the body and leave on the body as directed by agency policy.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

STEP

- 5 Remove indwelling devices (e.g., urinary catheter, endotracheal tube). Disconnect and cap off (no need to remove) intravenous lines. Do not remove indwelling devices in cases of autopsy (follow agency policy).
- 6 Place dentures in mouth for viewing. If they do not stay securely in mouth, place in denture cup and transport with body to mortuary. If culturally appropriate, close mouth with rolled-up towel under chin.
- 7 Place small pillow under head or position according to cultural preferences. Do not tie hands together on top of body. Check agency policy regarding need to secure hands and feet. Use only circular gauze bandaging on body.
- 8 Close eyes by gently pulling eyelids over them. Some cultures prefer that eyes remain open.
- 9 Shave male facial hair unless prohibited by cultural practices or if patient wore a beard.
- 10 Wash soiled body parts. Some cultural practices require that family members clean the body.
- 11 Remove soiled dressings and replace with clean dressings, using paper tape or circular gauze bandaging.

RATIONALE

- Creates a normal appearance for family viewing of the body. Removing intravenous catheters allows fluids to leak out. Removal of tubes and lines is contraindicated if an autopsy is planned.
- Gives face a more natural appearance. Jaw muscles relax after death, making it difficult to keep dentures in place. Mortuary personnel remove dentures to clean and seal mouth.
- Patient appears natural. Weight of limp arms causes skin damage and discoloration if hands are tied. Some agencies require securing appendages to prevent tissue damage when body is being moved.
- Closed eyes convey to some people a more peaceful and natural appearance.
- Presents patient in his normal appearance. Honors cultural or religious preferences.
- Prepares body for viewing and reduces odors. Mortuary personnel provide complete bath.
- Changing dressings controls odors and creates more acceptable appearance. Paper tape minimizes skin damage when tape is removed.

Clinical Decision Point *Turning a recently dead body to the side sometimes causes the flow of exhaled air. This is a normal event and not a sign of life.*

- 12 Place absorbent pad under buttocks.
- 13 Place clean gown on the body. Some agencies require gown removal before placing body in the shroud.
- 14 Brush and comb hair. Remove any clips, hairpins, or rubber bands.
- 15 Identify personal belongings that stay with the body and those to be given to the family.
- 16 If family requests viewing, place clean sheet over body up to chin with arms outside covers. Remove medical equipment from the room. Provide soft lighting and chairs.
- 17 Allow family time alone with the body and encourage them to say goodbye with religious rituals and in a culturally appropriate manner. Some cultural practices include maintaining silence at the time of death. Persons in other cultures express grief with intense emotional displays, loud wailing, or “falling out.” Do not rush any grieving process.
- 18 After viewing, remove linens and gown per agency policy. Place body in shroud provided by the agency (see illustration).

- Relaxation of sphincter muscles at time of death causes release of urine or feces.
- Provides privacy and prepares body for viewing.
- The deceased appears cared for. Hard objects damage or discolor face and scalp.
- Prevents loss of valuable or meaningful property.
- Maintains respect for patient and those viewing the body. Prevents exposure of body parts. Removing medical equipment provides more peaceful, natural setting.
- Compassionate care provides family members with a meaningful experience during the early phase of grief. Ensure privacy and a safe environment. Provide chair at bedside for family member who might collapse.
- Shroud protects injury to skin, avoids exposure of body, and provides barrier against potentially contaminated body fluids.

STEP 18 Body in shroud.

STEP	RATIONALE
19 Place identification label on outside of shroud if required by agency policy. Follow agency policy for marking a body that poses an infectious risk to others. Remove and dispose of personal protective equipment and perform hygiene.	Ensures proper identification of the body. Reduces exposure of morgue and mortuary staff to contamination.
20 Arrange prompt transportation of the body to the mortuary. If you anticipate a delay, transport body to the morgue.	Mortuary personnel get the best results if embalming occurs before full rigor mortis (i.e., stiffening of the body after death) occurs.

EVALUATION

1 Observe family members', friends', and significant others' response to the loss.	The need for referral or assistance is based on evaluation of person's unique response to loss.
2 Note appearance and condition of patient's skin during preparation of the body.	Provides information for postmortem care documentation.

Unexpected Outcomes

- 1 A family member becomes immobilized by grief and has difficulty functioning.
- 2 A grieving person becomes very agitated and threatens or strikes out against others.
- 3 Lacerations, bruises, or abrasions are noted on the body. Positioning or preparation of the body results in skin injury.

Related Interventions

- Enlist the help of a trusted friend or family member to provide direction and support.
- Call for assistance from a psychiatric nurse practitioner, spiritual care provider, or social worker who has a relationship with the family.
- Enlist help of security staff or crisis intervention professional if safety is a concern.
- Document according to policy.

Recording and Reporting

- Record time of death in the nurses' notes and EHR and other appropriate forms, describe any resuscitative measures taken (if applicable), and note the name of the professional certifying the death.
- Record any special preparation of the body for autopsy or organ/tissue donation. Note whom you called and who made the request for organ/tissue donation.
- Record names of mortuary and names of family members consulted at the time of death and their relationship to the deceased.

- Record on appropriate form personal articles left on the body (e.g., teeth or glasses), jewelry taped to skin, or tubes and lines left in place. Note how valuables and personal belongings were handled and who received them. Secure signatures as required by agency policy.
- Record time the body was transported and its destination. Note the location of body identification tags.

Pediatric Considerations

- Arrange for family members, especially parents, to be with the child throughout the dying process and at the time of death if they wish.

TABLE 16-1 Physical Signs and Symptoms in the Final Stages of Dying

Physical Signs and Symptoms	Rationale	Intervention
Coolness, color, and temperature change in hands, arms, feet, and legs; mottling of legs; perspiration	Peripheral circulation diminished as blood shunts to vital organs Patient may feel cool to touch, but core temperature normal	Place socks on feet. Cover with light blanket. Do not use electric blanket because person is unable to report excess heat.
Increased sleeping	Decreased energy, psychological withdrawal, medications	Spend time with person; hold his or her hand. Speak to person, even if no response.
Disorientation, confusion of time, place, person	Metabolic changes, medications, changing sleep/wake cycles, decreased oxygenation	Identify self by name; reorient person to time and place. Decrease environmental stimuli.
Incontinence of urine and/or bowel	Decreased muscle tone and consciousness	Change bedding as appropriate. Use bed pads; try not to use indwelling catheters.
Upper airway secretions; noisy respirations	Decreased cough reflex, inability to expectorate secretions or clear throat, relaxation of glottis, decreased muscle tone	Elevate head with pillow or raise head of bed; turn head to side to drain secretions. Suction minimally.
Restlessness	Metabolic changes and decrease in oxygen to brain	Calm patient by speech and action; reduce light, rub back, stroke arms, or read aloud. Do not use restraints.
Decreased intake of food and fluids, nausea	Blood shunted away from gastrointestinal (GI) tract, causing decreased GI motility and anorexia; ketosis	Do not force patient to eat or drink; give ice chips or popsicles if desired. Provide mouth care.

Modified from Ebersole P et al: *Toward healthy aging*, ed 7, St Louis, 2008, Mosby.

- Parents frequently want to hold their child’s body after death. Parents of deceased newborns often want a memento of their baby (e.g., picture, article of clothing, footprint, or lock of hair). Make every effort to honor parent requests.

Gerontologic Considerations

- Some older adults have very small families and surviving circles of friends. Nurses and other care providers are sometimes the only human presence during death. Arrange for someone to be with the person when death is imminent.

Home Care Considerations

- Educate family members caring for a patient dying at home about what to expect at the time of death (Table 16-1).

Encourage family members to talk with patient and say their goodbyes because research suggests that hearing remains intact near death.

- Consider the type of support that family members will need at the time of death and make arrangements.
- After death in the home, follow agency guidelines for body preparation and transfer and for disposal of durable medical equipment (e.g., tubing, needles, syringes), soiled dressings or linens, and medications. Instruct family members in safe and proper handling and disposal of medical waste.

? Critical Thinking Exercises

You are caring for Mr. Corbin, a 79-year-old man hospitalized for abdominal pain, anorexia, weight loss, and weakness. He was treated 10 years earlier for prostate cancer. Test results now confirm that he has a large tumor in his abdomen and the cancer has spread to the lymph nodes. No medical interventions are available to cure his disease. When you enter the room, Mr. Corbin tells you in an angry voice that he wants to transfer to a different hospital where people will help him fight his cancer.

- 1 What should you do first in response to Mr. Corbin’s statement?
- 2 The next day Mr. Corbin reports mild abdominal pain and mentions that he has not had a bowel movement for 3 days. His wife reports to you that he has not had anything to eat or drink for 24 hours. Which action will you take first on the basis of this information?
 - 1 Assure the patient that it is not abnormal to have infrequent bowel movements with decreased intake.
 - 2 Further assess Mr. Corbin’s pain and bowel patterns.
 - 3 Ask Mr. Corbin’s wife to describe what his pain was like when he first came to the hospital.
 - 4 Encourage Mr. Corbin to increase his fluid intake and activity to improve peristalsis.
- 3 Four weeks later you take care of Mr. Corbin again. His symptoms include weight loss, anorexia, abdominal pain, depression, and anxiety. His wife tells you that the nurse practitioner told them about home hospice care. His wife says to you, “I’m still not sure if hospice would be best for us.” Which key points would you include in a discussion with Mr. Corbin and his wife about hospice care?

- 1 Disenfranchised
- 2 Anticipatory
- 3 Normal
- 4 Overwhelming
- 3 A woman experiences the loss of a very early-term pregnancy. Her friends do not mention the loss, and someone suggests to her that she can “always try again.” The woman feels confusion over her sadness and stops talking about it with others. Which type of grief response might she be experiencing?
 - 1 Delayed
 - 2 Anticipated
 - 3 Exaggerated
 - 4 Disenfranchised
- 4 A home care nurse is asked by a family member what he should do if the patient’s serious chronic illness worsens even with increased medical interventions. How would the nurse best begin a conversation about the goals of care at the end of life?
 - 1 Initiate a discussion about advance directives with the patient, family, and health care team
 - 2 Avoid the discussion about advance directives because that has to do with medical, not nursing, diagnoses
 - 3 Encourage the family to think more positively about the patient’s new therapy
 - 4 Begin the discussion by asking the family member what he believes the goals should be
- 5 Mrs. Worth asks you for advice on how she might get her husband to eat more. She believes that if he ate more he would get stronger and enjoy life more. She feels sad that he refuses the meals she prepares. How would you best begin your conversation with her?
 - 1 “You might let him plan the menu so he can select what he wants.”
 - 2 “Several nutritional supplements are available that might help him gain weight.”
 - 3 “His appetite is decreased because he is not getting enough activity. If you encourage him to walk more, he might feel hungry at mealtimes.”
 - 4 “It must be distressing to see him lose his interest in eating. Loss of appetite is common and normal in people with serious illness.”
- 6 A family member of a recently deceased patient talks casually with a nurse at the time of the patient’s death and expresses relief that she will not have to visit at the hospital anymore. Which type of grief may apply to this family member?
 - 1 Complicated
 - 2 Anticipatory
 - 3 Dysfunctional
 - 4 Disenfranchised
- 7 A nurse suggests that a patient receive a palliative care consultation for symptom management related to anxiety and increasing pain. A family member asks the nurse if this means that the patient is dying and is now “in hospice.” What should the nurse tell the patient and family about the care that she is receiving?

✓ REVIEW QUESTIONS

- 1 A patient with cancer is admitted into hospice care. Which question by a nurse demonstrates an understanding of a primary goal of palliative care?
 - 1 “What arrangements have been made for your funeral and burial?”
 - 2 “Are you sure that you no longer want treatment for your disease?”
 - 3 “What are the most important things we can do to help during this time?”
 - 4 “Is pain your primary problem at the current time?”
- 2 A mother who recently lost her only son in a motorcycle accident does not feel like going back to work after the funeral and often believes that she hears her son’s motorcycle outside. Which type of grief would the nurse suspect that the mother is experiencing?

- 1 Hospice (end-of-life care) and palliative care are the same thing.
- 2 Palliative care is for any patient, any time, any disease, in any setting.
- 3 Palliative care strategies are primarily designed to treat the patient's illness.
- 4 Palliative care interventions relieve the symptoms of illness and treatment.
- 5 1 and 3
- 6 2 and 4
- 8 Which of the following nursing actions best reflects sensitivity to cultural differences related to end-of-life care?
 - 1 Practice honesty with everyone, telling patients about their illness, even if the news is not good.
 - 2 Ask family members if they would like to assist with the care of the body after death.
 - 3 Provide postmortem care at the time of death to relieve family members of this difficult job.
 - 4 Value patient self-determination, understanding that each person makes his or her own decisions.
 - 5 1, 2, and 4
 - 6 2 and 4
- 9 Regarding the request for organ and tissue donation at the time of death, a nurse should be aware that:
 - 1 Specially educated personnel make the donation request.
 - 2 Requests are usually made by the nurse caring for the patient at the time of death.
 - 3 Only patients who have given prior instruction regarding donation can become donors.
 - 4 Professionals should be very selective in whom they ask for organ and tissue donation.
- 10 A nurse has the responsibility of managing a deceased patient's postmortem care. Arrange the steps for postmortem care in the proper order.
 - 1 Bathe the deceased's body.
 - 2 Collect any needed specimens.
 - 3 Remove all drains and indwelling tubes.
 - 4 Position the body for family visit/viewing.
 - 5 Speak to the family members about their possible participation.
 - 6 Confirm that request for organ/tissue donation and/or autopsy has been made.
 - 7 Notify a support person (e.g., spiritual care provider, bereavement specialist) for the family.
 - 8 Accurately tag the body, indicating deceased's identity and safety issues regarding infection control.
 - 9 Elevate the head of the bed.

Cheilosis	Halitosis	Neuropathy	Sebum
Cuticle	Hygiene	NPO	Slough
Dental caries	Incontinence-Associated	Periodontal	Stomatitis
Dermatitis	Dermatitis	Periodontitis	Tepid
Eschar	Maceration	Plaque	Xerostomia
Flossing			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss guidelines used to provide personal hygiene to patients.
- Identify principles of aseptic technique applied while administering a bed bath.
- Administer a complete bed bath.
- Explain precautions to take when assisting patients with a tub bath or shower.
- Discuss precautions used to minimize transmission of infection during perineal care.
- Identify guidelines to follow when administering oral hygiene.

OBJECTIVES—cont'd

- Explain differences in providing oral hygiene to dependent versus unconscious patients.
- Discuss precautions used to prevent breakage of dentures.
- Identify guidelines for administering hair, nail, and foot care.
- Comb, brush, and shampoo the hair of a bed-bound patient.
- Shave a male or female patient.
- Identify risk factors for foot and nail problems.
- Safely administer nail care.
- Change the linen on an unoccupied and occupied bed.

Many patients who are totally dependent on someone else require assistance with personal hygiene or must learn or adapt new hygiene techniques. Hygiene is important for promoting and preserving health. Maintenance of personal hygiene is necessary for an individual's health, comfort, safety, and sense of well being. When performing hygiene, you have the opportunity to interact with patients to discuss emotional, social, and health-related concerns. Always convey sensitivity and respect for a patient's personal beliefs and habits and ensure a patient has as much privacy as possible. In addition, performing hygiene is an excellent time to conduct a physical assessment (see Chapter 6).

THE SKIN

Skin, the largest human body organ, protects the body from heat, light, injury and infection and serves to (1) help regulate body temperature; (2) store water, vitamin D, and fat; (3) help sense pain and other stimuli; and (4) prevent the entry of bacteria. Three primary layers make up the skin: the epidermis, dermis, and subcutaneous tissue. The skin covers the entire surface of the body and is continuous with mucous membranes of the mouth, eyes, ears, nose, vagina, and rectum. Thorough hygiene is essential for the integrity and function of each skin layer.

The epidermis, or outer skin layer, is the first line of defense against external injury and infection. It contains several thin layers of cells undergoing different stages of maturation. Sebum, secreted from hair follicles from sebaceous glands, provides an acidic coating. This acidic coating protects the epidermis against penetration by chemicals and microorganisms. It also minimizes loss of water and plasma proteins.

Two types of sweat glands, the eccrine and apocrine glands, are distributed over the surface of the skin. Eccrine glands secrete a watery fluid (sweat) that assists in temperature control through evaporation. The apocrine glands secrete sweat in the axillary and genital areas. Bacterial decomposition of sweat from the apocrine glands causes body odor.

The subcutaneous tissue layer contains blood vessels, nerves, lymph tissue, and loose connective tissue filled with fat cells. Fatty tissue insulates the body. Subcutaneous tissue also provides support for upper skin layers.

Bacteria reside on the outer surface of the skin. The resident bacteria are normal flora that do not cause disease but prevent disease-causing microorganisms from reproducing. Because a portion of the skin is usually exposed to environmental irritants and is an active organ sensitive to physiologic changes within the body, some skin problems commonly occur (Table 17-1). Assess for skin conditions while providing hygiene and suggest measures to alleviate these conditions. Skin problems cause changes that affect a patient's appearance and body image. Be sensitive to his or her feelings while attempting to care for a skin problem.

THE MOUTH

The oral cavity, which is lined with a normally moist and intact light pink mucous membrane, contains the teeth and gums. The membranous lining protects underlying organs; secretes mucus to keep the oral cavity lubricated; and absorbs water, salts, and other solutes. Saliva, a clear viscous fluid secreted by the mucous and salivary glands of the mouth, helps to prevent dental caries and plaque formation and lubricates the oral cavity. Lubrication of the oral cavity aids in chewing and swallowing. In addition, saliva provides a means for removing cellular and bacterial debris that can cause infection, particularly fungal infection (Sjögren's Syndrome Foundation, 2011). Hyposalivation results in dry mouth, or xerostomia, and compromises taste, swallowing, digestion, nutrition, and denture fit (Yasny and Silvay, 2010).

The teeth are organs of chewing, or mastication. Dentin, a hard, ivorylike substance that surrounds the pulp cavity, forms the major part of a tooth (Fig. 17-1). A layer of enamel, visible in the oral cavity, covers the upper portion of the tooth, or crown. The periodontal membrane, just below the gum margins, surrounds the tooth root and holds it firmly in place. A tooth receives its blood, lymph, and nerve supply from the base of the tooth socket within the jaw. Healthy teeth are smooth, shiny, and properly aligned.

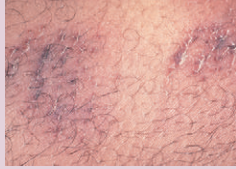

The gums, or gingivae, are mucous membranes with underlying supportive fibrous tissue. They encircle the necks of erupted teeth to hold them firmly in place. The gums are normally pink, moist, firm, and relatively inelastic. Regular oral hygiene is necessary to maintain the integrity of teeth surfaces and prevent gingivitis, or gum inflammation.

THE HAIR

Hair grows from follicles located within the dermis of the skin (Fig. 17-2). Tiny blood vessels supply each follicle with nourishment necessary for normal hair growth. Each hair has a shaft extending from the follicle. Sebaceous glands secrete the oily substance (i.e., sebum) into each follicle, which lubricates the hair and scalp. The hair shaft is normally shiny and pliant and is not excessively oily, dry, or brittle.

The primary function of hair is protection. For example, hair protects the scalp from injury. Eyebrows and eyelashes protect the eyes from foreign particles. Special hair-care practices focus primarily on care for scalp, axilla, and pubic areas. Hair growth, distribution, and pattern are indicators of a person's health status. Hormonal changes, emotional and physical stress, aging, intake of toxins (e.g., arsenic, cocaine), gender, race, nutrition, infection, and certain diseases affect hair characteristics. A person's appearance and sense of well-being often depend on the way the hair looks and feels. Illness or disability sometimes prevents patients from maintaining daily hair care. An immobilized patient's hair soon becomes tangled if not brushed or combed regularly. Dressings may leave sticky

TABLE 17-1 Common Skin Problems

Problem	Characteristics	Implications	Interventions
<p>Dry skin</p> 	<p>Flaky, rough texture resulting from lack of moisture in outer stratum corneum, resulting in less pliable epidermis; most common on anterior surfaces of lower legs, knees, elbows, and backs of hands</p>	<p>Skin may crack, bleed, and become inflamed. As a result, redness, pruritus, and discomfort may develop.</p>	<p>Effective treatment of dry skin does not include limiting frequency of bathing but lies in bathing with warm, not hot, water and use of moisturizers. Use super-fatted soap (e.g., Dove) for cleaning. Rinse body of all soap well because residue left can cause irritation and breakdown. Add moisture to air through use of humidifier. Increase fluid intake when skin is dry.</p>
<p>Acne</p>  <p>(From James WD, et al: <i>Andrew's diseases of the skin: Clinical dermatology</i>, ed 10, Philadelphia, 2007, Saunders.)</p>	<p>Inflammatory, papulopustular skin eruption, usually involving bacterial breakdown of sebum; appears on face, neck, shoulders, and back</p>	<p>Infected material within pustule can spread if area is squeezed or picked. Permanent scarring can result.</p>	<p>Wash hair and skin each day with warm water and soap to remove oil. Use cosmetics sparingly because oily cosmetics or creams accumulate in pores and tend to make condition worse. Implement necessary dietary restrictions by eliminating foods found to aggravate condition. Use prescribed topical antibiotics for severe acne.</p>
<p>Hirsutism</p>  <p>(From Goyal D, et al: Coffin-Siris syndrome with Mayer-Rokitansky-Küster-Hauser syndrome: A case report, <i>J Med Case Report</i> 4:354, 2010; DOI: 10.1186/1752-1947-4-354.)</p>	<p>Excessive growth of body and facial hair, especially in women</p>	<p>Hirsutism may cause negative body image by giving female a male appearance.</p>	<p>Shaving is safest method to remove hair. Electrolysis and laser permanently remove hair. Tweezing and bleaching are temporary.</p>
<p>Skin rashes</p> 	<p>Skin eruption that results from overexposure to sun or moisture or from allergic reaction; may be flat or raised, localized or systemic, pruritic or nonpruritic</p>	<p>If skin is continually scratched, inflammation and infection may occur. Rashes also cause discomfort.</p>	<p>Wash area thoroughly and apply antiseptic spray or lotion to prevent further itching and aid healing process. Warm or cold soaks may relieve inflammation.</p>
<p>Contact dermatitis</p>  <p>(From Lewis SL, et al: <i>Medical-surgical nursing: Assessment and management of clinical problems</i>, ed 8, St Louis, 2011, Mosby.)</p>	<p>Acute or chronic eczematous rash characterized by abrupt onset with well-defined geometric margins of erythema, pruritus, pain, and appearance of scaly, oozing lesions; appears on head, neck, scalp, hands, legs, dorsum of feet, and trunk</p>	<p>Dermatitis is often difficult to eliminate because person is usually in continual contact with substance causing skin reaction. Substance may be hard to identify.</p>	<p>Identify and avoid contributing agents (e.g., cleaners, poison ivy or oak, cosmetics, latex, shoes/rubber). Treatment consists of removing contributing agent, if identified, and applying over-the-counter topical steroids or calamine lotion. In some cases prescription steroids may be ordered. Patients may also find comfort with tepid baths.</p>
<p>Abrasion</p>  <p>(From Cottrian SR et al: From the teaching collection of the Department of Dermatology, University of Texas, Southwestern Medical School, Dallas.)</p>	<p>Scraping or rubbing away of epidermis may result in localized bleeding and later weeping of serous fluid</p>	<p>Infection occurs easily as result of loss of protective skin layer.</p>	<p>Nurses should always be careful not to scratch patients with their jewelry or fingernails. Wash abrasions with mild soap and water. Dressing or bandage could increase risk for infection because of retained moisture.</p>

FIG 17-1 Normal tooth.

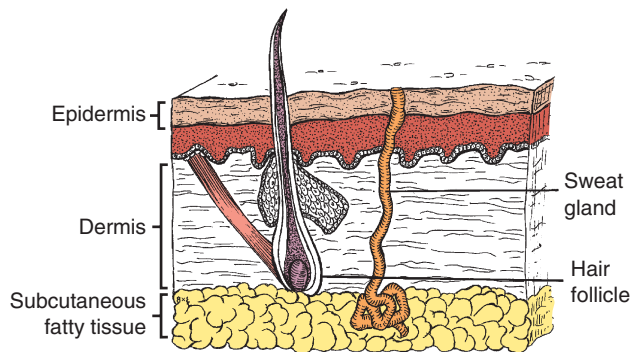

FIG 17-2 Cross section of hair follicle and supporting structures.

adhesive, blood, or antiseptic solutions on the hair. Diaphoresis leaves hair oily and unmanageable. Proper hair care is important to a person's body image.

THE NAILS

The nails are epithelial tissues that grow from the root of the nail bed, located in the skin at the nail groove. A normal, healthy nail is transparent, smooth, and convex, with a pink nail bed and translucent white tip. A normal color indicates adequate oxygenation to peripheral tissues. Pigment deposits or bands are common in nail beds of patients with dark skin. The nail is surrounded by a cuticle, which slowly grows over the nail and must be regularly pushed back with a soft nail brush.

The feet and nails require special care to prevent infection, odor, and injury. Problems typically result from abuse or poor care. Foot pain can often change a walking gait, causing strain on different muscle groups.

EVIDENCE-BASED PRACTICE

Evidence-based protocols for bathing and oral hygiene decrease hospital-acquired complications such as infection and skin ulceration (Eigsti, 2011). Concern with the number of patients with methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant enterococci (VRE), and *Clostridium difficile* infection (CDI) is related to cross-contamination and whether health care providers use antimicrobial soaps (Jury et al., 2011).

- A disposable bath is an all-in-one bathing package, which can decrease the spread of infection through decreased cross-contamination and washcloth-associated dermatitis (Johnson et al., 2009).
- Cost-effectiveness and a decrease in the time taken to administer a bath are also associated with disposable all-in-one bath products (Eigsti, 2011).
- Use of chlorhexidine gluconate-impregnated bathing cloths is well tolerated by the skin and is an effective broad antiseptic product (Eigsti, 2011).
- Moisturizer and skin protectant should be applied with each cleansing.

Adequate oral hygiene is important in preventing systemic illnesses (Wiech and Bayer, 2012; Stein and Henry, 2009). Critically ill patients in intensive care settings are especially prone to infection when oral hygiene is not performed. Approximately one fourth to one half of critically ill patients require mechanical ventilation (Grap, 2009), putting them at risk for ventilator-associated pneumonia (VAP). VAP results from the colonization of bacteria in the oral pharynx and is associated with increased morbidity and mortality (Munro et al., 2009; Wiech and Bayer, 2012). Current recommendations to reduce the risk of VAP include (Wiech and Bayer, 2012):

- Toothbrushing every 12 hours before the application of chlorhexidine
- Chlorhexidine 0.12% applied orally every 12 hours
- Head of bed elevated 30 degrees or more unless contraindicated

PATIENT-CENTERED CARE

Each culture is unique in how the provision and customs of personal hygiene are performed. Take patient's preferences and customs into consideration when providing hygiene. Having an understanding of transcultural nursing concepts and translating them into practice is key in providing culturally sensitive health care (Buschemi, 2011). Hygiene is a personal matter, and it is important to encourage patients to participate in their hygienic care. Consider patients' normal oral and bathing hygiene routines, including type of products used and the time of day when hygiene is routinely performed. Individualize your care based on patients' preferences. The nature of nursing is to provide compassionate care to patients and their families, which embodies the original focus of patient-centered care (Epstein and Street, 2011). Depending on the cultural considerations and the ability of the patient, it may be beneficial to involve a family member or significant other in the hygienic care of the patient so complete culturally sensitive patient-centered care is provided. For example, in some cultures it is not appropriate to expose the lower torso and arms, and the left hand is used for cleansing the perineal area. In other cultures, health care providers must be gender congruent whenever possible.

Safety Guidelines

- 1 Always assess the environment for safety before administering hygiene care to a patient. Check floors for spills and make sure that equipment is working properly.
- 2 When not performing procedures, patient's bed should be in the locked and low position with at least two, but not more than three side rails raised.
- 3 Keep all personal care items within a patient's reach. When the head of the bed is raised, the bedside stand is usually not within

easy reach and must be moved forward. If a patient must leave the bed to go to the bathroom, be sure that there is a clear pathway.

- 4 Observe standard precautions when providing care, which includes wearing clean gloves. Additional precautions requiring other personal protective equipment (PPE) may be necessary, depending on the patient's condition (see [Chapter 7](#)).
- 5 Be sure that the call light is easily accessible to a patient at all times. Often a patient has multiple intravenous (IV) lines

and drainage tubes connected to portable poles and suction machines, which make it difficult for him or her to get to out-of-reach items. This puts the patient at risk for falling or for an injury from a dislodged tube or IV catheter.

- 6 Monitor laboratory findings, such as coagulation studies before administering oral care to prevent bleeding.
- 7 Monitor patients who have a decrease in sensory perception such as peripheral neuropathy.

SKILL 17-1 Bathing a Patient

Video Clip

Bathing removes sweat, oil, dirt, and microorganisms from the skin. It also stimulates circulation and provides a refreshed and relaxed feeling. For some patients a bath is a time for socialization and pleasure, especially for those who are bedridden or seriously disabled.

The National Pressure Ulcer Advisory Panel and The European Pressure Ulcer Advisory Panel revised the stages of pressure ulcers and redefined important points for skin care ([NPUAP and EPUAP, 2010](#)). Although these were intended for pressure ulcer prevention, they provide sound principles for good bathing techniques.

- Clean the skin at the time of soiling and at routine intervals. Individualize frequency of cleaning according to patient need and preference. Problems such as incontinence, wound drainage, or excessive diaphoresis often require bathing several times a day.
- Avoid hot or excessively cold water and use a mild cleansing agent that minimizes irritation.
- Avoid use of force and friction when bathing a patient. Avoid massaging reddened areas, especially over bony prominences.
- Minimize environmental factors that lead to skin drying such as low humidity (less than 40%) and exposure to cold. Depending on the patient's age and physical condition, maintain room temperature between 20° and 23°C (68° and 74°F). Infants, older adults, and acutely ill patients may need a warmer temperature. However, certain critically ill patients require cooler room temperatures to lower the metabolic demands of the body. Controlling drafts and eliminating lingering odors from draining wounds, vomitus, bedpans, or urinals also improve a patient's comfort.
- Protect patients from injury by assessing and controlling bath water temperature. This is important for older adults and others with reduced sensation such as patients with diabetes or peripheral neuropathy or spinal cord-injury patients. It is also important for patients who are unable to communicate.
- Use bathing as a time to interact with and assess a patient. When giving a complete bath, perform a physical assessment of all body systems and discuss issues of concern for a patient.
- During bathing assist patients through normal joint range-of-motion (ROM) exercises to promote circulation and joint integrity.
- For patients who tire easily, consider giving a partial versus complete bed bath.

There are two categories of baths: cleansing and therapeutic. Cleansing baths include the bed bath, tub bath, sponge bath at the

sink, shower, and prepackaged disposable bed bath ([Box 17-1](#)). The type of cleansing bath to use depends on the assessment of a patient's physical capabilities and the degree of hygiene required. When a person is unable to perform personal care because of illness or disability, you are responsible for helping with bathing. This includes time for cleaning and grooming hair, shaving, and cleaning of nails. You can perform many of these procedures during or immediately after a bath.

Health care providers generally order therapeutic baths for a specific effect such as soothing the skin or for promoting the healing process. Types of therapeutic baths include:

- **Sitz bath:** Cleans and reduces pain and inflammation of perineal and anal areas. They are used for a patient who has undergone rectal or perineal surgery or childbirth or has local irritation from hemorrhoids or fissures. The patient sits in a special tub or basin (see [Chapter 40](#)).
- **Medicated bath** (addition of over-the-counter, herbal, or health care provider-ordered ingredient to bath): Relieves skin irritation and creates an antibacterial and drying effect.

Perineal care (see [Procedural Guideline 17-1](#)) involves thorough cleaning of a patient's external genitalia and surrounding skin. A patient routinely receives perineal care during a bath. However,

BOX 17-1 Types of Baths

- **Complete bed bath:** Bath administered to totally dependent patient in bed.
- **Partial bed bath:** Bed bath that consists of bathing only body parts that would cause discomfort if left unbathed such as the hands, face, axilla, and perineal area. Partial bath also includes washing back and providing back rub. Dependent patients in need of partial hygiene or self-sufficient bedridden patients who are unable to reach all body parts receive a partial bed bath.
- **Sponge bath at the sink:** Involves bathing from a bath basin or sink with patient sitting in a chair. Patient is able to perform a portion of the bath independently. Nurse helps with hard-to-reach areas.
- **Tub bath:** Involves immersion in a tub of water that allows more thorough washing and rinsing than a bed bath. Patients may require nurse's assistance. Some institutions have tubs equipped with lifting devices that facilitate positioning dependent patients in the tub.
- **Shower:** Patient sits or stands under a continuous stream of water. The shower provides more thorough cleaning than a bed bath but can be tiring.
- **Disposable bed bath/travel bath:** The bag bath contains several soft, nonwoven cotton cloths that are premoistened in a solution of no-rinse surfactant cleaner and emollient. The bag bath offers an alternative because of the ease of use, reduced time bathing, and patient comfort (Barrick et al., 2008; Meiner, 2010).

patients at risk for acquiring an infection need more frequent perineal care. These include patients who have incontinence-associated dermatitis (IAD), an indwelling Foley catheter, are postpartum, or are recovering from rectal or genital surgery.

Delegation and Collaboration

Assessment of the patient's skin, pain level, and ROM cannot be delegated to nursing assistive personnel (NAP). The skill of bathing can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- Not massaging reddened skin areas during bathing.
- Contraindications to soaking a patient's feet or trimming toenails.
- Reporting any signs of impaired skin integrity to the nurse.
- Proper ways to position male and female patients with musculoskeletal limitations or an indwelling Foley catheter or other equipment (e.g., intravenous [IV] tubing).

Equipment

- Washcloths and bath towels
- Bath blanket
- Cleansing product for bath
- Toiletry items (deodorant, lotion)
- Disposable wipes
- Warm water
- Clean hospital gown or patient's own pajamas or gown
- Laundry bag
- Clean gloves
- Washbasin
- Disposable all-in-one package bath product (if basin and water baths are not performed)
- Eye patch/shield and nonallergenic tape (for unconscious patient)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <p>1 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and that bed is in locked, low position).</p> | <p>Identifies safety hazards in patient environment that could cause or potentially lead to harm (<i>QSEN Quality/Safety Competencies, 2012</i>).</p> |
| <p>2 Assess patient's fall risk status (if partial bathing out of bed or self-bath is to be performed), tolerance for bathing and activity, comfort level, cognitive ability, musculoskeletal function, and presence of shortness of breath.</p> | <p>Determines patient's ability to perform bathing and what type of bath to administer (e.g., complete bath, partial bed bath).</p> |
| <p>3 Assess patient's visual status, ability to sit without support, hand grasp, ROM of extremities (see <i>Chapter 6</i>).</p> | <p>Determines degree of assistance needed for bathing.</p> |
| <p>4 Assess for presence and position of external medical device/equipment (e.g., IV line or oxygen tubing).</p> | <p>Affects how you will plan bathing activities.</p> |
| <p>5 Assess patient's bathing preferences, including frequency, time of day, and type of hygiene products used.</p> | <p>Allows patient to participate in plan of care. Promotes patient's comfort and willingness to cooperate.</p> |
| <p>6 Ask if patient has noticed any problems related to condition of skin and genitalia.</p> | <p>Provides information to direct physical assessment of skin and genitalia during bathing. Also influences selection of skin-care products.</p> |
| <p>7 Before or during bath, assess condition of patient's skin. Note the presence of dryness, indicated by flaking, redness, scaling, and cracking or excessive moisture, inflammation, or pressure ulcers (see <i>Chapter 18</i>).</p> | <p>Provides baseline for comparison of skin integrity over time.</p> |
| <p>8 Identify risks for skin impairment. <i>Option:</i> Use a pressure ulcer assessment tool (e.g., Braden Scale; see <i>Chapter 18</i>).</p> | <p>Risk factors increase the likelihood of injury to the skin because of pressure, impaired tissue synthesis, softening of or friction on tissues, and impaired circulation.</p> |
| <p>a Immobilization (e.g., patients with paralysis, immobilized extremities, traction; weakened or disabled patients)</p> | <p>Risk for pressure on dependent body parts.</p> |
| <p>b Reduced sensation (e.g., paresthesias, circulatory insufficiency, neuropathies)</p> | <p>Requires caution in regulating temperature of bath water to prevent risk of injury or burns to the skin.</p> |
| <p>c Nutritional and hydration alterations</p> | <p>Affects condition of skin with decreases in skin turgor, thickness, and elasticity. Skin integrity is easily susceptible to infections or breaks in skin.</p> |
| <p>d Excessive moisture on skin, particularly on skin surfaces that rub against one another (e.g., under breasts, perineal area)</p> | <p>Skinfolds trap moisture and cause friction between surfaces, which can lead to breaks in skin integrity and result in infection.</p> |
| <p>e Vascular insufficiencies</p> | <p>Result in poor circulation to skin.</p> |
| <p>f External devices applied to or around skin (e.g., casts, braces, restraints, dressings, catheters, tubes)</p> | <p>Improperly placed medical devices or movable devices that can cause pressure or friction can result in skin breakdown.</p> |
| <p>g Older-adults</p> | <p>Older adults with decreased appetites may have deficits in nutrients and fluids that increase risk of impaired skin integrity. Physical changes with age and decreased skin elasticity also contribute to higher incidence of impaired skin integrity.</p> |

STEP	RATIONALE
<ul style="list-style-type: none"> h Shear or friction (sliding down in bed) i Incontinence (bowel or bladder) 	<ul style="list-style-type: none"> Causes damage to skin and underlying tissues. Requires more frequent bathing to prevent skin maceration and infection.
9 Assess patient's comfort on a 0 to 10 pain scale.	Bath can soothe and comfort patient.
10 Assess patient's knowledge of skin hygiene in terms of its importance, preventive measures to take, and common problems encountered (see Table 17-1).	Determines patient's learning needs.
11 Review orders for specific precautions concerning patient's movement or positioning.	Prevents accidental injury to patient during bathing activities. Determines level of assistance required by patient.

NURSING DIAGNOSES

- Activity intolerance
- Bathing/self-care deficit
- Deficient knowledge regarding skin care
- Impaired physical mobility
- Impaired skin integrity
- Risk for impaired skin integrity
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Skin is free of excretions, drainage, or odor. • Skin shows decreased redness, cracking, flaking, and scaling. • Joint ROM remains same or improves from previous measurement. • Patient expresses sense of comfort and relaxation. • Patient tolerates bath without fatigue or chilling. | <ul style="list-style-type: none"> Skin is clean. Indicates reduction in skin dryness. Repeated ROM exercise during bathing helps prevent contractures and promotes joint movement. Bath relaxes patient and removes sources of discomfort. Fatigue during bathing indicates worsening of chronic cardio-pulmonary conditions. Demonstrates learning with ability to repeat back to demonstrate understanding. |
| 2 Gather equipment and supplies. | Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment. |
| 3 Adjust room temperature and ventilation. | Warm room that is free of drafts prevents rapid loss of body heat during bathing. |
| 4 Explain procedure and ask patient for suggestions on how to prepare supplies. If partial bath, ask how much of bath patient wishes to complete. | Promotes patient's cooperation and participation and promotion of self-care as appropriate. |
| 5 If it is necessary to leave the room, be sure that call light is within reach of patient. | Provides for patient's safety. |

Clinical Decision Point *Never leave the bedside without ensuring that at least two but not more than three side rails are raised and the bed is in the locked, low position. The number of side rails depends on the patient's fall risk assessment; however, having all side rails raised is considered a restraint. Check agency policy.*

IMPLEMENTATION

- | | |
|---|--|
| 1 Close room doors and windows and draw room divider curtain. | Privacy ensures patient's mental and physical comfort. |
| 2 Offer patient bedpan or urinal. Provide towel and moist washcloth. | Patient will feel more comfortable after voiding. Prevents interruption of bath. |
| 3 Perform hand hygiene. Apply clean gloves. | Reduces transmission of microorganisms. |
| 4 Place supplies on bedside table, including a washbasin two-thirds full with warm water. Check water temperature and have patient place fingers in water to test temperature tolerance. Place plastic container of bath lotion in bath water to warm if desired. | Warm water promotes comfort, relaxes muscles, and prevents unnecessary chilling. Testing temperature prevents accidental burns. Bath water warms lotion for application to patient's skin. |
| 5 Raise bed to comfortable working height. Lower side rail closest to you and help patient assume comfortable supine position, maintaining body alignment. Bring patient toward side closest to you. | Aids access to patient. Maintains patient's comfort throughout procedure. Uses proper body mechanics, thus minimizing strain on back muscles. |
| 6 Place bath blanket over patient. Have patient hold top of bath blanket and remove top sheet from under bath blanket without exposing patient. Place soiled linen in laundry bag. | Blanket provides warmth and privacy.
Take care to avoid linen contacting uniform. |
| 7 Remove patient's gown or pajamas. | Provides full exposure of body parts during bathing. |

STEP

RATIONALE

- a Whether or not patient has an IV line, simply unsnap sleeves and remove gown.
 - b If an extremity is *injured* or has reduced mobility, begin removal from *unaffected* side first.
 - c If patient has an IV line and gown with no snaps, remove gown from arm *without* IV line first. Then remove gown from arm with IV line (see illustration). Pause IV fluid infusion by pressing appropriate sensor on IV pump. Remove IV tubing from pump, then use regulator to slow IV infusion. Remove IV container from pole (see illustration) and slide IV container and tubing through arm of patient's gown (see illustration). Rehang IV container (see illustration), reconnect tubing to pump, open regulator clamp, and restart IV fluid infusion by pressing appropriate sensor on IV pump. If IV fluids are infusing by gravity, check IV flow rate and regulate if necessary. *Do not disconnect IV tubing to remove gown.*
- 8 Remove pillow if allowed. Raise head of bed 30 to 45 degrees. Place bath towel under patient's head. Place second bath towel over patient's chest.
 - 9 Wash face.
 - a Inquire if patient is wearing contact lenses.

Undressing unaffected side first allows easier manipulation of gown over body part with reduced ROM.
Manipulation of IV tubing and container can disrupt flow rate.

Removal of pillow makes it easier to wash patient's ears and neck.
Placement of towels prevents soiling of bed linen and bath blanket.

Prevents accidental injury to eyes.

STEP 7c A, Remove patient's gown. B, Remove IV bag from pole. C, Slide IV tubing and bag through arm of patient's gown. D, Rehang IV bag.

STEP

RATIONALE

- b** Form a mitt with washcloth (see illustration). Immerse in water and wring thoroughly.
- c** Wash patient's eyes with plain warm water, using a clean area of cloth for each eye and bathing from inner to outer canthus (see illustration). Soak any crusts on eyelid for 2 to 3 minutes with a warm, damp cloth before attempting removal. Dry around eyes gently and thoroughly.
- d** Ask if patient prefers to use soap on face. Wash, rinse, and dry forehead, cheeks, nose, neck, and ears without using soap. Ask men if they want to be shaved (see Skill 17-4).
- e** Provide eye care for unconscious patient.

Mitt retains water and heat better than loosely held washcloth; keeps cold edges from brushing against patient and prevents splashing.

Soap irritates eyes. Use of separate sections of mitt reduces infection transmission. Bathing eye gently from inner to outer canthus prevents secretions from entering nasolacrimal duct. Pressure causes internal injury.

Soap tends to dry face, which is exposed to air more than other body parts.

Patients who are unconscious have lost the normal protective corneal reflex of blinking, increasing the risk for corneal drying, abrasions, and eye infection.

(1) Instill eye drops or ointment per health care provider's order (see Chapter 21).

(2) In the absence of blink reflex, keep eyelids closed. Close eye gently, using back of your fingertip, before placing eye patch or shield. Place tape over patch or shield. Do not tape eyelid.

When blink reflex is absent, patient loses a protective mechanism. Keeping eyelids closed maintains eye moisture and prevents injury.

10 Wash upper extremities and trunk.

- a** Remove bath blanket from patient's arm that is closest to you. Place bath towel lengthwise under arm. Bathe with water and minimal soap using long, firm strokes from distal to proximal (fingers to axilla).
- b** Raise and support arm above head (if possible) to wash axilla, rinse, and dry thoroughly (see illustration). Apply deodorant to underarms as needed or desired.

Long, firm strokes promote venous return.

Movement of arm exposes axilla and exercises normal ROM of joint. Deodorant controls body odor.

STEP 9b Steps for folding washcloth to form a mitt.

STEP 9c Wash eye from inner to outer canthus.

STEP 10b Positioning arm to wash axilla.

STEP	RATIONALE
<ul style="list-style-type: none"> c Move to other side of bed and repeat steps with other arm. d Cover patient's chest with bath towel and fold bath blanket down to umbilicus. Bathe chest using long, firm strokes. Take special care with skin under female patient's breasts, lifting breast upward, if necessary with back of hand. Rinse and dry well. 	<p>Draping prevents unnecessary exposure of body parts. Towel maintains warmth and privacy. Secretions and dirt collect easily in areas of tight skinfolds. Skin under breasts is vulnerable to excoriation if not kept clean and dry.</p>
<p>11 Wash hands and nails.</p> <ul style="list-style-type: none"> a Fold bath towel in half and lay it on bed beside patient. Place basin on towel. Immerse patient's hand in water. Allow hand to soak for 3 to 5 minutes (if necessary) before cleaning fingernails (see Skill 17-5). Remove basin and dry hand well. Repeat for other hand. 	<p>Soaking softens cuticles and calluses of hand, loosens debris beneath nails, and enhances feeling of cleanliness. Thorough drying removes moisture from between fingers.</p>
<p>12 Check temperature of bath water and change water if necessary; otherwise continue.</p>	<p>Warm water maintains patient's comfort.</p>
<p>13 Wash abdomen.</p> <ul style="list-style-type: none"> a Place bath towel lengthwise over chest and abdomen. (You may need two towels.) Fold bath blanket down to just above pubic region. Bathe, rinse, and dry abdomen with special attention to umbilicus and skinfolds of abdomen and groin. Keep abdomen covered between washing and rinsing. Dry well. b Apply clean gown or pajama top by dressing affected side first. <i>Option:</i> You may omit this step until completion of bath. 	<p>Keeping skinfolds clean and dry helps prevent odor and skin irritation. Moisture and sediment that collects in skinfolds predispose skin to maceration.</p> <p>Maintains patient's warmth and comfort. Allows easier manipulation of gown over body part with reduced ROM.</p>
<p>Clinical Decision Point <i>If one extremity is injured or immobilized, always dress affected side first.</i></p>	
<p>14 Wash lower extremities.</p> <ul style="list-style-type: none"> a Cover chest and abdomen with top of bath blanket. Expose near leg by folding blanket toward midline. Be sure that other leg and perineum remain draped. Place bath towel under leg. b Wash leg using long, firm strokes from ankle to knee and knee to thigh (see illustration). Assess for signs of redness, swelling, or pain along leg. 	<p>Prevents overexposure.</p> <p>Promotes circulation and venous return. Assessment is a key to identifying signs and symptoms of venous thrombosis.</p>

STEP 14b Washing patient's leg.

STEP

RATIONALE

Clinical Decision Point During the bath assess for signs of warmth, redness, swelling, tenderness, and pain in the lower extremities because these might be early signs of deep vein thrombosis (DVT) (Emanuele, 2008).

- | | |
|--|---|
| <p>c Clean foot, making sure to bathe between toes. Clean and file nails as needed (check agency policy) (see Skill 17-5). Dry toes and feet completely. Soaking feet in warm water for 10 minutes can help maintain cleanliness of the nails and feet; however, do not soak feet of patients with diabetes mellitus.</p> <p>d Raise side rail; remove towel; move to opposite side of bed, lower side rail, place dry towel under second leg, and repeat Steps 14b and c for other leg and foot. Apply light layer of moisturizing lotion to both feet. When finished, remove used towel.</p> <p>e Cover patient with bath blanket, raise side rail, and change bath water.</p> | <p>Secretions and moisture are often present between toes, predisposing patient to maceration and skin breakdown.</p> <p>Can impair wound healing and cause maceration of tissue.</p> |
| <p>15 While patient is supine, provide perineal care (see Procedural Guideline 17-1).</p> | <p>Moisturizers are effective in reducing dry skin; however, in excess they can cause maceration.</p> |
| <p>16 Wash back.</p> <p>a Apply clean gloves. Lower side rail. Help patient assume prone or side-lying position (as applicable). Place towel lengthwise along patient's side.</p> <p>b If fecal material is present, enclose in fold of underpad or toilet tissue and remove with disposable wipes.</p> <p>c Keep patient draped by sliding bath blanket over shoulders and thighs during bathing. Wash, rinse, and dry back from neck to buttocks using long, firm strokes. Pay special attention to folds of buttocks and anus.</p> <p>d Clean buttocks and anus, washing front to back (see illustration). Clean, rinse, and dry area thoroughly. If needed, place clean absorbent pad under patient's buttocks.</p> | <p>Decreased bath water temperature causes chilling. Clean water reduces microorganism transmission.</p> <p>Exposes back and buttocks for bathing.</p> <p>Skinfolds near buttocks and anus may contain fecal secretions and microorganisms.</p> <p>Maintains warmth and prevents unnecessary exposure.</p> <p>Cleaning buttocks after back prevents contamination of water.</p> |

STEP 16d Clean from perineum to rectum (front to back).

- | | |
|--|--|
| <p>17 Remove gloves and massage back if patient desires (see Chapter 15).</p> <p>18 Apply body lotion to skin and topical moisturizing agents to dry, flaky, reddened, or scaling areas.</p> | <p>Promotes patient relaxation.</p> <p>Dry skin results in reduced pliability and cracking. Moisturizers help to prevent skin breakdown.</p> |
|--|--|

Clinical Decision Point Massage is contraindicated in the presence of acute inflammation and where there is the possibility of damaged blood vessels or fragile skin (NPUAP and EPUAP, 2010). Massage of the legs is also contraindicated because of the possible presence of a blood clot, which could become dislodged.

- | | |
|---|--|
| <p>19 Place clean gown on patient and adjust any external lines and equipment.</p> <p>20 Assist patient with grooming, oral hygiene, shaving, hair care, and application of makeup (if desired).</p> <p>21 Make patient's bed (see Procedural Guidelines 17-5 and 17-6).</p> <p>22 Check function and position of external devices (e.g., indwelling catheters, nasogastric tubes, IV tubes, braces).</p> | <p>Ensures patient privacy and comfort.</p> <p>Promotes patient's body image.</p> <p>Provides clean environment.</p> <p>Ensures that bathing activities did not disrupt systems.</p> |
|---|--|

STEP	RATIONALE
<p>23 Remove soiled linen and place in dirty laundry bag. Do not allow linen to contact uniform. Clean and replace bathing equipment. Replace call light and personal possessions. Place bed in low, locked position with at least two but no more than three side rails raised. Make sure that patient is as comfortable as possible.</p>	<p>Prevents transmission of infection. Clean environment promotes patient's comfort. Keeping call light and articles of care within reach promotes patient's safety.</p>
<p>24 Perform hand hygiene and leave room.</p>	<p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Observe skin; pay particular attention to areas that were previously soiled, reddened, flaking, scaling, or cracking or that showed early signs of breakdown. Inspect areas normally exposed to pressure.</p>	<p>Bathing should leave skin clean and clear. If there are signs of skin irritation (e.g., redness, blistering), take steps to reduce pressure.</p>
<p>2 Observe ROM during bathing.</p>	<p>Measures joint mobility.</p>
<p>3 Ask patient to rate level of comfort (on a scale of 0 to 10).</p>	<p>Determines changes in level of comfort during bathing.</p>
<p>4 Ask if patient feels tired.</p>	<p>Determines patient's tolerance of bathing activities.</p>

Unexpected Outcomes

- 1 Areas of excessive dryness, rashes, irritation, or pressure ulcer appear on skin.
- 2 Patient becomes excessively tired and unable to cooperate or participate in bathing.
- 3 Patient seems unusually restless or complains of discomfort.

Related Interventions

- Review agency skin-care policy regarding special cleansing and moisturizing products.
- Limit frequency of complete baths.
- Complete pressure ulcer assessment (see [Chapter 18](#)).
- Institute turning and positioning measures to keep patient off pressure ulcer.
- Obtain special bed surface if patient is at risk for skin breakdown.
- Notify health care provider and/or obtain wound consultation.
- Reschedule bathing to a time when patient is more rested.
- Patients with cardiopulmonary conditions and breathing difficulties require pillow or elevated head of bed during bathing.
- Notify health care provider about changes in patient's fatigue level.
- Perform hygiene measures in stages between scheduled rest periods.
- Use a less stressful method of bathing such as a disposable bath-in-a-bag product (see [Procedural Guideline 17-2](#)).
- Consider analgesia before bathing.
- Schedule rest periods before bathing.

Recording and Reporting

- Record procedure, including the amount of patient participation and how the patient tolerated procedure.
- Record condition of skin and any significant findings (e.g., reddened areas, bruises, nevi, joint or muscle pain) in nurses' notes and electronic health record (EHR).
- Report evidence of alterations in skin integrity, break in suture line, or increased wound secretions to nurse in charge or health care provider.

Special Considerations

Teaching

- Teach patients how to inspect surfaces between skinfolds for signs of irritation or breakdown.

Pediatric

- Some adolescents require and/or prefer more frequent bathing as a result of more active sebaceous glands.

- Young adolescent girls should learn basic perineal hygiene measures and know why they are predisposed to urinary tract infections.

Gerontologic

- When caring for cognitively impaired older adults, approach bathing in a calm manner and use the same bathing method and when possible the same caregiver.
- It is best to use the least distressing method first such as soaking in a bathtub or using a disposable bag bath. These approaches must be modified for each patient (i.e., soaking the feet rather than the whole body) ([Barrick et al., 2008](#); [Meiner, 2010](#)).
- Older adults with incontinence need meticulous skin care to reduce incontinence-associated dermatitis and the risk of infection.

Home Care

- Type of bath chosen depends on assessment of the home, availability of running water, and condition of bathing facilities.
- In the home setting set up equipment according to established routines. Patient is the best resource for what works in terms of convenience and saving time.
- Patients at risk for falls may benefit from the following:

- Installation of grab bars in shower
- Adhesive strips applied to shower or tub floor
- Addition of a shower chair or placement of a chair or stool

Long-Term Care

- Tubs in long-term care settings frequently come equipped with electronic thermometers to measure water temperature. The tubs also have hydraulic lifts to help residents into the tub.

PROCEDURAL GUIDELINE 17-1 Perineal Care

Perineal care involves thorough cleansing of the patient's external genitalia and surrounding skin. A patient routinely receives perineal care during a complete bed bath. However, patients who have fecal or urinary incontinence, an indwelling Foley catheter, or rectal or genital surgery may need more frequent perineal care. Wear gloves during perineal care because of the risk of contacting infectious organisms present in fecal, urinary, or vaginal secretions. To avoid embarrassment, always act in a professional and sensitive manner and provide privacy at all times.

Delegation and Collaboration

The skill of perineal care can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Avoid any physical restriction that affects proper positioning of patient.
- Properly position a patient with an indwelling Foley catheter.
- Inform the nurse of any perineal drainage, excoriation, or rash observed.

Equipment

- Washcloths, bath towels, and bath blanket
- Cleansing product, disposable wipes
- Warm water
- Laundry bag
- Wash basin, waterproof pad or bedpan
- Clean gloves
- Additional supplies when perineal care is provided other than during a bath (cotton balls or swabs, solution bottle or container filled with warm water or prescribed rinsing solution, waterproof bag).

Procedural Steps

- 1 Assess environment for safety (e.g., check the room for spills, make sure that equipment is working properly and that bed is in locked, low position).
- 2 Provide privacy and explain procedure and importance in preventing infection.
- 3 Perform hand hygiene. Apply clean gloves.

STEP 4d Drape patient for perineal care.

4 Perineal care for a female.

- a If patient is able to maneuver and handle washcloth, allow to clean perineum on own.
- b Help patient assume dorsal recumbent position. Note restrictions or a limitation in patient's positioning. Position waterproof pad under patient's buttocks.
- c Drape patient with bath blanket placed in shape of a diamond. Lift lower edge of bath blanket to expose perineum.
- d Fold lower corner of bath blanket up between patient's legs onto abdomen and under hip (see illustration). Wash and dry patient's upper thighs.
- e Wash labia majora. Use nondominant hand to gently retract labia from thigh. Use dominant hand to wash carefully in skinfolds. Wipe in direction from perineum to rectum (front to back). Repeat on opposite side using separate section of washcloth. Rinse and dry area thoroughly.
- f Gently separate labia with nondominant hand to expose urethral meatus and vaginal orifice. With dominant hand wash downward from pubic area toward rectum in one smooth stroke (see illustration). Use separate section of cloth for each stroke. Clean thoroughly over labia minora, clitoris, and vaginal orifice. Avoid tension on indwelling catheter if present and clean area around it thoroughly.
- g Rinse and dry area thoroughly, using front-to-back method.
- h If patient uses bedpan, pour warm water over perineal area and dry thoroughly.
- i Fold lower corner of bath blanket back between patient's legs and over perineum. Ask patient to lower legs and assume comfortable position.

5 Perineal care for a male.

- a If patient is able to maneuver and handle washcloth, allow him to clean perineum on his own.
- b Help patient to supine position. Note restriction in mobility.
- c Fold lower half of bath blanket up to expose upper thighs. Wash and dry thighs.
- d Cover thighs with bath towels. Raise bath blanket to expose genitalia. Gently raise penis and place bath towel

STEP 4f Clean from perineum to rectum (front to back)

PROCEDURAL GUIDELINE 17-1 Perineal Care—cont'd

underneath. Gently grasp shaft of penis. If patient is uncircumcised, retract foreskin. If patient has an erection, defer procedure until later.

- e Wash tip of penis at urethral meatus first. Using circular motion, clean from meatus outward (see illustration). Discard washcloth and repeat with clean cloth until penis is clean. Rinse and dry gently and thoroughly.
- f Return foreskin to its natural position.

Clinical Decision Point After administering male perineal care for uncircumcised males, make sure that foreskin is in its natural position. This is extremely important in patients with decreased sensation in their lower extremities. Tightening foreskin around shaft of penis causes local edema; discomfort; and, if not corrected, permanent urethral damage.

- g Gently clean shaft of penis and scrotum by having patient abduct legs. Pay special attention to underlying surface of penis. Lift scrotum carefully and wash underlying skinfolds. Rinse and dry thoroughly.

- h Fold bath blanket back over patient's perineum and help him to comfortable position.
- 6 Observe perineal area for any irritation, redness, or drainage that persists after perineal hygiene.
- 7 Dispose of gloves in receptacle and perform hand hygiene.

STEP 5e Use circular motion to clean tip of penis.

PROCEDURAL GUIDELINE 17-2 Use of Disposable Bed Bath, Tub, or Shower**Delegation and Collaboration**

The skill of bathing in a tub or shower or using a disposable bed bath can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Not massage reddened skin areas during bathing.
- Properly position male and female patients with musculo-skeletal limitations or an indwelling Foley catheter or other equipment (e.g., intravenous tubing).
- Report changes in skin or perineal area or signs of impaired skin integrity to the nurse.

Equipment

- ❑ Washcloths and bath towels (for tub or shower); bath blanket, cleansing product, toiletry items (deodorant, lotion), disposable wipes, clean hospital gown or patient's own pajamas or gown, laundry bag
- ❑ Prepackaged, disposable bathing system (alternative to soap and water)
- ❑ Clean gloves

Procedural Steps

- 1 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and bed is in locked, low position) and provide privacy.
- 2 Perform hand hygiene and apply clean gloves if there is a risk of exposure to body fluids.
- 3 **Disposable bed bath.**
 - a Position patient supine or in a position of comfort. Warm package in a microwave, following package directions. Do not use a microwave that is used for food preparation. The cleansing pack contains 8 to 10 premoistened towels.
 - b Use a single towel for each general body part cleansed. Follow the same order of cleaning as for total or partial bed bath (see Skill 17-1).

- c Allow skin to air dry for 30 seconds. It is permissible to lightly cover patient with bath towel to prevent chilling.
- d **NOTE:** If there is excessive soiling (e.g., in perineal region), use an extra cleansing pack or conventional washcloths, soap and water, and towels.

4 Tub bath or shower.

- a Assess patient's fall risk status, consider patient's condition, and review orders for precautions concerning his or her movement or positioning. A health care provider's order usually is needed for tub bath or shower.
- b Schedule use of shower or tub.
- c Check tub or shower for cleanliness. Use cleaning techniques outlined in agency policy. Place rubber mat on tub or shower bottom. Place skid-proof disposable bath mat or towel on floor in front of tub or shower.
- d Collect all hygienic aids, toiletry items, and linens requested by patient. Place within easy reach of tub or shower.
- e Help patient to bathroom if necessary. Have him or her wear robe and skid-proof slippers to bathroom.
- f Demonstrate how to use call signal for assistance. Place "occupied" sign on bathroom door.
- g Fill bathtub halfway with warm water. Check temperature of bath water, have patient test it, and adjust it if it is too warm or too cold. Explain which faucet controls hot water. *Do not use bath oil in tub water.*
- h If patient is taking shower, turn shower on and adjust water temperature before he or she enters shower stall. Use shower seat or tub chair if available (see illustration).
- i Instruct patient that you will not allow him or her to remain in tub longer than 20 minutes.
- j Check on patient every 5 minutes.
- k Return to bathroom when patient signals and knock before entering.
- l For patient who is unsteady, drain tub of water before he or she attempts to get out. Place bath towel over patient's

PROCEDURAL GUIDELINE 17-2 Use of Disposable Bed Bath, Tub, or Shower—cont'd

shoulders. Help him or her get out of tub as needed and help with drying. If possible have a shower chair available for patient to sit.

- m Help patient as needed to don clean gown or pajamas, slippers, and robe. (In home, extended care, or rehabilitation setting, encourage patient to wear regular clothing.)
- n Help patient to room and to comfortable position in bed or chair.
- o Evaluate patient's tolerance and fatigue level.
- p Clean tub or shower according to agency policy. Remove soiled linen and place in dirty laundry bag. Discard disposable equipment in proper receptacle. Place "unoccupied" sign on bathroom door. Return supplies to storage area.
- q Perform hand hygiene.

STEP 4h Shower seat for patient safety.

SKILL 17-2 Oral Hygiene

Maintenance of daily oral hygiene, including brushing, flossing, and rinsing, is essential for the prevention and control of plaque-associated oral diseases. In addition to preventing inflammation and infection, oral hygiene promotes comfort, nutrition, and verbal communication. Brushing cleans the teeth of food particles, plaque (the cause of dental caries), and bacteria; massages the gums; and relieves discomfort from unpleasant odors and tastes. Flossing removes tartar that collects at the gum line. Rinsing removes dislodged food particles and excess toothpaste.

When a patient becomes ill, many factors influence the need for oral hygiene. Offer oral hygiene assistance as required, from preparing needed supplies to actually brushing a patient's teeth. It is also your responsibility to determine the frequency that patients require oral hygiene. Plan the frequency of care based on the condition of the oral cavity and the patient's level of comfort.

In addition to recommendations for the general population, oral-care regimens have been developed to help relieve and facilitate healing of chemotherapy- and radiation therapy-related mucositis, stomatitis, and xerostomia. These lesions are very painful and interfere with a patient's nutrition. Specific regimens are discussed later in this chapter.

Delegation and Collaboration

The skill of oral hygiene (including toothbrushing, flossing, and rinsing) can be delegated to nursing assistive personnel (NAP). However, the nurse is responsible for assessing the patient's gag reflex to determine if the patient is at risk for aspiration. The nurse instructs the NAP to:

- Note types of changes in oral mucosa (e.g., presence of lesions or open areas) for which to observe and report to the nurse.
- Report patient's complaints of pain or occurrence of bleeding during oral care.
- Be aware of special precautions such as aspiration precautions, including:
 - a Keeping head of bed (HOB) raised to no lower than 30 degrees.
 - b Explaining need to report excessive coughing or choking during procedure.

Equipment

- Soft-bristled toothbrush (hard toothbrush damages enamel and gums) or toothette sponges for patients for whom a toothbrush is contraindicated
- Nonabrasive fluoride toothpaste or dentifrice
- Dental floss
- Tongue depressor
- Penlight
- Water glass with cool water, straw
- Alcohol-free antiseptic mouth rinse (*optional*)
- Emesis basin
- Bath towels to place over patient's chest
- Clean gloves

STEP

RATIONALE

ASSESSMENT

<p>1 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and that bed is in locked, low position).</p>	<p>Identifies safety hazards in patient environment that could cause or potentially lead to harm. (QSEN Quality/Safety Competencies, 2012).</p>
<p>2 Perform hand hygiene and apply clean gloves.</p>	<p>Reduces transmission of microorganisms in blood or saliva.</p>
<p>3 Instruct patient not to bite down. Using a penlight and tongue depressor, inspect integrity of lips, teeth, buccal mucosa, gums, palate, and tongue (see Chapter 6).</p>	<p>Determines status of patient's oral cavity and extent of need for oral hygiene.</p>
<p>4 Identify presence of common oral problems.</p>	<p>Helps determine type of hygiene patient requires and information patient requires for self-care.</p>
<p>a <i>Dental caries</i>: Chalky-white discoloration of tooth or presence of brown or black discoloration</p>	<p>Periodontal disease.</p>
<p>b <i>Gingivitis</i>: Inflammation of gums.</p>	<p>Periodontal disease.</p>
<p>c <i>Periodontitis</i>: Receding gum lines, inflammation, gaps between teeth</p>	<p>Periodontal disease.</p>
<p>d <i>Halitosis</i>: Bad breath</p>	<p>Periodontal disease.</p>
<p>e <i>Cheilosis</i>: Cracking lips</p>	<p>Prevents spread of microorganisms.</p>
<p>f <i>Stomatitis</i>: Inflammation of mouth tissues or structures</p>	<p>Certain conditions increase likelihood of impaired oral cavity integrity and need for preventive care.</p>
<p>g <i>Mucositis</i>: Inflammation of oral mucous membrane</p>	<p>Causes excess drying and fragility of mucous membranes and lips; increases accumulation of secretions on tongue and gums.</p>
<p>h Dry, cracked, coated tongue</p>	<p>Causes drying of mucosa.</p>
<p>5 Remove gloves and perform hand hygiene.</p>	<p>Drugs kill rapidly multiplying cells, including sloughing of normal cells lining oral cavity. Mucositis with ulcers and inflammation can develop.</p>
<p>6 Review medical record and assess risk for oral hygiene problems:</p>	<p>Reduces salivary flow and lowers pH of saliva; leads to stomatitis and tooth decay (Sjögren's Syndrome Foundation, 2011).</p>
<p>a Dehydration: Inability to take fluids or food by mouth, health care provider's order prohibiting food or fluids by mouth (NPO) for a procedure or because of patient's condition</p>	<p>Increases irritation to gums and mucosa. Excess secretions accumulate on teeth and tongue.</p>
<p>b Presence of nasogastric or oxygen tubes; mouth breathers</p>	<p>Predisposes to inflammation and bleeding of gums.</p>
<p>c Chemotherapeutic drugs</p>	<p>Break in mucosa increases risk for infection. Vigorous brushing can disrupt suture lines.</p>
<p>d Radiation therapy to head and neck</p>	<p>With advancing age mucosa becomes thin and less elastic.</p>
<p>e Presence of artificial airway (e.g., endotracheal tube)</p>	<p>Results from irritants such as alcohol, tobacco, acidic foods or side effects of medications (e.g., antibiotics, steroids, antidepressants).</p>
<p>f Blood-clotting disorders (e.g., leukemia, aplastic anemia)</p>	<p>Prone to dryness of mouth, gingivitis, periodontal disease, and loss of teeth.</p>
<p>g Oral surgery, trauma to mouth</p>	<p>Identifies errors in patient's technique, deficiencies in preventive oral hygiene, patient's level of knowledge regarding dental care. American Dental Association (ADA) (2011) recommends brushing teeth at least twice a day with ADA-accepted fluoride toothpaste and once-a-day flossing.</p>
<p>h Aging</p>	<p>Antimicrobial mouth rinses and toothpastes decrease bacteria and stop bacterial growth in dental plaque, which can cause an early, reversible form of gum disease called <i>gingivitis</i> (ADA, 2011).</p>
<p>i Chemical injury</p>	<p>Regular dental visits (e.g., every 6 months) are recommended by the ADA; however, frequency of visits can vary for each patient and should be determined by his or her dentist (ADA, 2011).</p>
<p>j Diabetes mellitus</p>	<p>Assessment determines level of assistance required from nurse. Some older patients or persons with musculoskeletal or nervous system alterations are unable to hold toothbrush with firm grip or manipulate brush. Large-handled toothbrushes or a toothbrush handle pushed through a small rubber ball may be of assistance.</p>
<p>7 Determine patient's oral hygiene practices.</p>	<p>Identifies errors in patient's technique, deficiencies in preventive oral hygiene, patient's level of knowledge regarding dental care. STEP

RATIONALE

NURSING DIAGNOSES

- Bathing/self-care deficit
- Deficient knowledge regarding oral hygiene care
- Impaired oral mucous membrane
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- Expected outcomes following completion of procedure:
 - Patient expresses feeling of mouth cleanliness.
 - Oral cavity structures have normal characteristics:
 - Oral mucosa is moist, intact, and of normal color.
 - Gums are pink, firm, and adherent to neck of teeth.
 - Teeth are clean, smooth, and shiny.
 - Tongue is pink and without secretions or coating.
 - Patient describes correct oral hygiene techniques and necessary frequency.
 - Patient makes choices regarding hygiene procedure and helps by flossing and brushing.
- Gather equipment and supplies.
- Explain procedure to patient and discuss preferences regarding use of hygiene aids.

Hygiene measures remove secretions and thickened mucosa. Maintains integrity of teeth and healthy oral mucosa.

Demonstrates understanding of instruction.

Patient is able to manage self-care.

Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment.

Some patients feel uncomfortable about having nurse care for their basic needs. Patient involvement with procedure minimizes anxiety.

IMPLEMENTATION

- Close room doors and windows and draw room divider curtain.
- Prepare and have supplies ready at bedside arranged within easy reach.
- Raise bed to comfortable working height. Raise HOB to at least semi-Fowler's position (unless contraindicated) and lower side rail. Move patient or help patient move close to side from which you choose to work. A side-lying position can be used.
- Place towel over patient's chest.
- Perform hand hygiene. Apply clean gloves.
- Apply toothpaste to brush bristles. Hold brush over emesis basin. Pour small amount of water over toothpaste.
- Patient may help by brushing. Hold toothbrush bristles at 45-degree angle to gum line (see illustration). Be sure that tips of bristles rest against and penetrate under gum line. Brush inner and outer surfaces of upper and lower teeth by brushing from gum to crown of each tooth. Clean biting surfaces of teeth by holding top of bristles parallel with teeth and brushing gently back and forth (see illustration). Brush sides of teeth by moving bristles back and forth (see illustration).

Privacy ensures patient's mental and physical comfort. Creates organized workspace.

Raising bed and positioning patient promotes good body mechanics and prevents nurse from muscle strain. Semi-Fowler's position helps prevent patient from choking or aspirating.

Prevents soiling of patient's gown.

Prevents transmission of microorganisms in body fluids.

Moisture aids in distribution of toothpaste over tooth surfaces.

Angle allows brush to reach all tooth surfaces and to clean under gum line where plaque and tartar accumulate. Back-and-forth motion loosens food particles caught between teeth and along chewing surfaces.

STEP 7 Directions of brush for toothbrushing.

- Have patient hold brush at 45-degree angle and lightly brush over surface and sides of tongue (see illustration). Avoid initiating gag reflex.

Microorganisms collect and grow on surface of tongue and contribute to bad breath. Gagging may cause aspiration of toothpaste.

STEP

RATIONALE

STEP 8 Nurse observes patient's toothbrushing technique.

- 9 Allow patient to rinse mouth thoroughly with water by taking several sips of water (may use straw), swishing water across all tooth surfaces, and spitting into emesis basin. Use this time to observe patient's brushing technique and teach importance of brushing teeth twice a day.
- 10 Have patient rinse teeth with alcohol-free antiseptic mouthwash for 30 seconds. Then have him or her spit rinse into emesis basin.
- 11 Help to wipe patient's mouth.
- 12 Allow patient to floss. Floss between all teeth. Hold floss against tooth while moving it up and down sides of teeth. Instruct patient in importance of daily flossing (see illustrations). Check to be sure that flossing is not contraindicated.

Rinsing removes food particles.

The [ADA \(2011\)](#) recommends that an antiseptic mouthwash is as effective as flossing for reducing plaque and gingivitis between teeth; effect on dental caries prevention has not been determined. Avoid using commercial brands of mouthwash that contain alcohol, which is drying to oral mucosa.

Promotes sense of comfort.

Flossing once daily removes plaque and decay-causing bacteria between teeth and under gum line, preventing gum disease.

Immunocompromised patients are sometimes on precautions that prohibit use of floss or water-piks because of dislodging of bacteria and possible bleeding of gums.

STEP 12 Flossing. **A**, Dental floss is held between middle fingers to floss upper teeth. **B**, Floss is moved in up-and-down motions between teeth. Floss is moved up and down from crown to gum line. **C**, Floss is held with index fingers to floss lower teeth.

- 13 Allow patient to rinse mouth thoroughly with cool water and spit into emesis basin. Help to wipe his or her mouth.
- 14 Help patient to comfortable position, remove emesis basin and over-bed table, raise side rail if appropriate, and lower bed to original position.
- 15 Wipe off over-bed table, discard soiled linen in dirty laundry bag, remove soiled gloves, and return equipment to proper place.
- 16 Perform hand hygiene.

Rinsing removes plaque and tartar from oral cavity.

Provides for patient comfort and safety.

Proper disposal of soiled equipment prevents spread of infection.

Reduces transmission of microorganisms.

STEP

RATIONALE

EVALUATION

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Ask patient if any area of oral cavity feels uncomfortable or irritated. 2 Apply clean gloves and inspect condition of oral cavity. 3 Ask patient to describe proper hygiene techniques and recommended frequency. | <p>Pain indicates need for further inspection for possible breaks in oral mucosa or identification of stomatitis or infection.</p> <p>Determines effectiveness of hygiene and rinsing.</p> <p>Evaluates patient's learning. Establish regular oral hygiene routine that is easy for patient to follow at home. The ADA (2011) currently recommends brushing at least twice per day and flossing daily.</p> |
| <ol style="list-style-type: none"> 4 Observe patient brushing and flossing. | <p>Evaluates patient's ability to demonstrate correct technique.</p> |

Unexpected Outcomes

- 1 Mucosa is dry and inflamed. Tongue has thick coating.
- 2 Cheilosis—Dry, cracked lips
- 3 Gum margins are retracted from teeth, with localized areas of inflammation. Bleeding occurs around gum margins.
- 4 Mucosa becomes inflamed from repeated chemotherapy administration, and a lesion from sloughing of tissue develops. These conditions can also be caused by radiation therapy used to treat head and neck cancers.

Related Interventions

- Increase patient's hydration.
- Increase frequency of tongue brushing.
- Apply moisturizing lubricant to patient's lips.
- Report findings because patient may have an underlying bleeding tendency.
- Switch to softer-bristled toothbrush.
- Avoid vigorous brushing and flossing.
- Determine best-practice oral regimen for chemotherapy- and radiation therapy-related mucositis and stomatitis. Common regimens used to promote healing and comfort include:
 - Use a fluoride toothpaste.
 - Use one of the following rinses made with salt and/or baking soda ([National Cancer Institute, 2011](#)):
 - 1 teaspoon salt in 4 cups of water
 - 1 teaspoon baking soda in 1 cup (8 ounces) of water
 - ½ teaspoon salt and 2 tablespoons baking soda in 4 cups of water
 - An antibacterial rinse 2 to 4 times a day for gum disease; rinse for 1 to 2 minutes
- If dry mouth (xerostomia) and hyposalivation occur such as with radiation therapy of the head and neck, additional rinses to increase moisture may be used. Brushing and gentle flossing should be continued as well.

Recording and Reporting

- Record procedure and note condition of oral cavity in nurses' notes and EHR.
- Report bleeding, pain, or presence of lesions to nurse in charge or health care provider.

Special Considerations

Teaching

- Use a variety of teaching formats (e.g., brochures, videos, DVDs) that are consistent with patient's health literacy level.
- Educate patients about methods to prevent tooth decay (e.g., reduce intake of carbohydrates, especially sweet sticky snacks between meals; brush within 30 minutes of eating sweets; rinse mouth thoroughly with water or alcohol-free antiseptic mouth rinse; use fluoride toothpaste).
- Educate patients to visit a dentist regularly (every 6 months) for professional cleaning and oral examination; however, frequency of visits can vary for each patient and should be determined by his or her dentist ([ADA, 2011](#)).
- When teaching special oral-care regimens, include family caregivers.
- Avoid mints if there are conditions of the mouth that are associated with ulcerations of the oral mucosa.

Pediatric

The following are recommended by the [ADA \(2011\)](#):

- Clean baby's gums with warm water and gauze after every feeding, even before teeth are formed. A dentist should be consulted before using fluoride toothpaste. The use of fluoride toothpaste usually begins at 2 years of age.
- Teach parents that infants should not be put to bed with a bottle; this causes tooth decay and ear infections.
- Limit snacks to three to four per day. Avoid sugary snacks and drinks and sticky candy.
- Notify dentist if family uses bottled or well water. A prescription for fluoride may be ordered.
- Dentist will evaluate for need of sealants for molars.
- Flossing requires parental supervision until at least 10 years of age.
- The first dental examination should be within 6 months after the first tooth comes in and no later than the first birthday, followed by dental examinations every 6 months.

Gerontologic

- A number of normal age-related changes occur in the oral cavity. Thinning of the oral mucosa and decreased vascularity of the gingivae predispose older adults to injury and periodontal disease. Loss of tissue elasticity and decreased mass and strength

of the muscles make chewing more difficult. Loss of the alveolar bone can loosen natural teeth.

- The number of taste buds declines with advancing age. In an attempt to enhance the taste of food, some older adults choose salty and sugary foods, which erode tooth enamel and expose dentin (Lau, 2008).
- Plaque retention is a problem in older adults, worsened by existing teeth restorations, missing teeth, gingival recession, and wearing of removable prosthesis. Some older adults may also

experience difficulty with maintaining good oral hygiene with flossing and brushing because of decreased dexterity and decreasing eyesight.

Home Care

- During the initial admission visit document the condition of the patient's mouth, teeth, and gums, thus providing a baseline for assessing the patient's ability to comply with special diets and fluid intake and carry out oral hygiene practices.

PROCEDURAL GUIDELINE 17-3 Care of Dentures

Video Clip

Oral bacteria from multiple strains and *Candida* species are found on acrylic dentures (Busscher et al., 2010). Encourage patients who wear dentures to continue to care for them and provide this care as frequently as with natural teeth. Loose dentures can cause discomfort and make it difficult for patients to chew food and speak clearly. Routine denture care reduces the risk for gingival infection. Some patients are unable to care for their dentures, and nurses become responsible for providing denture and oral care. Dentures are a patient's personal property; thus be sure to handle them with care because they are easy to break. Store them in an enclosed, labeled cup and soak them when not worn (e.g., at night, during surgery). Reinsert them as soon as possible.

Delegation and Collaboration

The skill of denture care can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Not use hot or excessively cold water when caring for dentures.
- Inform the nurse if there are cracks in dentures.
- Inform the nurse if the patient has any oral discomfort.

Equipment

- Soft-bristled toothbrush or denture toothbrush
- Denture dentifrice or toothpaste, denture adhesive (*optional*)
- Glass of water
- Emesis basin or sink
- 4 × 4-inch gauze
- Washcloth
- Denture cup (for storage)
- Clean gloves

Procedural Steps

- 1 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and that bed is in locked, low position).
- 2 Ask patient if dentures fit and if there is any gum or mucous membrane tenderness or irritation. Ask patient about denture care and product preferences.
- 3 Determine if patient can clean dentures independently or requires assistance. Dentures need cleaning as often as natural teeth.
- 4 Fill emesis basin with tepid water. (If using sink, place washcloth in bottom of sink and fill sink with approximately 2.5 cm [1 inch] of water.)
- 5 Perform hand hygiene. Apply clean gloves.
- 6 Ask patient to remove dentures. If patient is unable to do this independently, grasp upper plate at front with thumb and

index finger wrapped in gauze and pull downward. Gently lift lower denture from jaw and rotate one side downward to remove from patient's mouth. Place dentures in emesis basin or sink lined with washcloth and 2.5 cm (1 inch) of water.

- 7 Apply cleaning agent to brush and brush surfaces of dentures (see illustration). Hold dentures close to water. Hold brush horizontally and use back-and-forth motion to clean biting surfaces. Use short strokes from top of denture to biting surfaces to clean outer teeth surfaces. Hold brush vertically and use short strokes to clean inner teeth surfaces. Hold brush horizontally and use back-and-forth motion to clean under-surface of dentures (see Skill 17-2).

STEP 7 Brushing surface of dentures.

- 8 Rinse thoroughly in tepid water. If water is too cold, dentures can crack. If it is too hot, dentures can become warped and no longer fit.
- 9 Some patients use an adhesive to seal dentures in place. Apply a thin layer to undersurface before inserting.
- 10 If patient needs help with inserting dentures, moisten upper denture and press firmly to seal it in place. Insert moistened lower denture (if applicable). Ask if denture(s) feel comfortable.
- 11 Some patients prefer to store their dentures to give gums a rest and reduce risk for infection. Store in tepid water in denture cup. Keep denture cup in a secure place labeled with patient's name to prevent loss.
- 12 Dispose of supplies. Remove and discard gloves and perform hand hygiene.

SKILL 17-3 Performing Mouth Care for an Unconscious or Debilited Patient

Unconscious or debilitated patients pose challenges because of their risk for alterations of the oral cavity from drying of the mucous membrane, thickened secretions, and the inability to eat or drink. They are susceptible to infection because of the change in the normal flora of the oral cavity and at risk for infection because of increased plaque formation from the dryness of the mouth and decreased salivation. Dryness of the oral mucosa is also caused by mouth breathing and oxygen therapy. Respiratory secretions often are thick and place patients at risk for ineffective airway clearance, requiring suction. They are also at risk for aspiration. Although saliva production is decreased, saliva is present and can pool in the back of the oral cavity, which is another contributing factor to placing the patient at risk of aspiration. The secretions in the oral cavity change very rapidly to gram-negative pneumonia-producing bacteria if aspiration occurs.

The critically ill patient faces the same risk factors for oral problems as other patients such as dehydration, dryness of the oral mucosa, chemical injury to the mucosa, and oral trauma. Once intubated, an endotracheal tube causes a bypass of normal defenses, which also causes a rapid change in the normal oral flora (Browne et al., 2011). Some patients require mouth care as often as every 1 to 2 hours until the mucosa returns to normal. Optimal oral care should focus on plaque removal and stimulation of salivary flow (Munro et al., 2009). Chlorhexidine rinse or gel is an antibacterial solution used in critically ill patients and has been shown to prevent ventilator-associated pneumonia (VAP) (Labeau et al., 2011). Currently more research is underway in establishing oral-care regimens for all critically ill patients.

Many patients have no gag reflex as a result of change in consciousness or a neurologic injury. While providing oral care to an unconscious patient, protect him or her from choking and aspiration. The safest technique is to have two nurses provide care. You provide oral care while another nurse or nursing assistive personnel (NAP) suction oral secretions as necessary with a Yankauer suction tip. You can also delegate oral care to two NAPs with instructions. Place the unconscious or unresponsive patient in a Sim's or side-lying position with the head in a dependent position. Raise the head of bed (HOB) to at least 30 degrees, with patient's head turned to the side and toward the mattress in a dependent position. Proper oral hygiene requires keeping the oral mucosa moist and removing secretions that lead to infection. Use a moisturizing emollient for the lips as well.

Evaluate the level and frequency of oral care on a daily basis during assessment of the oral cavity. Routine suctioning of the mouth and pharynx is required to manage oral secretions to reduce the risk for aspiration. Chlorhexidine 2% gel or mouth rinse every 12 hours has been shown to effectively prevent VAP (Labeau et al., 2011). Research also suggests that toothbrushing provides additional benefit in reducing colonization of dental plaque (Berry et al., 2011). For patients who are not on ventilated-assisted breathing, toothbrushing and chlorhexidine are also effective.

Delegation and Collaboration

The skill of providing oral hygiene to an unconscious or debilitated patient can be delegated to nursing assistive personnel (NAP). The nurse must first assess the patient for a gag reflex. The nurse instructs the NAP to:

- Properly position patient for mouth care.
- Be aware of special precautions such as aspiration precautions.
- Use an oral suction catheter for clearing oral secretions (see Skill 25-1).
- Report signs of impaired integrity of oral mucosa to the nurse.
- Report any bleeding of mucosa or gums, excessive coughing or choking to the nurse.

Equipment

- Small pediatric, soft-bristled toothbrush or toothette sponges for patients for whom brushing is contraindicated.
- Antibacterial solution per organization protocol (e.g., chlorhexidine)
- Fluoride toothpaste
- Water-based mouth moisturizer
- Tongue blade
- Penlight
- Oral suction equipment
- Oral airway (uncooperative patient or patient who shows bite reflex)
- Water-soluble lip lubricant
- Water glass with cool water
- Face and bath towel
- Emesis basin
- Clean gloves

STEP

RATIONALE

ASSESSMENT

- 1 Assess environment for safety (e.g., check the room for spills, make sure that equipment is working properly and that bed is in locked, low position).
- 2 Perform hand hygiene, and apply clean gloves.
- 3 Test for presence of gag reflex by placing tongue blade on back half of tongue.

Identifies safety hazards in patient environment that could cause or potentially lead to harm (QSEN Quality/Safety Competencies, 2012).

Reduces transmission of microorganisms in blood or saliva.

Helps in determining aspiration risk.

Clinical Decision Point Patients with impaired gag reflex require oral care but are at risk for aspiration. Keep suction equipment available when caring for patients who are at risk for aspiration.

STEP	RATIONALE
4 Inspect condition of oral cavity (see Chapter 6).	Determines condition of oral cavity and need for hygiene.
5 Remove gloves. Perform hand hygiene.	Prevents spread of infection.
6 Assess patient's risk for oral hygiene problems (see Skill 17-2).	Certain conditions increase likelihood of alterations in integrity of oral cavity mucosa and structures, necessitating more frequent care.
7 Assess patient's respirations on a regular schedule.	Ensures early recognition of aspiration.

NURSING DIAGNOSES

- Impaired oral mucous membrane
- Risk for aspiration

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Buccal mucosa and tongue are pink, moist, and intact. Gums are moist and intact. Teeth are clean, smooth, and shiny. Tongue is pink and without coating. Lips are moist, smooth, and without cracks. • Debilitated patient expresses feeling of mouth cleanliness. • Oropharynx remains clear of secretions. 	Degree of improvement in condition of oral cavity structures depends on extent of secretions or changes that existed before care.
2 Gather equipment and supplies.	Comfort achieved. Secretions removed, thus avoiding aspiration. Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment.
3 Explain procedure.	

IMPLEMENTATION

1 Pull curtain around bed or close room door.	Provides privacy.
2 Perform hand hygiene and apply clean gloves.	Reduces transfer of microorganisms.
3 Place towel on over-bed table and arrange equipment. If needed turn on suction machine and connect tubing to suction catheter.	Prevents soiling of tabletop. Equipment prepared in advance ensures smooth, safe procedure. Supplies within reach create organized workspace.
4 Raise bed to appropriate working height; lower side rail. Unless contraindicated (e.g., head injury, neck trauma), lower side rail and position patient in Sims' or side-lying position. Turn patient's head toward mattress in dependent position with HOB elevated at least 30 degrees.	Use of good body mechanics with bed in high position prevents injury. Allows secretions to drain from mouth instead of collecting in back of pharynx. Prevents aspiration.
5 Place towel under patient's head and emesis basin under chin.	Prevents soiling of bed linen.
6 Remove dentures or partial plates if present.	Allows for thorough cleaning of prosthetics later (see Procedural Guideline 17-3). Provides clearer access to oral cavity.
7 If patient is uncooperative or having difficulty keeping mouth open, insert an oral airway. Insert upside down and turn airway sideways and over tongue to keep teeth apart. Insert when patient is relaxed if possible. Do not use force (see illustration).	Prevents patient from biting down on nurse's fingers and provides access to oral cavity.

STEP 7 Cleaning around oral airway with toothette.

STEP

RATIONALE

Clinical Decision Point *Never place fingers into the mouth of an unconscious or debilitated patient. The normal response is to bite down.*

- | | |
|--|--|
| <p>8 Clean mouth using brush moistened in water. Apply toothpaste or use antibacterial solution first to loosen crusts. Clean tooth surfaces using an up-and-down gentle motion. A toothette sponge can be used for patients for whom toothbrushing is contraindicated. Suction any accumulated secretions. Clean chewing and inner tooth surfaces first. Clean outer tooth surfaces (see Skill 17-2). Moisten brush with chlorhexidine solution to rinse. Use brush or toothette to clean roof of mouth, gums, and inside cheeks. Gently brush tongue but avoid stimulating gag reflex (if present). Repeat rinsing several times and use suction to remove secretions.</p> <p>9 Use brush or toothette sponge to apply thin layer of water-soluble moisturizer to lips (see illustration).</p> | <p>Brushing action removes food particles between teeth, along chewing surfaces and crusts for mucosa. Do not use commercial swabs because they do not clean teeth. Repeated rinsing removes all debris and aids in moistening mucosa.</p> <p>Suction removes secretions and fluids that collect in posterior pharynx. Reduces risk for aspiration.</p> <p>Lubricates lips to prevent drying and cracking.</p> |
|--|--|

STEP 9 Application of water-soluble moisturizer to lips.

- | | |
|--|--|
| <p>10 Inform patient that procedure is completed. Return him or her to comfortable and safe position.</p> <p>11 Raise side rails as appropriate and return bed to locked, low position.</p> <p>12 Clean equipment and return to its proper place. Place soiled linen in dirty laundry bag.</p> <p>13 Remove and dispose of gloves in proper receptacle and perform hand hygiene.</p> | <p>Provides meaningful stimulation to unconscious or less-responsive patient.</p> <p>Reduces risk of falls from bed.</p> <p>Proper disposal of soiled equipment prevents spread of infection.</p> <p>Reduces transmission of microorganisms.</p> |
|--|--|

EVALUATION

- | | |
|---|---|
| <p>1 Apply clean gloves and inspect oral cavity.</p> <p>2 Ask debilitated patient if mouth feels clean.</p> | <p>Determines efficacy of cleaning. Once thick secretions are removed, underlying inflammation or lesions may be revealed.</p> <p>Evaluates level of comfort.</p> |
|---|---|

Unexpected Outcomes

- 1 Secretions or crusts remain on mucosa, tongue, or gums.
- 2 Localized inflammation or bleeding of gums or mucosa is present.

- 3 Lips are cracked or inflamed.
- 4 Patient aspirates secretions.

Related Interventions

- Provide more frequent oral hygiene.
- Provide more frequent oral hygiene with toothette sponges.
- Apply a water-based mouth moisturizer to provide moisture and maintain integrity of oral mucosa.
- Chemotherapy and radiation can cause mucositis (inflammation of mucous membranes in mouth) because of sloughing of epithelial tissue. Room temperature saline rinses, bicarbonate and sterile water rinses, and oral care with a soft-bristled toothbrush decrease severity and duration of mucositis.
- Apply moisturizing gel or water-soluble lubricant to lips.
- Suction oral airway as secretions accumulate to maintain airway patency (see Chapter 25).
- Elevate patient's HOB to facilitate breathing.
- If aspiration is suspected, notify health care provider. Prepare patient for chest x-ray examination.

Recording and Reporting

- Record procedure on medical record. Include patient's ability to cooperate and whether suction is necessary for oral care.
- Document and report any pertinent observations (e.g., presence of gag reflex, presence of bleeding gums, dry mucosa, ulcerations, and crusts on tongue).
- Report any unusual findings to nurse in charge or health care provider.

Special Considerations

Teaching

- Family members may care for debilitated patient in the home. Instruction in mouth care is necessary so family understands

how to protect patient from aspirating while thoroughly cleaning oral cavity. Observe family caregiver perform mouth care procedure.

Home Care

- Irrigate oral cavity with bulb syringe; if unavailable, substitute gravity baster or large syringe. Caution family caregiver against instilling a large amount of water or rinsing agent in the oral cavity because of the risk of aspiration.
- Encourage family caregiver to clean patient's mouth at least twice a day. If patient breathes through mouth, a soft-bristled toothbrush moistened and used every 1 to 2 hours will keep mouth moist and fresh.

SKILL 17-4 Hair Care—Combing and Shaving

A person's appearance and sense of well-being are influenced by how the hair looks and feels. Brushing, combing, and shampooing are basic measures for all patients unable to provide self-care. Having the hair groomed makes a person feel more comfortable. Most long-term care facilities have beauty shops where patients can go for professional hair care.

Fever, malnutrition, emotional stress, and depression affect the condition of the hair. Diaphoresis leaves the hair oily and unmanageable. Excessively dry or oily hair may be associated with hormone changes. Dry, brittle hair occurs with aging and excessive use of shampoo.

Certain chemotherapy agents and radiation therapy cause loss of hair (alopecia). Many patients choose to wear a wig; however, some choose to wear hair scarves or turbans. Table 17-2 describes common hair and scalp conditions and nursing interventions.

Dependent patients with beards or mustaches need assistance keeping the facial hair clean, especially after eating. Food particles easily collect in the hair. Shaving facial hair is a task most men prefer to do for themselves daily. Because some religions and cultures forbid cutting or shaving any body hair, be certain to obtain consent from these patients.

Delegation and Collaboration

The skills of combing and shaving can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Properly position a patient with head or neck mobility restrictions.
- Report how the patient tolerated the procedure and any concerns (e.g., neck pain).
- Use an electric razor for any patient at risk for bleeding tendencies.

Equipment

Hair Care

- Wide-tooth comb and hairbrush

Shaving with Razor

- New disposable or electric razor
- Clean gloves
- Bath towel(s), mirror, washcloth, washbasin
- Shaving cream or soap, aftershave lotion (if patient desires and not contraindicated)

Mustache Care

- Scissors, brush or comb
- Bath towel
- Gooseneck lamp or overhead light

TABLE 17-2 Hair and Scalp Problems

Characteristics	Implications	Interventions
<i>Dandruff</i> —Scaling of scalp accompanied by itching; in severe cases dandruff on eyebrows	Dandruff causes embarrassment; if it enters eyes, conjunctivitis may develop.	Shampoo regularly with medicated shampoo; in severe cases obtain health care provider's advice.
<i>Ticks</i> —Small gray-brown parasites that burrow into skin and suck blood	Ticks transmit several diseases, including Rocky Mountain spotted fever, Lyme disease, and tularemia.	Do not pull ticks from skin because sucking apparatus remains and may become infected; placing drop of oil on tick or covering it with petrolatum eases removal; oil suffocates tick.
<i>Pediculosis capitis (head lice)</i> —Tiny gray brown–white parasitic insects that attach to hair strands; about size of a sesame seed; nits or eggs look like oval particles attached at an angle to hair shaft; bites or pustules may be observed behind ears and at hairline	Head lice are difficult to remove and, if not treated, may spread to furniture and other people.	Check entire scalp. Use medicated shampoo for eliminating lice or permethrin (Nix), available as a crème rinse. <i>Caution against use of products containing lindane because the ingredient is toxic and known to cause adverse reactions (National Pediculosis Association, 2009).</i> Remove patient's clothing before treatment and apply new clothing following treatment. Repeat treatment according to product directions. Check hair for nits and comb with nit comb for 2 to 3 days until sure all lice and nits have been removed. Manual removal of lice is best option when treatment has failed. Vacuum infested areas of home. Wash linens in hot water and dry for at least 30 minutes.
<i>Pediculosis corporis (body lice)</i> —Tend to cling to clothing; thus may not be easily seen; suck blood and lay eggs on clothing and furniture	Patient itches constantly; scratches on skin may become infected; hemorrhagic spots may appear on skin where lice are sucking blood. It may spread to other people.	Patient should bathe or shower thoroughly; after skin is dried, apply lotion for eliminating lice; after 12 to 24 hours another bath or shower should be taken; bag infested clothing or linen until laundered. Vacuum items that cannot be washed.
<i>Pediculosis pubis (crab lice)</i> —Found in pubic hair; gray-white with red legs	Lice may spread through bed linen, clothing, furniture, or sexual contact.	Shave hair of affected area; clean as for body lice; if lice were sexually transmitted, partner must be notified.
<i>Hair loss (alopecia)</i> —Balding patches in periphery of hairline; hair becomes brittle and broken; caused by diseases, medication side effects, and improper use of hair-care products and hair-styling devices	Patches of uneven hair growth and loss alter patient's appearance.	Offer patients access to scarves, hairpieces, or wigs. Stop hair-care practices that damage hair.

STEP

ASSESSMENT

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Inspect condition of hair and scalp. Inspect for presence of any infestation (e.g., pediculosis). <i>NOTE:</i> Apply clean gloves and gown if infestation is suspected. 2 Assess patient's hair-care and shaving product preferences (e.g., shampoo, aftershave lotion, skin conditioner). 3 Before shaving, assess if patient has bleeding tendency. Review medical history, medications, and laboratory values (e.g., platelet count, anticoagulation studies). 4 Assess patient's ability to manipulate razor. | <p>Indicates need for medicated applications or shampoo.</p> <p>Influences approach to grooming. Promotes patient's independence by participating in decision making.</p> <p>Determines need to use electric razor for patient's safety because of potential for bleeding.</p> <p>Determines level of assistance required.</p> |
|--|--|

NURSING DIAGNOSES

- Bathing/self-care deficit
- Dressing/self-care deficit
- Impaired physical mobility
- Risk for injury

Related factors are individualized based on patient's condition or needs.

STEP

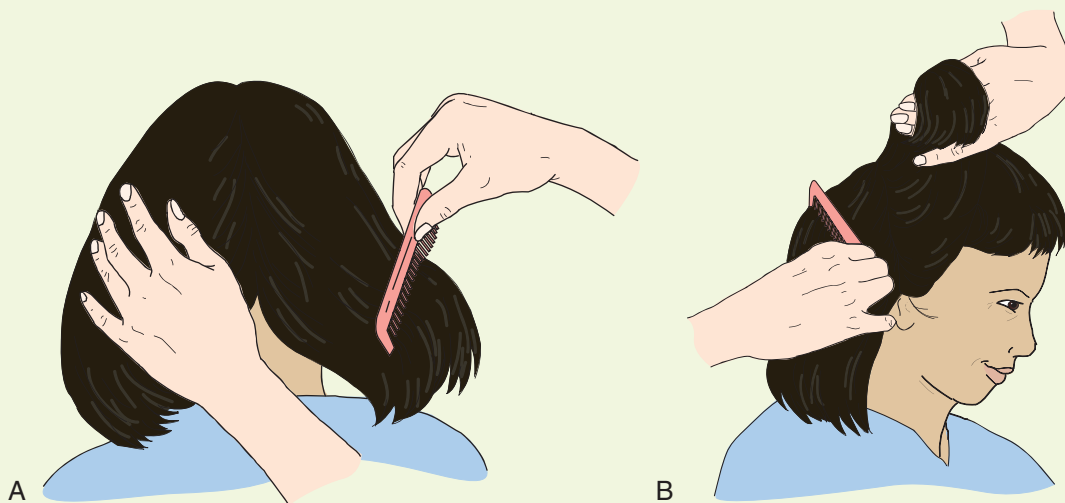

RATIONALE

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient expresses sense of comfort with hair and scalp grooming. • Patient expresses sense of comfort, with sensation of face feeling clean and refreshed. • Skin surface is smooth, well hydrated, and free of cuts. • Patient helps with procedure as tolerated. <p>2 Gather equipment and supplies.</p> <p>3 Explain procedure.</p> <p>4 Ask patient to explain during procedure steps that he or she uses to comb hair and/or shave. Ask patient to indicate if he or she becomes uncomfortable.</p> <p>5 Position patient sitting in chair or in bed with head elevated 45 to 90 degrees (as tolerated).</p> | <p>Scalp stimulated and areas of matted or tangled hair removed.</p> <p>Hair and soap lather are removed.</p> <p>Patient is free from injury.</p> <p>Participation provides sense of independence.</p> <p>Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment.</p> <p>Promotes patient's cooperation, participation, and self-care as appropriate.</p> <p>Patient involvement lessens anxiety.</p> <p>Elevation of head of bed makes it easier to access all sides of head and face.</p> |

Gently hold skin taut while shaving over surface of skin. Use gentle downward stroke of razor in direction of hair growth.</p> <p>d After completing shave, apply aftershave lotion as desired unless contraindicated.</p> <p>7 Mustache and beard care.</p> <p>a Place bath towel over patient's chest and shoulders.</p> <p>b If necessary gently comb mustache or beard.</p> <p>c Allow patient to use mirror and direct areas to trim with scissors.</p> <p>8 Help patient to comfortable position.</p> <p>9 Return equipment to proper place. Discard soiled linen in dirty laundry bag. Perform hand hygiene.</p> | <p>Prevents accumulation of shaving cream, which causes drying of skin.</p> <p>Retained moisture chaps skin.</p> <p>Softens skin and beard to reduce friction from razor head.</p> <p>Prevents pulling of beard and skin.</p> <p>Stimulates and lubricates skin.</p> <p>Straightens hair that requires trimming.</p> <p>Allows patient to make decisions about care; maintains sense of independence.</p> <p>Maintains cleanliness of patient's environment and reduces transmission of infection.</p> |
|--|--|

STEP

RATIONALE

EVALUATION

- 1 Ask patient how hair and scalp feel.
- 2 Inspect condition of shaved area and skin underneath beard or mustache.
- 3 Ask patient if face feels clean and comfortable.
- 4 Ask if patient is satisfied with degree of participation.

Evaluates patient's satisfaction with grooming.
Reveals areas of localized bleeding from cuts and areas of dryness.

Evaluates level of patient's comfort.
Patient maintains sense of independence.

Unexpected Outcomes

- 1 Patient senses tangles or discomfort in scalp.
- 2 Small isolated nicks or cuts appear on skin.
- 3 Skin surface appears dry.

Related Interventions

- Inspect scalp area. Repeat brushing/combing as needed.
- Obtain new disposable razor or change blade. If razor is reusable, be sure to clean according to agency policy.
- Change technique to glide razor over patient's skin.
- Use moisturizing shaving foam.
- Apply moisturizing lotion to patient's skin after completing shave.

Recording and Reporting

- Record shaving procedure on the clinical flow sheet or activities of daily living checklist. If there is no area indicated for shaving, make a nurse's note in the medical record. In addition, make note of how the patient tolerated procedure and any complications such as bleeding, pain, or problem skin areas.

Special Considerations

Teaching

- Shaving is a simple procedure that you can teach to a family caregiver. Teach safety precautions for shaving, especially if patient is receiving anticoagulant therapy.
- Instruct family caregiver in technique to follow in the event that patient is accidentally cut.

Pediatric

- Usually the facial hair of adolescents does not grow quickly; thus shaving daily is not necessary.
- Adolescents who shave should be asked about the frequency and allowed to perform activity as desired. Family caregivers

may wish to be involved in shaving their adolescent child if the child is unable to perform the activity on his own.

- Young girls with long hair may not tolerate brushing tangles out of hair. Tangling occurs easily in children restricted to bed. Once tangles are removed, it may be helpful to braid the hair.
- Children with lice should use a pediculocidal shampoo, followed with a visual examination for nits and removal if observed (see Table 17-2).

Gerontologic

- Usually the facial hair of older patients does not grow quickly; thus shaving daily is not necessary.
- The skin of older adults is thinner and at greater risk for injury when shaving.

Home Care

- Provide adequate towels around patient's neck to avoid spilling shaving cream or water on chest or bed.
- Perform procedure in comfortable setting with adequate lighting such as a bathroom or bedroom.

PROCEDURAL GUIDELINE 17-4 Hair Care–Shampooing

The frequency of shampooing depends on the condition of the hair and the person's daily routines and cultural preferences. Dry hair, which commonly results from aging and protein deficiency, requires less frequent shampooing than oily hair or the hair of people who actively exercise and perspire. In some health care agencies you need a health care provider's order to shampoo a patient who is dependent or has limited mobility because it is challenging to find ways to shampoo the hair without causing injury.

Remind hospitalized patients that more frequent shampooing is necessary when they remain in bed for extended periods of time, have excessive perspiration, or undergo treatments that leave blood or solutions in the hair. Two types of shampooing are available for patients: (1) traditional shampoo and water, or (2) a disposable dry shampoo cap. You can shampoo patients who are allowed to sit in a chair in front of a sink. Make sure that a patient's condition does not contraindicate neck hyperextension. Caution is needed with patients who have suffered neck injuries

because flexion and hyperextension of the neck could cause further injury. In addition, patients with positional vertigo are not able to tolerate neck hyperextension if it increases their dizziness. A folded towel placed under the neck on the edge of the sink provides added comfort. If a patient cannot sit in a chair or be transferred to a stretcher, you will need to shampoo the patient in bed, using traditional shampoo and water or a disposable shampoo product.

Delegation and Collaboration

The skill of shampooing the hair of bed-bound patients and the use of disposable shampoo product can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- Proper way to position a patient with a head or neck mobility restriction.
- Knowledge of care for lice, stressing steps to take to prevent transmission to other patients.

PROCEDURAL GUIDELINE 17-4 Hair Care—Shampooing—cont'd

Equipment**Regular Shampoo**

- Clean gloves
- Bath towels (two or more), washcloth
- Shampoo, hair conditioner (*optional*), hydrogen peroxide (*optional*)
- Water pitcher with warm water
- Plastic shampoo board, wash basin
- Bath blanket, waterproof pad
- Clean comb and brush, hair dryer (*optional*)
- Saline (*optional*)

Disposable Shampoo

- Clean gloves
- Disposable shampoo cap product
- Clean comb and brush
- Bath towel

Procedural Steps

- 1 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and that bed is in locked, low position).
- 2 Explain procedure and provide privacy.
- 3 Before washing patient's hair, determine that there are no contraindications to procedure. Check agency policy for health care provider order as needed. Certain medical conditions such as head and neck injuries, spinal cord injuries, and arthritis place patient at risk for injury during shampooing because of positioning and manipulation of patient's head and neck.
- 4 Perform hand hygiene.
- 5 Inspect hair and scalp before beginning shampoo. This determines if special shampoos or treatments are necessary (e.g., dandruff, lice, removal of blood). If draining head wounds are suspected, apply clean gloves. If lice are present, wear disposable gown in addition to gloves (*National Pediculosis Association, 2009*).
- 6 **Shampooing bed-bound patient with shampoo board.**
 - a Apply clean gloves. Place waterproof pad under patient's shoulders, neck, and head. Position patient supine, with head and shoulders at top edge of bed. Place shampoo board under patient's head and washbasin under end of trough spout (see illustration). Be sure that trough spout extends beyond edge of mattress.
 - b Place rolled towel under patient's neck and bath towel over patient's shoulders.
 - c Brush and comb patient's hair.
 - d Obtain pitcher with warm water.
 - e Ask patient to hold towel or washcloth over eyes.
 - f Slowly pour water from pitcher over hair until it is completely wet (see illustration). If hair contains matted blood, apply hydrogen peroxide to dissolve clots and rinse with saline. Apply small amount of shampoo.
 - g Work up lather with both hands. Start at hairline and work toward back of neck. Lift head slightly with one hand to wash back of head. Shampoo sides of head. Massage scalp by applying pressure with fingertips.
 - h Rinse hair with water. Make sure that water drains into basin. Repeat rinsing until hair is free of soap.
 - i Apply conditioner or crème rinse if requested and rinse hair thoroughly.
 - j Wrap patient's head in bath towel. Dry face with cloth used to protect eyes. Dry off any moisture along neck or shoulders.
 - k Dry patient's hair and scalp. Use second towel if first one becomes saturated.
 - l Comb hair to remove tangles and dry with dryer if desired.
 - m Apply oil preparation or conditioning product to hair if desired by patient.
 - n Variation for patients with coarse, curly hair: Condition hair after washing. To untangle hair, use wide teeth of comb. Beginning at nape of neck, comb small subsections of hair starting at hair ends. Continue to work through small sections until hair is free of tangles.
 - o Help patient to comfortable position and complete styling of hair.

STEP 6a Patient positioned over shampoo board. (From Sorrentino SA: Mosby's textbook for nursing assistants, ed 8, St Louis, 2012, Mosby.)

PROCEDURAL GUIDELINE 17-4 Hair Care—Shampooing—cont'd

- p Dispose and store supplies. Remove gloves and perform hand hygiene.
- 7 Shampooing using disposable shampoo product.**
- Patient can be sitting on chair or in bed. Apply clean gloves.
 - Comb hair to remove any tangles or debris.
 - Open package, apply cap, and secure all hair beneath cap (see illustration).
 - Massage head through cap. Check fitting around head to maintain correct fit.
 - Massage 2 to 4 minutes according to directions on package; additional time may be required for longer hair or hair matted with blood. (If blood is present, wear gloves.)
 - Discard cap in trash; do not dispose of in toilet because it may clog plumbing.
 - If patient desires, towel dry hair.
 - Brush or comb patient's hair.
 - Remove gloves. Perform hand hygiene.

STEP 7c Patient wearing disposable shampoo cap.

SKILL 17-5 Performing Nail and Foot Care

Include nail and foot care in a patient's daily hygiene; the best time is during the bath. Many agencies require a health care provider's order before you can trim nails. Feet and nails often require special care to prevent infection, odors, pain, and injury to soft tissues. Often people are unaware of foot or nail problems until discomfort or pain occurs. Common foot and nail problems are presented in Table 17-3. For proper foot and nail care, instruct patients to protect the feet from injury, keep them clean and dry, and wear appropriate footwear. Instruct patients in the proper way to inspect the feet for lesions, dryness, or signs of infection. To maintain and promote foot and nail health, patients should visit a podiatrist when necessary. This is especially important for patients with peripheral vascular diseases (PVDs) or diabetes mellitus, older adults, and patients who are immunocompromised.

Patients most at risk for developing serious foot problems are those with peripheral neuropathy and peripheral vascular disease. These two disorders, commonly found in patients with diabetes mellitus, cause a reduction in blood flow to the extremities and a loss of sensory, motor, and autonomic nerve function. As a result, a patient is unable to feel heat and cold, pain, pressure, and positioning of the foot or feet. The reduction in blood flow impairs healing and promotes risk for infection. The development of diabetic foot ulcers has three contributing factors: (1) peripheral neuropathy (changes in the function and efficiency of the nerves), (2) ischemia (decrease in the blood flow related to plaque formation

in arteries), and (3) a pivotal event (trauma caused by banging the toe or stepping on a foreign object). If foot ulcers do not heal, they can quickly become infected and lead to gangrene and subsequent amputation.

Delegation and Collaboration

The skill of nail and foot care of patients *without diabetes* or *circulatory compromise* can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- Not trimming patient's nails.
- Special considerations for patient positioning.
- Reporting any breaks in skin, redness, numbness, swelling, or pain.

Equipment

- Washbasin
- Emesis basin
- Washcloth and towel
- Nail clippers (check agency policy)
- Soft nail or cuticle brush
- Plastic applicator stick
- Emery board or nail file
- Body lotion
- Disposable bath mat
- Clean gloves

TABLE 17-3 Common Foot and Nail Problems

Condition	Characteristics	Implications	Interventions
<p>Callus</p> 	<p>Thickened portion of epidermis, consisting of mass of horny, keratotic cells; usually flat, painless, and found on undersurface of foot or on palm of hand; caused by local friction or pressure</p>	<p>Foot calluses may cause discomfort when wearing tight-fitting shoes.</p>	<p>Refer patient to podiatrist and do not self-treat. Use of orthotic devices cushions and redistributes weight and pressure off calluses.</p>
<p>Corns</p> 	<p>Keratosis caused by friction and pressure from shoes; mainly on toes, over bony prominence; usually cone-shaped, round, and raised; calluses with painful core</p>	<p>Conical shape compresses underlying dermis, making it thin and tender. Pain is aggravated by tight-fitting shoes. Patients may suffer alteration in gait because of pain.</p>	<p>Refer patient to podiatrist. Avoid use of oval corn pads, which increase pressure on toes. Use wider, softer shoes.</p>
<p>Plantar warts</p> 	<p>Fungating lesions on sole of foot caused by papillomavirus</p>	<p>Warts may be contagious, are painful, and make walking difficult.</p>	<p>Refer patient to podiatrist.</p>
<p>Athlete's foot (tinea pedis)</p> 	<p>Fungal infection of foot; scaliness and cracking of skin between toes and on soles of feet; small blisters containing fluid may appear, apparently induced by constricting footwear</p>	<p>Athlete's foot can spread to other body parts, especially hands. It is contagious and frequently recurs.</p>	<p>Feet should be well ventilated. Drying feet well after bathing and applying powder help prevent infection. Wearing clean socks or stockings reduces incidence. Health care provider orders application of griseofulvin, miconazole nitrate, or tolnaftate.</p>
<p>Ingrown nails</p> 	<p>Toenail or fingernail growing inward into soft tissue around nail; results from improper nail trimming, poor shoe fit, or heredity</p>	<p>Ingrown nails can cause localized pain when pressure is applied.</p>	<p>Treatment is frequent warm soaks (<i>exception: patient with diabetes</i>) in antiseptic solution and removal of portion of nail that has grown into skin. Instruct patient in proper nail-trimming techniques. Refer to podiatrist.</p>
<p>Paronychia</p> 	<p>Inflammation of tissue surrounding nail after hangnail or other injury; occurs in people who frequently have their hands in water; common in patients with diabetes</p>	<p>Area can become infected.</p>	<p>Treatment is warm compresses or soaks (<i>exception: patient with diabetes</i>) and local application of antibiotic ointments. Paronychia can be prevented by careful manicuring.</p>
<p>Foot odors</p>	<p>Result of excess perspiration promoting microorganism growth and possibly faulty foot hygiene or improper footwear</p>	<p>Excess perspiration causes discomfort.</p>	<p>Frequent washing, use of foot deodorants and powders, and clean footwear prevent or reduce this problem.</p>

STEP

RATIONALE

ASSESSMENT

1 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and that bed is in locked, low position).	Identifies safety hazards in patient environment that could cause or potentially lead to harm (QSEN Quality/Safety Competencies, 2012).
2 Inspect all surfaces of fingers, toes, feet, and nails. This can be done during the bath. Pay particular attention to areas of dryness, inflammation, or cracking. Also inspect areas between toes, heels, and soles of feet. Inspect socks for stains.	Integrity of feet and nails determines frequency and level of hygiene required. Heels, soles, and sides of feet are prone to irritation from ill-fitting shoes. Socks may become stained from bleeding or draining ulcer.
3 Assess color and temperature of toes, feet, and fingers. Assess capillary refill of nails. Palpate radial and ulnar pulse of each hand and dorsalis pedis pulse of foot; note character and symmetry of pulses (see Chapter 6).	Assess circulation to extremities. Peripheral artery disease (PAD) occurs when blood vessels in legs are narrowed or blocked by fatty deposits and blood flow to feet and legs decreases (American Diabetes Association, 2011).
4 Observe patient's walking gait (when appropriate). Have him or her walk down hall or walk straight line while wearing comfortable shoes or slippers (if able).	Alterations in bony structures of feet may cause pain, imbalance, and unsteady gait.
5 Ask if patient has history of leg pain on walking that is relieved with rest.	Claudicating pain is related to ischemia with diabetic and neuropathic disorders.
6 Ask patients about whether they use nail polish and polish remover frequently.	Chemicals in these products cause excessive dryness.
7 Assess type of footwear patient wears: Does patient wear socks? Are shoes tight or ill fitting? Are garters or knee-high nylons worn? Is footwear clean?	Some types of shoes and footwear predispose patient to foot and nail problems (e.g., infection, areas of friction, ulcerations).
8 Identify patient's risk for foot or nail problems.	Certain conditions increase likelihood of foot or nail problems.
a Older adult	Poor vision, lack of coordination, or inability to bend over contributes to difficulty in performing foot and nail care. Normal physiologic changes of aging can result in brittle nails. Discolored, extremely thickened, and deformed nails can indicate infection, fungus, or disease (Malkin and Berridge, 2009).
b Diabetes mellitus	Vascular changes associated with diabetes reduce blood flow to peripheral tissues. Break in skin integrity places patient with diabetes at high risk for skin infection.
c Heart failure, renal disease	Both conditions increase tissue edema, particularly in dependent areas (e.g., feet). Edema reduces blood flow to neighboring tissues.
d Cerebrovascular accident (stroke)	Presence of residual foot or leg weakness or paralysis results in altered walking patterns. Altered gait pattern causes increased friction and pressure on feet.
9 Assess for use of home remedies.	Certain preparations or applications cause more injury to soft tissue than the actual foot problem.
a Over-the-counter (OTC) liquid preparations to remove corns or warts	Patients with diabetes or circulatory insufficiency should seek professional treatment and avoid self-treating.
b Cutting corns or calluses with razor blade or scissors	Carries risk for cutting skin, which can lead to infection.
c Use of oval corn pads	May exert pressure on toes, thereby decreasing circulation to surrounding tissues. Seek professional treatment.
d Application of adhesive tape	Skin of older adult is thin and delicate and prone to tearing when adhesive tape is removed.
10 Assess patient's ability to care for nails or feet: visual alterations, fatigue, and musculoskeletal weakness.	Extent of patient's ability to perform self-care determines degree of assistance required from nurse.
11 Assess patient's knowledge of proper foot and nail care practices.	Health literacy level determines extent of teaching needed. Family caregivers should be involved in teaching process.

NURSING DIAGNOSES

- Bathing/self-care deficit
- Deficient knowledge regarding foot and nail care
- Impaired physical mobility
- Impaired skin integrity
- Ineffective tissue perfusion
- Risk for infection

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Nails are smooth. Cuticles and tissues surrounding nail are clear and of normal color. Surfaces of feet are smooth. • Patient walks freely, without pain or unusual gait. • Patient explains or demonstrates nail care correctly. <p>2 Gather equipment and supplies.</p> <p>3 Explain procedure to patient, including fact that proper soaking of nails on hands requires several minutes in warm water.</p> <p>4 Obtain health care provider's order for cutting nails (required by most clinical facilities). Obtaining order for podiatry consult should be initiated if patient has diabetes, PAD, or PVD.</p> | <p>Excess skin layers are removed. Nail integrity and cleanliness are maintained.</p> <p>Patient understands importance of proper fitting footwear.</p> <p>Patient learns skill.</p> <p>Avoids interrupting procedure or leaving patient unattended to retrieve missing equipment.</p> <p>Patient must be willing to place fingers in basin up to 10 minutes. Patient may become anxious or fatigued.</p> <p>Patient's skin may be cut accidentally. Certain patients are more at risk for infection, depending on their medical condition.</p> <p>A podiatrist should assess and develop a regular schedule for nail care for patients with vascular insufficiency or peripheral neuropathy.</p> |
|---|---|

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Perform hand hygiene and apply clean gloves. Arrange equipment on over-bed table.</p> <p>2 Pull curtain around bed or close room door to provide privacy.</p> <p>3 Help ambulatory patient sit in chair. Help bedfast patient to supine position with head of bed elevated 45 degrees. Place disposable bath mat on floor under patient's feet or place waterproof pad on mattress.</p> <p>4 Fill washbasin with warm water. Test water temperature. Place basin on floor or pad on mattress. Have patient immerse feet.</p> | <p>Reduces transmission of infection.</p> <p>Easy access to equipment prevents delays.</p> <p>Maintaining patient's privacy reduces anxiety.</p> <p>Sitting in chair facilitates immersing feet in basin. Bath mat protects feet from exposure to soil or debris.</p> <p>Prevents accidental burns to patient's skin.</p> |
|---|---|

Clinical Decision Point *Patients who have diabetes mellitus, peripheral neuropathy, or PVD should not soak their hands and feet because of the increased risk of trauma, inability to sense temperature, and increased risk for infection (American Diabetes Association, 2011; Malkin and Berridge, 2009).*

- | | |
|---|---|
| <p>5 Adjust over-bed table to low position and place it over patient's lap.</p> <p>6 Fill emesis basin with warm water and place basin on towel on over-bed table. Test water temperature.</p> <p>7 Instruct patient to place fingers in emesis basin and arms in comfortable position.</p> <p>8 Unless patient has diabetes mellitus, peripheral neuropathy, or PVD, allow feet and fingernails to soak 10 minutes.</p> <p>9 Clean gently under fingernails with end of plastic applicator stick while fingers are immersed.</p> <p>10 Use soft cuticle brush or nailbrush to clean around cuticles to decrease overgrowth.</p> <p>11 Remove emesis basin and dry fingers thoroughly.</p> | <p>Easy access prevents accidental spills.</p> <p>Warm water softens nails and thickened epidermal cells. Prevents accidental burns to patient's skin.</p> <p>Prolonged positioning causes discomfort unless normal anatomic alignment is maintained.</p> <p>Goal is to soften debris beneath nails so it can be removed easily.</p> <p>Removes debris under nails that harbors microorganisms.</p> <p>Nailbrush helps to prevent inflammation and injury to cuticles.</p> <p>Thorough drying impedes fungal growth and prevents maceration of tissues.</p> |
|---|---|

Clinical Decision Point *Check agency policy for appropriate process for cleaning beneath nails. Do not use an orange stick or end of cotton swab; these splinter and can cause injury.*

- | | |
|---|--|
| <p>12 Check agency policy on nail care regarding filing and trimming. Trim nails straight across at level of finger or follow curve of finger, ensuring that you do not cut down into nail grooves (see Illustration). Use disposable emery board and file nail to ensure that there are no sharp corners.</p> | <p>Trimming straight across avoids skin overgrowth at nail edges, which can lead to ingrown nails or infection.</p> <p>Filing nail straight across to eliminate sharp nail edges minimizes nail from injuring the adjacent finger (Malkin and Berridge, 2009).</p> |
|---|--|

STEP

RATIONALE

STEP 12 Trim nails straight across when using nail clipper.

- | | |
|--|---|
| <p>13 Move over-bed table away from patient. Scrub callused areas of feet with washcloth.</p> <p>14 Clean between toes with washcloth.</p> <p>15 Dry feet thoroughly and trim or cut nails following Step 12.</p> <p>16 Apply lotion to feet and hands. Rub in thoroughly. Help patient back to bed and into comfortable, safe position.</p> <p>17 Clean clippers with soap and water. If soiled with blood or body fluids, clean according to organizational policy and return equipment to proper place. Emery boards should be disposable. Dispose of soiled linen in dirty laundry bag. Remove gloves and perform hand hygiene.</p> | <p>Provides easier access to feet. Friction removes dead skin layers.</p> <p>Moisture can cause skin maceration.</p> <p>Lotion lubricates dry skin by helping to retain moisture.</p> <p>Reduces transmission of infection.</p> |
|--|---|

EVALUATION

- | | |
|---|---|
| <p>1 Inspect nails, areas between fingers and toes, and surrounding skin surfaces.</p> <p>2 Ask patient to explain or demonstrate nail care.</p> <p>3 Observe patient's walk after foot and nail care.</p> | <p>Inspection enables you to evaluate condition of skin and nails and allows you to note any remaining rough nail edges.</p> <p>Evaluates patient's level of learning techniques.</p> <p>Evaluate level of comfort and mobility achieved.</p> |
|---|---|

Unexpected Outcomes

- 1 Cuticles and surrounding tissues are inflamed and tender to touch.
- 2 Localized areas of tenderness occur on feet with calluses or corns at point of friction.
- 3 Ulcerations involving toes or feet may remain.

Related Interventions

- Repeat nail care.
- Evaluate need for antifungal cream.
- Change in footwear or corrective foot surgery may be needed for permanent improvement in calluses or corns.
- Refer patient to podiatrist.
- Institute wound care policies (see [Chapters 18 and 38](#)).
- Consult with wound care specialist and/or podiatrist.
- Increase frequency of assessment and hygiene.

Recording and Reporting

- Record procedure and observations in medical record (e.g., breaks in skin, inflammation, ulcerations).
- Report any breaks in skin or ulcerations to nurse in charge or health care provider.

Special Considerations

Teaching

- Use a variety of teaching formats regarding foot and nail care (e.g., brochures, videos, DVDs) that are consistent with patient's health literacy level.
- Instruct patient not to walk barefoot or use corn or callus products.

- Instruct a patient with diabetes, peripheral neuropathy, or peripheral vascular disease to do the following:
 - Inspect and bathe feet daily.
 - Inspect all surfaces of each foot.
 - Use a mirror to view bottom of each foot.
 - Clean around nails with a soft brush.
 - Dry the feet and pay special attention to drying between the toes.
 - Use lambswool between the toes if the skin stays moist or becomes macerated.
 - Wear socks made of natural fiber such as cotton that absorb perspiration and "breathe."

- Wear nonconstricting shoes with soft leather and an adequate toe box.
- See a podiatrist to develop a regular schedule for nail care.

Pediatric

- Children's nails should be assessed and trimmed to prevent injury from scratching themselves.
- Use appropriate-size clippers when clipping the nails of infants and small children (check agency policy).
- Do not use scissors.

Gerontologic

- Changes in aging skin include thinning of epidermis and subcutaneous fat and dryness because of decreased activity of oil and sweat glands. These changes are often evident in the feet. In addition, nails become discolored, thickened, deformed, and brittle.

- PVD, peripheral neuropathy, and long periods of limited exercise or bed rest impact balance, stability, and sensory impairment, resulting in impaired mobility.

Home Care

- Assess the home for any areas where a person could accidentally injure the feet such as rugs, objects that block pathways, or uneven walks or flooring.
- Avoid going barefoot or wearing open-toed shoes.
- *Alternative therapy:* Apply moleskin to friction areas of the foot or feet or wrap small pieces of lambswool around toes to reduce irritation from corns or bunions.
- Include family caregiver in foot and nail care education.
- Place contact information of podiatrist, health care provider, and home care nurse close by for easy access.

SKILL 17-6 Care of a Patient's Environment

When caring for patients who need to remain in or near their bed for an extended period, it is important to make that environment as comfortable as possible. A calm, comfortable restorative room is well ventilated; safe; and large enough to allow patients, visitors, and care providers to move about freely.

Although there are variations across health care settings, a typical room contains the following basic pieces of furniture: over-bed table, bedside stand, chairs, lamp, and bed. Long-term care and rehabilitation facilities often have similar equipment. The over-bed table rolls on wheels and can be adjusted to various heights over the bed or chair. The table provides ideal working space for nurses to perform procedures. It also provides a surface on which to place meal trays, toiletry items, and frequently used objects. Do not place the bedpan and urinal on an over-bed table. The bedside stand is for storing a patient's personal possessions and hygiene equipment. The telephone, water pitcher, and drinking cup are usually on top of the bedside stand.

Most hospital rooms contain an armless straight-backed chair or an upholstered lounge chair with arms. Straight-backed chairs are convenient when temporarily transferring a patient from the bed such as during bed making. Lounge chairs tend to be more comfortable when a patient is willing and able to sit for an extended period.

Proper lighting is necessary for everyone's safety and comfort. A brightly lit room is usually stimulating, but a darkened room is best for rest and sleep. Adjust room lighting by closing or opening drapes, regulating over-bed and floor lights, and closing or opening room doors. Position movable lights that extend over the bed from the wall for easy reach but move them aside when not in use.

Other equipment usually found in a patient's room includes a call light, a television set, a wall-mounted blood pressure gauge, oxygen and vacuum wall outlets, and personal care items. Special mattresses and bed boards are designed for comfort or positioning. Whenever using comfort and positioning equipment, check agency policy and manufacturer directions before application.

Beds

Because the bed is the piece of equipment that a patient uses most, it should be comfortable, safe, and adaptable to various positions. The typical hospital bed consists of a firm mattress on a metal frame that you can raise or lower horizontally. The frame is divided into three sections so the operator can raise and lower the head and foot of the bed separately and incline the entire bed with the head up or down. Each bed sits on four rollers, or casters, that allow you to move it easily. Table 17-4 lists common bed positions.

The position of a bed is usually changed by electric controls built into the side of the bed, at the foot of the bed, or on a bedside cable. Patients can raise or lower sections of the bed without expending much energy. It is important for you to instruct patients in the proper use of the controls and caution them against positions that will cause harm.

Often patients who are critically ill or are immobilized in traction are transported to different locations, such as the radiology department, in bed. There are beds in which scales are incorporated to facilitate routine weighing of a patient.

Beds contain a number of safety features. Use locks located on the wheels, casters, or at the center of the bed frame (Fig. 17-3) whenever a bed is stationary to prevent accidental movement during performance of a procedure (e.g., transferring a patient from bed to a stretcher). Side rails (i.e., adjustable metal frames [either four or two, depending on bed design] that you can raise or lower by pushing or pulling a knob) located on both sides of a bed help patients position themselves and provide upper-extremity support as a patient gets out of bed. Use caution when raising side rails. Research suggests that the risk for patient falls is greater when side rails on both sides of the bed are raised because patients try to climb over the rails to exit the bed. Raising only one rail (when there are only two) or three (when there are four rails) gives patients an exit route if they are able to move independently. The use of all

FIG 17-3 Lock on bed wheels.

side rails is considered a physical restraint (see [Chapter 13](#)). When you lower a side rail, do not leave the bedside with a patient still in bed. Most hospital beds are equipped with a bed alarm that alerts a nurse when a patient has gotten up without assistance. Each bed has a special headboard that is removable. This feature is important in emergency situations when the medical team must have easy access to a hard, flat surface to place under a patient during cardiopulmonary resuscitation (see [Chapter 27](#)).

Mattresses

Most standard mattresses are a water-repellent covered foam or pressure-reducing material that reduces pressure on bony prominences. These mattresses aid in the prevention of pressure ulcer development. In some specialized areas such as an intensive care unit (ICU) setting, foam or air therapy mattresses are used for all patients. Firm, water-repellent mattresses are still used in some areas.

TABLE 17-4 Common Bed Positions

Position	Description	Uses
Fowler's 	Head of bed raised to angle of 45 to 90 degrees; semi-sitting position; foot of bed may also raise at knee	Preferred while patient eats; used during nasogastric tube insertion and nasotracheal suction; promotes lung expansion
Semi-Fowler's 	Head of bed raised approximately 30 to 45 degrees; incline less than Fowler's position; foot of bed may also raise at knee	Promotes lung expansion; relieves strain on abdominal muscles Used when patients receive gastric feedings to reduce risk for aspiration

TABLE 17-4 Common Bed Positions—cont'd

Position	Description	Uses
<p>Trendelenburg's</p> 	<p>Entire bed frame tilted with head of bed down</p>	<p>For postural drainage; facilitates venous return in patients with poor peripheral perfusion</p>
<p>Reverse Trendelenburg's</p> 	<p>Entire bed frame tilted with foot of bed down</p>	<p>Used infrequently; promotes gastric emptying and prevents esophageal reflux</p>
<p>Supine or flat</p> 	<p>Entire bed frame horizontally parallel with floor</p>	<p>For patients with vertebral injuries and in cervical traction; position used for patients who are hypotensive and generally preferred by patients for sleeping</p>

PROCEDURAL GUIDELINE 17-5 Making an Occupied Bed

At times it is necessary to make a bed that is occupied by a patient. If a patient is confined to bed, you should make the bed in a way that conserves time and the patient's energy. In addition, you need to know how to position the patient safely while the bed linens are changed. It is easier to make an occupied bed with two people. Try to keep the patient as comfortable as possible. In cases in which a patient experiences severe pain, an analgesic administered 30 to 60 minutes before a procedure helps to control pain and maintain comfort.

Even though a patient is unable to get out of bed, encourage self-help as much as possible. For example, a patient can turn, help in moving up in bed, or hold top sheets while you apply linen. These activities help maintain patient's strength and mobility and allow participation in hygiene care.

Delegation Considerations

The skill of making an occupied bed can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- Any position or activity restrictions that apply.
- Looking for wound drainage, drainage tubes, or intravenous (IV) tubing that is found in the linens.
- Obtaining help with positioning patient during linen change, observe good body mechanics, and support alignment of patient if needed.
- Using special precautions such as aspiration precautions, including:
 - a Keeping head of bed (HOB) raised to no lower than 30 degrees.
 - b Explaining need to report excessive coughing or choking during procedure.

Equipment

- Linen bags
- Mattress pad (change only when soiled)
- Bottom sheet (flat or fitted)
- Drawsheet (*optional*), top sheet, bedspread
- Waterproof pads (*optional*), pillowcases
- Clean gloves
- Antiseptic cleanser
- Washcloth

Procedural Steps

- 1 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and that bed is in locked, low position. Pull room divider curtain or close door to provide privacy.
- 2 Determine if patient has been incontinent or if excess drainage is on linen.
- 3 Assess restrictions in mobility/positioning of patient. Explain procedure to patient, noting that patient will be asked to turn over layers of linen.
- 4 Perform hand hygiene and apply clean gloves if linen is soiled or there is risk of contact with blood or body fluids.
- 5 Assemble all equipment on bedside table.
- 6 Raise bed to a comfortable working height; lower HOB as tolerated, keeping patient comfortable. Remove call light. If patient is on aspiration precautions, keep HOB no lower than 30 degrees. Lower side rail from side where you are standing.
- 7 Loosen top linen at foot of bed.

- 8 Remove bedspread and blanket separately. If soiled, place in linen dirty laundry bag. If to be reused, fold into square and place over back of chair.
- 9 Cover patient with bath blanket, placing over top sheet. Have patient hold top edge of bath blanket or tuck blanket under shoulders. Reach beneath blanket and remove top sheet. Discard in dirty laundry bag.
- 10 Help patient to side-lying position facing away from you. Encourage him or her to use side rail to turn. Adjust pillow under patient's head.
- 11 Assess to make sure that there is no tension on any external medical devices.
- 12 Stand on side of bed. Loosen bottom linens, moving from head to foot. Fanfold or roll bottom sheet, drawsheet, and any cloth pads toward and under patient. Tuck edges of old bottom linen alongside patient's buttocks, back, and shoulders (see illustration).
- 13 Clean, disinfect, and dry mattress surface if needed.
- 14 Apply clean linen to exposed half of bed in separate layers. Start with mattress pad by placing lengthwise with center crease in middle of bed. Fanfold layer to center of bed alongside patient. Repeat process with bottom sheet and drawsheet (see Illustration).

STEP 12 Soiled linen tucked alongside patient.

STEP 14 Apply clean linen to bed and fanfold alongside patient.

PROCEDURAL GUIDELINE 17-5 Making an Occupied Bed—cont'd

- 15 Pull fitted sheet smoothly over mattress corner at top and bottom of bed. If using a flat sheet, allow edge of sheet to hang about 25 cm (10 inches) over mattress edge. Be sure that lower hem of bottom sheet lies seam down and even with bottom edge of mattress.
- 16 If bottom sheet is flat, miter top corner at HOB. Face HOB diagonally. Place hand away from HOB under top corner of mattress, lift, and with other hand tuck edge of bottom sheet smoothly under mattress so side edges of sheet above and below mattress meet when brought together.
- 17 To miter a corner, pick up top of sheet at about 45 cm (18 inches) from top of mattress (see illustration A). Lift sheet and lay it on top of mattress to form a triangular fold with lower base of triangle even with mattress side edges (see illustration B).
- 18 Tuck lower edge of sheet, which is hanging free under mattress. Hold portion of sheet covering side of mattress in place with one hand (see illustration). With the other hand pick up triangular linen fold and bring it down over side of mattress. Tuck with palms down, without pulling triangular fold. Tuck this portion under mattress (see illustrations).
- 19 Tuck remaining portion of sheet under mattress, moving toward foot of bed. Keep linen smooth.
- 20 Place open drawsheet along middle of bed lengthwise and tuck remainder under patient's buttocks and torso. Drawsheet should be fanfolded or rolled on top of the bottom sheet. Keep linen under patient as flat as possible because patient will need to roll over new layers of linen when you are ready to make other side of bed. You may also place waterproof pad under drawsheet.
- 21 Raise side rail and ask patient to turn toward you; help as needed. Tell patient that he or she will be rolling over layers of linen. Make sure that patient turns slowly to keep his or her body in correct alignment (see illustration).
- 22 Move to opposite side of bed; lower side rail. Help patient position on other side over folds of linen.
- 23 Loosen edges of soiled linen from under mattress. Remove soiled linen by folding into a bundle or square.
- 24 Hold linen away from your body and place it in laundry bag.
- 25 Clean, disinfect, and dry other half of mattress as needed.
- 26 Pull clean, fanfolded or rolled linen, mattress pad, and optional drawsheet over edge of mattress from HOB to foot of bed. If bottom sheet is fitted, pull corners over mattress edges. If flat sheet used, unfold and pull toward you. Miter top corner of bottom flat sheet (see Steps 15 to 17).
- 27 Facing side of bed, grasp remaining edge of bottom flat sheet. Lean back, keep back straight, and pull while tucking excess linen under mattress from HOB to foot of bed.
- 28 Make sure that sheets and pad are smooth and wrinkle free.
- 29 Help patient roll back into supine position.
- 30 Place top sheet over patient with vertical centerfold lengthwise down middle of bed. Open sheet out from head to foot and unfold over patient. Be sure that top edge of sheet is even with top edge of mattress.
- 31 Place clean or reused bed blanket on bed over patient. Make sure that top edge is parallel with top edge of sheet and 15 to 20 cm (6 to 8 inches) from edge of top sheet. Raise side rail.
- 32 Go to other side of bed. Lower side rail. Spread sheet and blanket out evenly.
- 33 Have patient hold onto sheet and blanket while you remove bath blanket.
- 34 Make cuff by turning edge of top sheet down over top edge of blanket.
- 35 Make horizontal toe pleat; stand at foot of bed and fanfold in sheet and blanket 5 to 10 cm (2 to 4 inches) across bed. Pull

STEP 17 A, Top edge of sheet picked up. B, Sheet on top of mattress in triangular fold.

STEP 21 Patient rolling over layers of linen.

STEP 18 Triangular fold placed over side of mattress; linen tucked under mattress.

PROCEDURAL GUIDELINE 17-5 Making an Occupied Bed—cont'd

sheet and blanket up from bottom to make fold approximately 15 cm (6 inches) from bottom edge of mattress.

- 36 Standing at side of bed, tuck in remaining portion of sheet and blanket under foot of mattress. Tuck top sheet and blanket together. Be sure that toe pleats are not pulled out.
- 37 Make modified mitered corner with top sheet and blanket. After making triangular fold, do not tuck tip of triangle (see illustration).
- 38 Go to other side of bed. Repeat Steps 36 and 37.
- 39 Apply clean pillowcase.
- 40 Place call light within patient's reach on bedrail or pillow, return bed to locked, low position, and raise side rail (as needed).
- 41 Place linen in dirty laundry bag. Remove and dispose of gloves.
- 42 Arrange and organize patient's room and perform hand hygiene.

STEP 37 Modified mitered corner.

PROCEDURAL GUIDELINE 17-6 Making an Unoccupied Bed

Bedmaking may be done with the patient out of the bed (unoccupied) or in the bed (occupied). In some settings bed linen is not changed every day; however, you always need to change any wet or soiled linen promptly. An unoccupied bed is one left open with the top sheets fanfolded down. A postoperative surgical bed is prepared for patients returning from the operating room (OR) or procedural area. The bed is left with the top sheets fanfolded lengthwise and not tucked in to facilitate a patient's transfer from a stretcher. A closed bed, which is made with the top sheets pulled up to the head of the bed, is used after a patient is discharged and housekeeping cleans the unit.

Delegation and Collaboration

The skill of making an unoccupied bed can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP about:

- Position or activity restrictions that apply to patient's ability to get out of bed.
- Use of special linen instructions if patient is on an airflow mattress.

Equipment

- Linen bags
- Mattress pad (change only when soiled)
- Bottom sheet (flat or fitted)
- Drawsheet (*optional*), top sheet, bedspread
- Waterproof pads (*optional*), pillowcases
- Clean gloves
- Antiseptic cleanser
- Washcloth

Procedural Steps

- 1 Perform hand hygiene and apply clean gloves if patient is incontinent or excess drainage is on linen.
- 2 Assess environment for safety (e.g., check room for spills, make sure that equipment is working properly and that bed is in locked, low position). Check position of chair for transfer. Pull room divider curtain or close room door to provide privacy.
- 3 Assess activity orders or restrictions in mobility in planning if patient can get out of bed for procedure. Help patient to bedside chair or recliner.
- 4 Lower side rails on both sides of bed and raise bed to comfortable working position.
- 5 Remove soiled linen, hold away from uniform, and place in dirty laundry bag. Avoid shaking or fanning linen.
- 6 Reposition mattress and wipe off any moisture with a washcloth moistened in antiseptic solution (consult agency housekeeping guidelines). Dry thoroughly.
- 7 Apply all bottom linen on one side of bed before moving to opposite side.
 - a *For fitted sheet:* Make sure that fitted sheet is placed smoothly over mattress and top and bottom mattress edge. Fit corners on one end and then the other.
 - b *For flat sheet:* Place sheet over mattress. Allow about 25 cm (10 inches) to hang over side mattress edge. Lower hem of sheet should lie seam down, even with bottom edge of mattress. Pull remaining top portion of sheet over top edge of mattress. While standing at head of bed, miter top corner of bottom sheet (see [Procedural Guideline 17-5](#), Steps 16 to 19). Tuck remaining portion of flat bottom sheet under mattress.
- 8 *Optional:* Apply drawsheet, laying centerfold along middle of bed lengthwise. Smooth drawsheet over mattress and tuck excess edge under mattress, keeping palms down.
- 9 Move to opposite side of bed and spread bottom sheet smoothly over edge of mattress from head to foot of bed.
 - a *For fitted sheet:* Make sure that fitted sheet is placed smoothly over mattress from head to foot of bed and over mattress edges.
 - b *For flat sheet:* Miter top corner of bottom sheet, making sure that corner is taut. Grasp remaining edge of flat bottom sheet and tuck tightly under mattress while moving from head to foot of bed.
- 10 Smooth folded drawsheet over bottom sheet and tuck under mattress, first at middle, then at top, and then at bottom.
- 11 If needed, apply waterproof pad over bottom sheet or drawsheet.

PROCEDURAL GUIDELINE 17-6 Making an Unoccupied Bed—cont'd

- 12 Place top sheet over bed with vertical centerfold lengthwise down middle of bed. Open sheet out from head to foot, being sure that top edge of sheet is even with top edge of mattress.
 - 13 Tuck in remaining portion of sheet under foot of mattress. Then place blanket over bed with top edge parallel to top edge of sheet and 15 to 20 cm (6 to 8 inches) down from edge of sheet. (*Optional:* Apply additional spread over bed.)
 - 14 Make cuff by turning edge of top sheet down over top edge of blanket and spread.
 - 15 Standing on one side at foot of bed, lift mattress corner slightly with one hand and with other hand tuck top sheet, blanket, and spread under mattress. Be sure that toe pleats are not pulled out.
 - 16 Make modified mitered corner with top sheet, blanket, and spread. After making triangular fold, do not tuck tip of triangle (see illustration).
 - 17 Go to other side of bed. Spread sheet, blanket, and spread out evenly. Make cuff with top sheet and blanket (closed bed). Make modified corner at foot of bed. Alternatively fanfold sheet, blanket, and spread at foot of bed, with top layer ready to be pulled up (this leaves an open bed).
- Optional:* Make horizontal toe pleat; stand at foot of bed and fanfold in sheet 5 to 10 cm (2 to 4 inches) across bed. Pull sheet up from bottom to make fold approximately 15 cm (6 inches) from bottom edge of mattress.
- 18 Apply clean pillowcase.
 - 19 Place call light within patient's reach on bedrail or pillow and return bed to lowest position, allowing for patient transfer. Help patient to bed.
 - 20 Place linen bag in dirty laundry bag. Remove and dispose of gloves.
 - 21 Arrange and organize patient's room and perform hand hygiene.

**STEP 16** Modified mitered corner.**Critical Thinking Exercises**

Mr. Bank is a 78-year-old male with a 3-year history of type 1 diabetes mellitus and hypertension. He was just discharged after 5 days of hospitalization with diagnoses of healing right-heel ulcer and controlled hypertension. His discharge summary notes that he requires assistance with daily dressing changes for the ulcer. Mr. Bank lives alone and is able to perform all routine activities of daily living (ADLs). During the initial home visit you assess that, although he understands the need for the daily dressing changes, he is not able to state which precautions are needed to prevent any recurrence.

- 1 Which three actions should Mr. Bank do to maintain good foot care?
 - 1 Wear properly fitting shoes
 - 2 Wear clean nylon socks
 - 3 Inspect feet daily, both top and bottom
 - 4 Have nails trimmed by professional
 - 5 Soak feet daily in warm water for 15 minutes
- 2 Identify a proactive foot-care intervention that Mr. Bank should perform.
 - 1 Self-treat corns and callus with over-the-counter products
 - 2 Seek a professional evaluation by a podiatrist and establish a foot-and-nail care schedule at least annually
 - 3 Cut toenails in a curved shape to the pink part of the nail
 - 4 Wear shoes without socks

- 2 Some patients require special positioning precautions when the hair is shampooed. Special positioning precautions are most appropriate for which patient?
 - 1 A patient with diabetes who has hypertension
 - 2 A patient with a hearing deficit
 - 3 A patient who has an endotracheal tube
 - 4 A patient with arthritis in her cervical spine
- 3 An 88-year-old patient diagnosed with dementia frequently becomes very agitated and aggressive with caregivers. Which approach for bathing this patient would be most appropriate?
 - 1 Help the patient with a shower
 - 2 Provide a complete bed bath
 - 3 Avoid bathing until the patient becomes more relaxed
 - 4 Provide a disposable bed bath in bed
- 4 A Muslim woman needs to have a bed bath. Which adjustment does the female nurse need to make when performing perineal care?
 - 1 She needs to use gloves when performing perineal care.
 - 2 She needs to have another nurse in attendance while doing perineal care.
 - 3 She needs to use her left hand when doing perineal care.
 - 4 She needs to use her dominant hand when doing perineal care.
- 5 A patient in the intensive care unit after a head injury has been unresponsive at times and can be aroused only after painful stimuli. Which assessment by the nurse is most crucial in determining whether it is safe to perform oral hygiene?
 - 1 Check the patient's pupillary response
 - 2 Evaluate the patient using the Glasgow Coma Scale
 - 3 Assess the condition of the oral cavity
 - 4 Determine the presence of a gag reflex
- 6 Cleaning baths include which of the following? (Select all that apply.)
 - 1 Bed bath
 - 2 Herbal bath
 - 3 Tub bath
 - 4 Shower

REVIEW QUESTIONS

- 1 Provide bathing at regular intervals to:
 - 1 Restore normal pH of the skin from acidic to alkaline.
 - 2 Remove resident bacteria that normally cause disease.
 - 3 Clean the outer layer of skin and remove dead skin cells.
 - 4 Promote the maturation of new skin cells.

- 7 A nurse is caring for a critically ill cardiac surgery patient who is on a ventilator. Which of the following solutions has been shown to decrease the incidence of ventilator-assisted pneumonia (VAP) in intubated patients?
 - 1 Peroxide
 - 2 Normal saline
 - 3 Chlorhexidine
 - 4 Tap water
- 8 While giving a complete bed bath to an unconscious patient, care is taken to:
 - 1 Tape the eyelids shut to preserve moisture.
 - 2 Close the eyelids with the back of the fingertip and place an eye patch or shield in place with tape.
 - 3 Place moistened cotton balls on the eyelids to moisten the eye.
 - 4 Allow the eyelids to stay open to help the nurse identify when the patient has regained consciousness.
- 9 A patient requires oral care every 2 hours. Indicate which order should be followed to safely prepare the patient for oral care.
 - 1 Assess environment for safety and provide privacy.
 - 2 Lower side rail.
 - 3 Raise bed to working height.
 - 4 Arrange supplies on over-bed table.
 - 5 Position patient.
- 10 Inflammation of the mucous membrane of the mouth is called _____.

KEY TERMS

Debridement	Exudate	Pressure ulcer	Slough
Deep tissue injury	Ischemia	Reactive hyperemia	Topical agents
Erythema	Maceration	Shear	Undermining
Eschar	Necrosis		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe guidelines for prevention of pressure ulcers.
- Identify risk factors for development of pressure ulcers.
- Identify outcome criteria for patients at risk for pressure ulcers or impaired skin integrity.
- Discuss the use of risk assessment tools commonly used in assessment of pressure ulcers.
- Describe patient and pressure ulcer characteristics to include in an assessment.
- Discuss indications for the use of topical agents in the treatment of pressure ulcers.
- Use topical agents correctly in the management of a pressure ulcer.
- Discuss teaching needs of patient and family regarding pressure ulcers.

A pressure ulcer is a localized area of injury to the skin and/or underlying tissue, usually over a bony prominence as a result of pressure or pressure in combination with shear and/or friction. A number of contributing factors are associated with pressure ulcers (e.g., moisture, blood flow); the significance of these factors is yet to be clarified in research (EPUAP and NPUAP, 2009). Pressure ulcers are inaccurately called *decubitus ulcers*, *pressure sores*, or *bedsores*. Many used to believe that only bed-bound persons developed these ulcers; however, we now know that pressure ulcers occur from unrelieved, prolonged soft tissue compression. Compression of soft tissue interferes with the blood flow to the tissue; if this compression continues for a prolonged period of time, the tissue dies from lack of blood flow, or ischemia. Ischemia develops when pressure on the skin is greater than pressure inside the vessels, causing the vessels to collapse and preventing the blood from reaching the tissue. The tissue dies from ischemic injury. Initially ischemia is often evident by skin discoloration such as redness and warmth in patients with light skin or purple and warmth in patients with darkly pigmented skin. If pressure is unrelieved or repeated, tissue will continue to break

down relative to a patient's general health and tolerance for pressure. If not relieved, this pressure can cause irreversible tissue damage in as little as 90 minutes (Kosiak, 1959).

The most common sites for pressure ulcers include the sacrum, coccyx, ischial tuberosities, greater trochanters, heels, scapulas, iliac crests, and lateral and medial malleoli (Pieper, 2012). Fig. 18-1 shows pressure points over bony prominences where pressure ulcers can develop in sitting or lying positions. Pressure injury occurs on any area of skin subjected to pressure. Nonbony locations in which pressure injuries occur include the nares, usually related to pressure caused from nasogastric (NG) tubes or oxygen cannulas; the ears, resulting from oxygen tubing; or the genitalia, with ulcers resulting from Foley catheter tension. Unlike pressure ulcers, nonbony pressure injuries cannot be staged.

Factors such as incontinence, friction and shear, immobility, loss of sensory perception, level of activity, and poor nutrition all contribute to pressure ulcer formation. Chronic moisture from fecal and urinary incontinence compromises the protective barrier of the skin and may overhydrate it,

FIG 18-1 A, Bony prominences most frequently underlying pressure ulcers. B, Pressure ulcer sites.
 From Trelease CC: *Developing standards for wound care*, *Ostomy Wound Manage* 26:50, 1988.

making it more susceptible to breakdown (Black et al., 2011). Friction, the mechanical force of two surfaces moving over each other, causes surface damage such as blisters. Shear damage is caused when the skin layers adhere to the linens while the deeper tissue layers move downward (Hanson et al., 2010). This force causes reduced blood flow to the tissues.

Immobility often restricts a patient's ability to change and control body position, thus increasing the pressure over bony prominences. Loss of sensory perception decreases the individual's ability to respond to increased, prolonged pressure in an area of the body and change positions accordingly. Level of activity refers to the person's normal physical movement. A person who is bed bound is at greater risk for skin breakdown than a person who is fully or partially mobile. Research indicates that malnutrition contributes to the development of pressure ulcers (WOCN, 2010). Pressure ulcers pose serious risks to a patient's health. A break in the skin, seen in stages II to IV pressure ulcers (Box 18-1), eliminates the first line of defense of the body against infection.

Reports vary as to the number of patients who are at risk for and develop pressure ulcers, but the number of patients who develop them is significant. Patients are now older and sicker, are hospitalized for shorter periods of time, and are discharged to home or intermediate or long-term care facilities at a more acute stage of illness (Pieper, 2012). These changes contribute to an increased number of patients at risk for developing pressure ulcers. Thus it is critical to respond with an aggressive preventive approach. As a nurse you must identify the factors that place your patients at risk for the development of pressure ulcers. Once you identify these factors, begin interventions to reduce or relieve the negative effects of each factor. When a pressure ulcer develops, explore the factors that contributed to skin breakdown, vigorously attempt to minimize the effects of these variables, and use current wound-healing principles in the management of ulcers (see Chapters 38 and 39).

EVIDENCE-BASED PRACTICE

When patients enter health care settings, perform risk assessments and repeat them regularly and as frequently as required by patients' conditions (EPUAP and NPUAP, 2009):

- Educate health care professionals about how to complete an accurate and reliable risk assessment.
- Consider patients who are bedfast and/or chair fast to be at risk of pressure ulcer development (EPUAP and NPUAP, 2009).
- Document all risk assessments (WOCN, 2010).
- Use risk scores to plan care by looking at the individual risk factors, and develop a care plan to decrease or eliminate the identified risk factors.
- The risk assessment findings indicate interventions to reduce the risk associated with pressure ulcer development. For example, a patient who is incontinent of stool and urine requires a plan that includes the use of a perineal cleanser and a skin barrier. When patients are at risk for skin breakdown related to immobility, the plan of care usually includes the use of a pressure-redistribution surface, a turning schedule, and regular skin assessments (WOCN, 2010).
- Perform pressure ulcer risk assessment systematically (WOCN, 2010).

Ensure that a complete skin assessment is part of the risk assessment screening policy in place in all health care settings (EPUAP and NPUAP, 2009; WOCN, 2010). Ongoing skin assessment is necessary to detect early signs of pressure damage:

- Skin inspection should include assessment for localized heat, edema, or induration, especially in patients with darkly pigmented skin.
- Observe the skin for pressure damage caused by medical devices.

BOX 18-1 Staging of Pressure Ulcers

Staging Definition

Suspected Deep Tissue Injury

Purple or maroon localized area of discolored intact skin or blood-filled blister caused by damage of underlying soft tissue from pressure and/or shear. The area may be preceded by tissue that is painful, firm, mushy, boggy, warmer, or cooler compared with adjacent tissue.

Stage I

Skin is intact with nonblanchable redness of a localized area, usually over a bony prominence. Darkly pigmented skin may not have visible blanching; its color may differ from the surrounding area.

Further description: The area may be painful, firm, soft, warmer, or cooler compared to adjacent tissue. Stage I may be difficult to detect in individuals with dark skin tones. May indicate “at-risk” person (a heralding risk).

Stage II

Partial-thickness loss of dermis presents as a shallow open ulcer with a red-pink wound bed without slough. This stage may also present as an intact or open/ruptured serum-filled blister.

Further description: This stage presents as a shiny or dry shallow ulcer without slough or bruising.* This stage should not be used to describe skin tears, tape burns, perineal dermatitis, maceration, or denudement.

Stage III

Full-thickness tissue loss. Subcutaneous fat may be visible; but bone, tendon, or muscle is *not* exposed. Slough may be present but does not obscure the depth of tissue loss. It *may* include undermining and tunneling.

Further description: The depth of a stage III pressure ulcer varies by anatomic location. The bridge of the nose, ear, occiput, and malleolus do not have (adipose) subcutaneous tissue; and stage III ulcers can be shallow. In contrast, areas of significant adipose tissue can develop extremely deep stage III pressure ulcers. Bone or tendon is not visible or directly palpable.

Continued

BOX 18-1 Staging of Pressure Ulcers—cont'd**Stage IV**

Full-thickness tissue loss with exposed bone, tendon, or muscle.

Slough or eschar may be present on some parts of the wound bed. *Often* includes undermining and tunneling.

Further description: The depth of a stage IV pressure ulcer varies by anatomic location. The bridge of the nose, ear, occiput, and malleolus do not have (adipose) subcutaneous tissue; and these ulcers can be shallow. Stage IV ulcers can extend into muscle and/or supporting structures (e.g., fascia, tendon, or joint capsule), making osteomyelitis possible. Exposed bone/tendon is visible or directly palpable.

**Unstageable**

Full-thickness tissue loss in which the base of the ulcer is completely obscured by slough (yellow, tan, gray, green, or brown) and/or eschar (tan, brown, black) in the wound bed.

Further description: Until enough slough and/or eschar are removed to expose the base of the wound, the true depth, and therefore stage, cannot be determined. Stable (dry, adherent, intact without erythema or fluctuance) eschar on the heels serves as “the natural (biologic) cover of the body” and should not be removed.

Data from European Pressure Ulcer Advisory Panel and National Pressure Ulcer Advisory Panel: *Treatment of pressure ulcers: quick reference guide*, Washington, DC, 2009, NPUAP.

*Bruising indicates suspected deep tissue injury.

- Document all skin assessments, noting details of any pain possibly related to pressure damage.

PATIENT-CENTERED CARE

Pressure ulcers and the associated treatments affect patients' lives emotionally, mentally, physically, and socially (Galhardo et al., 2010). Patients are aware of the amount and quality of care they receive, including levels of comfort during dressing changes and the timing of interventions. The presence of a pressure ulcer increases hospital stays and results in ongoing treatments. Given that it affects a patient's quality of life, providing culturally appropriate information about treatment and wound-healing expectations is an important aspect of care.

When planning care for a patient, consider issues such as skin tones, the issues related to patient and caregiver education, and the social effects of a pressure ulcer. Skin assessment depends on skin color, and detection becomes a challenge in dark-skinned patients (Nix, 2012). For example, redness in a dark-skinned patient is difficult to determine without the use of palpation and a comparison to other, nonaffected body parts (Box 18-2). When providing pressure ulcer care, remember that in some cultures hair has significance and should not be shaved. When shaving is absolutely necessary to prevent pain or trauma from taping hair around an ulcer, you may need the assistance of a patient's family or cultural elder.

When you educate patients and family caregivers, consider their primary language and reading ability when using printed materials. Frequently the initial use of pictures with labels can help determine if reading skills are adequate for printed educational materials. Part of the overall assessment of a patient includes how the presence of a pressure ulcer will affect the social situation (e.g., if a wound

BOX 18-2 Patient-Centered Care for Skin Assessment of Pressure Ulcers: Patients with Darkly Pigmented Skin

Patients with darkly pigmented skin cannot be assessed for pressure ulcer risk by examining only skin color. Teaching points and unique considerations include the following:

- 1 Assess localized skin color changes. Any of the following may appear:
 - Color remains unchanged when pressure is applied.
 - Color changes that differ from patient's usual skin color occur at site of pressure ulcer.
 - If patient previously had a pressure ulcer, that area of skin may be lighter than original color.
 - Localized area of skin may be purple/blue or violet instead of red.
- 2 Importance of lighting for skin assessment:
 - Use natural or halogen light.
 - If possible, avoid fluorescent lamps, which can give the skin a bluish tone.
 - Avoid wearing tinted lenses when assessing skin color.
- 3 Tissue consistency:
 - Edema may occur with induration of more than 15 mm in diameter and may appear taut and shiny.
 - Assess for edema, swelling, and a firm or boggy feel.
- 4 Skin temperature:
 - Localized heat can be detected by making comparisons with the surrounding skin. An area of coolness may be a sign of tissue devitalization.

Adapted from Nix DP: Skin and wound inspection and assessment. In Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts*, ed 4, St Louis, 2012, Mosby.

would prevent a patient from socializing in the community). The presence of a pressure ulcer can also cause pain and resultant disability, which affect family dynamics.

Safety Guidelines

- 1 Routinely assess patients for individual risks for development of pressure ulcers. Select and use a risk assessment tool; the Braden Scale is one of the most widely used and researched scales (Bryant and Nix, 2012). Perform pressure ulcer risk assessment on all patients who have one or more risk factors when admitted to an acute care facility, home care, hospice, or extended care facility.
- 2 Assess and inspect skin at least daily. Note all pressure points; document results.
- 3 Redistribute the amount and duration of pressure to prevent ischemic tissue injury. The National Quality Forum (NQF) considers prevention of pressure ulcers safe practices and the development of pressure ulcers—especially stage III, stage IV, and any unstageable ulcers—in a care setting a serious reportable event (NQF, 2011). These events are called “never” events; and the Centers for Medicare and Medicaid Services (CMS) will not financially reimburse acute care hospitals if a patient acquires one of these ulcers during hospitalization (CMS, 2012).
- 4 Turn and reposition a patient often to redistribute pressure from the superficial capillaries and allow tissues to compensate for temporary ischemia. Use safe patient handling measures to turn and reposition patients every 1 to 2 hours as their condition allows. Proper positioning helps minimize formation of pressure ulcers (see Chapter 9).
- 5 Specialized beds, overlays, and mattresses (see Chapter 12) redistribute pressure over the entire body to prevent excess pressure over bony prominences. By distributing pressure evenly over a patient’s body surface, less pressure is applied at the skin level. Place patients at high risk for pressure ulcer formation on these devices as soon as possible. Consider the use of a chair cushion to redistribute pressure when a patient is seated.
- 6 Clean patients who are incontinent of stool or urine as soon as possible. Prolonged skin moisture and wetness from urinary and fecal incontinence is a risk factor for skin breakdown (Gray et al., 2011). Protect areas subjected to repeated episodes of incontinence with a barrier ointment or barrier paste. Containment devices are available.
- 7 Use approaches to minimize friction and shear. Use lift sheets when repositioning patients to reduce rubbing skin against sheets. Raise the head of the bed no more than 30 degrees (unless medically contraindicated) to prevent sliding and shear injury (WOCN, 2010).
- 8 Adequate nutrition helps to prevent and treat pressure ulcers (WOCN, 2010). A diet high in protein with enough calories, vitamins, and minerals helps maintain normal tissue status and promotes healing. With tissue injury the body needs more calories for healing; nutrient deficiencies may result in impaired or delayed healing. Make sure that monitoring the nutritional status is part of your total assessment (WOCN, 2010).

SKILL 18-1 Risk Assessment, Skin Assessment, and Prevention Strategies

NSO Wound Care Module / Lessons 1 and 4

The goal in preventing the development of pressure ulcers is early identification of an at-risk patient and the implementation of prevention strategies. In 2010 the Wound, Ostomy and Continence Nurses (WOCN) Society updated the *Guideline for Prevention and Management of Pressure Ulcers*. A panel of experts completed an extensive literature review on the prevention and management of pressure ulcers (WOCN, 2010). The panel then established a level of evidence rating that cites the best available evidence in the prevention and management of pressure ulcers. The overall management goals suggested by WOCN (2010) include the following:

- 1 Identify individuals at risk for developing pressure ulcers and initiate an early prevention program.
- 2 Implement appropriate strategies/plans to:
 - a Attain/maintain intact skin.
 - b Prevent complications.
 - c Promptly identify or manage complications.
 - d Involve patient and caregiver in self-management.
- 3 Implement cost-effective strategies/plans that prevent and treat pressure ulcers.

The WOCN 2010 panel recommends performing a risk assessment on entry to a health care setting and repeating this on a regularly scheduled basis or when there is a significant change in an individual’s condition. For example, if a patient who was ambulatory becomes bed bound because of a surgical procedure; this person is potentially at higher risk for skin breakdown than when first admitted when ambulatory. Use risk assessment tools such as the

Braden Scale or the Norton Scale (WOCN, 2010). The Braden Scale (Table 18-1) has six parameters: sensory perception (ability to respond meaningfully to pressure-related discomfort), moisture (degree to which skin is exposed to moisture), activity (degree of physical activity), mobility (ability to change and control body position), nutrition (usual food intake pattern), and friction and shear (Ayello and Braden, 2002; Braden and Bergstrom, 1989, 1994). Risk cutoff scores vary for specific patient populations (Table 18-2). The Norton Scale, developed in 1962, includes five risk factors: physical condition, mental state, activity, mobility, and incontinence (Norton et al., 1975). It is important to understand how to interpret the meaning of a patient’s total score on whichever scale you use.

Inspect patient’s skin and bony prominences at least daily. Remove devices, shoes, socks, antiembolic stockings, and heel and elbow protectors for the skin inspection. Inspect all bony prominences, including back of head, shoulders, rib cage, elbows, hips, ischium, sacrum, coccyx, knees, ankles, and heels (see Fig. 18-1). Palpate any reddened or discolored areas with a gloved finger to determine if the erythema (redness of the skin caused by dilation and congestion of the capillaries) blanches (lightens in color). Blanching is normal. If you palpate an area that does not blanch (abnormal reactive hyperemia), this area is a site for potential skin breakdown.

Delegation and Collaboration

The skill of pressure ulcer risk assessment cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

TABLE 18-1 Braden Scale for Predicting Pressure Ulcer Risk***Sensory Perception**

Ability to respond meaningfully to pressure-related discomfort

1. *Completely limited:* Unresponsive (does not moan, flinch, or grasp) to painful stimuli because of diminished level of consciousness or sedation

or

Limited ability to feel pain over most of body

2. *Very limited:* Responds only to painful stimuli Cannot communicate discomfort except by moaning or restlessness

or

Has a sensory impairment that limits the ability to feel pain or discomfort over half of body

3. *Slightly limited:* Responds to verbal commands but cannot always communicate discomfort or need to be turned

or

Has some sensory impairment, which limits ability to feel pain or discomfort in one or two extremities

4. *No impairment:* Responds to verbal commands Has no sensory deficit that would limit ability to feel or voice pain or discomfort

Moisture

Degree to which skin is exposed to moisture

1. *Constantly moist:* Skin kept moist almost constantly by perspiration, urine, etc. Dampness detected every time patient is moved or turned

2. *Very moist:* Skin often but not always moist Linen must be changed at least once a shift

3. *Occasionally moist:* Skin occasionally moist, requiring extra linen change approximately once a day

4. *Rarely moist:* Skin usually dry; linen requires changing only at routine intervals

Activity

Degree of physical activity

1. *Bedfast:* Confined to bed

2. *Chair fast:* Ability to walk severely limited or nonexistent Cannot bear own weight and/or must be assisted into chair or wheelchair

3. *Walks occasionally:* Walks occasionally during day but for very short distances with or without assistance Spends most of each shift in bed or chair

4. *Walks frequently:* Walks outside room at least twice a day and inside room at least once every 2 hours during waking hours

Mobility

Ability to change and control body position

1. *Completely immobile:* Does not make even slight changes in body or extremity position without assistance

2. *Very limited:* Makes occasional slight changes in body or extremity position but unable to make frequent or significant changes independently

3. *Slightly limited:* Makes frequent though slight changes in body or extremity position independently

4. *No limitations:* Makes major and frequent changes in position without assistance

Nutrition

Usual food intake pattern

1. *Very poor:* Never eats a complete meal Rarely eats more than one third of any food offered Eats two servings or less of protein (meat or dairy products) per day Takes fluids poorly; does not take a liquid dietary supplement

or

Is NPO and/or maintained on clear liquids or IV infusions for more than 5 days

2. *Probably inadequate:* Rarely eats a complete meal and generally eats only about half of any food offered Protein intake includes only three servings of meat or dairy products per day Occasionally takes a dietary supplement

or

Receives less than optimal amount of liquid diet or tube feeding

3. *Adequate:* Eats over half of most meals Eats a total of four servings of protein (meat, dairy products) each day Occasionally refuses a meal but usually takes a supplement when offered

or

Is on a tube-feeding or TPN regimen that probably meets most of nutritional needs

4. *Excellent:* Eats most of every meal Never refuses a meal Usually eats a total of four or more servings of meat and dairy products Occasionally eats between meals Does not require supplementation

TABLE 18-1 Braden Scale for Predicting Pressure Ulcer Risk*—cont'd

Friction and Shear		
<p>1. Problem: Requires moderate-to-maximum assistance in moving. Complete lifting without sliding against sheets impossible. Frequently slides down in bed or chair; repositioning with maximal assistance. Spasticity, contractions, or agitation leads to almost constant friction.</p>	<p>2. Potential problem: Moves feebly or requires minimal assistance. During a move skin probably slides to some extent against sheets, chair, restraints, or other devices. Maintains relatively good position in chair or bed most of the time but occasionally slides down.</p>	<p>3. No apparent problem: Moves in bed and chair independently and has sufficient muscle strength to sit up completely during move. Maintains good position in bed or chair.</p>

Adapted from Barbara Braden, PhD, RN, Creighton University School of Nursing, Omaha, Neb.

IV, Intravenous; NPO, nothing by mouth; TPN, total parenteral nutrition.

*Score patient in each of the six subscales. Maximum score is 23, indicating little or no risk. A score of ≤16 indicates “at risk”; ≤9 indicates very high risk.

TABLE 18-2 Pressure Ulcer Braden Risk Scores by Patient Population

Patient Population	High Level of Risk for Pressure Ulcer Development If Below These Scores
General population	≤16
Intensive care unit patients	≤15
Older adults	≤18
Black and Latino patients	≤18

Data from Ayello E: Predicting pressure ulcer risk, *Best Pract Nurs Care Older Adult* 5:1. 2012; Braden BJ, Bergstrom N: Clinical utility of the Braden Scale for predicting pressure sore risk, *Decubitus* 2(3):44, 1989; Bergstrom N, Braden BJ: Predictive validity of the Braden Scale among black and white subjects, *Nurs Res* 51(6):398, 2002.

- Report any redness or break in the patient’s skin.
- Report any abrasion from assistive devices.

Equipment

- Risk assessment tool
- Documentation record
- Pressure-redistribution mattress, bed, and/or chair cushion
- Positioning aids
- Clean gloves

STEP

RATIONALE

ASSESSMENT

1 Assess patient’s risk for pressure ulcer formation:

- a** Paralysis or immobilization caused by restrictive devices
- b** Sensory loss (e.g., hemiplegia, spinal cord injury)
- c** Circulatory disorders (e.g., peripheral vascular diseases, vascular changes from diabetes mellitus, neuropathy)
- d** Fever
- e** Anemia
- f** Malnutrition
- g** Fecal or urinary incontinence
- h** Heavy sedation and anesthesia

Determines need to administer preventive care and identifies specific factors that place patient at risk (EPUAP and NPUAP, 2009).
 Patient is unable to turn or reposition independently to relieve pressure.
 Patient is unable to feel discomfort from pressure and does not independently change position.
 Reduce perfusion of tissue layers of skin.
 Increases metabolic demands of tissues.
 Accompanying diaphoresis leaves skin moist.
 Decreased hemoglobin level reduces oxygen-carrying capacity of blood and amount of oxygen available to tissues.
 Inadequate nutrition leads to weight loss, muscle atrophy, and reduced tissue mass.
 Nutrient deficiencies result in impaired or delayed healing (Stotts, 2012).
 Skin becomes exposed to moist environment that contains bacteria.
 Excessive moisture macerates skin (Gray et al., 2011).
 Patient is not mentally alert and does not turn or change position independently. Sedation alters sensory perception.

STEP	RATIONALE
<ul style="list-style-type: none"> i Age j Dehydration k Edema l Existing pressure ulcers m History of pressure ulcer 	<p>Neonates and very young children are at high risk, with the head being most common site of pressure ulcer occurrence (WOCN, 2010).</p> <p>There is a loss of dermal thickness in older adults, impairing ability to distribute pressure (Pieper, 2012).</p> <p>Results in decreased skin elasticity and turgor.</p> <p>Edematous tissues are less tolerant of pressure, friction, and shear.</p> <p>Limit surfaces available for position changes, placing available tissues at increased risk.</p> <p>Tensile strength of skin from previously healed pressure ulcer is 80% or less; therefore this area cannot tolerate pressure as much as undamaged skin (Doughty and Sparks-Defriese, 2012).</p>
<p>2 Select an agency-approved risk assessment tool such as the Braden Scale or Norton Scale. Perform risk assessment when patient enters health care setting and repeat on regularly scheduled basis or when there is a significant change in patient's condition (WOCN, 2010).</p>	<p>Valid and reliable risk assessment tools evaluate patient's risk for developing a pressure ulcer. Identifying risk factors that contribute to the potential for skin breakdown allows you to target specific interventions for decreasing risk for skin breakdown.</p>
<p>3 Obtain risk score (see Tables 18-1, 18-2, and 18-3) and evaluate its meaning based on patient's unique characteristics.</p>	<p>Risk cutoff score depends on instrument used. The score involves identifying risk factors that contributed to it and minimizing those specific deficits.</p>
<p>4 Assess condition of patient's skin over regions of pressure (see Fig. 18-1).</p>	<p>Body weight against bony prominences places underlying skin at risk for breakdown.</p>
<ul style="list-style-type: none"> a Inspect for skin discoloration (redness in light-tone skin; purplish or bluish in darkly pigmented skin) and tissue consistency (firm or boggy feel) and/or palpate for abnormal sensations (Nix, 2012). 	<p>Indicates that tissue was under pressure; hyperemia is a normal physiologic response to hypoxemia in tissues.</p>
<ul style="list-style-type: none"> b Palpate discolored area, release your fingertip, and look for blanching. 	<p>If on palpation an area of redness blanches (lightens in color), this indicates normal reactive hyperemia; the tissue is not at risk for skin breakdown. Tissue that does not blanch when palpated indicates abnormal reactive hyperemia; an indication of possible ischemic injury.</p>
<ul style="list-style-type: none"> c Inspect for pallor and mottling. 	<p>Persistent hypoxia in tissues that were under pressure; an abnormal physiologic response.</p>
<ul style="list-style-type: none"> d Inspect for absence of superficial skin layers. 	<p>Represents early pressure ulcer formation, usually a partial-thickness wound that may have resulted from friction and/or shear.</p>
<ul style="list-style-type: none"> e Inspect for localized heat, edema, or induration, especially in individuals with darkly pigmented skin (EPUAP and NPUAP, 2009). 	<p>Localized heat, edema, and induration have been identified as warning signs for pressure ulcer development. Since it is not always possible to see signs of redness on darkly pigmented skin, these additional signs should be considered in assessment (EPUAP and NPUAP, 2009).</p>
<p>5 Assess patient for additional areas of potential pressure injury:</p>	<p>Patients at high risk have multiple sites for pressure necrosis (tissue death) in addition to bony prominences.</p>
<ul style="list-style-type: none"> a Nares: Nasogastric (NG) tube, oxygen cannula 	<p>Stress against tissue at exit site or if tubing is caught under any part of the body.</p>
<ul style="list-style-type: none"> b Tongue and lips: oral airway, endotracheal (ET) tube 	<p>Wound drainage increases risk for skin breakdown because it is caustic to skin and underlying tissues.</p>
<ul style="list-style-type: none"> c Ears: oxygen cannula, pillow 	<p>For female patients the catheter can put pressure on the labia, especially when edematous. For male patients pressure from a catheter not properly anchored can put pressure on the tip of the penis and urethra.</p>
<ul style="list-style-type: none"> d Drainage or other tubing 	<p>Improperly fitted or applied devices have the potential to cause pressure on adjacent skin and underlying tissue.</p>
<ul style="list-style-type: none"> e Wound drainage 	<p>For female patients the catheter can put pressure on the labia, especially when edematous. For male patients pressure from a catheter not properly anchored can put pressure on the tip of the penis and urethra.</p>
<ul style="list-style-type: none"> f Indwelling urethral (Foley) catheter 	<p>Improperly fitted or applied devices have the potential to cause pressure on adjacent skin and underlying tissue.</p>
<ul style="list-style-type: none"> g Orthopedic and positioning devices 	<p>Improperly fitted or applied devices have the potential to cause pressure on adjacent skin and underlying tissue.</p>

Clinical Decision Point Inspect skin around and beneath orthopedic devices (e.g., cervical collar, braces, or cast). Note any abrasions or warmth in areas where devices can rub against the skin.

If you find a reddened area, gently press the area with a gloved finger to check for blanching. If the area does not blanch, suspect tissue injury and recheck in 1 hour. Any discoloration may vary from pink to a deep red.</p> <p>b If patient has darkly pigmented skin, look for color changes that differ from his or her normal skin color, such as red, blue, or purple tones.</p> <p>5 Check all treatment and assistive devices (catheters, feeding tubes, casts, braces) for potential pressure points. Remove gloves.</p> <p>6 Review patient's pressure ulcer score.</p> | <p>Reduces patient's risk for developing a pressure ulcer.</p> <p>Maintains patient privacy.</p> <p>Use of standard precautions prevents accidental exposure to body fluids.</p> <p>Routine skin inspection is fundamental to risk assessment and in designing interventions to reduce risk (WOCN, 2010). Persistent redness when lightly pigmented skin is pressed can indicate tissue injury. If an area of redness blanches (lightens in color), this indicates that skin is not at risk for breakdown.</p> <p>Darkly pigmented skin may not blanch. Although the skin may not show direct changes in color, the color may differ from the surrounding area (EPUAP and NPUAP, 2009) (see Box 18-2).</p> <p>Pressure from these devices increases the risk on bony prominences and other areas.</p> <p>Risk scores aid in identifying interventions to lessen or eliminate the present risk factors.</p> |
|---|--|

STEP

RATIONALE

Clinical Decision Point Do not massage reddened areas, because doing so may cause additional tissue trauma. Reddened areas indicate blood vessel damage, and massaging can further damage the vessel.

- 7 If immobility, inactivity, or poor sensory perception is a risk factor(s) for patient, consider one of the following interventions:
- a Reposition patient at least every 2 hours; use a written schedule (WOCN, 2010).
 - b When patient is in the side-lying position in bed, use the 30-degree lateral position (see illustration).
 - c When needed use pillow bridging (see illustration).
 - d Place patient (when lying in bed) on a pressure redistribution surface.
 - e Place patient (when in a chair) on a pressure redistribution device and shift the points under pressure at least every hour (WOCN, 2010).
- 8 If friction and shear are identified as risk factors, consider the following interventions:
- a Use two nurses and a pull sheet to reposition patient. Use a slide board (see Chapter 9) to transfer patient from bed to stretcher.

Immobility and inactivity reduce patient's ability or desire to independently change position. Poor sensory perception decreases patient's ability to feel the sensation of pressure or discomfort.

Reduces the duration and intensity of pressure. Some patients may require more frequent repositioning.

Reduces direct contact of the trochanter with the support surface.

Use of pillows prevents direct contact between bony prominences. Reduces amount of pressure exerted on tissues.

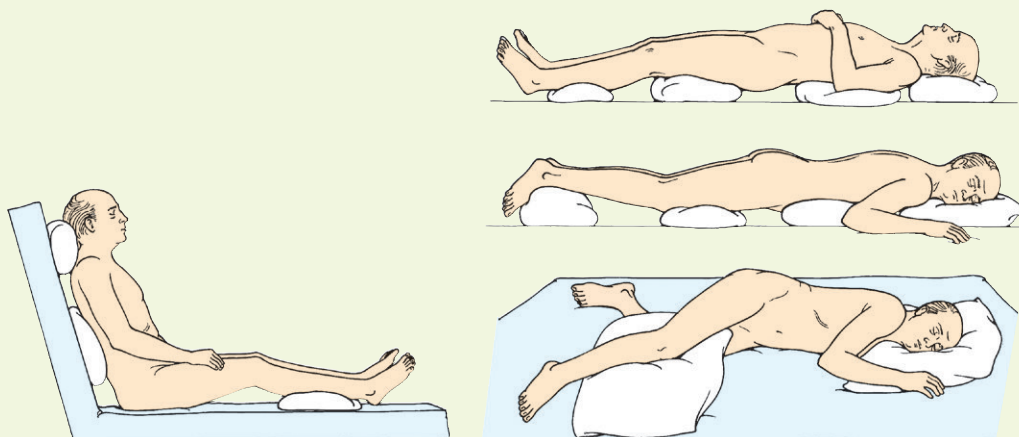

Reduces the amount of pressure on the sacral and ischial areas.

Friction and shear damage underlying skin.

Proper repositioning of patient prevents dragging along the sheets. Slide board provides slippery surface to reduce friction.

STEP 7b Thirty-degree lateral position with pillow placement.

STEP 7c Pillow bridging.

STEP	RATIONALE
<ul style="list-style-type: none"> b Ensure that heels are free from the surface of the bed by using a pillow under the calves to elevate the heels. c Maintain the head of the bed at 30 degrees. 	<p>“Floating” the heels from the bed surface eliminates shear and friction.</p> <p>Decreases potential for patient to slide toward foot of bed and incur a shear injury.</p>
<p>9 If patient receives a low score on a moisture subscale, consider one of the following interventions:</p> <ul style="list-style-type: none"> a Apply clean gloves. Apply a moisture barrier ointment to perineum and surrounding skin after each incontinent episode. b If skin is denuded, use a protective barrier paste after each incontinent episode. c If moisture source is from wound drainage, consider frequent dressing changes, skin protection with protective barriers, or collection devices. 	<p>Continual exposure of body fluids on the patient’s skin increases the risk for skin breakdown and pressure ulcer development.</p> <p>Protects the skin from fecal or urinary incontinence.</p> <p>Provides a barrier between the skin and the stool/urine, allowing for healing.</p> <p>Removes the frequent exposure of wound drainage from the skin.</p>
<p>10 Educate patient and family caregiver regarding pressure ulcer risk and prevention (WOCN, 2010).</p>	<p>Assists in adhering to interventions to reduce pressure ulcer risk.</p>
<p>11 Remove gloves and discard in appropriate receptacle. Perform hand hygiene.</p>	<p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Observe patient’s skin for areas at risk for tissue damage, noting change in color, appearance, or texture.</p>	<p>Enables you to evaluate success of prevention techniques.</p>
<p>2 Observe tolerance of patient for position change by measuring level of comfort on a pain scale.</p>	<p>Position changes sometimes interfere with patient’s sleep and rest pattern.</p>
<p>3 Compare subsequent risk assessment scores and skin assessments.</p>	<p>Provides ongoing comparison of patient’s risk level to facilitate appropriateness of plan of care.</p>

Unexpected Outcomes

- 1 Skin becomes mottled, reddened, purplish, or bluish.
- 2 Areas under pressure develop persistent discoloration, induration, or temperature changes.

Related Interventions

- Refer patient to wound, ostomy, and continence (WOC) nurse; dietitian; clinical nurse specialist (CNS); and/or physical therapist as necessary. Reevaluate position changes and bed surface.
- Refer patient to WOC nurse; dietitian; CNS; and/or physical therapist as necessary.
- Modify patient’s positioning and turning schedule.

Recording and Reporting

- Record any skin changes, patient’s risk score, and skin assessment. Describe positions, turning intervals, pressure-redistribution devices, and other prevention measures. Note patient’s response to the interventions.
- Report need for additional consultations for the high-risk patient to health care provider.

Special Considerations

Teaching

- Help patient and family caregiver understand multiple factors involved in preventing and treating pressure ulcers.
- Explain and demonstrate positioning options to achieve pressure redistribution.
- Explain the purpose and maintenance of pressure-redistribution devices (see Chapter 12).
- When teaching patients to change position for pressure redistribution, suggest using television programming and commercial intervals or a watch with an alarm as reminders.

Pediatric

- Infants and young children in diapers are at risk for skin breakdown.

Gerontologic

- Reevaluate sitting posture and position because body weight and muscle tone change with age.
- In older adults the dermis is not as thick. Skin over the legs and forearms is especially thin. There is less subcutaneous tissue, leading to less padding protection over bony prominences; and the time for epidermal regeneration is diminished, leading to slower healing (Wysocki, 2012).

Home Care

- Identify community resources such as neighbors and relatives to provide assistance if patient needs help with position changes.
- Closely monitor home care patients for pressure ulcer development if they have any of the following risk factors: wheelchair or bed dependence, incontinence, anemia, fracture, and or skin drainage.
- Remind patient and family caregiver that position changes need to occur while a patient is sitting in a chair. Consider shifts every 15 minutes. Small shifts such as moving or repositioning the legs redistributes pressure over bony prominences (WOCN, 2010).

SKILL 18-2 Treatment of Pressure Ulcers

Video Clip

Treatment of patients with pressure ulcers requires a holistic approach using a thorough assessment of patients and their ability to heal. Have a good understanding of the identified goal for a patient's overall care before implementing topical pressure ulcer treatment. The principles of managing patients with pressure ulcers includes systematic support of patients, reduction or elimination of the cause of skin breakdown, and management that provides an environment conducive to healing. Once you find the cause of the pressure ulcer, take steps to control or eliminate it. For example, if the ulcer is related to unrelieved pressure, choose the appropriate pressure-redistribution surface, develop a turning schedule, or choose the appropriate chair pad. Next assess the patient's wound-healing abilities: cardiovascular and pulmonary function, nutritional status, and conditions that interfere with wound healing such as diabetes, steroid administration, and immunosuppression (Doughty and Sparks-Defriese, 2012). Wound assessment tools such as the Bates-Jensen Wound Assessment Tool (BWAT) (Nix, 2012) and the PUSH tool can assist in determining the individual treatment goals for different pressure ulcers.

The principle that guides the selection and use of topical dressings is to provide a wound environment that supports healing (Rolstad, Bryant, and Nix, 2012). The best environment for wound healing is moist and free of necrotic tissue and infection. Choose interventions and dressings designed to support a clean, moist wound bed. Perform a thorough assessment of the wound and the periwound skin before initiating wound therapy. Data obtained will help to plan the appropriate care for a patient with a pressure ulcer.

No specific studies demonstrate the benefit of using one cleanser over another for pressure ulcers. In most cases water or saline is sufficient for cleaning a clean wound (WOCN, 2010). Hydrogen peroxide was once widely used but is now known to cause tissue damage. When a wound is contaminated with debris, necrotic tissue, or heavy drainage, use a cleanser that is noncytotoxic to healthy tissue. If the tissue in the wound is devitalized, consult with a patient's health care provider to consider debridement, which is the removal of devitalized tissue. Debridement is accomplished by the choice of dressing and the use of enzyme preparations or surgical or laser techniques. The choice of the type of debridement depends on a patient's overall condition, the condition of the wound, and the type of devitalized tissue.

Choose wound dressings to meet the characteristics of the wound bed (Rolstad, Bryant, and Nix, 2012). The choice of a wound dressing depends on the type of wound tissue in the base of the wound, the amount of wound drainage, the presence or absence of infection, the location of the wound, the size of the wound, the ease of use, cost-effectiveness, and patient comfort. Categories of

wound dressings include transparent films, hydrocolloids, hydrogels, foams, calcium alginates, gauze, and antimicrobial dressings (see Chapter 39). The type of dressings to use will change as the pressure ulcer characteristics change; frequent wound assessment is key.

Advanced wound care therapies used in select cases include growth factors, electrical stimulation, hyperbaric therapy, negative-pressure wound therapy, and tissue-engineered skin. Growth factors occur naturally in wound fluid and stimulate both granulation and epithelialization when applied topically. Pulsed electrical stimulation is a procedure usually performed by physical therapists with the goal of increased wound healing. Hyperbaric oxygen therapy uses increased amounts of pressurized oxygen delivered to patients in a variety of specialized methods. Negative-pressure wound therapy (NPWT) applies suction to facilitate healing and collect wound fluid (Netsch, 2012). NPWT works via a suction system and a wound filler (dressing such as foam or gauze) placed into the wound and covered with a semioclusive dressing. This therapy applies negative pressure to a wound through suction to facilitate healing and collect wound fluid (Netsch, 2012) (see Chapter 39). Tissue-engineered skin develops living cells that you place over a clean wound bed to facilitate wound closure. Advanced wound therapies may play an important role in pressure ulcer healing, but use only after consultation with a wound care expert.

Delegation and Collaboration

The skill of treatment of pressure ulcers and dressing changes cannot be delegated to the nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Report any wound drainage that might be on linens or intact skin, indicating the need to change the dressing or use an alternative dressing.
- Report any new areas of redness, blistering, or skin irritation.

Equipment

- Protective equipment: clean gloves, goggles, cover gown (if splash is a risk)
- Sterile gloves (optional)
- Plastic bag for dressing disposal
- Measuring device
- Sterile cotton-tipped applicators (check agency policy for use of sterile applicators)
- Topical agent (as ordered)
- Cleansing agent (as ordered)
- Sterile solution container
- Dressing of choice based on patient wound characteristics
- Hypoallergenic tape (if needed)
- Documentation records

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's level of comfort on a pain scale of 0 to 10. If patient is in pain, determine if a prn pain medication has been ordered and administer.
- 2 Determine if patient has allergies to topical agents.
- 3 Review the order for topical agent(s) and/or dressings.

Dressing change should not be a traumatic event for patient; evaluate wound pain before, during, and after wound care management (Hopf et al., 2012).

Topical agents could contain elements that cause localized skin reactions.

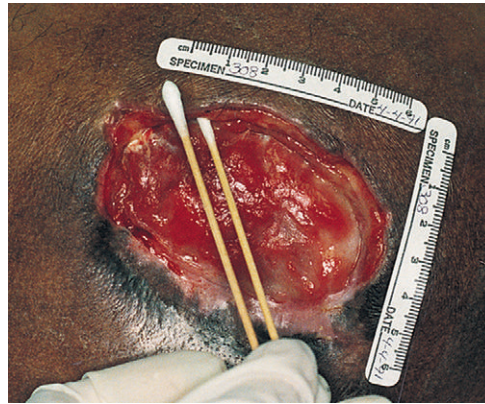

Ensures administration of proper medication and treatment.

STEP

RATIONALE

Clinical Decision Point Determine if the order is consistent with established wound care guidelines and outcomes for a patient. If the order is not consistent with guidelines or varies from the identified outcome for a patient, review it with the health care team.

- | | |
|--|--|
| <p>4 Close room door or bedside curtains. Perform hand hygiene and apply clean gloves.</p> <p>5 Position patient to allow dressing removal and position plastic bag for dressing disposal.</p> <p>6 Assess patient's wounds using wound parameters, and continue ongoing wound assessment per agency policy. NOTE: This may be done during procedure after dressing removal.</p> <p>a <i>Wound location:</i> Describe the body site where the wound is located.</p> <p>b <i>Stage of wound:</i> Describe the extent of tissue destruction (see Box 18-1).</p> <p>c <i>Wound size:</i> Length, width, and depth of the wound are measured per agency protocol. Use a disposable measuring guide for length and width. Use a cotton-tipped applicator to assess depth (see illustration).</p> | <p>Provides privacy. Reduces transmission of microorganisms and prevents accidental exposure to body fluids.</p> <p>Provides an accessible area for dressing change. Proper disposal of old dressing promotes proper handling of contaminated waste.</p> <p>Determines effectiveness of wound care and guides the treatment plan of care (WOCN, 2010).</p> <p>Staging is a way of assessing a pressure ulcer based on depth of tissue destruction. Wounds are documented as unstageable if the wound base is not visible (EPUAP and NPUAP, 2009).</p> <p>Ulcer size changes as healing progresses; therefore the longest and widest areas of the wound change over time. Measuring the width and length by measuring consistent areas provides a consistent measurement (Nix, 2012).</p> |
|--|--|

STEP 6c Measuring wound width, length, and undermining of skin.

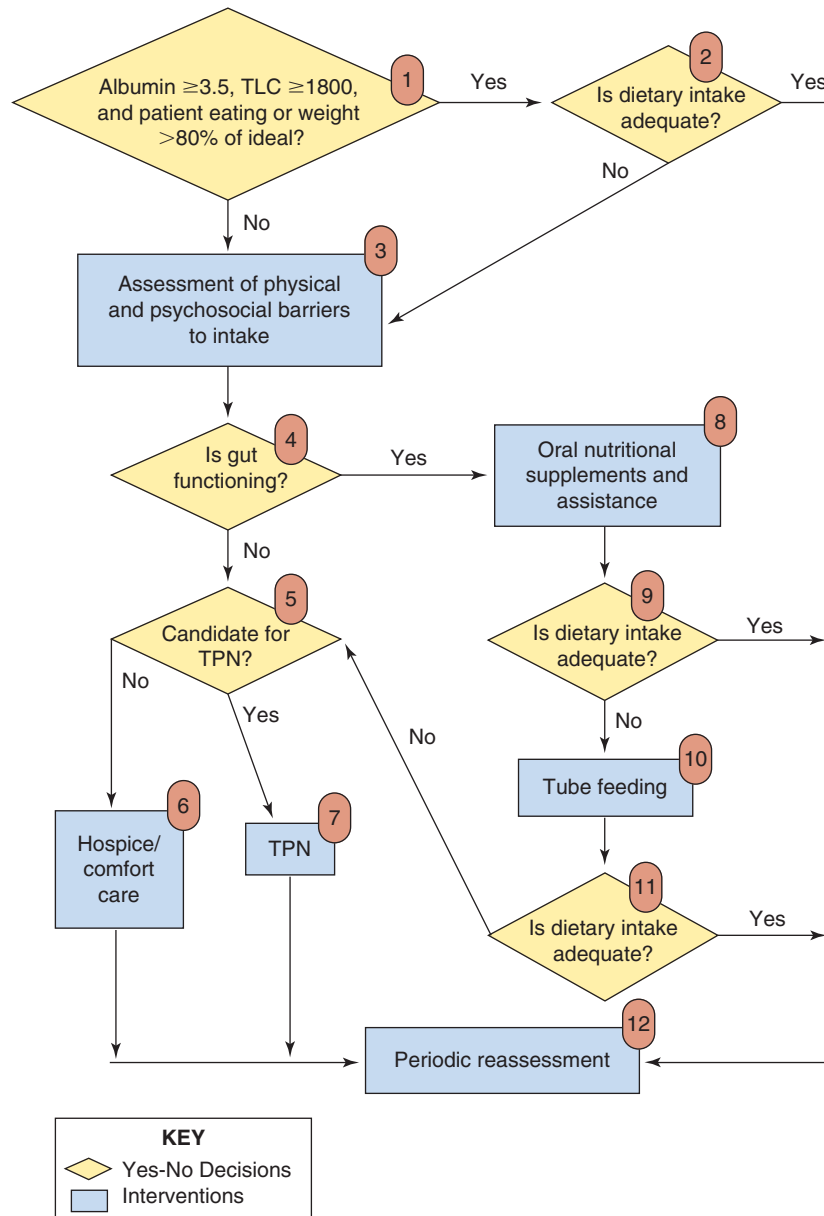

- | | |
|--|---|
| <p>d <i>Presence of undermining, sinus tracts, or tunnels:</i> Use a sterile cotton-tipped applicator to measure depth and, if needed, a gloved finger to examine the wound edges.</p> <p>e <i>Condition of wound bed:</i> Describe the type and percentage of tissue in the wound bed.</p> <p>f <i>Volume of exudate:</i> Describe the amount, characteristics, odor, and color.</p> <p>g <i>Condition of periwound skin:</i> Examine the skin for breaks, dryness, and the presence of a rash, swelling, redness, or warmth. Modify assessment based on patient's skin color (see Box 18-2).</p> <p>h <i>Wound edges:</i> Gives information regarding epithelialization, chronicity, and etiology.</p> <p>7 Remove gloves, discard appropriately, and perform hand hygiene.</p> <p>8 Assess for factors affecting wound healing: poor perfusion, immunosuppression, or preexisting infection.</p> | <p>Wound depth determines amount of tissue loss.</p> <p>The approximate percentage of each type of tissue in the wound provides critical information on the progress of wound healing and the choice of dressing. A wound with a high percentage of black tissue requires debridement, yellow tissue or slough tissue may indicate the presence of an infection or colonization, and granulation tissue indicates that a wound is moving toward healing.</p> <p>Amount and type of exudate may indicate type and frequency of dressing changes.</p> <p>Impaired skin condition at the edge of an ulcer indicates progressive tissue damage. Maceration on periwound skin shows a need to alter the choice of wound dressing.</p> <p>Reduces transmission of microorganisms. Repeated hand hygiene is needed as you assess other pressure areas. Different organisms contaminate different wounds.</p> <p>Factors will affect treatment and wound healing.</p> |
|--|---|

STEP

RATIONALE

9 Assess patient's nutritional status (see Chapter 30). Clinically significant malnutrition is present if (1) serum albumin level is less than 3.5 g/dL, (2) lymphocyte count is less than 1800/mm³, or (3) body weight decreases more than 15% (see illustration) (WOCN, 2010).

Delayed wound healing occurs in poorly nourished patients.

STEP 9 Nutritional assessment and support. *TLC*, Total lymphocyte count; *TPN*, total parenteral nutrition. From Bergstrom N et al: Treatment of pressure ulcers, AHCPR Pub No. 95-0652, Rockville, Md, 1994, Agency for Health Care Policy and Research, Public Health Service, U.S. Department of Health and Human Services.

Clinical Decision Point When you suspect malnutrition, consider a nutritional consultation to modify patient's diet to promote wound healing.

10 Assess patient's and caregiver's understanding of prevention, treatment, and factors contributing to recurrence of pressure ulcers (WOCN, 2010).

Patient and caregiver need to partner with health care providers to prevent further skin breakdown.

STEP	RATIONALE
------	-----------

NURSING DIAGNOSES

- | | | |
|--|---|---|
| <ul style="list-style-type: none"> • Deficient knowledge regarding pressure ulcer treatment plan • Imbalanced nutrition: less than body requirements | <ul style="list-style-type: none"> • Impaired physical mobility • Impaired skin integrity | <ul style="list-style-type: none"> • Ineffective tissue perfusion • Pain (acute, chronic) |
|--|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Ulcer drainage decreases. • Granulation tissue is present in wound base. • Skin surrounding ulcer remains healthy and intact. • Nutritional intake meets caloric and nutrient targets. • Patient's overall skin remains intact and without further breakdown. <p>2 Explain procedure to patient and family caregiver. Individualize teaching plan for older adults, taking into account normal aging changes that affect learning.</p> <p>3 Prepare the following necessary equipment and supplies:</p> <p>a Normal saline or other wound-cleansing agent in sterile solution container</p> | <p>Reflects decrease in inflammatory process and progress toward healing.</p> <p>Evidence that wound is moving toward healing.</p> <p>No additional damage is evident; dressing is appropriate to contain wound drainage.</p> <p>Nutritional therapy provides adequate protein to support wound healing.</p> <p>Patient remains at risk for further breakdown while existing ulcer heals.</p> <p>Preparatory explanations relieve anxiety, correct any misconceptions about the ulcer and its treatment, and offer an opportunity for patient and family education.</p> <p>Clean ulcer surface before applying topical agents and new dressing.</p> |
|---|---|

Clinical Decision Point *Use only noncytotoxic agents to clean ulcers.*

- | | |
|---|---|
| <p>b Prescribed topical agent:</p> <p>(1) Enzyme debriding agents (Follow specific manufacturer directions for frequency of application)</p> <p style="text-align: center;"><i>or</i></p> <p>(2) Topical antibiotics</p> | <p>Enzymes debride dead tissue to clean ulcer surface. Enzymes are not applied to healthy tissue.</p> <p>Topical antibiotics decrease bioburden of wound and should be considered for use if no healing is noted after 2 to 4 weeks of optimal care (WOCN, 2010).</p> |
|---|---|

Clinical Decision Point *If using an enzymatic debriding agent, do not use wound-cleansing agents with metals.*

- | | |
|---|---|
| <p>c Select an appropriate dressing based on pressure ulcer characteristics, principles of wound management, and patient care setting. Dressing options include (Table 18-4) (see Chapter 39):</p> <p>(1) Gauze. Apply as a moist dressing, a dry cover dressing when using enzymes or topical antibiotics, or as a means to deliver solution to a wound (see Chapter 39).</p> | <p>Dressing should maintain moist environment for wound while keeping surrounding skin dry (Rolstad, Bryant, and Nix, 2012).</p> <p>Gauze delivers moisture to a wound and is absorptive.</p> |
|---|---|

Clinical Decision Point *Make sure that absorbency of dressing is adequate for the amount of wound drainage. Check that wound does not dry out or surrounding skin does not become macerated.*

- | | |
|--|---|
| <p>(2) Transparent film dressing. Apply over superficial ulcers with minimal or no exudate and skin subjected to friction.</p> | <p>Maintains a moist environment and offers intact skin protection.</p> |
|--|---|

Clinical Decision Point *Use transparent dressings for autolytic debridement of noninfected superficial pressure ulcers.*

- | | |
|----------------------------------|---|
| <p>(3) Hydrocolloid dressing</p> | <p>Maintains moist environment to facilitate wound healing while protecting wound base.</p> |
|----------------------------------|---|

Clinical Decision Point *Use a hydrocolloid to protect skin from friction. Some brands have custom shapes available for specific anatomic parts such as heel, elbows, and sacrum.*

STEP	RATIONALE
(4) Hydrogel—Available in a sheet or in tube	Maintains moist environment to facilitate wound healing.
(5) Calcium alginate	Highly absorbent of wound exudate in heavily draining wounds.
(6) Foam dressings	Protective and prevents wound dehydration; also absorbs moderate-to-large amounts of drainage.
(7) Silver impregnated dressings/gels	Controls bacterial burden in wound.
(8) Wound fillers	Fills shallow wounds, hydrates, and absorbs
d Obtain hypoallergenic tape or adhesive dressing sheet	Used to secure nonadherent dressing. Prevents skin irritation and tearing.

TABLE 18-4 Dressings by Pressure Ulcer Stage

Pressure Ulcer Stage	Pressure Ulcer Status	Dressing	Comments*	Expected Change	Adjuvants
I	Intact	None Transparent dressing Hydrocolloid	Allows visual assessment. Protects from shear. Do not use in presence of excessive moisture. Does not allow visual assessment.	Resolves slowly without epidermal loss over 7 to 14 days	Turning schedule. Support hydration. Nutritional support. Pressure-redistribution bed or use of chair cushion.
II	Clean	Composite film Hydrocolloid Hydrogel	Limits shear. Change when seal of dressing breaks, maximal wear time 7 days. Provides moist environment.	Heals through reepithelialization	See previous stage. Manage incontinence.
III	Clean	Hydrocolloid Hydrogel covered with foam dressing Calcium alginate Gauze Growth factors	Change when seal of dressing breaks, maximum wear time 7 days. Apply over wound to protect and absorb moisture. Use when there is significant exudate. Cover with secondary dressing. Use with normal saline or other prescribed solution. Wring out excess solution; unfold to make contact with wound. Use with gauze per manufacturer instructions.	Heals through granulation and reepithelialization	See previous stages. Evaluate pressure-redistribution needs.
IV	Clean	Hydrogel covered with foam dressing Calcium alginate Gauze	See stage III clean. Used with significant exudate; must cover with secondary dressing See stage III clean.	Heals through granulation, scar tissue development, and reepithelialization.	Surgical consultation may be necessary for closure. See stages I, II, and III.
Unstageable	Wound covered with eschar	Adherent film Gauze plus ordered solution Enzymes None	Facilitates softening of eschar. Delivers solution and wicks wound drainage. Breaks down eschar, providing debridement. Rarely, if eschar is dry and intact, no dressing is used, allowing eschar to act as physiologic cover.	Eschar lifts at edges as healing progresses Eschar loosens over time.	See previous stages. Surgical consultation may be considered for debridement. May be considered for slow debridement.

*As with *all* occlusive dressings, wounds should not be clinically infected.

STEP	RATIONALE
IMPLEMENTATION	RATIONALE
1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures patient identity. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2 Assemble supplies at bedside. Close room door or bedside curtains.	Maintains patient privacy.
3 Perform hand hygiene and apply clean gloves. Open sterile packages and topical solution containers. Keep dressings sterile. Wear goggles, mask, and moisture-proof cover gown if potential for contamination from spray exists when cleaning wound.	Reduces transmission of microorganisms.
4 Remove bed linen and arrange patient's gown to expose ulcer and surrounding skin. Keep remaining body parts draped.	Prevents unnecessary exposure of body parts.
5 Remove old dressing and discard in appropriate receptacle. Assess condition of wound and amount and color of wound drainage if present. Remove gloves and discard.	With each dressing change note progress of wound healing.
6 Perform hand hygiene and change gloves.	Maintains aseptic technique during cleaning, measuring, and applying dressings. Refer to agency policy regarding use of clean or sterile gloves.
7 Clean wound thoroughly with normal saline or prescribed wound-cleansing agent (see Chapter 39) from least contaminated to most contaminated area.	Cleansing wound removes wound exudate and/or dressing residue and reduces surface bacteria.
8 Apply topical agents to wound using cotton-tipped applicators or gauze as ordered:	
a Enzymes	Follow manufacturer directions for method and frequency of application. Be aware of which solutions inactivate enzymes and avoid their use in wound cleaning.
(1) Apply small amount of enzyme debridement ointment directly to necrotic areas in pressure ulcer. <i>Do not apply enzyme to surrounding skin.</i>	Proper distribution of ointment ensures effective action.
(2) Place moist gauze dressing directly over ulcer and tape in place. Follow specific manufacturer recommendation for type of dressing material to use to cover a pressure ulcer when using enzymes.	Protects wound and prevents removal of ointment during turning or repositioning.
b Antibacterials	Reduces bacterial growth.
Examples include bacitracin, metronidazole, and silver sulfadiazine.	
9 Apply prescribed wound dressing:	
a Hydrogel	Provides moist environment to facilitate wound healing.
(1) Cover surface of ulcer with a thick layer of the amorphous hydrogel, or cut a sheet to fit wound base.	
(2) Apply secondary dressing such as dry gauze; tape in place.	Holds hydrogel against wound surface because amorphous hydrogel (in tube) or sheet form does not adhere to wound and requires a secondary dressing to hold it in place.
(3) If using impregnated gauze, pack loosely into wound; cover with secondary gauze dressing and tape.	A loosely packed dressing delivers the gel to the wound base and allows any wound debris to be trapped in the gauze.
b Calcium alginate	Use in heavily draining wounds.
(1) Lightly pack wound with alginate using sterile cotton-tipped applicator or gloved finger.	The dressing swells and increases in size; tight packing can compromise blood flow to the tissues.
(2) Apply a secondary dressing and tape in place.	
c Transparent film dressing; hydrocolloid; and foam dressings (see Chapter 39)	
10 Reposition patient comfortably off pressure ulcer.	Prevents pressure to ulcer.
11 Remove gloves and dispose of soiled supplies. Perform hand hygiene.	Reduces transmission of microorganisms.

STEP

RATIONALE

EVALUATION

- 1 Observe skin surrounding ulcer for inflammation, edema, and tenderness.
- 2 Inspect dressings and exposed ulcers, observing for drainage, foul odor, and tissue necrosis. Monitor patient for signs and symptoms of infection: fever and elevated white blood cell (WBC) count.
- 3 Compare subsequent ulcer measurements, using one of the scales designed to measure wound healing such as the PUSH Tool or the BWAT Assessment.

Determines progress of wound healing.

Ulcers can become infected.

Allows comparison of serial measurements to evaluate wound healing. Provides standard method of data collection that demonstrates wound progress or lack thereof.

Unexpected Outcomes

- 1 Skin surrounding ulcer becomes macerated.
- 2 Ulcer becomes deeper with increased drainage and/or development of necrotic tissue.
- 3 Pressure ulcer extends beyond original margins.

Related Interventions

- Reduce exposure of surrounding skin to topical agents and moisture.
- Select a dressing that has increased moisture-absorbing capacity.
- Review current wound care management.
- Consult with multidisciplinary team regarding changes in wound care regimen.
- Obtain wound cultures (see Chapter 43).
- Monitor for systemic signs and symptoms of poor wound healing such as abnormal laboratory results (WBC count, levels of hemoglobin/hematocrit, serum albumin, serum prealbumin, total proteins), weight loss, and fluid imbalances.
- Assess and revise current turning schedule.
- Consider further pressure-redistribution devices.

Recording and Reporting

- Record type of wound tissue present in ulcer, ulcer measurements, periwound skin condition, character of drainage or exudate, type of topical agent used, dressing applied, and patient's response.
- Report any deterioration in ulcer appearance to nurse in charge or health care provider.

Special Considerations

Teaching

- Discuss treatment and identify individual(s) who will help with care at home.
- Discuss process of wound healing and expected wound appearance. For example, discuss patient's perception about appearance of the pressure ulcer. Sometimes eschar looks like a scab to a patient, and he or she needs to understand the difference. A scab is caused by exudate, and an eschar is dead tissue that the patient should not remove.
- Discuss with patient and family caregivers perceptions about size of pressure ulcer. Some wounds, especially after debridement, may appear larger and are very troublesome to patients and support persons.
- Discuss with patient and support persons perceptions about treatment. Some patients and family caregivers believe that it is cruel for staff to keep turning and positioning a patient on a frequent basis.
- Review prevention guidelines to prevent further breakdown.
- Discuss options for maintaining good nutrition.

Gerontologic

- Wound healing is often slower in older adults (Doughty and Sparks-Defriese, 2012).

- The normal reduction in the Langerhans cells in the older adult's epidermis causes a decrease in T-cell function and immunity.
- Because older skin has a slower and less intense inflammatory reaction, monitor older patients more closely for altered responses to skin irritants.

Home Care

- Consider family caregiver time when selecting a dressing. In the home care setting caregivers may sometimes choose more expensive dressing materials to reduce the frequency of dressing changes.
- Some patients have more time than financial resources. They may choose a less expensive treatment option (e.g., dressing material), especially if there is no third-party reimbursement. Another example is to teach the family caregiver to make a normal saline solution rather than buying it ready-made.
- Identify clean storage area for dressing supplies. Determine availability of required supplies. Discuss need for home care nurse.
- Discuss need for home pressure-redistribution surface or bed. Identify adaptive equipment needed to care for patient at home.
- Medicare regulations limit reimbursement of some types of support surfaces in the treatment of pressure ulcers.

Long-Term Care

- Rehabilitation units often use a variety of support surfaces and beds.
- Some patients may be discharged to long-term care facilities that specialize in pressure ulcer and wound care.

Critical Thinking Exercises

Ms. Willet is a 72-year-old white woman who recently underwent a total hip replacement, left side. Her significant medical history includes rheumatoid arthritis and coronary artery disease. This is her first postoperative day, and she is resting in bed with an immobilizer (a foam wedge that is placed between her thighs to keep her hip in position) in place. She weighs 200 lbs and is approximately 5 feet 6 inches tall. A physical therapist is scheduled to see her today to help her get out of bed for the first time since surgery. When the physical therapist is not available, Ms. Willet is on bed rest. Skin assessment reveals a 2.5-cm (1 inch), round, black right heel ulcer and a 2-cm red warm spot located over the sacrum.

- The Braden risk assessment tool was used to determine the risk factors that place Ms. Willet at risk for skin breakdown. Which factors in the above scenario may contribute to the potential for skin breakdown?
- The black tissue on Ms. Willet's heel is best described as and would be staged as:
 - Granulation, stage II.
 - Eschar, nonstageable.
 - Slough, stage III.
 - Induration, stage I.
- The red warm spot noted over her sacrum is described as:
 - Erythema.
 - Sheet burn.
 - Blistering.
 - Bruising.
 Explain your choice.
- Identify the likely cause of the red warm area over Ms. Willet's sacrum and name one approach to determine if there is skin breakdown. Explain your choice.

REVIEW QUESTIONS

- Which of the following patients has factors that negatively affect wound healing? (Select all that apply.)
 - A patient whose surgical wound is producing yellowish drainage and whose white blood cell count is elevated
 - A cancer patient receiving the antiinflammatory drug cortisol
 - An older adult who has been advised to add more sources of vitamin C to her diet
 - A trauma patient with an open wound that is being treated with a moist dressing
- A nurse on a surgical unit is providing care to patients who have recently undergone major abdominal procedures. How often should a pressure ulcer risk assessment be performed for these patients?
 - At least every day of their hospital stay
 - On admission to the unit, on a regularly scheduled basis, and as their condition changes
 - Every other day until the fifth postoperative day
 - If indicated by the presence of a history of pressure ulcers
- A patient who is completely immobile and who does not make even slight changes in body or extremity position without assistance is being assessed for risk for developing a pressure ulcer using the Braden Scale. Which intervention would be appropriate to prevent pressure ulcers in this patient?
 - Use a moisture barrier ointment at least 3 times per day.
 - Consult with the wound clinical nurse specialist about the most appropriate bed surface to reduce pressure.
 - Order a nutrition consultation to be sure that the patient has adequate vitamin and mineral intake.
 - Consult with the physical therapy staff to determine exercises to increase muscle strength.
- A patient is recovering from abdominal surgery and has a nasogastric tube inserted for stomach decompression. An intravenous (IV) line of normal saline is infusing into the left arm at 100 drops/min. The patient uses an incentive spirometer to perform deep-breathing exercises and has a drain exiting the wound and draining fluid into a small enclosed container. The patient is at risk for a pressure injury in which area? (Select all that apply.)
 - Lips
 - Nares
 - Left arm
 - Skin
- An order for a hydrocolloid dressing is written for a patient with a pressure ulcer. What is the rationale for using a hydrocolloid dressing?
 - It provides an antibiotic solution to decrease surface bacteria, which helps healing.
 - It protects the wound base and provides a moist environment.
 - It can be changed several times per day without damaging the wound bed.
 - It contains a debriding agent to clean a wound environment.
- The pediatric nursing team is orienting new nurses on preventing pressure ulcers in neonates and young children. Where should the nurses check frequently for the occurrence of these ulcerations in these children?
 - Shoulders
 - Head
 - Sacrum
 - Heels
- When using gauze moistened in normal saline for a wound dressing, why is the gauze pad wrung out before application?
 - To prevent excessive delivery of the solution to the wound
 - To keep the healing wound moist and wick any excessive drainage
 - To prevent moistening the secondary dressing and causing maceration
 - To allow the wound to become slightly dry to facilitate healing
- What is the primary mechanism of action of a hydrocolloid dressing?
 - It covers the wound, preventing staff from viewing the affected area.
 - It forms a gel over the wound to facilitate moist healing.
 - It forms a temporary membrane over the wound, allowing oxygen transport directly to the wound.
 - It delivers epithelial growth factors to the wound base.
- Which of the following patients is most at risk for developing a pressure ulcer?
 - An 80-year-old adult with Alzheimer's who has poor oral intake
 - A 45-year-old male who is confined to a wheelchair as a result of paraplegia
 - A 50-year-old male with type I diabetes who underwent major heart surgery 24 hours ago and has diaphoresis
 - A 60-year-old female who underwent bladder surgery and now has urinary incontinence
- The dressing ordered for a patient's sacral pressure ulcer is a hydrocolloid dressing. Place the following steps in the correct order for the dressing application.
 - Clean wound with ordered solution.
 - Remove paper backing from dressing.
 - Explain to patient the purpose of the dressing change.
 - Position patient to gain access to the pressure ulcer.
 - Measure wound to determine correct size of dressing.
 - Place dressing over wound; apply light pressure for 30 to 60 seconds.

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Explain safety guidelines used in the proper care of eye and ear prostheses.
- Identify patient-centered care guidelines used in caring for eye and ear prostheses.
- Correctly remove, store, clean, and insert a contact lens.
- Explain the rationale for maintaining aseptic technique during care of an artificial eye.
- Correctly perform eye and ear irrigations.
- Describe techniques that determine whether a hearing aid functions properly.
- Correctly remove, clean, and reinsert a hearing aid.

Artificial sensory devices help to replace or restore sensory function. Eyeglasses and contact lenses help to restore visual loss, and hearing aids improve sound reception. A patient may also depend on a prosthetic device such as an artificial eye to maintain an attractive appearance. Artificial eyes in particular help patients maintain a normal appearance when an eye is lost as a result of injury or disease (Goiato et al., 2010).

Artificial sensory devices must fit and work properly if patients are to function optimally within their environment. Breakage or loss is expensive and may result in serious impairment that can put a patient at risk for injury and interfere with communication, isolate a patient socially, and increase patient dependence and thereby threaten self-esteem. Understandably patients are especially sensitive about care of contact lenses, hearing aids, or artificial eyes.

An artificial eye or hearing aid requires regular cleaning to ensure proper function and prevent injury. Most patients have an established routine for cleaning their devices. When patients are unable to care for their device, you must understand the correct method to clean, handle, and store contact lenses, hearing aids, and artificial eyes. Careful handling is vital to avoiding damage to these devices or to a patient's eyes or ears.

EVIDENCE-BASED PRACTICE

Often vision and hearing change as people age. However, some of these changes are beyond the normal expectation of aging. Dual sensory impairment (DSI), the concurrent losses in vision and hearing, has the potential to cause cognitive function decline or contribute to acute confusion

or depression (Saunders and Echt, 2011). Furthermore, DSI in rehabilitation or long-term care settings affect a patient's success in using assistive devices and rehabilitation services and progressing to a higher level of independent function (McDonnall, 2009). Although the evidence is not conclusive, some literature suggests that DSI is more debilitating than a single sensory impairment, whereas other literature suggests that the vision impairment component of DSI has the main impact on individuals (Smith et al., 2008).

Age-related hearing loss is gradual, progressive, and often bilateral. Older adults may not actually perceive their hearing loss because initially it is mild; however, as it progresses, they usually avoid or delay hearing evaluation (Chou et al., 2011). Hearing loss is the third leading chronic condition affecting adults over 75 years of age (Cacchione, 2010). There is a high prevalence of hearing loss in nursing facility residents (Adams-Wendling, 2008).

Vision impairment is the functional limitation of the eyes (e.g., reduced visual acuity, visual field loss, contrast sensitivity reduction, glare disability) that cannot be corrected with standard glasses or contact lenses (Smith et al., 2008). There are multiple definitions and classifications of levels of vision impairment and blindness, which adds to the complexity in understanding DSI. In addition, the psychosocial and functional impacts of DSI are not well understood when compared with those of a single sensory impairment (Smith et al., 2008). A person with DSI is likely to be at greater risk for disability, but evidence is mixed.

In community settings sensory impairments negatively impact the use of community support services and health-related quality of life (McDonnall, 2009). DSI decreases independence, socialization, and quality of life of individuals and, in many cases, their families (Swann, 2008).

- Common screening tests for hearing loss can help identify patients at higher risk for hearing loss. The whispered voice test at 2 feet and a single question regarding perceived hearing loss are comparable with more detailed screening questionnaires and audiometric devices for identifying at least mild hearing loss (Chou et al., 2011).
- Identify patients at risk for hearing impairments: Male over age 65, male or female over age 75, resident in nursing facility, existing visual impairment, chronic ear infection, prolonged exposure to loud noises, and use of ototoxic medication (Cacchione, 2010; Adams-Wendling et al., 2008).
- Involving patients with DSI in volunteer work has been shown to result in fewer depressive symptoms compared to persons without sensory loss who volunteer (McDonnall, 2011).
- Patients with DSI will have unique communication needs that require a thorough assessment.
- Evaluate nursing facility residents for hearing impairment on admission and routinely thereafter (Adams-Wendling, 2008).
- Verify that patients are able to see, hear, and understand instructions about their therapy.

PATIENT-CENTERED CARE

Any intervention, device, or prosthesis needed to improve sensory perception must fit and work properly if patients are to function optimally within their environment. It is important to know a patient's preferences and have a discussion with your patients about

how to use and care for a device or prosthesis. Breakage or loss of a patient's hearing aid or eye prosthesis often results in costly repair and replacement. When a patient is without visual or hearing aids, it interferes with communication, isolates a patient socially, and increases patient dependence. In addition, especially in the case of an eye prosthesis, the loss of the device threatens a patient's self-esteem.

Hospitals, rehabilitation centers, and skilled nursing facilities are environments that make hearing difficult. The hard flooring surfaces, medical equipment, televisions, and constant need to speak with other health care professionals all produce noise. For the hearing impaired this increased background noise makes hearing even more difficult (Wallhagen and Pettengill, 2008). When a patient has visual impairments, the increased background noise in an unfamiliar environment often makes a patient more anxious and decreases his or her ability to adjust to new surroundings.

Communication is vital to people from all cultures. When vision and/or hearing is threatened or impaired, that change must be understood in terms of a patient's culture. In cultures such as the Navajo Indian and in some Asian and Middle Eastern cultures, limited eye contact is the norm and is a nonverbal form of respect (Galanti, 2008). Changes in the ability to move the eyes, as with a prosthesis, present a social difficulty because a patient is unable to lower the eyes. The Navajo Indians are comfortable with the soft-spoken word and silence (Galanti, 2008).

Hearing impairments may force a patient's family and friends to speak loudly, which is not effective. In addition, because of the comfort with silence, one can easily mistake a patient's silence for a measure of comfort and never correctly assess what he or she is able to hear or if the information is heard correctly. At times you will use touch to get the attention of a patient with decreased hearing. In some cultures such as Muslim, same-sex caregivers are required before touch can be used. Remember this before using touch to gain a patient's attention.

The following list includes interventions for patients with sensory loss. As always it is important to carefully communicate with a patient about the course of action and verify that a patient saw, heard, and understood these interventions.

- Understand the cause of a person's sensory loss and then determine the patient's own perception of the reason for the loss.
- Identify patient's usual practices in using sensory assistive devices and the preferred maintenance.
- Provide large-print educational materials for patients with visual impairments.
- Design nursing interventions based on the type of sensory loss, patient safety, and patient preference.

Safety Guidelines

- 1 Whenever you care for patients with sensory alterations, safety is a priority. Anticipate how the sensory alteration places a patient at risk for injury (e.g., ability to maneuver through home, climb stairs, respond to alarms).
- 2 Orient patient to any new environment or changes within an existing environment to minimize safety hazards. In addition, educate family and friends about the best way to help patient adapt to sensory loss.
- 3 When patients have visual impairments, they may have difficulty with tasks requiring visual detail (e.g., reading

prescriptions or syringes). This increases the risk of improper administration of medications in the home setting. In addition, certain eye conditions such as cataracts and macular degeneration cause a patient difficulty when adjusting to changes in contrast and brightness.

- 4 Provide additional time for patients with hearing loss to ask repeated questions about their care or upcoming procedure.
- 5 If a patient must sign a consent form for a procedure or surgery, be sure to have a method to verify that patient read, heard, and understood the procedure.

PROCEDURAL GUIDELINE 19-1 Eye Care for Comatose Patients

Comatose patients do not have natural protective mechanisms, including blinking and lubrication of the eye, to protect the cornea (Rosenberg and Eisen, 2008). The blinking reflex flushes debris out of the eye. When patients are heavily sedated or in a coma, tear production is reduced; as a result the normal lubrication of the eye surface is decreased (So et al., 2008). Tears maintain a moist environment, lubricate the eyes, wash away foreign material and cell debris, prevent organisms from adhering to the ocular surface, and transport oxygen to the outer eye surface (Marshall et al., 2008). When a patient's normal protective eye mechanisms are not effective, a nurse is responsible for providing this care. Left unprotected, damage to the cornea can occur. This damage ranges from corneal scarring to premature cataract formation or vision changes. Simple nursing measures such as protecting the eyes or administering sterile lubricant decrease the risk for or prevent damage to the cornea (Oh et al., 2008).

Delegation and Collaboration

The skill of eye care for a comatose patient can be delegated to nursing assistive personnel (NAP). However, it is the nurse's responsibility to assess a patient's eyes and administer the sterile lubricant. The nurse directs the NAP to:

- Adapt the skill for specific patients (e.g., using skin-sensitive tape to affix eye pads for patients with sensitive skin).
- Immediately report any eye drainage or irritation to the nurse for further assessment.

Equipment

- Clean gloves
- Water or normal saline solution
- Clean washcloth
- Cotton balls
- Eye pads or patches
- Paper tape
- Eyedropper bulb syringe
- Sterile lubricant or eye preparations as ordered

NOTE: A moisture chamber (e.g., polyethylene covers or swimming goggles) to completely seal off the eye from the environment may also be used; verify with agency policy.

Procedural Steps

- 1 Perform hand hygiene.
- 2 Observe patient's eyes for drainage, irritation, redness, and lesions. Apply clean gloves if drainage is present.
- 3 Continually explain each step of the procedure. It is unknown how much a comatose patient can hear; thus it is important to continually orient a patient to any procedure.
- 4 Assess for blink reflex.
- 5 Perform pupillary examination: Determine if pupils are equal, round, and react to light (PERRL) (see Chapter 6).
- 6 Observe patient's eye movements, noting symmetry of eye movement.
- 7 Explain procedure to patient and family members.
- 8 Position patient in supine position.
- 9 Use clean washcloth or cotton balls moistened with water or saline and gently wipe each eye from inner to outer canthus. Use a separate, clean cotton ball or corner of the washcloth for each eye.
- 10 Use an eyedropper to instill the prescribed lubricant (e.g., saline, methylcellulose, liquid tears) as ordered, wiping away any excess lubricant.
- 11 If the blink reflex is absent, gently close patient's eyes and apply eye patches, pads, or a moisture chamber. Secure patch, being careful not to tape a patient's eyes.
- 12 Dispose of excess material, remove gloves, and perform hand hygiene.
- 13 Remove eye pads or patches every 4 hours or as ordered and observe condition of patient's eyes for drainage, irritation, redness, and lesions.
- 14 Document eye exam findings and administration of lubricant.
- 15 Notify health care provider if signs of irritation or infection are present.

PROCEDURAL GUIDELINE 19-2 Taking Care of Contact Lenses

A contact lens is a thin, concave disk that fits directly over the cornea of the eye. It is transparent over at least the pupil and may be colorless or tinted. Contact lenses correct refractive errors of the eye or abnormalities in the shape of the cornea that distort vision. They are relatively easy to apply and remove.

All modern contact lenses are gas (oxygen) permeable and adhere to the cornea by surface tension. There are two basic types of contact lenses in use today: rigid gas permeable (RGP) and soft. They differ primarily in size, flexibility, and durability. Rigid contact lenses are made of firm, durable plastic and are smaller

than the cornea. Soft contact lenses are made of a flexible hydrogel plastic and cover the entire cornea and a small rim of the sclera. There are many different kinds of both RGP and soft lenses to accommodate patient needs for comfort, vision correction, and convenience. Contact lenses have specific prescribed wear and replacement schedules.

It is important to remember that all lenses must be removed periodically to prevent infection and corneal damage and that proper cleaning is necessary before reinserting a lens. As contact lenses are worn, secretions and foreign matter adhere to the lens

PROCEDURAL GUIDELINE 19-2 Taking Care of Contact Lenses—cont'd

surface (American Optometric Association, 2011). It is extremely important to determine whether patients wear contact lenses, particularly when they are admitted to hospitals or agencies in unresponsive or confused states. If a seriously ill patient is wearing contact lenses and this fact goes undetected, severe corneal injury can result.

Delegation and Collaboration

The skill of taking care of contact lenses can be delegated to the nursing assistive personnel (NAP). The nurse directs the NAP to:

- Know a patient's specific type of contact lens, including cleaning solutions and routine, wear schedule, storage, and replacement schedule.
- Report immediately to the nurse any eye pain or discomfort, redness, swelling, tearing, or drainage.
- Carefully handle the lens to prevent damage and injury.

Equipment

- Bath towels or waterproof pads
- Sterile saline solution
- Sterile lens care solution(s) for cleaning, disinfecting, and rinsing
- Sterile wetting or conditioning solution (depends on care regimen)
- Sterile enzyme solution (depends on care regimen)
- Flashlight or penlight
- Clean lens storage container
- Suction cup (optional)
- Powder-free, clean gloves

Procedural Steps

- 1 Inspect patient's eyes or ask patient if contact lens is in place.

Clinical Decision Point *If a patient is unconscious or confused, you must assess for presence of contact lenses, which are often difficult to detect if they are colorless (untinted).*

- 2 Determine if patient is able to manipulate and hold contact lenses and if glasses are available for periods when contacts are not in use. Determine patient's usual routine for wearing, cleaning, and storing lenses.
- 3 Assess patient for any unusual visual signs/symptoms (e.g., change in visual acuity, blurred vision, halos, photophobia).
- 4 Review types of medication prescribed for patient: sedatives, hypnotics, muscle relaxants, antihistamines, or another medication that decreases blink reflex and subsequent lubrication of cornea.
- 5 Explain procedure to patient.
- 6 Perform hand hygiene.
- 7 Verify expiration date of all solutions and assemble equipment at bedside.
- 8 Be sure that your fingernails are short and smooth.
- 9 Position patient in supine or high-Fowler's position in bed.
- 10 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.
- 11 Apply clean gloves. Place towel just below patient's face.

12 Removing lenses:

- a Removal of soft lens: Follow Steps (1) through (6) for each eye.

- (1) If you are unable to visualize the lens, shine a penlight or flashlight sideways onto the eye to locate the position of the lens.
- (2) Add 2 to 3 drops of sterile saline solution to patient's eye.
- (3) If possible ask patient to look straight ahead. Retract lower eyelid and expose lower edge of lens.
- (4) Use pad of index finger to slide lens off cornea down onto lower sclera (white of the eye).
- (5) Pull upper eyelid down gently with thumb of other hand and compress lens slightly between thumb and index finger.
- (6) Gently pinch lens and lift out without allowing edges to stick together. Place lens in storage case.

Clinical Decision Point *If lens edges stick together, place lens in palm and soak thoroughly with sterile saline solution. Gently roll lens with index finger in back-and-forth motion. If necessary, soak lens in storage solution, which may return lens to normal shape.*

- b Removal of hard lenses: Follow Steps (1) through (6) for each eye.

- (1) Inspect the eye to be sure that lens is positioned directly over the cornea. If you are unable to visualize the lens, shine a penlight or flashlight sideways onto the eye to locate the position of the lens.

Clinical Decision Point *If lens is not positioned directly over the cornea, have patient close eyelid, place index and middle fingers of one hand on eyelid just beside the lens and beneath, and gently attempt to massage lens back into place. If lens cannot be repositioned, an immediate referral to an ophthalmologist is needed.*

- (2) Place index finger on outer corner of patient's eye and draw skin gently back toward ear.
- (3) Ask patient to blink. Do not release pressure until blink is completed.

Clinical Decision Point *For patients unable to open eye or blink on command, a lens suction cup can be used to remove lens from eye. Gently apply suction cup to lens surface and lift out.*

- (4) If lens does not dislodge, gently retract eyelid beyond edge of lens. Press lower eyelid gently against lower edge of lens to dislodge lens.
- (5) Allow both eyelids to close slightly and grasp lens as it rises from the eye. Cup lens in hand.
- (6) Inspect lens to be sure that it is intact. Place it in storage container.

- c After lenses are removed, inspect eye for redness, pain, swelling of eyelids or conjunctiva, discharge, or excess tearing.

13 Cleaning and storage:

Typical cleaning and disinfecting of contact lenses (verify specific method for lenses):

- a Apply 1 or 2 drops of cleaning solution to lens in palm of hand. Using index finger (soft lenses) or little finger (rigid lenses), rub lens gently but thoroughly on both sides for 20 to 30 seconds.
- b Holding lens over emesis basin, rinse thoroughly with recommended rinsing solution.

PROCEDURAL GUIDELINE 19-2 Taking Care of Contact Lenses—cont'd

Clinical Decision Point Do not use tap water for cleaning, rinsing, or storage. Tap water contains microbes and may be absorbed into the lens, making them uncomfortable to wear. Periodic cleaning with enzymatic cleaner and/or heat disinfecting may be part of the prescribed regimen. Follow prescriber's instructions and schedules.

- c Place lens in proper storage case compartment: "R" for right lens and "L" for left. Rigid lenses are placed inside up.
- d Fill with recommended disinfectant or storage solution.
- e Secure cover(s) over storage case. Label case with patient's name, identification number, and room number.

14 Inserting lenses:

- a Inserting a soft lens: Follow Steps (1) through (5) for each eye.
 - (1) Remove right lens from storage case and rinse with recommended rinsing solution; inspect lens for foreign materials, tears, and other damage.
 - (2) Hold lens on tip of index finger of dominant hand with concave side up.
 - (3) Inspect lens from side at eye level to ensure that it is not inverted (see illustration).
 - (4) Using middle or index finger of opposite hand, retract upper lid until iris is exposed (see illustration). Using

STEP 14a(3) Correct position of soft lens before insertion.

- middle finger of hand holding the lens, pull down lower lid.
- (5) Instruct patient to look straight ahead and focus on an object in the distance. Gently place lens directly on cornea and release lids slowly, starting with lower lid.

- b Inserting a rigid lens: Follow Steps (1) through (6) for each eye.
 - (1) Remove right lens from storage case; attempt to lift lens straight up.
 - (2) Hold lens on tip of index finger of dominant hand with concave side up.
 - (3) Inspect the lens to ensure that it is moist, clean, clear, and free of chips or cracks.
 - (4) Wet lens surfaces using a few drops of prescribed wetting solution.
 - (5) Using middle finger of hand holding lens, pull down lower lid (see illustration).
 - (6) Instruct patient to look straight ahead and focus on an object in the distance (see illustration). Gently place lens directly on cornea and release lids slowly, starting with lower lid.

STEP 14a(4) Correct position of hands for soft lens insertion.

STEP 14b(5) Hand position for rigid lens insertion.

STEP 14b(6) Instruct patient to look straight ahead and focus on an object in the distance.

PROCEDURAL GUIDELINE 19-2 Taking Care of Contact Lenses—cont'd

(a) Ask patient to close eyes briefly and avoid blinking.

15 Inspect eye to ensure that lens is on cornea.

Clinical Decision Point *If lens is on sclera rather than cornea, ask patient to slowly close eye and look toward the lens. Gentle pressure on the eyelid may help to center the lens on the cornea. Ask patient to blink a few times.*

16 Ask patient to cover other eye with hand and report if vision is clear and lens is comfortable.

17 Repeat procedure to insert lens in other eye.

18 Discard solution from storage case and rinse case thoroughly with sterile lens storage solution. Sterilize or replace case as recommended by manufacturer. Allow case to air dry. Dispose of towel, remove gloves, and perform hand hygiene.

19 Ask patient if lens feels comfortable after removal and reinsertion of lenses.

20 Observe for unexpected outcomes (e.g., blurred vision, burning, pain, foreign body sensation).

PROCEDURAL GUIDELINE 19-3 Taking Care of an Artificial Eye

As a result of tumor, infection, congenital blindness, or severe trauma to the eye, patients may undergo *enucleation*, the complete surgical removal of the eyeball. During this surgical procedure a spherical implant is placed in the orbit to maintain the natural eye structure and provide support for a cosmetic prosthesis (Goiato et al., 2010). The muscles and other tissues of the eye are sewn around the implant, holding it in place. Therefore the implant is not visible (Fig. 19-1). Modern implants are made of glass or plastic and are porous so the tissues of the eye grow into the sphere (Center for Ocular Prosthetics, 2011). Like a healthy eye, this integrated implant moves as the companion eye moves.

A concave cosmetic prosthesis is placed over the implant, resulting in a nearly normal appearance. Some implants are fitted with a peg that secures and optimally transfers implant movement to the prosthesis. The prosthesis (i.e., the artificial eye) is glass or plastic and colored to match the companion eye.

Prostheses are relatively easy to remove and insert and are usually worn day and night. Cleaning with sterile saline or soap and water is done at intervals of up to a year based on ophthalmologist recommendations and patient's preference (Kolberg Ocular Prosthetics, 2011). Too much handling of the prosthesis causes socket irritation and increases secretions (Erickson Laboratories, n.d.). Patients are instructed to have the artificial eye checked and polished at least twice a year to avoid unnecessary discomfort as a result of protein deposits or scratches on the surface.

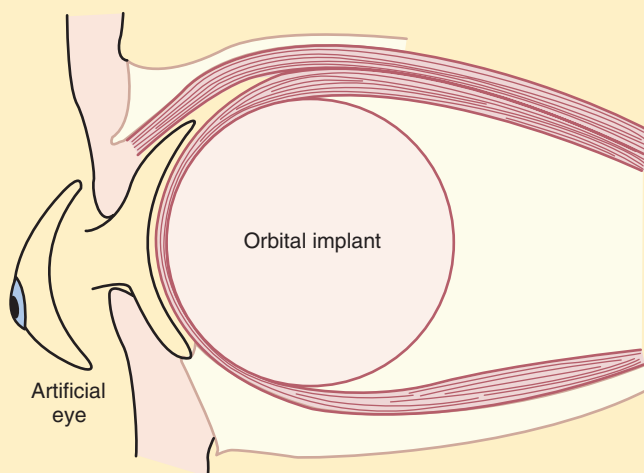

FIG 19-1 Side view of orbital implant, artificial eye removed.

An artificial eye is usually replaced every 5 years (Erickson Laboratories, n.d.).

Delegation and Collaboration

The skill of taking care of an artificial eye can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report eye pain or discomfort, inflammation, drainage, or odor.
- Understand the importance of careful handling of the prosthesis to prevent damage or injury.

Equipment

- Bath towels or waterproof pads (2)
- Sterile saline for washing prosthesis
- Irrigation bulb or large syringe (without needle)
- Sterile saline: 30 to 180 mL at 32° to 38° F (about 90° to 100° C)
- Emesis basin
- 4 × 4-inch gauze pads
- Clean gloves
- Facial tissues (*optional*)
- Washbasin with warm water and mild soap (*optional*)
- Suction device (or medicine dropper bulb) (*optional*)
- Covered plastic storage case (*optional*)

Procedural Steps

- 1 Perform hand hygiene
- 2 Ask patient or inspect eyes to determine which eye is artificial. Some implants allow movement of the prosthesis and can make distinguishing it from the natural eye difficult. An artificial eye pupil does not react to changes in light or accommodation (see Chapter 6).
- 3 Assess for patient's frequency and method of cleaning and length of time since last cleaning.

Clinical Decision Point *Unless a patient's eye-care practitioner advises otherwise, the prosthesis is usually not removed unless a patient experiences discomfort because excessive handling may cause irritation and increased secretions (Kolberg Ocular Prosthetics, 2011).*

- 4 Assess patient's ability to remove, clean, and reinsert prosthesis.
- 5 Before and after removal of prosthesis, assess eyelids and socket for inflammation, tenderness, swelling, drainage, or odor. Pay particular attention to the implant peg if present. Assess patient's pain or other symptoms.

PROCEDURAL GUIDELINE 19-3 Taking Care of an Artificial Eye—cont'd

Clinical Decision Point Signs/symptoms such as pain or discharge may indicate infection or injury. Infection can spread easily to neighboring eye, underlying sinuses, or brain tissue. The implant peg is a common site of infection.

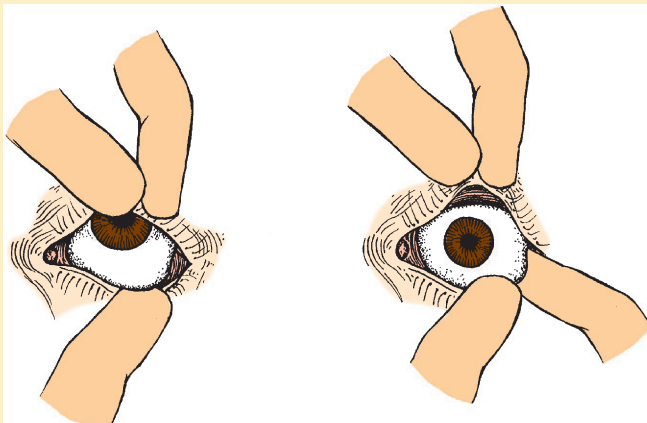

- 6 Discuss procedure with patient.
- 7 Assemble supplies at bedside. Place one towel over work area.
- 8 **Removing prosthesis:**
 - a Position patient in sitting or supine position with head elevated. Provide privacy.
 - b Perform hand hygiene. Apply clean gloves.
 - c Place towel just below patient's face.
 - d With thumb or forefinger of dominant hand gently retract lower eyelid against lower orbital ridge (see illustration).
 - e Exert slight pressure below eyelid and slide prosthesis out (see illustration).

Clinical Decision Point If prosthesis does not slide out, use moistened suction device to apply direct suction to it (Kolberg Ocular Prosthetics, 2011).

- f Note presence and orientation of colored dot at margin of prosthesis.
- g Place prosthesis in palm of hand.
- h Clean prosthesis by washing with mild soap and warm water or plain saline solution by rubbing well between

STEP 8d Retraction of lower lid to aid removal of eye prosthesis.

STEP 8e Exertion of pressure below eyelid and removal of prosthesis.

thumb and index finger (see manufacturer instructions). NOTE: Never use alcohol or other products because they are harmful to the prosthesis (Erickson Laboratories, n.d.).

- i Inspect prosthesis for rough edges or surfaces. Set aside on towel.
- 9 If prosthesis will not be reinserted immediately, store in sterile saline in a labeled case in a documented location (see manufacturer instructions).
- 10 **Clean eyelid margins and socket:**
 - a Wash and rinse eyelid margins with mild soap and water. Wipe from inner to outer canthus using a clean section of cloth with each wipe.
 - b Retract upper and lower eyelid margins with thumb and index finger.
 - c Gently irrigate socket with sterile saline solution. Note presence of discharge or odor.
 - d Remove excess moisture with gauze pads by wiping from inner to outer canthus.
- 11 **Insert prosthesis:**
 - a Moisten prosthesis in water or sterile saline.
 - b Retract patient's upper eyelid with index finger or thumb of nondominant hand.
 - c With dominant hand hold prosthesis so iris faces outward and colored dot is properly oriented (see illustration).
 - d Gently slide prosthesis up under upper eyelid and push down lower lid to allow prosthesis to slip into place.
 - e Ask patient if prosthesis fits comfortably and without pain.
- 12 Inspect eyelids and socket for signs of infection such as excessive, purulent, or foul drainage; excessive tearing or clear discharge; excessive itching; or lashes turned toward prosthesis.
- 13 Observe patient removing, cleaning, and reinserting prosthesis.
- 14 Teach patient and family how to inspect eye socket for redness, drainage, or excessive dryness.
- 15 Teach patient and family how to inspect artificial eye for damage, scratches, or areas of roughness. Alert patient to report any odor noted on eye or prosthesis to the health care provider.

STEP 11c Prosthesis must be oriented for correct insertion.

SKILL 19-1 Eye Irrigation

Eye irrigations effectively flush out exudates, irritating solutions, or foreign bodies from the eye. The procedure is typically used in emergency situations when a foreign object or some other substance has entered the eye. When a chemical or irritating substance contaminates the eyes, irrigate immediately with copious amounts of cool water for at least 15 minutes to minimize corneal damage (U.S. National Library of Medicine, 2011b). Users of contact lenses or artificial eyes may need eye irrigation to flush out particles of dust or fibers from the eye socket. Patients with artificial eyes are also at risk for socket irritation secondary to the composite material of the artificial eye itself, and irrigation assists in relieving the irritation (Cao et al., 2009).

A chemical injury to the eye is considered an emergency and requires flushing the eye with copious amounts of irrigation fluid (Rodrigues, 2009). Often cool tap water is recommended for emergency eye flushing because it is effective, immediately available for first aid, and initially helps to dilute the concentration of the chemical. The goal in treating ocular chemical injury is to prevent or reduce visual loss caused by the burn (Rodrigues, 2009).

Chemical injuries to the eye can be from alkaline or acid solutions. In treatment settings the best type of solutions are normal saline or lactated Ringers because they are more effective in restoring pH after a chemical injury to the eye. Continue to irrigate the

eye because the irrigating solution helps to dilute and flush out the chemical. Once the acute phase is over, an irrigation solution that buffers alkali or acid chemical is then selected (Babineau and Sanchez, 2008).

Delegation and Collaboration

The skill of eye irrigation cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report any patient complaint of discomfort or excess tearing following irrigation.

Equipment

- Prescribed irrigating solution: volume usually 30 to 180 mL at 32° to 38° C (90° to 100° F) (For chemical flushing, use normal saline or lactated Ringers fluid in large volume to provide continuous irrigation over 15 minutes.)
- Sterile basin or bag of solution
- Curved emesis basin
- Waterproof pad or towel
- 4 × 4-inch gauze pads
- Soft bulb syringe, eyedropper, or intravenous (IV) tubing
- Clean gloves
- Penlight
- Medication administration record (MAR)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| 1 Review health care provider's medication order, including solution to be instilled and affected eye(s) (right, left, or both) to receive irrigation. | Ensures safe and correct administration of irrigant. |
| 2 Obtain history of the injury to assess reason for eye irrigation. | Determines amount and type of solution and immediacy of need for treatment. |
| 3 Determine patient's ability to open affected eye. | Spasm of the eyelid or pain makes opening the eye difficult. Local anesthetics such as proparacaine or tetracaine cause topical numbness and are used before eye examination procedures. Provides baseline information. |
| 4 If time permits, do a complete eye examination, including determining if pupils are equal, round, and react to light and accommodation (PERRLA) (see Chapter 6). | Establishes baseline signs and symptoms. |
| 5 Assess eye for redness, excessive tearing, discharge, and swelling. Ask patient about symptoms of itching, burning, pain, blurred vision, or photophobia. | Establishes baseline for level of pain. |
| 6 Ask patient to rate level of pain. Use scale of 0 to 10. | Determines level of assistance needed. |
| 7 Assess patient's ability to cooperate. | |

NURSING DIAGNOSES

- Acute pain
 - Risk for infection
 - Risk for injury
- Related factors are individualized based on patient's condition or needs.*

PLANNING

- | | |
|---|---|
| 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient demonstrates minimal anxiety during and after irrigation. • Patient verbalizes reduced pain, burning, or itching and improved visual acuity after irrigation. • Patient maintains normal pupillary reaction and eye movement after irrigation. | <p>Potential for anxiety and pain is high during emergency.</p> <p>Reflects effectiveness of procedure in removing irritant.</p> <p>Reflects effectiveness of procedure in minimizing exposure to irritant and preventing eye damage.</p> |
|---|---|

STEP	RATIONALE
2 Discuss procedure with patient.	Decreases patient anxiety.
3 Check accuracy and completeness of each MAR with health care provider's written medication or procedure order. Check patient's name, irrigation solution name and concentration, route of administration, and time for administration. Compare MAR with label of eye irrigation solution.	The order sheet is the most reliable source and only legal record of drugs or procedure that patient is to receive. Ensures that patient receives correct medication.
4 Assemble supplies at bedside.	Provides easy access to supplies.
5 Help patient to side-lying position on side of affected eye. Turn head toward affected eye. If both eyes are affected, place patient supine for simultaneous irrigation of both eyes.	Position facilitates flow of solution from inner to outer canthus, preventing contamination of unaffected eye and nasolacrimal duct.

IMPLEMENTATION

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 2 Perform hand hygiene. Apply clean gloves.
- 3 Remove any contact lens if possible (see [Procedural Guideline 19-2](#)). Remove gloves after contact lens is removed. Reapply new gloves.

RATIONALE

- Ensures correct patient. Complies with [The Joint Commission standards and improves patient safety \(TJC, 2012\)](#).
- Reduces transmission of microorganisms. Protects hands from chemical irritants.
- Prompt removal of lenses is needed to safely and completely irrigate foreign substances from patient's eyes. Removal of gloves following contact lens removal prevents reintroduction of chemical transferred from lens to glove.

Clinical Decision Point *In an emergency such as first aid for a chemical burn, do not delay by removing patient's contact lens before irrigation. Do not remove lens unless rapid swelling is occurring. Flush eye from the inner to outer canthus with cool tap water immediately (U.S. National Library of Medicine, 2011b). Advise patient to consult health care provider before using contact lens.*

- | | |
|---|--|
| 4 Explain to patient that eye can be closed periodically and that no object will touch it. | Informing patients what to expect decreases anxiety and reassures them. |
| 5 Place towel or waterproof pad under patient's face and curved emesis basin just below patient's cheek on side of affected eye. | Catches irrigation fluid. |
| 6 Using gauze moistened with prescriber's solution (or normal saline), gently clean visible secretions or foreign material from eyelid margins and eyelashes, wiping from inner to outer canthus. | Minimizes transfer of material into eye during irrigation. Prevents secretions from entering nasolacrimal duct. |
| 7 Explain next steps to patient and encourage relaxation: <ol style="list-style-type: none"> a With gloved finger gently retract upper and lower eyelids to expose conjunctival sacs. b To hold lids open, apply gentle pressure to lower bony orbit and bony prominence beneath eyebrow. Do not apply pressure over eye. | Retraction minimizes blinking and allows irrigation of conjunctiva. |
| 8 Hold irrigating syringe, dropper, or IV tubing approximately 2.5 cm (1 inch) from inner canthus. | Direct contact with irrigation equipment may injure the eye. |
| 9 Ask patient to look toward brow. Gently irrigate with steady stream toward lower conjunctival sac, moving from inner to outer canthus (see illustration). | Minimizes force of stream on patient's cornea. Flushes irritant out and away from the other eye and nasolacrimal duct. |

STEP

RATIONALE

STEP 9 Irrigation of eye from inner to outer canthus.

- | | |
|---|--|
| <p>10 Reinforce importance of procedure and encourage patient by using calm, confident, soft voice.</p> <p>11 Allow patient to blink periodically.</p> <p>12 Continue irrigation with prescribed solution volume or time or until secretions are cleared. (NOTE: An irrigation of 15 minutes or more is needed to flush chemicals.)</p> <p>13 Blot excess moisture from eyelids and face with gauze or towel.</p> <p>14 Dispose of soiled supplies, remove gloves, and perform hand hygiene.</p> | <p>Reduces anxiety.</p> <p>Lid closure moves secretions from upper conjunctival sac.</p> <p>Assessment of eye secretion pH may be necessary if eye was exposed to an acidic or basic solution during injury (U.S. National Library of Medicine, 2011b).</p> <p>Reduces transmission of microorganisms.</p> |
|---|--|

EVALUATION

- | | |
|--|---|
| <p>1 Observe for verbal and nonverbal signs of anxiety during irrigation.</p> <p>2 Assess patient's comfort level after irrigation.</p> <p>3 Inspect eye for movement and to determine if pupils are equal, round, react to light and accommodation (PERRLA).</p> <p>4 Ask patient about improved visual acuity.</p> | <p>Verifies that patient is adequately comforted.</p> <p>Verifies effective removal of irritant.</p> <p>Impaired reaction to light, accommodation, or movement may indicate injury.</p> <p>Corneal damage from irritant can result in altered visual acuity (e.g., blurred vision, cloudiness).</p> |
|--|---|

Unexpected Outcomes

- 1 Anxiety
- 2 Patient complains of pain or foreign body sensation in eye following irrigation, excessive tearing, or photophobia.

Related Interventions

- Reinforce rationale for irrigation.
- Allow patient to close eye periodically during irrigation.
- Instruct patient to take slow, deep breaths.
- Advise patient to close eye and avoid eye movement.
- Immediately notify health care provider or eye care practitioner.

Recording and Reporting

- Record in nurses' notes and electronic health record (EHR) condition of eye and patient's report of pain and visual symptoms. Record amount and type of irrigation on patient's MAR.
- Report continuing symptoms of pain or blurred vision.

- Review first-aid procedures for eye emergencies with patient and/or caregiver.
- Instruct patient to not press or rub an injured eye.

Pediatric

- A child with a foreign body or chemical in the eye may panic. It may be necessary to restrain the child to safely and quickly irrigate the eye.

Special Considerations

Teaching

- Help patient identify potential hazards at home and work and take steps to prevent accidents such as use of safety goggles while working with dust or chemicals.

SKILL 19-2 Ear Irrigation

The common indications for irrigation of the external ear are presence of foreign bodies, local inflammation, and buildup of cerumen in the ear canal. The procedure is not without potential hazards. Usually irrigations are performed with liquid warmed to body temperature to avoid vertigo or nausea in patients. The greatest danger during ear irrigation is rupture of the tympanic membrane by forcing irrigant into the canal under pressure. Damage to the external auditory meatus may occur by scratching the lining of the canal if a patient suddenly moves or if there is inadequate control of the irrigating syringe (Kraszewski, 2008; U.S. National Library of Medicine, 2011a). Improperly drying the ear may lead to acute otitis externa (infection of the outer ear).

Ear emergencies can include the presence of foreign bodies, insect bites, or percussion injuries. In addition, a patient can also have damage from inside the ear, which includes blood and drainage. Sometimes the cause of bloody drainage may be the result of a head or neck injury. If a head or neck injury is suspected, do not move patient. Cover the outside of the ear with a sterile dressing (if available), get medical help immediately, and do not irrigate the ear (U.S. National Library of Medicine, 2011a). In addition, do not irrigate the ear if vegetable matter or an insect is present in the canal; the tympanic membrane is ruptured; or a patient has otitis externa, myringotomy tubes, or a mastoid cavity (Hockenberry and Wilson, 2011).

Delegation and Collaboration

The skill of administering ear irrigation cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Immediately report any potential side effects of ear irrigation (e.g., pain, drainage, dizziness).
- Help a patient when ambulating because some light-headedness may be present, which increases a patient's risk for falling.

Equipment

- Clean gloves
- Irrigation syringe
- Basin for irrigating solution (Use sterile basin if sterile irrigating solution is used.)
- Emesis basin for drainage or irrigating solution exiting the ear
- Towel
- Cotton balls or 4 × 4-inch gauze
- Prescribed irrigating solution warmed to body temperature or mineral oil, over-the-counter softener
- Medication administration record (MAR)
- Otoscope (optional)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| 1 Review health care provider's medication order, including solution to be instilled and affected ear(s) (right, left, or both) to receive irrigation. | Ensures safe and correct administration of medication. |
| 2 Review medical record for history of ruptured tympanic membrane, placement of myringotomy tubes, or surgery of the auditory canal. | These conditions contradict irrigation. |
| 3 Inspect pinna and external auditory meatus for redness, swelling, drainage, abrasions, and presence of cerumen or foreign objects.
a Always attempt to remove foreign objects in ear by first simply straightening ear canal. | Findings provide baseline to monitor effects of medication or solution.
This may cause object to fall out. |

Clinical Decision Point If vegetable matter (such as a dried bean or pea) is occluded in the canal, do not perform irrigation. The material can swell on contact with water and cause further damage to the canal.

- | | |
|--|--|
| 4 Use otoscope to inspect deeper portions of auditory canal and tympanic membrane. | Verifies if tympanic membrane is intact. |
| 5 Ask if patient is experiencing discomfort, using a scale of 0 to 10. Note patient's ability to hear clearly. | Pain is symptomatic of external ear infection or inflammation.
Occlusion of auditory canal by cerumen or foreign object can impair hearing. |
| 6 Review patient's knowledge of purpose for irrigation and normal care of ears. | May indicate need for instruction regarding hygiene. |

NURSING DIAGNOSES

- Deficient knowledge (regarding purpose for irrigation)
- Pain (acute or chronic)
- Risk for injury

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient denies pain during instillation.
 - Patient demonstrates hearing conversation more clearly in affected ear.
 - Patient is able to discuss purpose of irrigation and describe correct ear-care techniques.
 - Patient's canal is clear of cerumen, foreign material, and discharge.
- 2 Check accuracy and completeness of each MAR with health care provider's written medication or procedure order. Check patient's name, drug name and dosage, route of administration, and time for administration. Compare MAR with label of ear irrigation solution.
- 3 If patient is found to have impacted cerumen, instill 1 to 2 drops of mineral oil or over-the-counter softener into ear twice a day for 2 to 3 days before irrigation.
- 4 Explain procedure. Warn that irrigation may cause sensation of dizziness, ear fullness, and warmth.

RATIONALE

- Fluid is properly instilled.
Obstruction in ear canal is resolved.
- Feedback reflects patient's learning.
- Inflammation, irritation, and occlusion of canal are relieved.
- The order sheet is the most reliable source and only legal record of drugs or procedure that patient is to receive. Ensures that patient receives correct medication.
- Loosens cerumen and ensures easier removal during irrigation.
- Prepares patient to anticipate effects of irrigation and promotes cooperation.

IMPLEMENTATION

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
 - 2 Perform hand hygiene and arrange supplies at bedside.
 - 3 Close curtain or room door.
 - 4 Help patient to sitting or lying position with head turned toward affected ear. Place towel under patient's head and shoulder and have patient, if able, hold emesis basin under affected ear.
 - 5 Pour prescribed irrigating solution into basin. Check temperature of solution by pouring small drop on your inner forearm.
NOTE: If sterile irrigating solution is used, sterile basin is required.
 - 6 Apply clean gloves. Gently clean auricle and outer ear canal with gauze or cotton balls. Do not force drainage or cerumen into ear canal.
 - 7 Fill irrigating syringe with solution (approximately 50 mL).
 - 8 For adults and children over 3 years old, gently pull pinna up and back. In children 3 years or younger, pinna should be pulled down and back (Hockenberry and Wilson, 2011). Adults can lie supine. Place tip of irrigating device just inside the external meatus. Leave space around irrigating tip and canal.
 - 9 Slowly instill irrigating solution by holding tip of syringe 1 cm ($\frac{1}{2}$ inch) above opening to ear canal. Direct fluid toward superior aspect of ear canal. Allow it to drain out into basin during instillation. Continue until canal is cleaned or solution is used (see illustration).
- Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
- Reduces transfer of microorganisms; helps nurse perform procedure smoothly.
Maintains privacy.
Position minimizes leakage of fluids around neck and facial area.
Solution will flow from ear canal to basin.
- Prevents infected material from reentering ear canal. Forceful instillation of solution into occluded canal can cause injury to eardrum.
Enough fluid is needed to provide a steady irrigating stream.
Pulling pinna straightens external ear canal. Prevents obstruction of canal with device, which can lead to increased pressure on tympanic membrane.
- Slow instillation prevents buildup of pressure in ear canal and ensures contact of solution with all canal surfaces.

STEP

RATIONALE

STEP 9 Tip of syringe does not occlude ear canal during irrigation.

- | | |
|---|--|
| <p>10 Maintain flow of irrigation in steady stream until pieces of cerumen flow from canal.</p> <p>11 Periodically ask if patient is experiencing pain, nausea, or vertigo.</p> <p>12 Drain excessive fluid from ear by having patient tilt head toward affected side.</p> <p>13 Dry outer ear canal gently with cotton ball. Leave cotton ball in place for 5 to 10 minutes.</p> <p>14 Help patient to a sitting position.</p> <p>15 Remove gloves, dispose of supplies, and perform hand hygiene.</p> | <p>Constant flow of fluid loosens cerumen.</p> <p>Symptoms indicate that irrigating solution is too hot or too cold or instilled with too much pressure.</p> <p>Excess fluid may promote microorganism growth.</p> <p>Drying prevents buildup of moisture that can lead to otitis externa.</p> <p>Maintains comfort.</p> <p>Reduces transmission of infection.</p> |
|---|--|

EVALUATION

- | | |
|---|--|
| <p>1 Ask patient if discomfort is noted during instillation of solution.</p> <p>2 Ask patient about sensations of light-headedness or dizziness.</p> <p>3 Reinspect condition of meatus and canal.</p> <p>4 Measure patient's hearing acuity.</p> <p>5 Ask patient to describe purpose of irrigation and proper techniques for ear care.</p> | <p>Fluid instilled improperly under pressure causes discomfort.</p> <p>Instillation of fluid into ear can cause some light-headedness or dizziness, which can put patient at risk for falling.</p> <p>Determines if solution relieves symptoms and removes foreign materials.</p> <p>Determines if conduction deafness is relieved.</p> <p>Reflects patient's understanding of procedure and proper hygiene.</p> |
|---|--|

Unexpected Outcomes

- 1 Patient complains of increased ear pain during irrigation.
- 2 Ear canal remains occluded with cerumen.
- 3 Foreign body remains in ear canal.
- 4 Patient is unable to explain ear-care practices.

Related Interventions

- Rupture of eardrum may have occurred. Stop irrigations immediately and notify health care provider immediately.
- Repeat irrigation.
- Refer patient to otolaryngologist if foreign object remains after irrigation.
- Repeat instruction and have patient explain and/or demonstrate procedure.
- Include family members or caregivers if possible.

Recording and Reporting

- Record in nurses' notes, EHR, and/or MAR the procedure, amount of solution instilled, time of administration, and ear receiving irrigation.
- Record appearance of external ear and patient's hearing acuity in nurses' notes and EHR.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider.

Special Considerations

Teaching

- Instruct patient that cerumen has an antibacterial effect that maintains an acid pH in the auditory canal.
- Instruct patients to clean ears daily with a washcloth, soap, and warm water.
- Warn patients against placing objects (including cotton swabs) in ears.

Pediatric

- When cleaning the ear of a small child, be certain that child's head is immobilized to prevent puncturing eardrum. It may be necessary to have child's parent or staff participate.

Home Care

- Instruct patient to use a clean bulb syringe for irrigation. Mineral oil drops or over-the-counter otic preparations can help with removal of cerumen.

SKILL 19-3 Care of Hearing Aids

Hearing is vital for normal communication and orientation to sounds in the environment. Hearing loss is the most common sensory deficit in older adults (Adams-Wendling et al., 2008). When hearing loss occurs, it is difficult to hear doorbells, car horns, sirens, and alarms. According to the *National Institute on Deafness and other Communication Disorders (2010)*, hearing loss affects 36 million people. In addition, 50% of residents in assisted-living and residential facilities are hearing impaired (Cacchione, 2010; Wallhagen and Pettengill, 2008). Only one out of five people who actually need a hearing aid wear one. Those who do not wear a hearing aid often say that it is because of the quality of sound that the aid produces.

Any hearing loss has social implications, and the person may not engage in social activities. There are also many safety considerations. Not only do people with hearing loss have difficulty hearing car horns and emergency sirens; they also have difficulty understanding patient education and, as a result, may not safely manage their symptoms or therapies.

For people with hearing loss, a proper hearing aid improves the ability to hear and understand spoken words. Hearing aids amplify sound so it is heard at a more effective level. All hearing aids have four basic components:

- 1 A microphone, which receives and converts sound into electrical signals
- 2 An amplifier, which increases the strength of the electrical signal
- 3 A receiver, which converts the strengthened signal back into sound
- 4 A power source (batteries)

In addition, programmable hearing aids are now available. The programmable hearing aids are in analog and digital formats. Digital technology uses a tiny processor to convert the sound before it is amplified (Kuk et al., 2010). This allows the signal to be analyzed to remove background noise and automatically adjust the volume. Patients seeking these aids need to be evaluated by a licensed audiologist to determine the type of aid and which frequencies are needed for an individual patient. These aids are

adjusted to accommodate the range of a patient's residual hearing. Programmable aids independently amplify high-frequency (soft-spoken consonants) from low-frequency (loudly spoken vowels) sounds; this process occurs rapidly and continuously (Ebersole et al., 2008). Several styles of hearing aids are available to patients today (Table 19-1).

It is a challenge to adjust one's communication style to accommodate a patient with a hearing impairment. Use patient as a resource for communication techniques that are generally helpful. Be sure that a patient can see your face; speak slowly in a normal tone; and rephrase rather than repeat if he or she cannot understand you. Also remember that a patient is unable to hear alerts such as fire alarms or overhead announcements.

Hearing aids are usually worn only while a patient is awake and are cleaned as needed after removal. Remember that a hearing aid is delicate and must be protected from moisture, heat, and breakage.

Delegation and Collaboration

This skill of caring for a hearing aid can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report ear pain, inflammation, drainage, odor, or changes in hearing.
- Identify alternative ways to communicate with a patient while the aid is not in use.
- Learn how to carefully handle the aid to prevent damage or injury.

Equipment

- Soft towel and washcloth
- Facial tissues
- Brush or wax loop
- Storage case
- Warm water and soap
- Spare battery, size depends on aid (*optional*)
- Clean gloves (if drainage present)

STEP**RATIONALE****ASSESSMENT**

- 1 Determine whether patient can hear clearly with hearing aid by talking slowly and clearly in normal tone of voice.
- 2 Ask if patient is able to manipulate and hold hearing aid or observe patient insert aid independently.
- 3 Assess if hearing aid is working by removing from patient's ear. Close battery case and turn volume slowly to high. Cup hand over hearing aid. If you hear a squealing sound (feedback), it is working. If no sound is heard, replace batteries and test again.
- 4 Determine patient's usual hearing aid-care practices.

Inability to hear may indicate a problem with the hearing aid or battery or that that particular model is no longer effective for patient.

Determines level of assistance required in care.

May indicate malfunctioning of hearing aid.

Provides information as to how patient cares for device and identifies patient preferences.

TABLE 19-1 Types of Hearing Aids

Type	Advantages	Disadvantages	Cautions
<p><i>In-the-ear (ITE)</i> hearing aids fit completely in the outer ear and are used for mild-to-severe hearing loss.</p> 	Design of the aid can improve sound transmission through telephone calls.	ITE aids are damaged by earwax and ear drainage, and their small size can cause adjustment problems and feedback.	Not usually worn by children because the casings need to be replaced as the ear grows
<p><i>Behind-the-ear (BTE)</i> hearing aids are worn behind the ear and are connected to a plastic earmold that fits inside the outer ear.</p> 	Sound travels through the earmold into the ear. People of all ages wear BTE aids for mild-to-profound hearing loss.	Poorly fitting BTE earmolds can cause feedback, a whistling sound caused by the fit of the hearing aid.	May not be appropriate for children or adults who are active in sports because of potential for damage of the device
<p><i>Completely-in-canal (CIC)</i> aids are customized to fit the size and shape of the ear canal.</p> 	Used for mild to moderately severe hearing loss and are largely concealed in the ear canal.	Because of their small size, canal aids may be difficult for the user to adjust and remove and may not be able to hold additional devices such as a telecoil.	Expensive and not recommended for children Can also be damaged by earwax and ear drainage
<p>Digital hearing aids</p>  <p><i>(Used with permission of GN Resound. All rights reserved.)</i></p>	Digital aids analyze sounds to remove background noise; Program for low- and high-frequency sounds.	Need to be programmed and adjusted by a licensed audiologist.	Digital aids can also be damaged by earwax and ear drainage.

STEP

RATIONALE

- | | |
|--|---|
| <p>5 Assess patient for any unusual physical or auditory signs/symptoms (pain, itching, redness, discharge, odor, tinnitus, decreased acuity).</p> <p>6 Inspect earmold for cracked or rough edges.</p> <p>7 Inspect for accumulation of cerumen around aid and plugging of opening in aid.</p> <p>8 Assess patient's knowledge of and routines for cleaning and caring for hearing aid.</p> | <p>May indicate injury, infection, or cerumen accumulation.</p> <p>Poorly fitting hearing aids cause irritation and/or discomfort to external ear canal.</p> <p>Cerumen can block sound reception (U.S. National Library of Medicine, 2011c).</p> <p>Determines compliance with and knowledge of self-care.</p> |
|--|---|

STEP

RATIONALE

NURSING DIAGNOSES

- Risk for situational low self-esteem
- Deficient knowledge regarding hearing aid care
- Impaired verbal communication
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient verbalizes comfort after removal and reinsertion of hearing aid. • Patient responds appropriately to normal conversation and environmental sounds. • Patient demonstrates proper care of hearing aid. | <p>Hearing aid is removed or inserted properly and positioned correctly.</p> <p>Hearing aid and batteries are operational. Aid is secure and unobstructed.</p> <p>Learning is achieved.</p> |
| <p>2 Discuss procedure with patient. Explain all steps before removing aid.</p> | <p>Patient can assist in planning by explaining additional tips for care. Patient may be confused or anxious if verbal instructions are given after removal of hearing aid.</p> |
| <p>3 Assemble supplies at bedside. Place towel over work area.</p> | <p>Provides easy access to supplies. Towel catches aid if accidentally dropped and avoids breakage.</p> |
| <p>4 Have patient assume supine, side-lying, or sitting position in bed or chair.</p> | <p>Provides easy access for nurse. Promotes patient comfort.</p> |

IMPLEMENTATION

- 1** Removing and cleaning hearing aid (perform Steps a through g for both ears if bilateral aids are present):
- a** Perform hand hygiene. Apply clean gloves if drainage is present.
 - b** Turn hearing aid volume off, usually by turning volume control to left or toward patient's nose. Grasp aid securely and gently remove device following natural ear contour.

RATIONALE

- Reduces transmission of microorganisms.
- Prevents feedback (whistling) during removal. Prevents dropping hearing aid. Prevents injury to ear.

Clinical Decision Point *Some ITC and CIC devices have no volume control but are turned off by opening the battery door. Ask patient if this is necessary. CIC devices have a clear plastic, fiber handle for removal. Firmly grasp handle and gently pull straight out.*

- c** Hold aid over towel and wipe exterior with tissue to remove cerumen.
 - d** Inspect all openings in aid for accumulated cerumen. Carefully remove cerumen with wax loop or other device supplied with hearing aid.
- Prevents breakage if dropped. Cerumen may irritate canal and interfere with fit.
- Cerumen may block sound from receiver. Cerumen may block pressure equalization channel and create feeling of ear pressure. Makeshift tools may damage hearing aid.

Clinical Decision Point *The pressure equalization channel is a tiny hole through the entire length of the earmold and should be clear for the entire length. The receiver points into the ear through another opening. It is easily damaged. NEVER insert anything into the receiver port!*

- e** Inspect earmold for rough edges or any frays in cords.
 - f** Open battery door, place hearing aid in labeled storage container, and allow it to air dry.
 - g** Assess ear for redness, tenderness, discharge, or odor.
 - h** Place towel beneath patient's ear(s). Wash ear canal(s) with washcloth moistened in soap and water. Rinse and dry.
 - i** Dispose of towels, remove gloves, and perform hand hygiene.
 - j** If storing hearing aid, place it in dry storage case with desiccant material. Label case with patient's name and room number. If more than one aid, note right or left. Indicate in patient's medical record where aid is stored.
- May irritate ear canal.
- Allows drying of internal components. Protects against breakage and loss.
- Signs may indicate injury or infection.
- Absorbs excess water. Removes cerumen from ear canal. Removes soap residue and water that may harbor microbes or damage aid.
- Reduces transmission of microorganisms.
- Protects hearing aid against damage, moisture, and breakage. Documents how and where hearing aid is stored.
- 2** Inserting hearing aid (perform Steps a through g if bilateral aids are present):
- a** Perform hand hygiene and apply clean gloves if patient has ear drainage.
- Reduces transmission of microorganisms.

STEP	RATIONALE
b Remove hearing aid from storage case, and check battery (see assessment). Check that volume is off.	Proper orientation prevents damage and injury.
c Identify hearing aid as either right (marked “R” or red color coded) or left (marked “L” or blue color coded).	Prevents dropping. Proper positioning prevents injury. Pulling on ear may distort canal and make insertion more difficult.
d When possible, allow patient to insert aid. Otherwise hold hearing aid with thumb and index finger of dominant hand so canal (long portion with holes) is at bottom. Insert pointed end of earmold into ear canal. Follow natural ear contours to guide aid into place.	Prevents pieces from falling and breaking.
e Anchor any separate pieces, as in case of BTE aid or body aid.	Gradual adjustment prevents discomfort and injury to ear.
f Adjust or have patient adjust volume gradually to comfortable level for talking to patient in regular voice 3 to 4 feet away. Rotate volume control toward nose to increase volume and away from nose to decrease volume.	Preserves desiccant. Prevents loss. Reduces transmission of microorganisms.
g Close and store case. Perform hand hygiene.	

EVALUATION

- | | |
|---|--|
| 1 Ask patient to rate level of comfort after removal or insertion. | Verifies proper technique and positioning. |
| 2 Observe patient during normal conversation and in response to environmental sounds. | Verifies that aid is operational, correctly positioned, unobstructed, and effective. |
| 3 Observe patient removing, cleaning, and reinserting hearing aid. | Assesses patient’s understanding of and ability to perform techniques. |

Unexpected Outcomes

- 1 Patient is unable to hear conversations or environmental sounds. Patient’s verbal responses are inappropriate.
- 2 Patient experiences discomfort or pain, inflammation, drainage, or odor from affected ear.
- 3 Patient lacks knowledge and/or skills to perform hearing aid care properly.

Related Interventions

- Check function, type, and placement of battery and replace it if indicated.
- Increase volume if adjustable.
- Inspect aid and ear canal for cerumen blockage.
- Refer to audiologist for reassessment.
- Remove aid and inspect for sharp or rough edges. Refer to provider for repair.
- Assess ear for signs of injury or infection.
- Confirm R or L. Reposition hearing aid (pain).
- Teach patient and home care provider hearing aid–care skills.
- Provide written instructions and brochures with needed information.

Recording and Reporting

- Record removal of hearing aid, storage location if not reinserted after cleaning, and patient’s preferred communication techniques. If family takes aid home, be sure that this information is in the patient’s medical record.
- Report any signs or symptoms of infection or injury or sudden decrease in hearing acuity.

Special Considerations

Teaching

- Batteries are toxic if swallowed; keep them away from pets and children.
- Patients should insert the aid after their hair is dried and any hair spray applied. Heat from the hair dryer or perfumes and hair spray can damage the aid.
- Dogs in particular and cats are attracted to the smell of used hearing aids. Advise patient to protect the hearing aids and their pets by properly storing the aids out of reach.
- Encourage patients to identify helpful communication tips and teach them to others. Many patients find facial cues informative. Speakers must:

- 1 Face patient, stay within 3 to 4 feet away, and keep hands away from mouth.
- 2 Get patient’s attention before speaking.
- 3 Rephrase rather than repeat when a patient cannot understand.
- 4 Reduce background noise or move to a quiet area.

Pediatric

- Children are more often fitted with BTE hearing aids because the ear canal is still growing.
- The aid is made less conspicuous with hair styling or becomes a statement of fashion and personality with a brightly colored or transparent case.
- Children need help to prevent acoustic feedback (whistling), which they are unable to hear. This is usually eliminated by removing and reinserting the device and making sure that no hair is caught between the earmold and canal or lowering the volume of the device (Hockenberry and Wilson, 2011).

Gerontologic

- Advise patient to protect the hearing aid from water, alcohol, hair spray or cologne, perspiration, rain, and snow and to avoid exposing the hearing aid to extremes of temperature.

- Encourage patient to store hearing aids and batteries with desiccant or in an electronic dryer to prolong life, minimize repairs, and preserve batteries.
- The small size of some hearing aids may make them difficult to manipulate, particularly for individuals with decreased dexterity or visual acuity. Consult an audiologist to identify an aid that accommodates a patient's particular need.

Critical Thinking Exercises

Mr. Kupec is married and enjoys a socially active life. He and his wife have two grown children who are married with children. He has worn bilateral-in-the-ear (ITE) hearing aids for the last 10 years. He knows how to care for his aids. He is comfortable with them and is satisfied with the assistance they provide. He notes that, when the aids are working well, he hears his family and coworkers clearly, has minimal distortion in large gatherings, and is able to distinguish emergency sirens and car horns when he is driving.

- 1 Mr. Kupec now complains of diminished hearing in the left ear and senses drainage from the ear. The nurse decides to check the functioning of the hearing aid. Place the following steps in appropriate order for cleaning the hearing aid.
 - a Wash ear canal.
 - b Place hearing aid in storage case.
 - c Apply clean gloves.
 - d Grasp aid securely and remove from ear following natural ear contour.
 - e Use brush to clean holes in the aid.
 - f Have patient turn hearing aid volume off.
 - 1 f, d, c, a, b, e
 - 2 c, f, d, e, a, b
 - 3 c, f, d, a, e, b
 - 4 f, d, c, e, a, b
- 2 Mr. Kupec's preschool grandchildren visit frequently and are curious about the hearing aids. Which safety concerns for preschool children should the nurse teach him? (Select all that apply.)
 - 1 Batteries are toxic if swallowed.
 - 2 Tell the children to face grandpa.
 - 3 Keep batteries and aids out of children's reach.
 - 4 Show the children how the aid fits in the ear.
- 3 What would you teach Mr. Kupec and his wife about these aids?

REVIEW QUESTIONS

- 1 A patient who wears contact lenses in both eyes is scheduled for hand surgery and will have her hand in a cast for 6 weeks. What is the priority nursing diagnosis for this patient?
 - 1 Anxiety
 - 2 Self-health management
 - 3 Imbalanced nutrition: less than body requirements
 - 4 Disturbed personal identity
 - 2 A patient is being discharged following care for severe conjunctivitis related to noncompliance with the prescribed lens care regimen. Which patient statement indicates a need for further teaching?
 - 1 "I should discard my open lens care solutions when I get home."
 - 2 "Cloudy solutions should be discarded even if they haven't expired."
 - 3 "Plain soap is the best thing for washing my hands before I touch my contacts."
 - 4 "I'm switching to disposable contacts so I won't have to worry about getting another infection."
- ### Home Care
- Determine presence and willingness of caregiver to perform necessary care of hearing aid.
 - Assess patient's home and determine need for special precautions given patient's limited hearing.
- 3 A nurse who wears contact lenses splashes rubbing alcohol into his right eye. What is the priority action to take?
 - 1 Carefully remove the contact lens from the affected eye
 - 2 Gently cover the eye with a comfortable patch
 - 3 Test the pH of the secretions with litmus paper
 - 4 Irrigate the eye with water or prescribed solution
 - 4 A patient is being discharged home after having an enucleation and an artificial eye placed. Which statement by a patient indicates a need for further teaching?
 - 1 "I'll clean the eye at least once a week."
 - 2 "I should use sterile saline for cleaning the eyes."
 - 3 "The colored dot is there to show me which way to put it in."
 - 4 "Rubbing alcohol and fingernail polish remover are bad for the eye."
 - 5 The nurse is caring for a patient who is hearing impaired. Which approach(es) by the nurse is/are most appropriate to best facilitate communication? (Select all that apply.)
 - 1 Speaking slightly more loudly than usual
 - 2 Speaking slightly more slowly using a normal tone
 - 3 Standing so patient can see the nurse's face
 - 4 Using hand gestures to help explain what is being said.
 - 6 The nurse is performing a neurologic assessment on a patient with an artificial eye. How would the nurse confirm identification of the natural eye?
 - 1 Only the natural eye would produce tears and lubrication.
 - 2 The artificial eye would have more natural movement.
 - 3 The artificial eye would respond slightly to a light stimulus.
 - 4 Accommodation would only be present in the natural eye.
 - 7 A patient has just received a new hearing aid and instruction about its care. Which statement by a patient indicates a need for further teaching?
 - 1 "I need to store my hearing aid batteries away from my children and dogs."
 - 2 "I need to keep hair spray and cologne away from the hearing aid."
 - 3 "I can blow dry my hair while wearing my hearing aid."
 - 4 "I need to store my hearing aid and batteries with a desiccant."
 - 8 A patient with bilateral hearing aids is experiencing some discomfort in his right ear. What should the nurse do for this patient initially?
 - 1 Ask if he understands how to care for his hearing aids
 - 2 Check his ears for any signs of irritation
 - 3 Teach him how to reposition his hearing aids if they are uncomfortable
 - 4 Reduce the volume of the hearing aid in his left ear
 - 9 The nurse is caring for a comatose patient. What is the most important nursing responsibility pertaining to the patient's eye care?
 - 1 Performing frequent eye irrigations to remove secretions
 - 2 Gently securing his eyelids with paper tape
 - 3 Checking for the pupillary response
 - 4 Preventing injury to the patient's corneas
 - 10 A patient calls the nurse at the health care provider's office about increasing pain in her left ear. What should be the nurse's initial response?
 - 1 "Clean your ears daily with soap and water."
 - 2 "Try to get as much earwax out of your ear as possible."
 - 3 "Put a drop or two of mineral oil in your left ear."
 - 4 "Tell me more about the ear pain you're having."

KEY TERMS

Adverse drug events (ADEs)	Medication tolerance	Peak concentration	Summation
Anaphylaxis	NPO	Pharmacokinetics	Synergistic effect
Duration of action	Onset of medication action	Plateau	Therapeutic effect
Idiosyncratic reaction	Over-the-counter (OTC) medication	Polypharmacy	Toxic effects
Medication administration record (MAR)	Parenteral	prn	Trough concentration
Medication dependence	Peak action	Serum half-life	Unit-dose system
Medication reconciliation		Side effect	Verbal order

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss National Patient Safety Goals for medication administration.
- Discuss factors that contribute to medication errors.
- Discuss the types of medication actions.
- List and discuss the six rights of medication administration.
- Identify the system of measurement for a given prescribed medication.
- Accurately calculate medication doses.
- Describe the safety features of medication delivery systems.
- Identify guidelines for safe administration of medications.
- Identify steps to take in reporting medication errors.

Safe and accurate medication administration is a challenging and important nursing responsibility. A nurse is responsible for having a full understanding of medication administration and the related nursing implications. The Institute of Medicine (IOM) (2000) published the book *To*

Err Is Human: Building a Safer Health System, which created a national awareness of problems within the health care system. It is estimated that approximately 1.5 million preventable adverse drug events (ADEs) occur annually, costing more than \$3.5 billion (Macdonald, 2010). The IOM has a national

agenda for reducing medical errors and improving patient safety. One essential IOM recommendation is to develop standards for patient safety to establish minimum levels of performance and set expectations for health professionals. The Institute for Safe Medicine Practices (ISMP) also developed strategies to prevent harm from “high-alert medications” such as anticoagulants, sedatives, narcotics, and insulin (ISMP, 2011a). In addition, the National Quality Forum (NQF) includes a recommendation for safe medication practice that all health care organizations develop, reconcile, and communicate accurate patient medication information throughout the continuum of care (NQF, 2010).

Many factors contribute to medication errors, especially at patient care-transition points such as during hospital admission, transfer from one unit to another, and discharge to home or another agency (LaMantia et al., 2010). Almost 37% of total medication errors are related to errors of administration (Anderson and Townsend, 2010). In a recent study nurses identified factors contributing to medication errors such as being unfamiliar with the drug, the need for advanced drug preparation, and failure to recheck a medication before administration. Other factors included workload, miscommunication around verbal orders, clinician miscommunication, and not being alert while checking medications (Kim et al., 2011). In many cases drug errors occur as a result of failure of nurses to follow policy (Shane, 2009). Nurses need to make clinical judgments when administering medications and not simply give drugs automatically. This includes thorough patient assessment and an understanding of pharmacokinetics, growth and development, nutrition, and mathematics.

The Joint Commission (TJC) defines a medication error as any preventable event that may cause inappropriate medication use or jeopardize patient safety (TJC, 2012a). Medication errors include inaccurate prescribing; administering the wrong medication, route, and time interval; and administering extra doses or failing to administer a medication. Medication safety is always one of the National Patient Safety Goals (TJC, 2012b) (Box 20-1).

All professional nurses need to understand the implications involved in medication administration. Safe medication administration requires good judgment and clinical decision-making skills. Registered nurses (RNs) and licensed practical nurses (LPNs) are able to administer medications under the direction of a licensed physician and according to State Practice Acts. Advanced practice nurses (APNs) have some prescriptive authority in almost every state, but the degree of required physician involvement varies.

NSO Safe Medication Administration Module / Lesson 1

PATIENT-CENTERED CARE

A nurse’s responsibility when administering medications safely must include effective communication with staff, pharmacy, patients, and family caregivers. Patients are an important resource for understanding the knowledge they have about their medications, their perceptions about the effects of medications, and their expectations for treatment. Consider factors that influence patient’s abilities to communicate effectively such as anxiety, pain, hearing, or their cultural background. Therapeutic communication is essential to nursing practice.

A new scientific field, pharmacogenetics, involves the study of the genetic influence on drug response that occurs from inherited metabolic defects or deficiencies. As a nurse you cannot detect a genetic abnormality. However, you can learn to become aware of cultural differences in drug responses to better monitor drug therapy.

BOX 20-1 The Joint Commission 2012 Hospital National Patient Safety Goals: Implications for Medication Administration

- Identify patients correctly.
- Use at least two patient identifiers (neither can be patient’s room number) when providing care, treatment (e.g., medications), or services.
- Improve the effectiveness of communication among caregivers.
- Verbal or telephone orders require a verification “read-back” of the complete order or test result by the person receiving the order/test result.
- Standardize a list of abbreviations, acronyms, symbols, and dose designations that are *not* to be used throughout an organization.
- Improve the safety of using medications.
- Identify and at a minimum annually review a list of look-alike/sound-alike drugs used by the organization.
- Before a procedure, label all medications and medication containers (e.g., syringes, medicine cups) that are not labeled. Do this in areas where medicines and supplies are set up, such as on and off the sterile field in perioperative and other procedural settings. Labels include drug name, strength, amount, expiration date when not used within 24 hours, and expiration time when expiration occurs in less than 24 hours.
- Take extra care with patients who take anticoagulants. Use only oral unit-dose products and premixed infusions. When heparin is administered intravenously and continuously, use programmable infusion pumps.
- Maintain and communicate accurate patient medication information.
- Accurately and completely reconcile medications across the continuum of care.
- There is a process for comparing the patient’s current medications with those ordered for the patient while under the care of the health care organization.
- Communicate a complete list of the patient’s medications to the next provider of service when a patient is referred or transferred to another setting, service, or level of care. Also provide the complete list to the patient on discharge from the agency.
- Encourage patients’ active involvement in their own care as a patient safety strategy.

Modified from The Joint Commission: 2012 *National Patient Safety Goals*, Oakbrook Terrace, IL, 2012, The Commission, available at http://www.jointcommission.org/standards_information/npsgs.aspx.

Culturally a patient’s values and beliefs affect medication response. A patient’s level of education, prior experience with medication therapy, and the family’s influence on actions significantly influence medication adherence. For example, in some cultures it is not acceptable to complain about gastrointestinal problems; thus it is common for patients not to report nausea, vomiting, and bowel changes related to medication use. Use of herbal and homeopathic remedies in some cultures alters response to a medication. Ethnicity needs to be considered when medications are prescribed and administered.

PHARMACOLOGIC CONCEPTS

Medication Names

Some medications have as many as three different names. The chemical name describes the drug composition and molecular structure, such as *N*-acetyl-para-aminophenol, commonly known as Tylenol. The chemical name provides an exact description of its

composition and molecular structure. It is rarely used in clinical practice. A manufacturer who first develops a medication provides the generic name (e.g., acetaminophen is the generic name for Tylenol). The generic name is the official name that is listed in official publications such as the *United States Pharmacopeia* (USP). A medication trade name or brand name is used to market the medication. The trade name has the symbol™ at the upper right of the name, indicating a manufacturer trademark of the name (e.g., Panadol™, Tempra™, Tylenol™).

Many companies choose brand and generic names that are easy to remember and can be very similar, which contributes to medication errors. The USP identifies several problematic medications with similar names and spelling such as Lamictal for epilepsy and Lamisil for fungal infections; Levoxine for hypothyroidism and Lanoxin for heart failure; Zebeta for hypertension and Diabeta for type 2 diabetes. The ISMP (2010a) and TJC (2012a) both publish a list of medications that are frequently confused with one another. Another measure to help address the confusion around drugs having similar names includes the use of tall-man lettering (ISMP, 2011b). This measure uses capital letters in specific parts of a word and helps distinguish dissimilarities in drug names; for example, TEGretol (for seizures) can be confused with (T)RENTal, which is prescribed for intermittent claudication; but the tall-man letters emphasize the difference in the drug name).

The physical appearances of some drugs with similar color, size, and shape have led to medication errors. For example, St. Joseph's aspirin and Crestor, a lipid-lowering agent, have a similar peach color, size, and circular shape. Generic drugs are often prescribed as a more cost-efficient substitution for brand-name medications. However, there may be dramatic differences in appearance of generic drugs, depending on the manufacturer (Greene et al., 2011). Patients may be confused as to why their medication has a different color or shape when the prescription is refilled. Hospital and clinic pharmacies try to consistently dispense medications with the same trade names so nurses will become familiar with them. However, nurses find medications under a variety of different names and must be careful to obtain the exact name and spelling before administering a medication. TJC (2012a) publishes on its website (<http://www.jointcommision.org>) a look-alike/sound-alike drug list and recommendations for nurses, prescribers, and health care organizations to prevent mixing up look-alike/sound-alike medications.

Classification

Medications with similar characteristics are categorized by their class. Medication classification indicates the effect of a medication on a body system, the symptoms the medication relieves, or the desired effect of the medication. For example, patients with type 2 diabetes often take oral hypoglycemic medications to control their blood glucose levels. The sulfonylureas are one classification of 11 medications used to treat hyperglycemia. Many adults with type 2 diabetes are treated with more than one class of diabetic medication (Bennett et al., 2011). Some medications are part of more than one class. For example, aspirin is an analgesic, antipyretic, and antiinflammatory medication.

Medication Forms

Medications are available in a variety of forms or preparations. The form of the medication determines its route of administration. The composition of a medication influences its absorption and metabolism. Many medications are made in several forms such as tablets, caplets, or suppositories. When administering a medication, be certain to use the proper form (Table 20-1).

Pharmacokinetics

A medication must enter a patient's body; be absorbed and distributed to cells, tissues, or a specific organ; and then alter physiologic function to be therapeutic. Pharmacokinetics is the study of how medications enter the body, reach their site of action, are metabolized, and exit the body. Understanding pharmacokinetics allows you to properly time medication administration, select an administration route, and judge a patient's response to medications. Absorption is the passage of medication molecules into the blood from the site of administration. Factors that influence the rate of absorption include the administration route, ability of a medication to dissolve, blood flow to the administration site, body surface area, and lipid solubility of a medication (Table 20-2). After a medication is absorbed, it is distributed to tissues and organs and finally to the site of drug action. The rate and extent of distribution depends on circulation, cell membrane permeability, and protein binding. Poor perfusion (e.g., heart failure) alters medication distribution. A medication must pass through biologic membranes to reach certain organs. Some membranes are barriers to the passage of medications. For example, the blood-brain barrier allows only fat-soluble medications to pass into the brain and cerebrospinal fluid. The degree to which medications bind to serum proteins such as albumin affects distribution. Most medications bind to albumin to some extent. When this happens, they are unable to exert pharmacologic activity. Only the unbound, or "free," medication is active. Older adults and patients with liver disease or malnutrition have reduced albumin, which increases their risk for medication toxicity.

After a medication reaches its site of action, it becomes metabolized into a less active or inactive form. Biotransformation occurs under the influence of enzymes that detoxify, degrade (break down), and remove biologically active chemicals. Most biotransformation occurs in the liver, although the lungs, kidneys, blood, and intestines also play a role. Patients (e.g., older adults and those with chronic disease) are at risk for medication toxicity if their organs cannot metabolize medications effectively.

The final aspect of pharmacokinetics is excretion, the process by which medications exit the body through the lungs, exocrine glands, bowel, kidneys, and liver. The chemical makeup of a medication determines the organ of excretion. For example, gaseous and volatile compounds such as alcohol and nitrous oxide exit through the lungs. The site of excretion poses implications for nursing care. For example, when medications exit through sweat glands, you provide skin care to reduce irritation. You must know if a drug is excreted through the intestines because the administration of laxatives or enemas increases peristalsis, accelerates excretion, and thus lessens the time for drug effects. When patients have reduced renal function, they are at risk for medication toxicity since kidneys are the main organs for medication excretion.

TYPES OF MEDICATION ACTION

Medications vary in the way they act and their types of action. Patients do not always respond in the same way to each successive dose of a medication. Sometimes the same medication causes very different responses in different patients. Therefore it is essential to understand all the effects that medications have on patients.

Therapeutic Effects

Each medication has a therapeutic effect, the intended or desired physiologic response of a medication. For example, you administer morphine sulfate, an analgesic, to relieve a patient's pain. Sometimes a single medication has many therapeutic effects. For

TABLE 20-1 Forms of Medication

Form	Description
Medication Forms Commonly Prepared for Administration by Oral Route	
<i>Solid Forms</i>	
Caplet	Shaped like a capsule and coated for ease of swallowing
Capsule	Medication encased in a gelatin shell
Tablet	Powdered medication compressed into a hard disk or cylinder; in addition to primary medication, contains binders (adhesive to allow powder to stick together), disintegrators (to promote table dissolution), lubricants (for ease of manufacturing), and fillers (for convenient tablet size)
Enteric coated	Coated tablet that does not dissolve in stomach; coating dissolves in intestine, where medication is absorbed
<i>Liquid Forms</i>	
Elixir	Clear fluid containing water and alcohol; often sweetened
Extract	Syrup or dried form of pharmacologically active medication, usually made by evaporating solution
Aqueous solution	Substance dissolved in water and syrups
Suspension	Finely dissolved drug particles in liquid medium must be shaken When left standing, particles settle to bottom of container
Syrup	Medication dissolved in concentrated sugar solution
Tincture	Alcohol extract from plant or vegetable
Other Oral Forms and Terms Associated With Oral Preparations	
Troche (lozenge)	Flat, round tablet that dissolves in mouth to release medication; not meant for ingestion
Aerosol	Aqueous medication sprayed and absorbed in mouth and upper airway; not meant for ingestion
Sustained release	Tablet or capsule that contains small particles of a medication coated with material that requires a varying amount of time to dissolve
Medication Forms Commonly Prepared for Administration by Topical Route	
Ointment (salve or cream)	Semisolid, externally applied preparation, usually containing one or more medications
Liniment	Usually contains alcohol, oil, or soapy emollient applied to skin
Lotion	Liquid suspension that usually protects, cools, or cleans skin.
Paste	Medication preparation that is thicker than ointment; absorbed through skin more slowly than ointment; often used for skin protection
Transdermal patch or disk	Disk or patch embedded with medication that is applied to skin Drug absorbed through the skin over a designated period of time
Medication Forms Commonly Prepared for Administration by Parenteral Route	
Solution	Sterile preparation that contains water/normal saline with one or more dissolved compounds
Powder	Sterile particles of medication that are dissolved in a sterile liquid (e.g., water, normal saline) before administration
Medication Forms Commonly Prepared for Instillation Into Body Cavities	
Suppository	Solid dosage form mixed with gelatin and shaped in form of a pellet for insertion into body cavity (rectum or vagina) (Suppository melts when it reaches body temperature and is then absorbed.)
Intraocular disk	Small, flexible oval (similar to a contact lens) consisting of two soft outer layers and a middle layer containing medication; slowly releases medication when moistened by ocular fluid.

example, aspirin relieves pain and reduces fever and tissue inflammation. Knowing the desired therapeutic effect for each medication allows you to provide patient education and accurately evaluate its desired effect.

Side Effects/Adverse Effects

Every medication has the potential to harm a patient. No medication is totally safe and absolutely free of nontherapeutic effects. Side effects are predictable and often unavoidable secondary effects produced at a usual therapeutic drug dose. They are either harmless or cause injury. The intensity of side effects is often dose

dependent. If the side effects are serious enough to outweigh the benefits of the therapeutic action of a medication, the prescriber will likely discontinue the medication. Patients commonly stop taking medications because of side effects such as anorexia, nausea, vomiting, dizziness, drowsiness, dry mouth, constipation, and diarrhea. Report any side effect to the prescriber to ensure that it is not incorrectly interpreted as a more serious adverse medication reaction.

Adverse drug events or effects (ADEs) are unintended, undesirable, and often unpredictable. Unfortunately, although they sometimes are apparent immediately, they often take weeks or months

TABLE 20-2 Medication Absorption

Absorption Factor	Physiologic Effects
Route of administration	Topical applications on skin absorb slowly. Medications applied to mucous membranes and respiratory airways absorb quickly. Oral medications pass through the gastrointestinal tract and absorb slowly. The intravenous route absorbs most rapidly.
Ability to dissolve	Solutions and liquid suspensions absorb more readily than tablets or capsules. Acidic medications absorb rapidly, whereas basic medications (pH >7.0) do not absorb before reaching the small intestine.
