- Explaining how to modify the bandage application such as with special taping.
- Reviewing what to observe and report back to the nurse (e.g., patient's complaint of pain, numbness, or tingling after application or changes in patient's skin color or temperature).

Equipment

- Correct width and number of gauze or elastic bandages
- Clips or adhesive tape
- Clean gloves if wound drainage is present
- Option:* Pillow

Procedural Steps

- 1 Review patient's medical record for specific orders related to application of gauze or elastic bandage. Note area to be covered, type of bandage required, frequency of change, and previous response to treatment.
- 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.
- 3 Observe adequacy of circulation by palpating temperature of skin and pulses, presence of edema, and sensation (distal to area to be bandaged). Observe skin color and movement of body part to be wrapped. **NOTE:** Impaired circulation may

result in pain, coolness to touch when compared with the opposite side of the body, cyanosis or pallor of skin, diminished or absent pulses, edema or localized pooling, and numbness and/or tingling of body part.

- 4 Assess patient's level of comfort (pain scale of 0 to 10). Administer prescribed analgesic as needed before dressing change.
- 5 Apply clean gloves (if drainage or break in skin is present). Inspect skin of area to be bandaged for alterations in integrity as indicated by presence of abrasion, discoloration, or chafing. Pay close attention to areas over bony prominences.
- 6 Inspect the condition of any wound for appearance, size, and presence and character of drainage and be sure that it is covered with a proper dressing. If not, reapply dressing (check agency policy for type of gloves to use). Remove clean gloves and perform hand hygiene.
- 7 Assess for size of bandage:
 - a *Gauze or basic elastic bandage to secure a dressing:* Assess size of area to be covered. Each successive roll of gauze/elastic should overlap previous layer. Use smaller widths for upper extremities, larger widths for lower extremities.
 - b *Elastic bandage to provide simple compression:* Assess circumference of lower extremity before or shortly after patient gets out of bed in the morning or after patient has been in bed for at least 15 minutes. Select width that will cover and overlap without bulkiness.

PROCEDURE GUIDELINE 39-1 Applying Gauze and Elastic Bandages—cont'd

- 8 Identify patient's and primary caregiver's present knowledge level and ability to manipulate bandage if bandaging will be continued at home.
- 9 Close room door or curtains. Position patient comfortably in an anatomically correct supine position in bed.
- 10 Perform hand hygiene and apply clean gloves if drainage is present.
- 11 Apply gauze or elastic bandage to secure dressings:
 - a Elevate dependent extremity for 15 minutes before applying elastic bandage to promote venous return.
 - b Make sure that primary dressing over wound is securely in place.
 - c Hold roll of bandage in your dominant hand and use other hand to lightly hold beginning layer of bandage at distal body part.
 - d Begin with two circular turns to anchor bandage. Continue transferring roll to dominant hand as you wrap bandage (see illustration).
 - f Alternate ascending and descending turns (figure-eight pattern) if you are wrapping a joint.
 - g Ensure that bandage is snug but not tight and that primary dressing or splint is positioned correctly. A tight bandage may cause numbness and tingling from impaired circulation and/or pressure on peripheral nerves.
 - h While unrolling an elastic bandage, stretch bandage slightly. Explain to patient that smooth, even pressure will be applied to improve circulation, reduce swelling, immobilize body part, and provide pressure.
 - i End bandage with two circular turns; secure end of gauze or elastic bandage to outside layer of bandage, not skin, with tape or clips (see illustration).

STEP 11d Hold elastic bandage in dominant hand and apply with circular turns.

- e Apply bandage from distal point toward proximal boundary (see illustration), using appropriate turns to cover various shapes of body parts (see [Table 39-3](#)). Roll gauze, overlapping each layer by one half to two thirds the width of the bandage.

STEP 11e Apply bandage from distal to proximal.

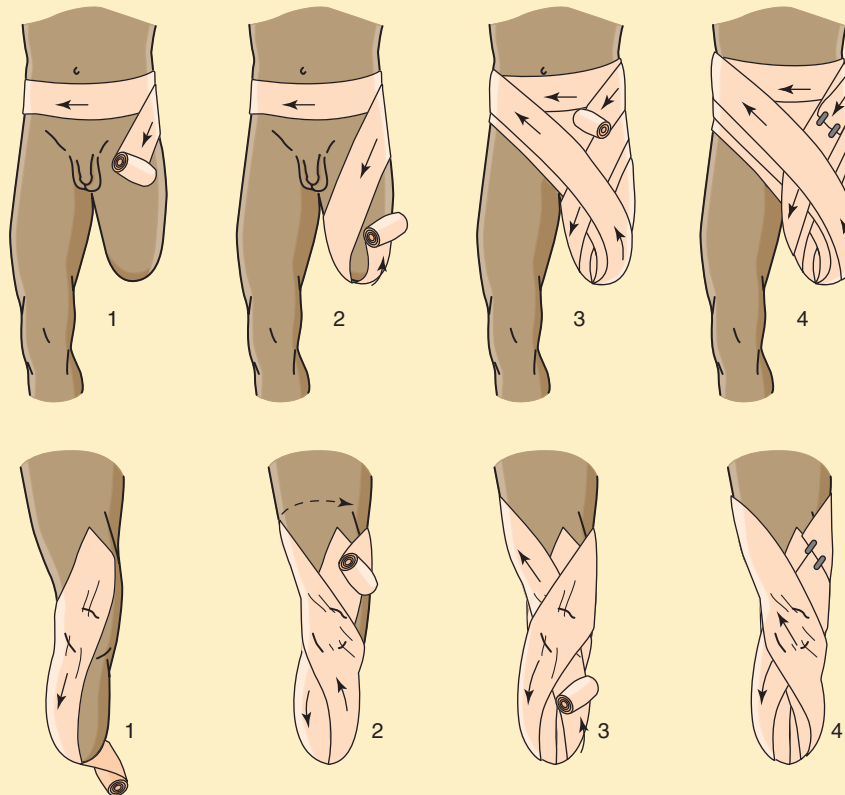

STEP 11i Secure with tape or closure device.

Clinical Decision Point Keep toes or fingertips uncovered and visible for follow-up circulatory assessment, except in cases in which toes or fingers are treated because of wounds.

- 12 Apply elastic bandage over stump (see illustrations):
 - a Elevate stump with pillow or support it with the assistance of another person.
 - b Secure bandage by wrapping it twice around proximal end of stump or person's waist (depending on size of stump)
 - c Make half turn with bandage perpendicular to its edge.
 - d Bring body of bandage over distal end of stump.
 - e Continue to fold bandage over stump, wrapping from distal to proximal points.
 - f Secure with metal clips, Velcro if provided, or tape.
- 13 Remove gloves if worn and perform hand hygiene.
- 14 Remove and reapply elastic bandage, securing the dressing once every 8 hours unless otherwise directed by health care provider.
- 15 Evaluate degree of tightness of bandage.
- 16 Evaluate distal circulation when bandage application is complete, at least twice during next 8 hours, and then at least every shift.
 - a Observe skin color for pallor or cyanosis.
 - b Palpate skin for warmth.
 - c Palpate distal pulses and compare bilaterally.
 - d Ask patient to rate any pain on scale of 0 to 10 and to describe any numbness, tingling, or other discomfort to evaluate for neurologic and vascular changes.

PROCEDURE GUIDELINE 39-1 Applying Gauze and Elastic Bandages—cont'd

STEP 12 *Top*, Correct method for bandaging midhigh amputation stump. Note that bandage must be anchored around patient's waist. *Bottom*, Correct method for bandaging midcalf amputation stump. Note that bandage need not be anchored around waist. (From Monahan F et al: Phipps' medical-surgical nursing: health and illness perspectives, ed 8, St Louis, 2006, Mosby.)

- 17 Observe mobility of extremity.
- 18 Evaluate bandage for wrinkles, looseness, and presence of drainage.
- 19 Have patient or family caregiver demonstrate bandage application.
- 20 Record patient's baseline and postbandage application, including level of comfort, circulation, type of bandage applied, presence of any swelling, and range of motion.
- 21 Record condition of wound or skin integrity if dressing is present and type of bandage applied.
- 22 Report any changes in neurologic or circulatory status to nurse in charge or health care provider immediately.

PROCEDURAL GUIDELINE 39-2 Applying an Abdominal Binder

Binders are bandages made of large pieces of material specially designed to fit a specific body part. Most binders are made of elastic or cotton. The most common types are the abdominal binder and breast binder. Breast binders are not used as often in current practice. Sports bras are preferred for breast support following certain surgeries (Michaels, Coon, and Rubin, 2011).

An abdominal binder supports large abdominal incisions (e.g., following abdominal laparotomy) that are vulnerable to tension or stress as a patient moves or coughs (Fig. 39-5). The binder also lessens pain in postoperative patients (Larson et al., 2009). In addition, abdominal binders provide a noninvasive intervention for enhancing recovery of walk performance, controlling pain, and improving patient's experience following major abdominal surgery (Cheifetz et al., 2010). Binders support underlying muscles and large incisions, lessening muscle stress when a person moves. The muscles and viscera surrounding an operative site may require support during the postoperative period to reduce trauma and

FIG 39-5 Abdominal binder with Velcro closures. (Courtesy Dale Medical Products, Plainville, Mass.)

PROCEDURAL GUIDELINE 39-2 Applying an Abdominal Binder—cont'd

edema. This promotes healing and permits a patient to move more freely without additional discomfort. The basic shape of an abdominal binder is a rectangle that is wide enough to extend from the groin to the waistline and long enough to encircle the abdomen with an overlap for closure.

Delegation and Collaboration

The skill of applying a binder can be delegated to nursing assistive personnel (NAP). A nurse assesses the condition of any incision, the skin, and patient's ability to breathe before binder application. The nurse directs the NAP about:

- How to modify the skill such as special wrapping or manner of securing the binder.
- Reporting patient's complaint of pain, numbness, tingling, or difficulty breathing after applying abdominal binder or any changes in patient's skin color or temperature.

Equipment

- Clean gloves if wound drainage present
- Gauze bandage as needed
- Correct type and size of binder
- Closures for cloth binder

Procedural Steps

- 1 Observe patient who needs support of thorax or abdomen; observe ability to breathe deeply, cough effectively, and turn or move independently.
- 2 Review medical record for order for binder (check agency policy).
- 3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.
- 4 Inspect skin for actual or potential alterations in integrity. Observe for irritation, abrasion, and skin surfaces that rub against one another.
- 5 Inspect any surgical dressing for intactness, presence of drainage, and coverage of incision. Change any soiled dressing before applying binder (using clean gloves).
- 6 Determine patient's level of comfort using scale of 0 to 10. Administer prescribed analgesic 30 minutes before dressing change.
- 7 Gather necessary data regarding size of patient and appropriate binder to use (see manufacturer guidelines) to ensure proper fit.
- 8 Determine patient's knowledge of purpose of binder.
- 9 Close curtains or room door.
- 10 Perform hand hygiene and apply clean gloves (if likely to contact wound drainage).
- 11 Apply abdominal binder:
 - a Position patient in supine position with head slightly elevated and knees slightly flexed.
 - b Help patient roll on side away from you toward raised side rail while firmly supporting abdominal incision and dressing with hands. Fanfold far side of binder toward midline of binder.
 - c Place binder flat on bed, right side up. Fanfold far side of binder toward midline of binder so patient can roll over with minimal effort.
 - d Place fanfolded ends of binder under patient.
 - e Instruct patient or help him or her roll over folded binder. For overweight patients consider asking nurse colleague to assist.
 - f Unfold and stretch ends out smoothly on far side of bed. Then stretch out ends on near side of bed.
 - g Instruct patient to roll back into supine position.
 - h Adjust binder so supine patient is centered over binder, using symphysis pubis and costal margins as lower and upper landmarks.
 - i If patient is very thin, pad iliac prominences with gauze bandage.
 - j Close binder. Pull one end of binder over center of patient's abdomen. While maintaining tension on that end of binder, pull opposite end of binder over center and secure with Velcro closure tabs or metal fasteners. Provides continuous wound support and comfort.
- 12 Assess patient's comfort level and adjust binder as necessary.
- 13 Remove gloves and perform hand hygiene.
- 14 Ask patient to rate pain on scale of 0 to 10.
- 15 Remove binder and surgical dressing to assess skin and wound characteristics at least every 8 hours.
- 16 Evaluate patient's ability to ventilate properly, including deep breathing and coughing, every 4 hours to determine presence of impaired ventilation and potential pulmonary complications.
- 17 Record baseline and postbinder condition of skin, circulation, integrity of underlying dressing, and patient's comfort level. Also record type of bandage applied.
- 18 Report any complications (e.g., pain, skin irritation, impaired ventilation) to nurse in charge.
- 19 Report reduced ventilation (e.g., pulse oximetry, pulmonary function tests) to health care provider immediately.

Clinical Decision Point *At this point recheck patient's ability to breathe deeply and cough effectively. When applied correctly, an abdominal binder over midline abdominal incisions has no significant effect on pulmonary function (Larson et al., 2009).*

Critical Thinking Exercises

Mr. Williams is a 72-year-old patient who has a stage II pressure ulcer over his left heel. The ulcer has required dressing changes for the last 2 weeks. Mr. Williams cares for it at home by applying a hydrocolloid powder on the ulcer and then covering it with a hydrocolloid wafer. His 70-year-old wife is his family caregiver.

- 1 The patient tells you that he has trouble getting the dressing to stay on the heel during application. Which step is he likely having difficulty performing?
- 2 While educating Mr. and Mrs. Williams about this dressing, which benefits of the dressing would you describe?
- 3 Mr. Williams tells you that, when his wife changed the dressing 2 days ago, she noticed that there was a soft whitish gel over the ulcer. He asks you, "Am I getting an infection in there?" What would your response be?

REVIEW QUESTIONS

- 1 The nurse is removing a moist-to-dry dressing from a packed wound 6 hours after it was placed in the wound. Which observation indicates that the packing technique was incorrect?
 - 1 The patient experiences some pain when the dressing is removed.
 - 2 The gauze removed is still wet.
 - 3 Necrotic tissue is seen in the removed packed gauze.
 - 4 The wound bed looks pink with some granulation tissue.
- 2 Place the following steps for application of a hydrocolloid dressing in the correct order:
 - 1 Hold dressing in place for 30 to 60 seconds.
 - 2 Secure with nonallergenic tape.
 - 3 Remove paper backing from adhesive side of wafer and place over wound.
 - 4 Select proper size so it extends onto periwound skin at least 2.4 cm (1 inch).
 - 5 Mold wafer to affected body part.
- 3 A patient has a small surgical wound with necrotic tissue that requires mechanical debridement. Which of the following dressing options is used in this type of wound treatment?
 - 1 A dry Telfa pad placed between the wound and the outer layer of a gauze abdominal (ABD) dressing
 - 2 A moist-to-dry dressing placed on the wound bed
 - 3 A hydrogel dressing
 - 4 Self-adhesive transparent film
- 4 The nurse is caring for a patient with a painful burn wound. The wound care would be most appropriate if the nurse applied which type of dressing?
 - 1 Hydrocolloid
 - 2 Hydrogel
 - 3 Alginate
 - 4 Foam
- 5 A wound care nurse is reviewing the charts of a group of patients to be seen in the clinic. Which patients are most at risk for wound-healing problems? (Select all that apply.)
 - 1 A 58-year-old woman who is on immunosuppressive drugs for arthritis
 - 2 A 34-year-old man who has had diabetes mellitus since the age of 12
 - 3 A 42-year-old woman who has been using steroids for asthma
 - 4 A 65-year-old African-American man who is 4.5 kg (10 lbs) overweight
 - 5 An 80-year-old woman with a history of osteoporosis
 - 6 A 20-year-old man who is receiving radiation near the wound

- 6 After the nurse applies an abdominal binder to a patient, the patient begins to experience shallow, rapid respirations. What is the first appropriate nursing action?
 - 1 Notify the health care provider
 - 2 Elevate the head of the bed
 - 3 Check the patient's vital signs
 - 4 Remove and reapply the abdominal binder
- 7 A patient with a large infected wound needs negative-pressure wound therapy (NPWT) and asks the wound care nurse how the technique works. Which statement by the nurse is most accurate?
 - 1 Several small foam pieces are packed firmly into the wound bed; solution is poured over the foam, and pressure pushes the fluid into the wound to facilitate healing.
 - 2 A measured foam pad is placed over the open area along with an occlusive dressing. Negative pressure removes drainage and contracts the wound bed.
 - 3 The wound bed is flooded with solution, the foam is placed around the edges of the wound bed, and pressure is used to remove the solution and wound drainage.
 - 4 A skin protectant is coated lightly inside the wound. Several damp gauze pads with the prescribed solution are placed in the wound, and the vacuum device removes the fluid and heals the wound.
- 8 A patient has an elastic bandage applied to the left leg that holds a large dressing in place over a surgical incision. Which evaluation approach should the nurse use to determine if the patient has neurologic changes?
 - 1 Palpates distal pulses in left foot
 - 2 Observes color of skin in left foot
 - 3 Inspects the surface of the bandage for drainage
 - 4 Asks the patient to rate his level of pain on a scale of 0 to 10.
- 9 You are mentoring a student nurse on a surgical floor. You observe the student removing a dry gauze dressing from a patient who had an abdominal laparotomy 24 hours ago. The student applies a pair of clean gloves, uses the dominant hand to remove all of the gauze dressings at one time, and places them in a plastic trash bag. What would be your best reaction to this technique?
 - 1 "You are using good aseptic technique."
 - 2 "You should remove one layer of gauze at a time to be sure that you don't pull on any underlying drain."
 - 3 "Next time, when you remove the dressing, use a pair of sterile gloves."
 - 4 "When you remove the gauze, you should moisten it first with saline."
- 10 A patient on the general surgery unit has a 4 inch–long incision that has developed a wound infection. On inspection there is a moderate amount of yellowish drainage that has a distinct odor. The health care provider has ordered a foam dressing. A gauze abdominal (ABD) pad is the secondary dressing for covering the foam. Since the dressing has to be changed every 24 hours, which is the best material to use to secure the ABD pads?
 - 1 Nonallergenic tape
 - 2 Transparent film dressing
 - 3 Montgomery ties
 - 4 Adhesive tape

KEY TERMS

Compress	Evaporation	Neuropathy	Vasoconstriction
Conduction	Insulator	Piloerection	Vasodilation
Cryotherapy	Maceration	Sitz bath	

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify the effects of heat and cold on a patient.
- Differentiate the types of injuries or conditions that benefit from heat and cold applications.
- Identify the risks to patients related to heat and cold applications.
- Explain common guidelines used to protect patients who receive heat and cold applications.
- Correctly apply heat and cold applications.

Local application of moderate heat and cold to body parts provides comfort and pain relief, reduces muscle spasm, improves mobility, and promotes healing. To use heat and cold therapies safely, you need to understand how the body responds to temperature variations normally and the risks connected with these applications.

Exposure to heat or cold causes both systemic and local responses (Table 40-1). The hypothalamus regulates body temperature through a variety of mechanisms that control heat production and loss (Garner and Fendius, 2011). Body temperature is affected by environmental and internal factors. When the skin is exposed to warm or hot temperatures, vasodilation and perspiration occur to promote heat loss. As perspiration evaporates from the skin, cooling occurs. When the skin is exposed to cool or cold temperatures, the systemic response includes vasoconstriction and piloerection to conserve heat. Shivering occurs in response to cooler temperatures, producing heat through skeletal muscle contraction.

Sensory adaptation to local temperature extremes can occur quickly within the body. Although a person may initially feel a temperature extreme, once the sensory receptors

adapt, he or she may become unaware of any temperature variation. Eventually excessive heat causes a burning sensation, and excessive cold causes a numbing sensation before pain is sensed. Because of this physiologic phenomenon, there is a high risk for tissue injury from heat and cold applications. Certain patients have a greater risk for injury from warm and cold applications (Table 40-2). You play an important role in maintaining patients' safety in the application of heat and cold. An order for a heat or cold application is always necessary, and it should include the duration of the treatment and the desired temperature to be used when settings can be controlled. In health care agencies materials distribution departments typically set temperature settings on heat and cold devices. Because many of these therapies can be used at home, instruct patients and their families in their proper use.

When using heat or cold therapies, you can use either dry or moist applications. The selection depends on the expected outcome of the therapy. Temperature travels from an external source such as a compress or heating pad to the surface of the skin. A substance that conducts temperatures poorly is a good insulator and thus a protector for skin and tissues. However,

there are distinct advantages to using both dry and moist applications (Table 40-3).

EVIDENCE-BASED PRACTICE

The application of ice or cryotherapy is one of the most widely used therapeutic modalities in the management of acute musculoskeletal injuries (Pescasio et al., 2008). The use of cryotherapy has a direct effect on the conduction of pain impulses, which occurs when the skin temperature is lowered (Lane and Latham, 2009). The use of cryotherapy for various injuries has a positive effect on pain relief. First, cold vasoconstricts the vasculature in adjacent tissues and slows bleeding into damaged tissues. Second, cryotherapy decreases the release of inflammatory mediators from the damaged tissues, which hinders protein release from the vasculature and decreases edema. Last, cold has an analgesic effect, which is believed to be caused by slowing of nerve conduction (Gottschalk, 2011). Cold in combination with compression reduces bleeding, edema, and muscle spasm. In addition, it reduces recovery time as part of the rehabilitation program for the treatment of both acute and chronic injuries (Markert, 2011).

Hypothermia and hyperthermia devices are used selectively for specific clinical conditions. They are designed to raise, lower, or maintain temperature through heat or cold transfer between the device and the patient. A systematic review noted that

mild-to-moderate prophylactic hypothermia improves neurologic recovery after brain injury (Fox et al., 2010). In addition, another study, which examined the best method to prevent hypothermia during surgery, tested a variety of warming devices. This study noted that circulating water devices were the most effective in maintaining body temperature control during surgery (Galvao et al., 2010).

- Do not microwave towels or medical products used for heat application.
- Consider patient age, skin and circulation, vital signs, ability to sense temperature, and ability to communicate before applying heat or cold therapies (Ebbinghaus and Kobayashi, 2010).
- A combination of cold and heat therapy is effective in adults and children with musculoskeletal injuries to reduce inflammation and edema and improve joint function (Gottschalk, 2011; Lane and Latham, 2009).

	Cold	Hot

Spasm	↓	↓
Metabolism	↓	↑
Blood flow	↓	↑
Inflammation	↓	↑
Edema	↓	↑
Extensibility	↓	↑

Modified from Garner A, Fendius A: Temperature physiology, assessment and control, *Br J Neurosci Nurs* 6(8): 397, 2011; Physiotherapy Canada: 6. Superficial heat, *Physiother Can* 62(5):47, 2010, DOI:10.3138/ptc2009-09-s6.

Type	Advantages	Disadvantages
Moist application	Reduces drying of skin and softens wound exudate Conforms well to body area being treated Penetrates deeply into tissue layers Lessens sweating and insensible fluid loss	Can cause maceration of skin with prolonged exposure Cools rapidly because of moisture evaporation Creates greater risk for burns to skin because moisture conducts heat
Dry application	Less likely to burn skin Does not cause skin maceration Retains temperature longer because not influenced by evaporation	Increases insensible fluid loss through sweating Does not penetrate deep into tissue Causes increased drying of skin

	Examples of Conditions	Precautions	Adverse Outcomes
Cold application	Immediately after direct trauma such as sprain, strains, fractures, muscle spasms; after superficial lacerations or puncture wounds; after minor burns; chronic pain from arthritis, joint trauma; delayed-onset muscle soreness; inflammation	Circulatory insufficiency Cold allergy Diabetes mellitus	Cardiovascular effects (bradycardia) Raynaud’s phenomenon Cold urticaria Nerve and tissue damage Slow wound healing Frostbite
Heat application	Inflamed or edematous body part; new surgical wound; infected wound; arthritis; degenerative joint disease; localized joint pain, muscle strains; low back pain; menstrual cramping; hemorrhoidal, perianal, and vaginal inflammation; local abscess	Pregnancy Laminectomy sites Spinal cord Malignancy Vascular insufficiency Eyes, testes, heart	Burns Infections Increased pain Increased inflammation

Modified from Physiotherapy Canada: 6. Superficial heat, *Physiother Can* 62(5):47, 2010, DOI:10.3138/ptc2009-09-s6.

PATIENT-CENTERED CARE

It is important to individualize care to meet a patient's needs and preferences. Remember that patient safety, comfort, and privacy are important when using warm or cold therapies. Burns and skin injuries sustained from hot or cold therapies are serious reportable events and are preventable errors (NQF, 2011). Patients with vascular diseases such as peripheral vascular disease or diabetes are at increased risk for injuries from hot or cold therapies because they have decreased sensation in the hands, feet, and other areas. As a result, a patient may not perceive the sensation of burning or numbness.

Instruct the patient to report any sensations in the affected area such as burning, tingling, pain, excessive redness, or pallor, which may indicate discontinuation of therapy. Involving a patient and family caregivers in these therapeutic modalities helps prepare for discharge and provides an opportunity for a nurse to understand patient or caregiver concerns. When explaining the use of warm and cold therapy to patients, the meaning and significance of the therapy can take on very different interpretations based on a patient's culture. Therefore it is important to assess the culture-specific applications of warm and cold principles for each patient and his or her family members:

- Assess how warm and cold are used normally in the care of the patient in the home.
- Reinforce the purpose of the therapy and identify patient concerns or questions.
- During the application of heat or cold therapy, the patient or his or her extremities may be exposed; maintain comfort and privacy by additional blankets, privacy curtains, and room doors. Some patients refuse being exposed to reduce body temperature.
- Many cultures such as Hispanic, Arab, Asian, African, Caribbean, and Eastern European adhere to the hot-and-cold theory. It is believed that too much exposure to something "hot" or "cold" causes an illness (Giger, 2013).
 - For Asians hot and cold concepts are part of the yin and yang concept that integrates balance and holistic health. The goal of hot and cold principles is to restore balance by providing the opposite of the cause or problem (e.g., pneumonia, cramps, and colic are considered "cold" diseases). For example, wrapping extremities and layering blankets are common treatments for colds.
- Use cultural brokers such as family members, health care providers, and religious leaders to increase acceptance of critical therapies such as hypothermia or ice packs that contradict a patient's or family's beliefs and practices.

Safety Guidelines

- 1 Exposed layers of skin are more sensitive to temperature variations than intact skin. Therefore protect damaged skin when applying hot or cold therapy.
- 2 Know the temperature of the application being used. Many devices such as heating pads or water-flow pads (e.g., Aqua-K pads) have thermostats to regulate temperature. Always check the temperature of a device and of a moist compress applied directly to the skin.
- 3 Burns and injuries from hot or cold therapies are preventable events (NQF, 2011). If they occur, there are functional implications for patients. In addition, because these are preventable events, there is a potential that the health care costs for these injuries will not be reimbursed to the health care agency.
- 4 Extremities or perineal areas have decreased fat and underlying tissue and are more sensitive than others to temperature extremes. Modify the intensity of heat and cold when treating sensitive skin areas.
- 5 Check the patient frequently during a heat or cold application. The condition of the skin indicates whether tissue injury is occurring. Observe for signs of excessive redness, maceration, or blistering.
- 6 Know your patient's risk for injury from heat or cold. Certain patients are more predisposed to injury than others (see Table 40-2).
- 7 Do not allow patients to adjust temperature settings. It is common for a patient to adapt to a temperature extreme and then want to adjust the temperature.
- 8 Never position patients so they cannot move away from the temperature source. This avoids the risk for injuries from temperature exposure. The hospitalized patient should always have a call light within reach.
- 9 If patients have diabetes mellitus or peripheral vascular diseases, it is important to use caution when applying hot or cold therapies. In addition, these patients require more frequent skin assessment during the treatment.
- 10 Do not leave a patient unattended if he or she is unable to sense temperature changes or move away from the temperature source. You are responsible for the patient's safety.
- 11 Discourage a patient from moving an application. This may cause injury to an unprotected area of the body and decrease the effectiveness of therapy.
- 12 Be aware of the impact that heat application has on a patient's vital signs. In particular, a Sitz bath causes localized vasodilation. If this vasodilation is significant, the patient's blood pressure may decrease, causing dizziness and increasing a patient's risk for falls.

SKILL 40-1 Applying Moist Heat

Application of heat promotes relaxation and healing and relieves muscle spasm and joint stiffness. Factors to consider before application include level of temperature and duration of the heat therapy and the nature of the tissues being treated.

Warm compresses and commercial heat packs (Fig. 40-1) are examples of moist heat applications used for a variety of conditions. A warm compress is a section of sterile or clean gauze moistened with a prescribed heated solution (i.e., normal saline or sterile water) and applied directly to an affected area. Commercially

packaged sterile, premoistened compresses are available in some agencies. They require the use of a special infrared lamp to heat. You heat plain sterile or clean gauze by adding the gauze to a container of warmed solution. A commercial heat pack produces its own moisture by drawing moisture from humidity in the air and retaining it in the hot pack's outer flannel cover.

Moist heat application also includes the use of warm baths, soaks, and sitz baths. A warm bath or soak involves immersion of a body part into a warmed solution. Warm soaks and sitz

FIG 40-1 Digital moist-heat pack. (Image used with permission from Theratherm, Chattanooga, a DJO Company. All rights reserved.)

FIG 40-2 Disposable sitz bath. (Used with permission, Briggs Corporation.)

baths promote circulation, reduce edema and inflammation, promote muscle relaxation, debride wounds, and apply medicated solutions. If a body part is too large to immerse, you can soak it by wrapping it in a dressing saturated with the prepared, warmed solution.

You give a sitz bath with a special tub or chair basin that allows a patient to sit in water without immersing the legs, feet, and upper trunk (Fig. 40-2). Sitz basins are disposable and especially easy to use in the home. Portable baths fit easily on top of toilets. Patients who have undergone perineal or rectal surgery, who have had an episiotomy during childbirth, or who have painful hemorrhoids or perineal inflammation benefit from a sitz bath.

When preparing a soak or bath, remember that the heated solution is in direct contact with the patient's skin. Be sure to check water temperature frequently to prevent burns. It is desirable to keep the solution temperature constant to enhance the therapeutic effects of the moist heat. Whenever you add heated solution to a soak basin or bath, remove the patient's body part and reimmerse once the solution has mixed.

Delegation and Collaboration

The skill of applying moist heat can be delegated to nursing assistive personnel (NAP). The nurse must assess the condition of the skin and tissues in the area that is treated, evaluate the patient's response, and explain the purpose of the treatment. The nurse instructs the NAP about:

- Proper temperature of the application.
- Skin changes to immediately report to the nurse (e.g., burning or excessive redness).
- Informing the nurse if the patient complains of dizziness or light-headedness.
- Reporting when treatment is complete so an evaluation of the patient's response can be made.

Equipment

All Moist Heat Applications

- Warmed prescribed solution (i.e., normal saline) or commercially prepared compresses or commercial heat pack
- Dry bath towel, bath blanket
- Clean gloves
- Waterproof pad

Clean Compress

- Warmed prescribed solution (i.e., normal saline) or commercially prepared compresses
- Waterproof pad
- Ties or cloth tape
- Aquathermia pad (optional)
- Biohazard waste bag
- Clean gloves
- Clean basin
- Clean gauze or towel

Sterile Compress (see Clean Compress above)

- Warmed prescribed sterile solution (i.e., normal saline)
- Sterile gloves
- Sterile basin
- Sterile gauze or towel

Soak or Sitz Bath

- Clean basin, tub, or sitz bath (basin may need to be sterile if body part to be soaked has an open wound)
- Prescribed solution warmed to appropriate temperature (tap water is commonly used for sitz baths)
- Prescribed medication (if ordered)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|--|
| <p>1 Refer to health care provider's order for type of moist heat application, location and duration of application, desired temperature, and agency policies regarding temperature.</p> <p>2 Assess skin around area to be treated. Perform neurovascular assessments for sensitivity to temperature and pain by measuring light touch, pinprick, and temperature sensation (see Chapter 6).</p> | <p>Ensures safe and correct application.</p> <p>Certain conditions alter conduction of sensory impulses that transmit temperature and pain, predisposing patients to injury from heat applications. Patients with diminished sensation to heat or cold must be monitored closely during treatment.</p> |
|---|--|

Clinical Decision Point *Patients with diabetes mellitus, stroke or spinal cord injury, peripheral neuropathy, and rheumatoid arthritis are at greater risk for thermal injury (Physiotherapy Canada, 2010).*

- | | |
|--|---|
| <p>3 Refer to patient's medical record to identify any contraindications to moist heat application: unstable cardiac conditions, active bleeding, nitroglycerin or other therapeutic medicinal patch, acute inflammatory reactions, recent (<72 hours) musculoskeletal injury, and skin conditions such as eczema.</p> | <p>Patients with certain cardiovascular conditions and who exhibit side effects of certain medications may be at risk for sudden changes in blood pressure and blood flow caused by vasodilation (Physiotherapy Canada, 2010). Heat causes vasodilation, which aggravates active bleeding, which can increase hemorrhage or bleeding into the soft tissues adjacent to a musculoskeletal injury (Lane and Latham, 2009). Vasodilation increases the rate of medication absorption when direct heat is applied over a medication patch. Eczema is a heat-sensitive condition, and topical application of heat can worsen condition (Physiotherapy Canada, 2010).</p> |
|--|---|

Clinical Decision Point *Reconfirm the health care provider's order when there is an area of active bleeding or inflammation.*

- | | |
|--|--|
| <p>4 Inspect any wound for size, color, drainage, tenderness, and odor (this may be deferred until dressing is removed and heat is applied).</p> <p>5 Assess patient's blood pressure and pulse.</p> <p>6 Assess patient's mobility: ability to position self for soak application, position self in bath, and sit up from bath.</p> <p>7 Assess patient's overall level of comfort using an appropriate pain scale (0 to 10).</p> <p>8 Assess patient's and family member's understanding of application and related safety factors.</p> | <p>Provides baseline to determine change in a wound following heat application.</p> <p>Establishes baseline to determine response to therapy (Physiotherapy Canada, 2010).</p> <p>Determines level of assistance needed to position patient for treatment.</p> <p>Provides baseline for patient's comfort level.</p> <p>Determines need for health teaching.</p> |
|--|--|

NURSING DIAGNOSES

- | | | |
|--|--|---|
| <ul style="list-style-type: none"> • Acute pain • Chronic pain | <ul style="list-style-type: none"> • Deficient knowledge regarding heat therapy • Impaired physical mobility | <ul style="list-style-type: none"> • Impaired skin integrity • Ineffective peripheral tissue perfusion • Risk for injury |
|--|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Affected area is pink and warm to touch immediately after heat application. • After multiple applications, wound shows signs of healing (e.g., tissue granulation; reduced edema, inflammation, drainage). • Patient denies burning sensation. • Patient reports measurable decrease in pain. <p>• Blood pressure and pulse are within patient's normal range.</p> <p>• Patient is able to self-apply therapy safely.</p> | <p>Vasodilation increases blood flow to site.</p> <p>Moist heat increases blood flow, enhances white blood cell infiltration, and removes waste products from cells (Lane and Latham, 2009).</p> <p>Indicates appropriate temperature applied.</p> <p>Heat reduces edema/inflammation and relaxes stiff and strained muscles. Heat applications cause pain signals to be overridden and decrease pain perception in cerebral cortex (Lane and Latham, 2009).</p> <p>No systemic vascular changes occur. Goal of therapy is to achieve a localized vascular response.</p> <p>Measures level of learning; necessary for home care.</p> |
|---|--|

STEP	RATIONALE
2 Assemble and prepare equipment and supplies.	Organization of supplies prevents unnecessary delays in procedure.
3 Explain steps of procedure and purpose to patient. Describe sensation that patient will feel such as decreasing warmth and wetness. Explain precautions to prevent burning.	Minimizes patient's anxiety and promotes cooperation during procedure.
IMPLEMENTATION	
1 Close door if in private room and/or close bedside curtains.	Decreases drafts, thus decreasing transmission of microorganisms. Provides for privacy.
2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission Standards and improves patient safety (TJC, 2012).
3 Perform hand hygiene and apply clean gloves.	Reduces transmission of infection.
4 Place waterproof pad under patient (exception: do not do this with sitz bath or a commercial heat pad).	Protects bed linen from moisture and soiling.
5 Apply moist sterile compress:	
a Help patient to comfortable position in proper body alignment. Expose body part to be covered with compress and drape patient with bath blanket.	Limited mobility in uncomfortable position causes muscular stress. Prevents cooling.
b Heat prescribed solution to desired temperature by immersing closed bottle of solution in basin of very warm water.	Prevents burns by ensuring proper temperature of solution.
c Remove any present existing dressing covering wound. Dispose of gloves and dressings in biohazard bag.	Reduces transmission of microorganisms.
d Inspect condition of wound and surrounding skin. Inflamed wound appears reddened, but surrounding skin is less red in color.	Provides baseline to measure wound healing.
Clinical Decision Point <i>If skin surrounding wound is inflamed or reddened or has active drainage, moist heat application may be contraindicated.</i>	
e Perform hand hygiene.	Reduces transmission of microorganisms.
f Prepare compress.	
(1) Open sterile supplies (see Chapter 8). Pour warmed solution into sterile container.	Sterile compress is needed when applied to open wound.
(2) Use sterile technique to add sterile gauze into warmed sterile solution to immerse gauze.	
(3) If using portable heating source, warm solution. NOTE: <i>If using a commercially prepared compress, follow manufacturer instructions for warming.</i>	
Clinical Decision Point <i>To avoid injury to a patient, test temperature of sterile solution by applying drop to your forearm (without contaminating solution). It should feel warm to the skin without burning.</i>	
g Prepare aquathermia pad (option) (see Skill 40-2) or commercial heat pack (if needed).	Aquathermia pad or heat pack is often needed to maintain temperature of a gauze compress.
h Apply sterile gloves if dressing change is sterile; otherwise apply clean gloves.	Allows you to manipulate sterile dressing and touch open wound.
i Pick up one layer of immersed gauze, wring out any excess solution, and apply it lightly to open wound; avoid surrounding skin.	Excess moisture macerates skin and increases risk for burns and infection. Skin is sensitive to sudden change in temperature.
j After a few seconds, lift edge of gauze to assess for redness.	Increased redness indicates burn. Burns and injuries from hot therapies are preventable events (NQF, 2011).
k If patient tolerates compress, pack gauze snugly against wound. Be sure to cover all wound surfaces with warm compress.	Packing compress prevents rapid cooling from underlying air currents.
l Cover moist compress with dry sterile dressing and bath towel. If necessary, pin or tie in place. Remove and dispose of sterile gloves.	Dry sterile dressing prevents transfer of microorganisms to wound via capillary action caused by moist compress. Towel insulates compress to prevent heat loss.

STEP	RATIONALE
m Apply aquathermia, commercial heat pack, or waterproof heating pad (see Skill 40-2) over towel. Keep it in place for desired duration of application.	Provides constant temperature to compress.
n If aquathermia pad or commercial heat pack is <i>not</i> used, change warm compress using sterile technique every 5 to 10 minutes or as ordered during duration of therapy.	Prevents cooling and maintains therapeutic benefit of compress.
o After prescribed time, apply clean gloves and remove pad, towel, and compress. Reassess wound and condition of skin and replace dry sterile dressing (using sterile gloves) as ordered.	Continued exposure to moisture macerates skin. Prevents entrance of microorganisms into wound site.
p Help patient to preferred comfortable position.	Maintains patient's comfort.
q Dispose of equipment and soiled compress. Perform hand hygiene.	Reduces transmission of microorganisms.
6 Sitz bath or warm soak to intact skin or wound:	
a Remove any existing dressing covering wound. Dispose of gloves and dressings in proper receptacle and perform hand hygiene.	Reduces transmission of microorganisms.
b Inspect condition of wound and surrounding skin. Pay particular attention to suture line.	Provides baseline to determine response to warm soak.
c When exudate is present, apply clean gloves and clean intact skin around open area with clean cloth and soap and water or sterile gauze, in which case sterile gloves and sterile normal saline or water are needed. Dispose of gloves and perform hand hygiene.	Cleaning prevents transmission of microorganisms.
d Fill sitz bath or bathtub in bathroom with warmed solution. Check temperature (check agency policy).	Ensures proper temperature and reduces risk for burns.
e Help patient to bathroom to immerse body part in sitz bath, bathtub, or basin. Cover patient with bath blanket or towel as needed.	Prevents falls. Covering patient prevents heat loss through evaporation and maintains constant temperature.
f Assess heart rate. Make sure that patient does not feel light-headed or dizzy and that call light is within reach.	Provides baseline to determine if vascular response to vasodilation occurs during treatment.
g Maintain constant temperature throughout 15- to 20-minute soak.	Ensures proper therapeutic effect.
h After 15 to 20 minutes remove patient from soak or bath; dry body parts thoroughly. (Wear clean gloves if drainage is present.)	Avoids chilling. Enhances patient's comfort.
i Drain solution from basin or tub. Clean and place in proper storage area. Dispose of soiled linen and gloves; perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Inspect condition of body part or wound treated for evidence of healing. Observe skin color, temperature, edema, and sensitivity to touch.	Evaluates effectiveness of treatment and risk for potential injury.
2 Ask patient to describe level of comfort on scale of 0 to 10. Ask about any sensation of burning following treatment.	Determines if patient was exposed to temperature extreme, resulting in burn. Evaluates patient's subjective response to therapy.
3 Obtain vital signs and compare with baseline.	Determines if systemic vascular response to vasodilation has occurred.
4 Observe patient demonstrate application of therapy and explain its purpose.	Measures level of learning and ability to perform application.

Unexpected Outcomes

- 1 Patient's skin is reddened and sensitive to touch. Extreme warmth caused burning of skin layer.
- 2 Patient complains of burning and discomfort.

Related Interventions

- Discontinue moist application immediately.
- Verify proper temperature or check device for proper functioning.
- Notify health care provider and, if there is a burn, complete an incident report (see agency policy).
- Reduce temperature.
- Assess for skin breakdown.
- Notify health care provider.

Recording and Reporting

- Record and report procedure, noting type, location, and duration of application; solution and temperature; condition of body part, wound, and skin before and after treatment; and patient's response to therapy.
- Record preprocedure and postprocedure vital signs (as indicated).
- Record any instructions given and patient's ability to explain and perform procedure.

Special Considerations

Teaching

- If a patient needs to continue heat applications after discharge, have patient or family member give a return demonstration before discharge.
- Teach patient how to gently pack wound to avoid discomfort.
- Caregivers and patients need to learn that careful assessment is needed for patients with reduced sensation to determine if temperature of compress is too hot.

Pediatric

- The skin of infants and children is thin and fragile and therefore easily damaged. Use special caution with application of heat in this population (Hockenberry and Wilson, 2011). Remain with children during procedure for safety and effectiveness.

- It is often helpful to incorporate play into the time a child is required to soak. Placing items with which the child can interact in the basin is helpful. Place boats or other similar water toys in the bath with a child who requires a bath soak. Adult supervision is necessary.

Gerontologic

- An older adult who is receiving long-term steroid therapy or is malnourished can develop thin, fragile skin, which is more easily damaged. Skin becomes less elastic and more prone to tears with aging. An older adult may have impaired circulation to a given skin region or impaired sensation for pain or temperature (Meiner, 2011).
- Older adults who have lost subcutaneous tissue and fat have lost the insulating effect of these tissues and may experience alterations in thermoregulation (Meiner, 2011).
- In some frail older patients with cardiac conditions, it is necessary to monitor vital signs throughout procedure.

Home Care

- When necessary, assess availability of family caregiver to help patient in application of moist heat, family caregiver's understanding of purpose of procedure, and willingness of caregiver to comply with procedure and not leave patient.
- Assess physical environment to determine adequacy of facilities for use by patient. Patient may need assistive devices to get in or out of a tub or a commode chair to set up a sitz bath.

SKILL 40-2 Applying Dry Heat

A water-flow pad such as an aquathermia pad, electric heating pads, and commercial heat packs (Fig. 40-3) are common forms of dry heat therapy. A new product, an air-activated wearable heat wrap, maintains a temperature of 40°C (104°F) and can be worn from 8 to 10 hours (Ebbinghaus and Kobayashi, 2010). Dry heat devices are applied directly to the surface of the skin; for this reason you need to take extra precautions to prevent burns, dry skin, and loss of body fluids. The aquathermia pad (water-flow pad) used in health care settings consists of a waterproof rubber or plastic pad connected by two hoses to an electrical control unit that has a heating element and motor. Distilled water circulates through hollowed channels in the pad to the control unit where water is heated (or cooled). In most health care facilities the central supply department sets the temperature regulators to the recommended temperature. A temperature of 40°C (104°F) is a safe temperature to expose the skin for a long duration (Ebbinghaus and Kobayashi,

2010). Dry-heat treatments penetrate a child's skin superficially about $\frac{1}{2}$ inch (0.5 cm) but maintain temperature changes longer than moist-heat treatments (Ebbinghaus and Kobayashi, 2010).

A conventional heating pad used in the home care setting consists of an electric coil enclosed in a waterproof cover. A cotton or flannel cloth covers the outer pad. The pad connects to an electrical cord that has a temperature-regulating unit for high, medium, or low settings. These pads are not used in health care facilities. Because it is so easy to readjust temperature settings on heating pads, instruct patients not to turn the setting higher once they have adapted to the temperature. Instruct patient and family not to use the highest setting.

Delegation and Collaboration

The skill of applying dry heat can be delegated to nursing assistive personnel (NAP) (see agency policy). The nurse must assess and evaluate the condition of the skin and tissues in the area that is treated and explain the purpose of the treatment. If there are risks or expected complications, this skill cannot be delegated. The nurse directs the NAP about:

- Specific positioning and time requirements to keep the application in place based on health care provider order or agency policy.
- What to observe and report immediately such as excessive redness and pain during application.
- Reporting when treatment is complete so the patient's response can be evaluated.

Equipment

- Aquathermia or commercial heat pack
- Distilled water (for aquathermia pad)
- Bath towel or pillowcase
- Tape ties or gauze roll

FIG 40-3 Dry heat wrap. (Image used with permission, ThermaWrap, Pfizer Consumer Healthcare. All rights reserved.)

STEP

RATIONALE

ASSESSMENT

1 Refer to health care provider's order for location of application and duration of therapy. Agency policy usually sets recommended temperature for aquathermia pad.	Order required to help ensure patient's safety. Preset temperature on device reduces risk of skin and tissue injury.
2 Assess condition of skin and underlying tissue in area where you will apply pad for skin integrity, color, temperature, sensitivity to touch, blistering, and excessive dryness (see Chapter 6).	Provides baseline to determine change in skin condition after heat application.
3 Ask patient to describe level of comfort on a scale of 0 to 10. Assess range of motion (ROM) if patient is being treated for muscle sprain.	Provides baseline to determine if pain relief is achieved.
4 Check electrical plugs and cords for obvious fraying or cracking.	Prevents injury from accidental electrical shock.
5 Determine patient's or family member's knowledge of procedure, including steps for application and safety precautions.	Heating pads are frequently used in home. Assessment determines extent of health teaching required.

NURSING DIAGNOSES

- | | | |
|--|--|---|
| <ul style="list-style-type: none"> • Acute pain • Chronic pain | <ul style="list-style-type: none"> • Deficient knowledge regarding heat application • Impaired physical mobility | <ul style="list-style-type: none"> • Impaired skin integrity • Ineffective peripheral tissue perfusion • Risk for injury |
|--|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Skin is pink and warm to touch after application. • Patient reports less pain of inflamed tissues or strained muscles. • Patient's ROM increases. • Patient correctly applies pad. 	<p>Vasodilation from heat exposure increases blood flow to affected part.</p> <p>Thermoreceptors, special temperature-sensitive nerve endings, are activated by changes in skin temperature. These receptors initiate nerve signals that block pain signal (Gottschalk, 2011). Heat reduces stiffness and improves ROM (Lane and Latham, 2009).</p> <p>Documents learning.</p>
2 Prepare equipment and supplies.	Organization of supplies prevents unnecessary delays in procedure.
3 Explain procedure and precautions.	Improves likelihood of patient's adherence to therapy.

IMPLEMENTATION

1 Close door if in private room and/or close bedside curtains.	Provides for patient's privacy.
2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission Standards and improves patient safety (TJC, 2012).
3 Perform hand hygiene and position patient to expose area being treated.	Reduces transfer of microorganisms. Patient must be able to assume position for several minutes during application.
4 Apply dry heat device. <ul style="list-style-type: none"> a Aquathermia heating pad <ul style="list-style-type: none"> (1) Cover or wrap area to be treated with a bath towel or enclose pad with pillowcase. 	Prevents heated surface from touching patient's skin directly and increasing risk for injury to patient's skin.

Clinical Decision Point *Do not pin wrap to pad because this may cause a leak in device.*

- | | |
|--|--|
| (2) Place pad over affected area and secure with tape, tie, or gauze as needed (see illustration). | Pad delivers dry warm heat to injured tissues. Pad should not slip onto different body part. |
|--|--|

Clinical Decision Point *Never position patient so he or she is lying directly on pad. This position prevents dissipation of heat and increases risk for burns.*

- | | |
|---|--|
| (3) Turn on aquathermia unit and check temperature setting. | Prevents exposure of patient to temperature extremes. |
| b Apply commercially prepared heat pack: break pouch inside larger pack (follow manufacturer guidelines). | Activates chemicals within pack to warm outer surface. |

STEP	RATIONALE
5 Monitor condition of skin over site every 5 minutes and ask patient about sensation of burning.	Determines if heat exposure is causing any burn, blistering, or injury to underlying skin.
6 After 20 to 30 minutes (or time ordered by health care provider), remove pad and store.	Continued exposure results in burns. Muscles located 1 to 2 cm (0.4 to 0.8 inch) below skin surface in children require heat applied for 20 to 30 minutes to be effective (Ebbinghaus and Kobayashi, 2010).
7 Help patient return to preferred comfortable position, dispose of soiled linen, and perform hand hygiene.	Promotes relaxing environment. Reduces transmission of microorganisms.

STEP 4a(2) Aquathermia pad.

EVALUATION

1 Inspect condition of skin for integrity, color, temperature, dryness, and blistering. Evaluate again 30 minutes following treatment.	Evaluates response of skin to heat exposure.
2 Assess ROM. Ask patient to rate pain on scale of 0 to 10.	Heat reduces edema and relieves pain from muscle stiffness and spasm (Lane and Latham, 2009). Patient can adequately rate pain relief.

Clinical Decision Point Do not have patient actively exercise muscle to evaluate results of therapy. Active exercise can aggravate muscle strain.

3 Observe patient or family caregiver apply pad to be used in home.	Measures level of learning.
---	-----------------------------

Unexpected Outcomes

- 1 See Skill 40-1, Unexpected Outcomes.
- 2 Body part is painful to move. Movement stretches burn-sensitive nerve fibers in skin.
- 3 Patient applies heat incorrectly or is unable to explain precautions.

Related Interventions

- Discontinue aquathermia pad or heat pack use. Wait for swelling to resolve before attempting to reapply.
- Notify nurse in charge or contact health care provider.
- Reinstruct patient or family caregiver as necessary. Consider possible home health referral.

Recording and Reporting

- Record type of application, temperature and duration of therapy, and patient's response.
- Describe any instruction given and patient's/family caregiver's success in demonstrating procedure.
- Report pain level, ROM of body part, skin integrity, color, temperature, sensitivity to touch, blistering and dryness.

Special Considerations

Teaching

- Highlight safety precautions during procedure so they are followed during application.

Pediatric

- The skin of infants and children is thin and fragile and therefore easily damaged. Use special caution in this population. Remain with children during procedure for safety and effectiveness.
- Assess body temperature gain and loss, which occurs more readily in pediatric patients.

Gerontologic

- Older adults are more at risk for burns because of loss of heat sensation. Check site frequently during all treatments.
- Older patients have thin, more fragile skin that is susceptible to burns.

Home Care

- Assess patient and primary caregiver as to their understanding, ability, and motivation to comply with procedure.
- Assess home environment for facilities (e.g., condition of electrical outlets and equipment) to comply with implementation of procedure.

SKILL 40-3 Applying Cold

There are a variety of cold (cryotherapy) modalities such as ice packs, moist cold compresses, chemical cold packs, electromechanical or compression devices, or cold soak immersion of a body part. Cold therapy treats localized inflammatory responses that lead to edema, hemorrhage, muscle spasm, or pain (see Table 40-1). Cold exerts a profound physiologic effect on the body, reducing inflammation caused by injuries to the musculoskeletal system (Markert, 2011). Because reduction of inflammation is the primary goal, cryotherapy is the treatment of choice for the first 24 to 48 hours after an injury (Gottschalk, 2011).

Vasoconstriction resulting from cold application reduces blood flow to the injured part and thus reduces fluid accumulation and slows bleeding and hematoma formation associated with trauma. The lower temperature also suppresses muscle spasm and produces a local anesthetic response, resulting frequently in the reduction of the use of analgesic medications (Lane and Latham, 2009). When used appropriately, cold applications significantly lessen pain and immobility by reducing swelling of injured tissues (Physiotherapy Canada, 2010). This is an important point for nurses to know when deciding on the choice of heat or cold for the treatment of acute injuries. Cold is also indicated as an adjunct analgesic for chronic pain and spasticity control.

A cold compress usually consists of a commercial cold pack or a gauze dressing or washcloth that has been immersed in iced or chilled solution to achieve the desired temperature. The compress may be sterile or clean; however, a clean compress is most common. Any open wounds require sterile applications. There are many sizes or thicknesses of gauze, depending on the site of injury. For example, a cold compress to the eye requires thicker gauze that fits a small area to maintain a cold temperature. Thin gauze works more effectively for larger areas such as the face.

Ice bags and cold packs come in a variety of sizes to fit different body parts (Fig. 40-4). When a commercial ice bag or cold pack is unavailable, use a plastic bag or glove filled halfway with crushed ice. Squeeze the bag or glove to expel air, which hampers cold conduction. In the home a patient can substitute a bag of frozen vegetables (such as peas or corn) for an ice bag. Wrap all of these items in a towel or cloth before application.

There are electrically controlled continuous cold-flow therapy devices that simultaneously provide cold and compression (e.g.,

Cryo/Cuff [Fig. 40-5]). Compression acts with cold to reduce the blood flow and edema formation while providing support to the soft tissues. The cooling pad has the advantage of delivering a constant cool temperature. Elevating the extremity during treatment further augments venous return. A person who undergoes treatment with one of these devices is simultaneously receiving all five components of the protection, rest, ice, compression, and elevation (PRICE) method for managing this type of injury.

Delegation and Collaboration

The skill of applying cold applications can be delegated to nursing assistive personnel (NAP) in special situations (see agency policy). The nurse must assess and evaluate the patient and explain the purpose of the treatment. If there are risks or possible complications, this skill is not delegated. The nurse directs the NAP to:

- Keep the application in place for only the length of time specified in the health care provider's order.
- Immediately report to the nurse any excessive redness on the skin, increase in pain, or decrease in sensation.
- Report when treatment is complete so a nurse can evaluate the patient's response.

Equipment

All Compresses, Bags, and Packs

- Clean gloves (if blood or body fluids are present)
- Cloth tape or ties or elastic wrap bandage
- Soft cloth cover: towel, pillowcase, or stockinette
- Bath towel or blanket and waterproof pad

FIG 40-4 Commercial ice pack.

FIG 40-5 Cryo/Cuff includes integrated cooler. (Image of AirCast Cryo/Cuff used with permission of DJO Global.)

Cold Compress

- Absorbent gauze (clean or sterile) folded to desired size
- Basin
- Prescribed solution at desired temperature

Ice Bag or Gel Pack

- Ice bag
 - Ice chips and water
- or

- Reusable commercial gel pack (cold pack)

- Disposable commercial chemical cold pack

Electrically Controlled Cooling Device

- Cool water-flow pad or cooling pad and electrical pump
- Gauze roll or elastic wrap

STEP	RATIONALE
------	-----------

ASSESSMENT

- | | |
|--|--|
| <p>1 Refer to health care provider's order for type, location, and duration of application. Temperature of a cooling pad will be ordered or preset.</p> | <p>Health care provider's order is required for all cold applications.</p> |
| <p>2 Inspect condition of injured or affected part. Gently palpate area for edema.</p> | <p>Provides baseline for determining change in condition of injured tissues.</p> |

Clinical Decision Point *Keep injured part in alignment and immobilized. Movement can cause further injury to strains, sprains, or fractures.*

- | | |
|--|---|
| <p>3 Consider time in which injury occurred.</p> | <p>Apply cold as soon as possible after injury to reduce tissue bleeding and edema (Gottschalk, 2011).</p> |
| <p>4 Ask patient to describe character of pain and rate severity on a scale of 0 to 10 (or other pain scale when applicable) if able.</p> | <p>Provides baseline for determining pain relief with therapy.</p> |
| <p>5 Perform neurovascular check and inspect surrounding skin for integrity, circulation, color, temperature, and sensitivity to touch (see Chapter 6).</p> | <p>Determines if patient is insensitive to cold extremes.</p> |
| <p>6 Assess patient's understanding and/or awareness of procedure.</p> | <p>Patients who are confused or have altered levels of consciousness may not be able to alert nurse that there is decreased sensation or discomfort to underlying skin.</p> |

NURSING DIAGNOSES

- | | | |
|--|--|---|

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> Affected area is slightly pale and cool to touch. There is decreased edema and/or bleeding in tissues at site of injury. Patient reports decreased pain as measured on scale of 0 to 10. Patient correctly states how to apply cold and provides demonstration. | <p>Result of vasoconstriction.</p> <p>Cold reduces blood flow to affected part by reducing protein extravasation from the vasculature and subsequent edema formation (Gottschalk, 2011).</p> <p>Cold decreases local nerve conduction and subsequent pain, creating localized analgesic effect (Gottschalk, 2011).</p> <p>Documents learning.</p> |
| <p>2 Prepare equipment and supplies.</p> | <p>Organization prevents unnecessary delays.</p> |
| <p>3 Explain procedure and precautions.</p> | <p>Improves likelihood of patient's adherence to therapy.</p> |

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Close room door and bedside curtain. Perform hand hygiene.</p> | <p>Provides privacy for patient. Reduces spread of microorganisms.</p> |
| <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> | <p>Ensures correct patient. Complies with The Joint Commission Standards and improves patient safety (TJC, 2012).</p> |
| <p>3 Position patient carefully, keeping body part in proper alignment and only exposing area to be treated, and drape patient with bath blankets.</p> | <p>Prevents further injury to body part. Avoids unnecessary exposure of body parts, maintaining patient's comfort and privacy.</p> |
| <p>4 Place towel or absorbent pad under area that you will treat.</p> | <p>Prevents soiling of bed linen.</p> |

STEP	RATIONALE
5 Apply clean gloves.	Reduces spread of infection.
6 Apply cold compress:	
a Place ice and water in basin and test temperature on inner aspect of arm.	Extreme temperature can cause tissue damage.
b Submerge gauze into basin filled with cold solution; wring out excess moisture.	Dripping gauze is uncomfortable to patient.
c Apply compress to affected area, molding it gently over site.	Ensures that cold is directed over site of injury.
d Remove, remoisten, and reapply to maintain temperature as needed.	
7 Apply ice pack or bag:	
a Fill bag with water, secure cap, and invert.	Ensures that there are no leaks.
b Empty water and fill bag two-thirds full with small ice chips and water.	Bag is easier to mold over body part when it is not full.
c Express excess air from bag, secure bag closure, and wipe bag dry.	Excess air interferes with cold conduction. Allows bag to conform to area and promotes maximum contact.
d Squeeze or knead commercial ice pack.	Releases alcohol-based solution to create cold temperature.
e Wrap pack or bag with towel, pillowcase, or stockinette.	Protects patient's tissue and absorbs condensation. Prevents direct exposure of cold against patient's skin.
8 Apply commercial gel pack:	
a Remove from freezer.	
b Wrap pack with towel, pillowcase, or stockinette. Apply pack directly over injury.	Protects patient's tissue and absorbs condensation. Prevents direct exposure of cold against patient's skin.
c Secure with gauze, cloth tape, or ties as needed.	

Clinical Decision Point Do not reapply ice pack to red or bluish areas; continual use of ice pack makes ischemia worse.

9 Apply electrically controlled cooling device:	
a Make sure that all connections are intact and temperature, if adjustable, is set (see agency policy).	Ensures safe temperature application.
b Wrap cool-water flow pad in towel or pillowcase.	Prevents adverse reactions from cold such as burn or frostbite.
c Wrap cool pad around body part.	Ensures even application of cold temperature.
d Turn device on and check correct temperature. (NOTE: Temperature is usually preset in health care settings [check agency policy]).	Ensures effective therapy. Present temperature reduces risk of skin and tissue injury.
e Secure with elastic wrap bandage, gauze roll, or ties.	
10 Remove and dispose of gloves in proper container.	Reduces transmission of microorganisms.
11 Check condition of skin every 5 minutes for duration of application.	Determines if there are adverse reactions to cold (e.g., mottling, redness, burning, blistering, numbness) (<i>Physiotherapy Canada, 2010</i>).
a If area is edematous, sensation may be reduced; use extra caution during cold therapy and assess site more often.	
b Numbness and tingling are common sensations with cold applications and indicate adverse reactions only when severe and coupled with other symptoms. Stop when patient complains of burning sensation or skin begins to feel numb.	When applying cold, skin will initially feel cold, followed by relief of pain. As cryotherapy continues, patient will feel burning sensation, then pain in the skin, and finally numbness (<i>Physiotherapy Canada, 2010</i>).
12 After 15 to 20 minutes (or as ordered by health care provider), apply clean gloves, remove compress or pad, and gently dry off any moisture.	Drying prevents maceration of skin.

Clinical Decision Point Areas with little body fat (such as knee, ankle, and elbow) do not tolerate cold as well as fatty areas (such as thigh and buttocks). For bony areas decrease time of cold application to lower range.

13 Help patient to comfortable position.	Maintains relaxing environment.
14 Remove and dispose of supplies. Empty basin, if used, and dry. Dispose of soiled linen and gloves. Perform hand hygiene.	Reduces transmission of microorganisms.

STEP

RATIONALE

EVALUATION

- 1 Inspect affected area for integrity, color, temperature, sensitivity to touch. Reevaluate 30 minutes after procedure.
- 2 Palpate affected area gently for edema, bruising, and bleeding.
- 3 Ask patient to report pain level on scale of 0 to 10.
- 4 Observe patient, apply cold application, and explain risks of treatment.

- Determines reaction to cold application.
- Determines level of edema.
- Determines if pain has been relieved.
- Measures level of learning.

Unexpected Outcomes

- 1 Skin appears mottled, reddened, or bluish-purple as result of prolonged exposure.
- 2 Patient complains of burning type of pain and numbness.
- 3 Patient is unable to describe application or use compress correctly.

Related Interventions

- Stop treatment.
- Notify nurse in charge or health care provider.
- Different therapy will be needed for injured area.
- Stop treatment because these are signs of ischemia.
- Notify nurse in charge or health care provider.
- Provide reinstruction and clarification.

Recording and Reporting

- Record procedure, including type, location, and duration of application and patient's response.
- Describe any instruction given and patient's success in demonstrating procedure.
- Report any sensations of burning, numbness, or unrelieved skin color changes to health care provider.

Special Considerations

Teaching

- Injuries requiring this type of therapy usually occur outside of acute care settings. Patients active in sports should know steps to take to minimize extent of injury.

Pediatric

- A greater metabolic rate and larger trunk in relation to the rest of the body make children more prone to hypothermia

(Hockenberry and Wilson, 2011). Exercise caution with young patients.

- Infants have an unstable temperature control mechanism; thus mottling of extremities is common and does not always indicate an adverse reaction (Hockenberry and Wilson, 2011).
- Cool soaks also decrease itching with some skin lesions. Use the same precautions and play techniques as with warm soaks.

Gerontologic

- Older adults are more at risk for tissue damage because of altered responses to change in body temperature (Meiner, 2011). Check site frequently during all treatments.

SKILL 40-4 Caring for Patients Requiring Hypothermia or Hyperthermia Blankets

A hypothermia-hyperthermia blanket raises, lowers, or maintains body temperature through conductive heat or cold transfer between the blanket and the patient. When placed on top of a patient, the blanket helps to raise or lower his or her body temperature (Fig. 40-6). When operated manually the unit maintains a set temperature, regardless of the patient's temperature. Because you assess a patient's temperature using conventional thermometers, the temperature of the unit is manually adjusted to reach a different temperature setting. When operating in the automatic setting, the unit continually monitors a patient's temperature with a thermistor probe (rectal, skin, or esophageal). The system increases or decreases the preset target temperature of the circulating water in response to the preset target temperature and actual measured patient temperature.

Patients can have high, prolonged fevers from infectious neurologic diseases and as side effects from anesthesia. Recent research shows that induced hypothermia prevents or moderates neurologic outcomes following neurosurgery or traumatic brain injury and acute stroke (Fox et al., 2010; Linares and Mayer, 2009;

FIG 40-6 Hypothermia cooling blanket is applied over paper sheet before additional top sheet is applied to bed. (Courtesy Cincinnati SubZero Maxi-Therm Hyper-Hypothermia Blanket.)

Polderman, 2008; Polderman and Herold, 2009). Mild hypothermia (32° to 34° C [89.6° F to 93.2° F]) in the first hours after an ischemic event and for 72 hours or until stabilization occurs helps prevent permanent damage (Fox et al., 2010).

Delegation and Collaboration

The skill of applying a hypothermia or hyperthermia blanket can be delegated to nursing assistive personnel (NAP) (see agency policy). The nurse is responsible for assessing and evaluating treatment and related patient education. If the patient is unstable and at risk for complications, this skill is not delegated. The nurse directs the NAP to:

- Maintain proper temperature of the application throughout the treatment and discontinue the application as specified in the health care provider's order.

- Inform the nurse of any unexpected patient outcomes (e.g., shivering or redness to the skin).
- Report when treatment is complete so an evaluation of patient's response can be made.

Equipment

- Hypothermia or hyperthermia blanket with control panel and rectal probe
- Sheet or thin bath blanket
- Distilled water to fill the units if necessary
- Clean gloves
- Rectal thermometer

STEP

RATIONALE

ASSESSMENT

- 1 Refer to health care provider's order and check that patient's current body temperature indicates use of hypothermia or hyperthermia blanket.
- 2 Assess vital signs, neurologic status, mental status, and peripheral circulation.
- 3 Verify that other, less intensive measures cannot return patient's body temperature to normal.

Instituting therapy requires health care provider's order.

Establishes baseline data to use for comparison during therapy.

Use of hypothermia and hyperthermia blanket is not without risk and should be instituted only when other measures are not effective.

Clinical Decision Point Antipyretic therapy may be used in combination with a cooling blanket. Temperatures greater than 41°C (105.8°F) have detrimental effects in the neurological patient. As a result some neurological injuries and their sequelae are permanent. A 1°C (1.8°F) rise in body temperature results in a 10% increase in metabolic demands of the body (Kiekkas et al., 2008, 2011).

- 4 Assess patient's skin on chest and extremities, paying close attention to bony prominences such as hands and feet.

These areas are more exposed to blanket and consequently are at greater risk for injury. Baseline data enable you to quickly determine if injury to skin or development of pressure ulcer is result of therapy.

NURSING DIAGNOSES

- Hyperthermia
- Impaired skin integrity
- Ineffective peripheral tissue perfusion
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Temperature is within normal range.
 - Absence of shivering with hypothermia blanket.
- 2 Explain procedure to patient.
- 3 Position patient comfortably.
- 4 Prepare blanket according to agency policy and manufacturer instructions. Manufacturer instructions are usually located on machine.

Indicates that therapy is effective.

Shivering increases metabolic rate and heat production but also increases oxygen consumption. In addition, shivering causes vasoconstriction, which can injure skin of distal body regions (Garner and Fendius, 2011).

Distal regions of patient's skin are at greatest risk for injury from blanket. Indicates that treatment is causing no adverse effects.

Increases cooperation and reduces anxiety.

Agencies have specific policies on maintaining equipment in functional order. Each type of blanket varies from one manufacturer to another.

STEP

RATIONALE

IMPLEMENTATION

1 Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission Standards and improves patient safety (TJC, 2012).
3 Apply lanolin or mixture of lanolin and cold cream to patient's skin where it will touch blanket.	Helps protect skin from heat and cold sensations.
4 Turn on blanket and observe that cool or warm light is on. Precool or prewarm blanket, setting pad temperature to desired level.	Verifies that blanket is correctly set to help reduce (cool) or increase (warm) patient's body temperature. Prepares blanket for prescribed therapy.
5 Verify that pad temperature limits are set at desired safety ranges.	Safety ranges prevent excessive cooling or warming. The blanket automatically shuts off when preset body temperature is achieved.
6 Cover hypothermia or hyperthermia blanket with thin paper or cloth sheet or bath blanket.	Injuries from hot or cold therapies are preventable events (NQF, 2011). Thin sheet protects patient's skin from direct contact with blanket, thus reducing risk for injury to skin. Sheet or blanket covers plastic and provides insulation between patient and appliance.
7 Position hypothermia or hyperthermia blanket on top of patient.	Provides wide distribution of blanket against patient's skin.
a Wrap patient's hands and feet in gauze.	Reduces risk for thermal injury to distal areas of body.
b Wrap scrotum with towels.	Protects sensitive tissue from direct contact with cold.
8 Lubricate rectal probe and insert into patient's rectum.	When using hypothermia or hyperthermia blanket, it is imperative that you continuously monitor patient's core interior (rectal) temperature.
9 Turn and position patient regularly to protect from pressure ulcer development and impaired body alignment (see Chapter 10). Keep linens free of perspiration and condensation.	Patient has increased risk for pressure ulcer development because of skin moisture created by blanket and patient's body temperature.
10 Double-check fluid thermometer on control panel of blanket before leaving room.	Verifies that pad temperature is maintained at desired level.
11 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Monitor patient's temperature and vital signs every 15 minutes during first hour and every 30 minutes of therapy thereafter.	Provides continuous evaluation of response of patient's body temperature to therapy during initial and continual therapy.
2 Evaluate automatic temperature control every 30 minutes visually and every 4 hours by taking patient's rectal temperature.	Ensures removal of hypothermia or hyperthermia blanket when patient's temperature returns to desired level. Decreases risk for subnormal body temperature. Verifies accuracy of rectal probe and automatic temperature control device.
3 Observe skin for indications of burns, change in color, and other signs of injury.	Hypothermia and hyperthermia blankets have potential to cause skin injuries.
4 Observe patient for signs of shivering.	Early signs of shivering, which may harm patient, include electrocardiographic changes, facial muscle twitching, or hyperventilation.
5 Determine patient's level of comfort.	Therapy has potential to cause discomfort. Prompt assessment reduces risk for severe injuries.

Unexpected Outcomes

- 1 Patient's core body temperature decreases or rises rapidly. This indicates that temperature is too extreme and might produce injury to patient.
- 2 Patient's core temperature remains unchanged.
- 3 Patient begins to shiver. Shivering increases metabolic rate and heat production, causing patient's core body temperature to rise, and increases oxygen consumption.
- 4 Skin breaks down, indicating that patient's skin may have received thermal injury (frostbite or burn) from blanket.

Recording and Reporting

- Record baseline data: vital signs, neurologic and mental status, status of peripheral circulation, and skin integrity when therapy was initiated.
- Note type of hyperthermia-hypothermia unit used; control settings (manual or automatic, and temperature settings); date, time, duration; and patient's tolerance of treatment.
- Chart on temperature graphic repeated measurements of vital signs to document response to therapy.
- Report any unexpected outcome to health care provider. Further treatment may be needed.

Special Considerations

Teaching

- Instruct patients and their families not to move patient off blanket.

Related Interventions

- Adjust blanket temperature no more than 1°F (0.6°C) every 15 minutes to avoid complications.
- Patient may need hypothermic or hyperthermic treatment of additional sites such as axilla, groin, and neck in addition to those covered by blanket.
- Discuss use of antipyretic with health care provider.
- Adjust temperature to more comfortable range and assess if shivering decreases.
- If shivering continues, stop treatment and notify health care provider.
- Stop treatment.
- Notify health care provider.

Pediatric

- A greater metabolic rate and larger trunk in relation to the rest of the body make children more prone to hypothermia. Exercise caution with young patients.
- Infants have an unstable temperature control mechanism; thus mottling of extremities is common and does not always indicate an adverse reaction.

Gerontologic

- Some older adults are more at risk for tissue damage because of loss of cold sensation. Check patient frequently during all treatments.

Critical Thinking Exercises

You are assigned to care for Adam Montgomery, an 82-year-old male patient with diabetes mellitus who is postoperative day 1 for total left knee arthroplasty. The surgeon has ordered an electronically controlled cold compression cuff to be applied to the left knee for 2 to 3 hours, followed by a 1-to 2-hour break with compression loosened. Your patient has been confused off and on since returning to the patient care unit and is receiving hydrocodone 5/500 1 to 2 tablets by mouth every 4 hours for pain.

- 1 What do you need to do to begin Mr. Montgomery's cold application? (Select all that apply.) Explain your choice(s).
 - 1 Refer to health care provider's order for location and duration of the application
 - 2 Assess current pain level
 - 3 Assess condition of injured or affected body part
 - 4 Explain the procedure and precautions to avoid injury to the skin
- 2 Mr. Montgomery's risks for cold applications include which of the following? (Select all that apply.)
 - 1 A chronic pain condition
 - 2 A condition causing circulatory insufficiency to extremities
 - 3 An acute injury less than 2 days old
 - 4 An inability to provide feedback about tissue temperature
- 3 Can you delegate the application of the cold compression cuff to nursing assistive personnel (NAP)? Why or why not?

REVIEW QUESTIONS

- 1 A patient has been diagnosed with a severe muscle strain of the lower back, and the health care provider has ordered heat applications to the lower back for 48 hours. Which nursing intervention has the greatest priority in this situation?
 - 1 Frequently assessing the setting on the heat delivery system
 - 2 Placing a plastic wrap over the compress for better penetration
 - 3 Frequently assessing the area where the heat is being applied
 - 4 Encouraging the patient to increase his oral fluid intake
- 2 Which of the following patients would be at risk for injury from heat application? (Select all that apply.)
 - 1 A patient with a lot of body fat
 - 2 A patient being treated for anxiety
 - 3 A patient with peripheral vascular disease
 - 4 A patient with type 1 diabetes
 - 5 A patient with dehydration
 - 6 A malnourished patient
 - 7 A patient who has been on long-term steroid therapy
- 3 The nurse has just completed a cold application to a patient's knee. Which observation would be expected as a result of the treatment?
 - 1 The affected area is slightly pale and cool to touch.
 - 2 The amount of edema has increased.
 - 3 The patient relates a measurable increase in pain.
 - 4 The affected area is mottled or bluish purple.

- 4 The nurse is preparing to apply a cold application to a patient's elbow. Which nursing intervention would be indicated?
- 1 Decreasing the length of time the cold application would normally be applied
 - 2 Increasing the length of time the cold application would normally be applied
 - 3 Keeping the time length of the cold application the same as when the application is over a fatty area
 - 4 Leaving the cold application in place until it naturally cools to allow for deeper penetration
- 5 Depending on the application method and duration, the physiologic effects of cold therapy may include which of the following? (Select all that apply.)
- 1 Reducing localized pain
 - 2 Vasodilation
 - 3 Muscle relaxation
 - 4 Vasoconstriction
- 6 A patient placed on a hypothermia blanket begins to shiver. Why should the nurse be concerned about the patient's response to this therapy?
- 1 Shivering decreases a patient's metabolic rate and amount of heat loss.
 - 2 Shivering decreases the amount of oxygen consumption by a patient.
 - 3 Shivering increases a patient's metabolic rate and heat production.
 - 4 Shivering causes general vasoconstriction, which is contraindicated for this patient.
- 7 An alert older patient with limited mobility and strength has a moist heat wrap applied. Which is the most important nursing intervention for this patient?
- 1 Checking on patient's response to the therapy in 1 hour
 - 2 Ensuring that patient's call light is placed within reach
 - 3 Telling patient to move the heat wrap if it becomes uncomfortable
 - 4 Securing the device to the affected area with plastic wrap
- 8 A patient is using a smoking cessation patch and needs a moist heat application. Before the initial application of the heat, which nursing intervention is most important?
- 1 Performing a full skin assessment to determine any potential areas of injury
 - 2 Notifying the health care provider of the patient's use of the medicinal patch
 - 3 Performing an assessment of the patient's desired comfort level
 - 4 Ensuring proper body alignment so only the affected area is heated
- 9 A patient with a strained muscle receives a dry heat application. How does the nurse evaluate the effectiveness of this therapy?
- 1 Asks the patient to rate pain using a pain scale
 - 2 Has the patient gently perform an activity using the affected muscle
 - 3 Encourages the patient to actively exercise the affected muscle
 - 4 Watches the patient's face as he uses the affected muscle group
- 10 A patient just injured his ankle, and a cold pack has been placed on the affected area. What is the appropriate evaluation immediately after injury?
- 1 The nurse checks the skin on the patient's ankle 15 to 20 minutes after the cold pack is applied.
 - 2 The ice pack is wrapped with plastic to ensure even application of the therapy.
 - 3 The patient sits on a chair while his ankle is placed in a bucket of ice on the floor.
 - 4 The patient's skin temperature and appearance is checked approximately every 5 minutes.

Wandering

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify patients at risk for safety problems and possible accidents in the home.
- Promote self-care of patients in the home.
- Describe factors within a home environment that create risks for patient injury.
- Perform a home safety risk assessment.
- Identify interventions that modify the home environment for physical safety.
- Identify interventions to reduce safety risks for patients with sensory, cognitive, and mental status alterations.
- Recommend strategies to ensure safe drug administration within the home.
- Perform a geriatric fall risk assessment.

Home safety is defined as being in an environment and feeling secure in one's surroundings. Home care safety begins before a patient is discharged. *Patient Education Management* (2009) highlights the need for communication between patient, family caregivers, and home care providers before discharge. Frequently patients deal with problems as they arise rather than preparing and preventing issues. Remember that insurance coverage, including Medicare, can be very limited for home care. Therefore the time spent in the home with a patient must be well planned and used to the fullest.

Healthy People 2020 identifies injury and violence prevention as a topic area, with objectives geared toward preventing unintentional injuries (USDHHS, 2011). *Healthy People 2020* stresses that injuries and violence affect both an individual, the family, and the community. One of the overarching goals of *Healthy People 2020* addresses obtaining a higher quality and longer life through prevention of injury. In accordance with *Healthy People 2020*, home care nurses must assess a patient and home environment for risk. For example, patients with chronic conditions such as diabetes mellitus may be at risk for falls because of neuropathies. Patients living in socioeconomically disadvantaged areas may be at risk for injury as a result of violence or poor living conditions.

Accident prevention begins with making timely and adequate home repairs (e.g., replacing loose floor tile, securing railings on stairwells). However, many patients do not have the resources for maintaining a safe home environment. The nurse plays an important role in improving and maintaining a patient's safety by collaborating with patients, family members, caregivers, and other health care providers in the community in finding the best approaches for meeting a patient's safety needs. The ultimate goal is to create an environment in which patient and family can provide self-care safely and effectively.

Fall prevention is a critical aspect of care for older adults. You can address it by taking a patient history to assess for risks and reasons for recent falls and plan appropriate interventions. Some of the risk factors to consider include previous fall history, older age, incontinence, multiple medications, fewer numbers of activity of daily living limitations, unsteady gait, poor balance, tremors, reduced lower body strength, reduced vision, absence of supervision, cognitive impairments, postural hypotension, and home environmental hazards (Fortinsky et al., 2008; Yamashita et al., 2011). If home care clinicians are given evidence-based interventions related to these risk factors, research suggests that the likelihood of preventing injury increases, which in turn enhances a patient's quality of life and safety.

EVIDENCE-BASED PRACTICE

Older adults can be especially at risk for falls. Often they believe that limiting their activity will help to decrease this risk. Fletcher et al. (2010) conducted a study to understand the fears of falling in older adults. The researchers sought to determine associated risk factors for adults who chose to restrict their activity in the community. The researchers found several risk factors for restriction of activity, including:

- Being female
- The presence of pain
- Previous history of falling

Older adults and their family caregivers may believe that restricting activity will help prevent falls; however, the research findings did not support this belief (Fletcher et al., 2010). Older adults may actually experience a decline in functional abilities and compromised balance as a result of inactivity. Therefore it is important for a nurse to address a patient's fear of falling and to provide education for safe activity in the home and community.

Greene et al. (2009) designed a fall prevention initiative for older adults and conducted a home visit to question patients about their history of falls and awareness of risk factors in their homes. The researchers conducted a brief motor assessment and made recommendations to decrease falls and increase fall risk awareness. In addition, they examined external risk factors such as lighting and the height of a patient's bed, comparing their findings to falls of older adults in nursing homes and assisted-living facilities. The researchers concluded that:

- Characteristics of falls in the home are unique compared to those in other settings. Health care providers must tailor prevention initiatives appropriate to the setting (e.g., home versus nursing home) and patient needs.
- Fall prevention initiatives impact patient behavior, raise caution and awareness, and improve problem solving.

PATIENT-CENTERED CARE

Many factors influence a patient's lifestyle and the manner in which he or she structures and maintains the home environment. Communication is essential in home care and is a continuous process between you and a patient. At the first meeting introduce

yourself, explaining how you would like the patient to address you, and ask the patient how you should refer to him or her (Abele, 2011). Recognize that time orientation is different for each culture. For example, Asians, Africans, East Indians, and Native Americans tend to focus on the past and value long-standing traditions. These patients may look to ancestors for guidance in issues of illness and protection. Recognize this and talk with the patient to address safety issues in a culturally congruent manner that respects this time orientation (Abele, 2011).

Collaborate with patients in assessing their home environments. Assess for culture-specific health-related beliefs that may impact his or her willingness to use home care services. For example, Mexican-Americans may prefer to care for their older adult family members in the home without outside assistance (Crist et al., 2011). When assessing the availability of family caregivers in the home, recognize that many collectivist cultures (e.g., Jewish, Hispanic, Arabic, Asian) value an active presence and caring for ill family members. With the patient's permission, include these family members when performing the home safety assessment. Assess and provide support for informal and family caregivers; the presence or absence of these could be the difference between a patient remaining in the home or being readmitted to an acute care facility (Abele and Nies, 2011).

Safety Guidelines

- 1 When helping a patient change the home environment, retain as much of his or her independence and ability to provide self-care as possible.
- 2 Ask if patient and/or family caregiver has concerns or questions about safety and if they have any suggestions to improve their safety (Mullin, 2010).
- 3 Reinforce the importance of preserving patient autonomy as much as possible with family caregivers.
- 4 Make modifications to the home environment only after consulting with and considering patients' physical strengths, remaining functional abilities, and resources for making change.
- 5 Be sure that patient and family caregivers know what to do in case of an emergency and how to reach you if needed (Mullin, 2010).

SKILL 41-1 Home Environment Assessment and Safety

The home environment should be a place where individuals feel healthy, comfortable, and safe. People want to be able to move about freely within their homes, regardless of the size of the home, and to have a sense of control over daily living routines. This requires maintaining personal space and a sense of privacy. As the home care nurse you can help a patient maintain independence and reduce risk in the home environment by conducting a safety assessment.

Patients requiring home care often experience physical alterations (e.g., progressive physical changes of aging) that require changes in their home environment. For example, if a patient has poor balance but good upper arm strength, make modifications so he or she can safely walk or move throughout the house, ascend and descend stairs, and enter and exit a bathtub or shower. Teaching a patient to safely use assistive devices (e.g., walker or cane) helps him or her increase mobility and maintain independence (Fig. 41-1).

Respect the concept of personal space. Making changes too rapidly without a patient's consent will cause more problems than

benefits. Appreciate the arrangement of a patient's space within the home and do not move things or suggest modifications without permission. Provide a rationale to the patient as to why the changes are beneficial and/or needed. Knowing the rooms that a patient uses most frequently helps in making the adjustments to create a safe environment.

Delegation and Collaboration

The skill of conducting an initial home safety assessment cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Inform the nurse of suggestions for ways to make the home safer.

Equipment

- Home safety checklist

FIG 41-1 Use of walker may help patient remain mobile.

STEP

RATIONALE

ASSESSMENT

1 Review risk factors that predispose patients to accidents within the home:

- a Known visual impairment
- b Hearing impairment
- c Neuromuscular dysfunction (e.g., lower- extremity weakness, unsteady gait, impaired balance, poor ankle dorsiflexion)
- d Reduced energy or fatigue
- e Incontinence or nocturia
- f History of stroke, parkinsonism, delirium, seizures, dementia, arrhythmias, gait disturbances, muscle weakness, and syncope
- g Postural hypotension, palpitations, difficulty breathing, or shortness of breath
- h Medication usage and history, including polypharmacy and use of sedatives, antihypertensives, antidepressants, and diuretics
- i History of previous fall

2 Determine if patient has had history of falls or other injuries within the home. Be specific in your assessment. Use the mnemonic SPLATT (Meiner, 2011):

- Reduced visual function alters patient's balance, depth perception, or adaptation to dark or glaring light (Ebersole et al., 2008).
- Prevents patient from hearing normal environmental sounds clearly as source of orientation. Prevents clear perception of any home-installed alarms (e.g., smoke alarm).
- Interferes with communication for patients with co-morbidities to hear and interpret what you are saying (Wallhagen and Pettengill, 2008).
- Factors predispose patients to fall. Recurrent falls are associated with difficulty standing up from a chair (Touhy, 2010b).
- Predisposes patients to falls.
- Frequent trips to bathroom often cause patient with other deficits to accidentally trip or fall over barriers.
- Dementia does not cause incontinence but it will affect patient's ability to find a bathroom and recognize need to void (Touhy, 2010a).
- There are usually multiple reasons for falls, including neurologic, sensory, cognitive, medication, and musculoskeletal problems (Touhy, 2010b).
- Gait disorders make patients vulnerable to tripping and falling (Ebersole et al., 2008). Age-related changes of neurologic system include slowing of reaction time (Meiner, 2011).
- Dizziness and light-headedness predispose to falls (Touhy, 2010b) and cause patient to be unsteady and compensate for difficulties.
- Use of multiple medications has been associated with falls. Medications that alter sensorium affect balance and judgment (Muir et al., 2010).
- Increases risk for future fall. Recurrent or multiple fallers are more likely to benefit from fall prevention efforts (Fletcher et al., 2009).
- Key symptoms are helpful in identifying cause of fall. Onset, location, and activity associated with fall provide further details on causative factors and how to prevent future falls.
- SPLATT test allows patient to explain symptoms in own words; it is important to understand circumstances around fall (Meiner, 2011).

STEP	RATIONALE
<ul style="list-style-type: none"> • Symptoms at time of fall • Previous fall • Location of fall • Activity at time of fall • Time of fall • Trauma after fall 	
<p>3 Have patient who has had a near fall or actual fall maintain a fall diary (Box 41-1).</p>	<p>Information in fall diary is very helpful in determining antecedents and consequences of falling (Meiner, 2011).</p>
<p>4 Conduct a Timed Get Up and Go (TUG) test for basic mobility. Instruct patient to rise from standard chair, walk approximately 3 meters (10 feet), turn around, walk back to chair, and sit in chair again. Time patient while he or she performs activity. Have patient perform test three times and calculate mean score.</p>	<p>Simple screening examination is very useful in detecting difficulties with balance or gait. Normal required time to finish test is less than 20 seconds, with no staggering when turning or need to hold on to something. Helps in diagnosis and treatment of underlying causes; refer to physical therapist for gait and progressive balance training (Ebersole et al., 2008). TUG time performance is associated with a past history of falls, but its predictive ability for future falls remains limited (Beauchet et al., 2011).</p>
<p>5 Determine if patient has fear of falling. Possible indicators include apprehension during ambulation (observed in facial expressions); sweating or trembling while ambulating; clutching people or objects while ambulating; reluctance to change position or ambulate; and new onset of wobbly, reduced mobility after a fall.</p>	<p>Fear of falling occurs variably in older adults. Some patients limit activity because of fear of falling, which is risk factor itself for falling (Muir et al., 2010).</p>

Clinical Decision Point *In addition to patient, include family caregivers as a resource in assessments because they may witness accident trends or patterns.*

<p>6 Partner with patient and family caregivers to conduct home safety assessment:</p>	<p>Provides comprehensive review of all areas within home that pose hazardous situations.</p>
<p>a Front and back entrances</p>	
<p>(1) Are walkways to front/back door even and free from holes or cracks?</p>	<p>Entrances pose barriers in surfaces over which patient must walk. Uneven pavement and holes may not be seen by patient, causing tripping and falls.</p>
<p>(2) Are home entrances, including walkways, well lit?</p>	<p>Poorly lit areas prevent individuals from seeing variations in walking surface.</p>
<p>(3) Does patient have nonskid strips/safety treads or bright-colored paint on outdoor steps? Which colors are most easily seen by patient? Are these colors used?</p>	<p>Nonskid surfaces cause fewer slips on stairs. Color on steps permits individual to see edges, accommodating for any reduced depth perception.</p>
<p>(4) Are doormats in good repair with nonskid backing and tapered edge?</p>	<p>Raised edges pose risk for tripping. Doormats without nonskid backing will slide when stepped on, causing patient to lose balance.</p>
<p>(5) Are doors in good repair and do they open and close easily? Can patient open and close all doors easily?</p>	<p>Act of opening and closing door can cause fall. Automatic door openers, level doorknob handles, and hook-and-chain locks may be easier to use (Touhy, 2010b).</p>
<p>(6) Is there sturdy handrail on both sides of stairs leading to entrance?</p>	<p>Handrails provide greater support while ascending and descending stairs.</p>
	<p>Ideally handrails on both sides of stairwell will provide greatest stability for patient. If entrance space does not allow this, install at least on one side to prevent fall from imbalance (Touhy, 2010b).</p>

BOX 41-1 Fall/Near-Fall Diary

- Keep a notebook and across the longest edge of the paper write the headings: “Date,” “Time of Fall,” “Activity at Time of Fall,” “Symptoms,” and “Injury.”
- As soon as possible after a fall, have patient or family caregiver complete information under each heading.
- If a family caregiver witnesses the fall, the family member records what happened on a separate piece of paper.
- List emergency contact numbers in the diary for patient to call in case a fall results in serious injury.
- Instruct patient to bring the diary to their health care provider’s office at the next scheduled visit or share information with home care nurse on next home visit.

STEP	RATIONALE
(7) Are steps in good condition with even, flat surfaces? (8) Are doorways and stairs free of clutter?	Uneven surfaces predispose to tripping. Reduces risk for tripping and/or falling.
b Kitchen	Kitchen is one of most hazard-oriented rooms in home and poses serious hazards for fire.
(1) Does patient wear clothing with short or close-fitting sleeves when cooking?	Short or close-fitting sleeves are less likely to accidentally catch on fire when person works at stove.
(2) Does patient always stay in kitchen when cooking?	Lack of attention when using fire is risk.
(3) Does patient have loud timer to signal when food is cooked?	Prevents burning food and risk for fire.
(4) Does patient keep stove top and oven clean and grease free?	Grease is highly flammable.
(5) Are stove control dials easy to see and use?	Patient may accidentally use higher flame than is necessary for cooking safely.
(6) Is charged, easy-to-use fire extinguisher close at hand?	Extinguisher should be ready for use at all times.
Clinical Decision Point <i>Have patient demonstrate steps of how to use extinguisher.</i>	
(7) Are emergency numbers for police, fire, and poison control posted on or near telephone?	Emergency phone numbers and extinguisher ensure quick response if fire occurs.
(8) Can items in kitchen cabinets and shelves be reached without climbing on stool or chair?	Climbing on step stools or chairs creates risks for falls.
(9) Is there adequate lighting over sink, stove, and work areas?	Poor lighting makes it difficult to see control knobs or dials and provides inadequate illumination when using sharp knives or utensils.
(10) Are kitchen throw rugs and mats slip resistant?	Rugs or mats that are not slip resistant can easily slide on tile or wood floors.
c Bathrooms	
(1) Can patient unlock bathroom door from both sides of door?	Functional locks prevent person from being trapped in bathroom.
(2) Is tub or shower equipped with nonskid mats, abrasive strips, or surfaces that are not slippery?	Bathrooms are hazardous. Wet floors and tub or shower bottoms can be very slippery, creating risk for falls.
(3) Does bathroom floor have nonslip surface or rug with nonskid backing?	Slippery tile predisposes to falls.
(4) Does patient avoid using slippery bath oils when bathing?	Use of bath oils makes tub surface slippery and increases risk for falls.
(5) Do bathtub and shower have at least one grab bar or handrail placed where patient can reach it?	Grab bars provide extra support while maneuvering into and out of tubs or showers (Home Safety Council, 2011). Grab bars placed in correct place where patient can safely reach them help to steady gait and lessen chance of falls (Meiner, 2011).
(6) Is patient careful not to place towels on grab bars?	Some patients accidentally grab towel instead of bar when needing support. Towel can slip off bar.
(7) Does shower have stable stool or chair and handheld sprayer? Is shower easy to access (walk-in versus step-in to tub area)?	Shower stool allows patient to sit while showering.
(8) Are cold and hot water faucets clearly marked, and is temperature on water heater 120°F (48.8°C) or lower?	Accidental burns can occur from exposure to hot water.
d Bedroom	
(1) Is night-light placed in bedroom and/or bath?	Older adults have altered night vision.
(2) Is working smoke detector just outside bedroom door?	Alarm situated just outside bedroom can awaken person early enough to escape fire.
(3) Can patient turn on light without having to get out of bed in dark? Is flashlight available at bedside?	Getting out of bed without proper lighting or ability to adjust to light changes and reaching for necessary objects put patient at risk for falls.
(4) Is furniture arranged to provide clear path from bed to bathroom?	Obstructed path creates barrier that causes tripping and falls.
(5) Is phone with emergency numbers within easy reach of bed?	If patients develop physical symptoms while in bed, they need to be able to reach phone without having to get out of bed.
(6) Are other alarm systems available? Push buttons that call for help? Nursery listening devices for cognitively impaired or nonambulatory patients?	Alarm systems placed in readily accessible location can alert family caregivers when person requires immediate assistance.

STEP	RATIONALE
<p>e Living room/family room</p> <ol style="list-style-type: none"> (1) Are electrical or extension cords removed from under furniture and carpeting? Kept out of way of traffic? (2) Can patient turn on light without having to walk into dark room? (3) Are hallways and walkways free from objects and clutter? (4) Are loose area rugs securely attached to floor and not placed over carpeting? (For best safety, consider removing throw rugs.) (5) Is furniture arranged in each room so patient can walk around easily? (6) Is all furniture steady and without sharp edges? 	<p>Patients can easily trip or fall over electrical cords. Hidden cords are trip and fire hazard.</p> <p>Darkened room can disorient and prevent patient from seeing uneven surfaces.</p> <p>Objects and clutter in common walkway can cause falls.</p> <p>Loose edges of rugs are easy for persons to trip over (Touhy, 2010b).</p> <p>Furniture creates obstacles to walking in room.</p> <p>Patients often use edge of furniture for support when standing.</p>
<p>f Around the house</p> <ol style="list-style-type: none"> (1) Are all living areas and stairways well lit? (2) Is flooring or carpeting throughout house in good repair? (3) Are all thresholds level with floor or no more than ½ inch (1.27 cm) in height? (4) Is light switch at both top and bottom of stairs? (5) Does lighting produce glare or shadows on stairs or floor surfaces? (6) Do handrails run continuously from top to bottom of flights of stairs? (7) Are handrails securely attached to wall? (8) Are step coverings in good condition? (9) Are guns kept in house? Are trigger locks installed on all guns? Are guns stored unloaded? Is ammunition in secure location? 	<p>Adequate lighting helps persons see any barriers or uneven walking surfaces.</p> <p>Frayed carpet or irregular surfaces can cause tripping and result in fall.</p> <p>Uneven thresholds can cause tripping.</p> <p>Prevents individual from having to walk portion of stairs in dark. Older adults are sensitive to glare because their visual pathway becomes distorted.</p> <p>Handrails provide source of physical support when ascending and descending stairs.</p> <p>Loosened covering can cause tripping.</p> <p>Following gun safety standards decreases risk for injury and death related to gun use (NRA, 2011).</p>
<p>g General fire safety</p> <ol style="list-style-type: none"> (1) Does patient have properly working smoke detectors with fresh batteries? 	<p>Smoke alarms properly located, functioning well, and with batteries replaced twice a year can provide timely alert for fire.</p>
<p>Clinical Decision Point Check to see when smoke-alarm battery was last changed; battery should be changed every 6 months. Instruct patients to change battery each time they change their house clocks for daylight savings.</p>	
<ol style="list-style-type: none"> (2) Does patient have several emergency exit plans in case of fire? (3) Has family determined meeting place in event of emergency such as at mailbox in front of home? (4) Does patient use portable space heaters? Are they kept at least 3 feet (1 meter) away from flammable items? (5) Is furnace area free of things that can catch on fire? (6) Does a qualified professional check furnace and chimney annually? (7) Does patient who smokes report smoking in bed? 	<p>Exit plan helps people anticipate route of escape when fire does occur. Exit should not have locks that are difficult to open or any physical barriers.</p> <p>Use of common emergency meeting location is efficient method for determining that all family members are safely out of house. Heaters, furnaces, and chimneys pose risks for fire.</p> <p>Heating equipment was second-most common cause of home fire fatalities from 2005 through 2009 (National Fire Protection Association [NFPA], 2011).</p> <p>Smoking was leading cause of home fire deaths in 2005 through 2009 (NFPA, 2011). Smoking in bed has added risk of patient falling asleep while cigarette is lit.</p>
<p>h General electrical safety</p> <ol style="list-style-type: none"> (1) Are electrical cords in good condition (i.e., not frayed, spliced, or cracked)? (2) Are electrical cords kept away from water? (3) Does patient use extension cord/outlet extenders with built-in circuit breaker or fuse? (4) Do all wall outlets and switches have cover plates? 	<p>Damaged cords can short circuit and lead to fire.</p> <p>Use of any appliance or device that is exposed to water creates risk for electrical shock.</p> <p>Prevents overloading of circuit that can lead to fire.</p> <p>Prevents physical contact with wiring.</p>

STEP	RATIONALE
(5) Does patient use light bulbs of correct wattage for each fixture?	Use of excessive wattage can lead to fire.
(6) Is main electrical fuse box for home easily accessible and clearly labeled?	In event of emergency, fuse box should be easy to access so proper circuit can be cut off.
i Carbon monoxide prevention	
(1) Are furnace flues checked regularly for patency?	Obstructed flues are common cause of carbon monoxide toxicity.
(2) Is there a carbon monoxide detector in home?	
7 Assess patient's financial resources; determine monthly income used for ongoing expenses.	Determines potential for making repairs to home. Reveals need for low-cost community service support.
8 Assess patient's and family caregiver's willingness to make changes. Has patient accepted limitations that pose risk for injury? Determine how important functional independence is for patient.	Some patients perceive attempts to improve safety within home as intrusive. If you show that necessary revisions to home environment will preserve independence, patient will participate more willingly.

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding safety risks
- Ineffective health maintenance
- Impaired home maintenance
- Impaired memory
- Impaired physical mobility
- Risk for falls
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1** Expected outcomes following completion of procedure:
 - Patient and/or family describes potential environmental risks within home that predispose to accidents.
 - Patient and/or family initiate actions to correct environmental risks, making home safer.
 - Patient remains free of injury.
- 2** Prioritize with patient and family environmental barriers that pose greatest risk.
- 3** Recommend calling in reliable contractor if major home repairs are necessary.

During home safety assessment nurse instructs patient in risks that are of greatest concern.
 Patient sees value in altering living environment.
 Environmental barriers are reduced or removed to minimize injuries.
 Patient's own physical and/or cognitive deficits make certain environmental risks more hazardous. Prioritization helps patient make best choices.
 Ensures that repairs are made safely and correctly.

IMPLEMENTATION

- 1** General home safety:
 - a** Provide direct light source in areas where patient reads, cooks, uses tools, or conducts hobby work. High-intensity light on object or surface that is involved works best.

Visual impairment in older adults usually is a result of cataracts, macular degeneration, glaucoma, or diabetic retinopathy (Touhy, 2010c).

Clinical Decision Point *Avoid fluorescent lighting because it creates excessive glare.*

- b** Consider satin and nonglossy finishes for walls, cabinets, and countertops in kitchen. Have sheer curtains or adjustable shades in other living areas.
- c** Apply colored tape or paint to color code controls of stove, oven, dryer, toaster, and other appliances.
- d** Consider installing lazy Susans or pull-out drawers with glide mechanisms in kitchen cabinets. Install C-ring handles in lower cabinets.
- 2** Fall prevention steps:
 - a** Paint edges of concrete stairs bright yellow, orange, or white.
 - b** Install treads with uniform depth of 22.5 cm (9 inches) and 22.5-cm (9-inch) risers (vertical face of steps).
 - c** Rearrange furniture to open up space through hallways and major rooms.
 - d** Reduce clutter within living areas (e.g., footstools, flower pots, extension cords, children's toys, stacked newspapers or magazines).

Reduces glare for older adults.
 Patients with reduced visual acuity may adjust appliance to wrong setting, creating potential risk for fire or burning.
 Makes access to food and kitchen supplies easier.
 Patient can see edge of stairs more clearly.
 If stairs are of uniform size, patient does not have to continually adjust vision or stride.
 Creates unobstructed pathway for ambulation.
 Mobility hazards resulting from clutter are especially a risk at night (Ebersole et al., 2008).

STEP

RATIONALE

- e Secure all carpeting, mats, and tile; place nonskid backing under small rugs and doormats. Remove throw rugs/mats in nonessential (dry) areas. Reduces chance of patient slipping when stepping on rug surface (Touhy, 2010b).
 - f Pad floor and use specialized tile that absorbs impact of falls. Cushions person's fall.
 - g Use low-rise beds, futon beds, or mattress on floor if not contraindicated. Lowers distance to floor surface.
 - h Have enough electrical outlets installed to be able to plug light or electronic device (e.g., television, video) into nearby outlet. Secure electrical cords against baseboards. Prevents need to run extension cords across walkways.
 - i Install nonskid strips on surface of bathtub and/or shower stall. Be sure that floor is clean and dry (Home Safety Council, 2011). Reduces chances of slipping on tub/shower stall surface.
 - j Have grab bar installed in studs at tub, toilet, and/or shower (see illustration). Have patient select vertical or horizontal placement if choice available. Be sure that bar is different color than wall and easy to see. Bar provides stability for maneuvering in bathroom (Home Safety Council, 2011).
 - k Have handrails installed along side of any stairway (see illustration). Be sure that stairways are well lit, with switches at top and bottom of steps. Install at least on one side (Touhy, 2010b). Older adults have difficulty seeing edges of stairs.
 - l Install appropriate broad-beam lighting for outside walkways. Provides full illumination.
 - m Keep lighted phone easily accessible, next to patient's bed. Prevents patient from having to get up out of bed, often in dark.
 - n Install motion sensor exterior lighting for walkways/driveway. Reduces risk for patient falls caused by dark surroundings.
 - o Have patient use padding or types of clothing that will cushion bony prominences, especially high-risk bony prominences (e.g., hips). Specially designed hip protectors are available. Helps to absorb impact of falling body.
- 3** Prevent spread of infection:
- a Teach patient cleaning practices to prevent spread of infection. Family caregivers need instruction in infection control practices.
 - b Instruct patient not to share eating and drinking utensils. Some infections are spread by saliva.
 - c Instruct patient to clean appliances and surfaces daily. Regular cleaning prevents risk for contamination and spread of infection.
- 4** Fire safety:
- a Have smoke detectors installed near each bedroom, in kitchen, and in basement of home. Be sure that detector is on each floor of home. Fires most frequently start in basement near furnace, dryer, or electrical wiring; kitchen; or in living areas where there is extensive wiring. Alarm should be close to alert patient and family when sleeping.

STEP 2j Grab bars and safety seat installed in shower.

STEP 2k Handrails installed along stairways provide security for patients with visual, balance, and coordination problems.

STEP

RATIONALE

- b** Have patient select fire extinguisher that is easy to handle and manipulate (see illustration). Ask him or her to read instructions and demonstrate its proper use.
- c** Have area around furnace cleared of any flammable items.
- d** Instruct patient to be sure that portable space heater has emergency shut off and that equipment housing and electrical cords are intact (Meiner, 2011).
- e** Have patient make appointments for maintenance of furnace and chimney cleaning in appropriate season.
- f** Have patient check light bulb wattage in all fixtures.
- g** Have patient establish routine during cooking that keeps him or her in kitchen. Be sure that cooking range is clean and items such as potholders and towels are away from burners.
- h** If patient is a smoker, review need to keep ashtrays clean and emptied. Placing small amount of water or sand in bottom of ashtray is useful if patient is visually impaired.
- i** Strongly discourage smoking in bed, smoking in chair when there is possibility of falling asleep, and smoking after taking medication that diminishes alertness. Instruct patient to put cigarette or cigar out at first sign of feeling drowsy (Meiner, 2011).
- j** Recommend that patient install power strips or surge protectors for plugging in multiple appliances/devices.
- 5** Burn safety:
- a** Have setting on hot water heater adjusted to 49°C (120°F) or lower.
- b** Instruct patient to always turn cold water on first.
- c** Install touch pads on lamps.
- d** Use color codes of red for hot and blue for cold on water faucets. (If patient has difficulty distinguishing colors, choose two that are easily distinguished.)
- 6** Carbon monoxide safety:
- a** Have condition of furnace venting checked annually just before turning on furnace.
- b** Caution patients against using gas stove or barbecue grill for heating inside home.
- c** Have battery-operated carbon monoxide detector installed in home; check or replace battery when you change your clocks in fall and spring (see illustration).
- Some older adults or patients with disabilities have difficulty gripping mechanisms on certain extinguishers.
- Reduces risk for fire.
- Space heaters can be overturned by accident, which can cause fire; safety mechanism will turn unit off immediately (Meiner, 2011).
- Furnace maintenance prevents short circuits and fires. Accumulation of creosote on chimney walls can lead to fire.
- Ensures that proper wattage being used; wattage that exceeds recommendation can cause fire.
- Food cooking on stove can easily boil over or begin to burn when unattended.
- Patient with reduced vision may be unable to tell if cigarette, cigar, or match has extinguished.
- Risks factors for burns and fire. Patient's reaction time may be slower when tired.
- Prevents risk for electrical short, which can cause fire.
- Prevents scalding burns (Meiner, 2011).
- Prevents direct exposure to hot water.
- Light is easy to turn on without risk for touching hot light bulb.
- Prevents accidental burning from turning on wrong faucet.
- Improper venting prevents escape of carbon monoxide, a poisonous gas that alters hemoglobin to prevent formation of oxyhemoglobin, and reduces oxygen supply to tissues.
- Both are sources of carbon monoxide (Meiner, 2011).
- Detector alarms when carbon monoxide reaches unsafe levels. Battery operation will not be affected by power outages (Meiner, 2011).

STEP 4b Fire extinguisher accessible in kitchen.

STEP 6c Carbon monoxide detector.

STEP	RATIONALE
<p>7 Firearm safety:</p> <ul style="list-style-type: none"> a Teach patient about dangers associated with keeping guns in home. b If guns are in home, teach patient to install trigger locks and store them unloaded in locked cabinet. Teach patient to store ammunition in secured area separate from guns. Store keys in place inaccessible to children. 	<p>Risk of suicide increases in homes with firearms (Edelman and Mandle, 2009). Following gun safety standards decreases risk of injury and death related to gun use (Hockenberry and Wilson, 2011).</p>

EVALUATION

1 Have patient and family member(s) identify safety risks revealed in home safety assessment.	Demonstrates what patient recognizes as risk and its relative importance for changing.
2 During follow-up visit or call to home ask patient to discuss plans for making any modification and observe what changes patient has implemented.	Evaluates extent to which patient sees risks as potentially harmful and complies with suggested changes.
3 During follow-up visits or calls ask if patient has experienced any falls or other injuries within home.	Reveals if risks have been eliminated, depending on patient's previous history of injury.
4 Reassess for progression of dementia.	Assesses for potential risk to patient and caregiver.

Unexpected Outcomes

- 1 Patient and family do not acknowledge risks identified from home safety assessment.
- 2 Patient fails to make changes agreed on in previous plan.
- 3 Patient suffers fall or burn within home.

Related Interventions

- Determine if reluctance to make changes is caused by limited resources, disbelief concerning need to make changes, fear of loss of autonomy, or other reasons.
- Review implications of risks to patient's safety and welfare.
- Determine reason for failure to make changes.
- Help prioritize greatest risks.
- Conduct assessment of contributing factors and conditions in environment at time of injury.
- Make revisions based on assessment findings.

Recording and Reporting

- Retain copy of home safety assessment in patient's home care record.
- Record any instruction provided, patient's response, and changes made within environment in progress notes.

Special Considerations

Teaching

- Family and caregivers will benefit from learning how to safely help patient ambulate or transfer from bed to chair or wheelchair to chair, depending on patient's mobility limitations (see Chapter 9).
- Instruct patient and caregiver about what to do in case patient falls, including access to emergency assistance and how to prevent further injury.
- When appropriate, teach caregiver and patient how to use any emergency assistive devices (e.g., devices that are worn around patient's neck and a special monitor connected to patient's telephone). Patients summon help by pressing button on device if phone is inaccessible. Refer the family to local health care agencies and department of aging for options.

Pediatric

- Caution parents when working in the kitchen to never pour hot liquids when an infant or young child is near.

- Remove all crib toys that are strung across crib or playpen when child begins to push up on hands or knees (4 to 7 months) (Hockenberry and Wilson, 2011).
- Keep guns and ammunition in separate, secured places.
- Install safety measures appropriate to developmental level (e.g., cabinet locks and gates).
- Do not let young children use the sink or tub without adult assistance; when child is in tub, stay with him or her (Home Safety Council, 2011).

Gerontologic

- Use "aging in place" resources and designs to accommodate the needs of seniors or disabled individuals without having to completely redesign the home. For example, install grab bars in bathrooms, movable cabinets under the sink so someone in a wheelchair can use the space, and light switches and electrical outlets at heights that can be reached easily (USDHHS Administration on Aging, 2009).
- Place a bedside commode (with bedpan removed) over a conventional toilet seat. Commode level is usually higher than toilet and can also be moved near the bed for nighttime use.

SKILL 41-2 Adapting the Home Setting for Patients with Cognitive Deficits

An important aspect of safety is a person's ability to perform routine activities of daily living (ADLs) and instrumental activities of daily living (IADLs) to make correct decisions about home-management activities. ADLs include a patient's ability to bathe, dress, go to the toilet, transfer, and feed oneself. IADLs include the ability to use a telephone, prepare meals, travel, do housework, take medication, and shop.

Some patients who are unable to perform these activities or who require assistance have physical disabilities and/or cognitive limitations. Cognitive and physical limitations can threaten a person's autonomy. Family members often misunderstand certain behaviors associated with cognitive changes and become concerned about whether the individual can function safely within the home. Be aware that you may face situations in which you have to make decisions about whether a patient is competent to perform self-care.

Common cognitive conditions affecting patients in the home are dementia, delirium, and depression. Delirium can occur in up to 80% of hospitalized patients and continues to manifest symptoms in 30% to 90% of these patients after discharge (Ebersole et al., 2008). Dementia is a chronic generalized impairment of intellectual functioning that leads to a decline in the ability to perform basic ADLs and IADLs. Dementia is characterized by a gradual, progressive, irreversible cerebral dysfunction. Alzheimer's disease is the most common form of dementia and accounts for 50% to 80% of dementia cases (Alzheimer's Association, 2012). As it progresses, older adults become more dependent on family caregivers for assistance. Caregivers will need access to respite programs, which will allow them planned time away from their caregiving role (Mueh, 2011).

Alzheimer's disease is a form of dementia, causing problems with memory, thinking, or behavior; for some individuals with

Alzheimer's disease there is a risk for wandering (Alzheimer's Association, 2012). A wandering patient may walk around the house trying repeatedly to carry out a task independently or try to leave his or her place of residence but is stopped by family caregivers. If wandering is an ongoing problem, the family caregiver should provide current photographs of the patient to local police. The patient can also be enrolled in the national MedicAlert + Alzheimer's Association Safe Return program, which provides 24-hour emergency and wandering response services and support services for family and caregivers (Alzheimer's Association, 2011). Local resources can also be explored to ensure safety for the patient inside and outside of the home.

Delegation and Collaboration

The skill of adapting the home environment for patients with cognitive deficits cannot be delegated to nursing assistive personnel (NAP). The nurse is responsible for the assessment of cognitive function. The nurse directs the NAP to:

- Inform the nurse when there is a change in patient's mood, memory, and ability to maintain home.

Equipment

- Mini-Mental State Examination (MMSE)
- Short Geriatric Depression Scale (SGDS)
- Beck Depression Inventory (BDI)
- Calendar
- Paper for making lists
- Medication organizer (*optional*)
- Bulletin board or poster board (*optional*)
- Motion detector (*optional*)

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient over short period of time and be sensitive to his or her sensory needs or disabilities.
- 2 Be sure that room in which you meet with patient and family is well lit with minimal outside noises or interruptions. Speak clearly and in normal tone of voice.
- 3 Ask patient to describe own level of health and have him or her describe how it affects ability to perform self-care skills (e.g., bathing, dressing, eating, toileting).

Respects human dignity of patient.

Optimal environment for assessment of patient's cognitive and mental status provides more valid assessment.

Question requires patient to focus on one topic. Allows nurse to assess attention and concentration. Also determines if patient is fully perceptive of physical capabilities.

Clinical Decision Point Do not create situation in which patient thinks that you are not listening to his or her views. The additional person supplements answers with patient's consent, but patient remains the focus of the interview.

- 4 Ask how patient is handling home management responsibilities: "Tell me what bills you pay each month. Can you tell me what each one is for?
Ability to perform ADLs: Can you tell me about your normal day—when do you get up, eat meals, dress? Do you have problems dressing or bathing?"

Provides good comparison of patient and family perceptions. Interaction will help to measure short-term memory, judgment, and problem solving.

STEP	RATIONALE
<p>5 Assess patient’s medications. Review number and type of medications, purpose as prescribed, time of day taken, and dosages. Assess where patient stores medications. Give special attention to pain medications, anticonvulsants, antihypertensives (especially beta-adrenergic blockers), diuretics, digoxin, aspirin, and anticoagulants. Have patient or caregiver keep updated list of medications that can be brought to emergency department if needed. Ask to see medications and/or list used.</p> <p>6 Determine if patient has a family caregiver who helps with self-care or home-management responsibilities. What level of support is provided by caregiver? How frequently is caregiver available? Does patient perceive satisfaction in caregiver’s support? What level of satisfaction does caregiver perceive? Does caregiver have access to and/or take advantage of respite care?</p> <p>7 During discussion observe patient’s dress, nonverbal expressions, appearance, and cleanliness.</p>	<p>Older adults frequently suffer drug interactions from polypharmacy (i.e., concurrent prescribing of multiple medications). Some drugs and/or combinations of drugs place patient at risk for side effects that increase chances of injury as result of physical or cognitive changes. Keeping list of medications allows health care provider easy access to medication history.</p> <p>Relationship between family caregiver and patient helps define how difficult it is to provide caregiving support. Role of family caregiver is often stressful, particularly if individual has other responsibilities such as parenting, work, or school. Determines availability of resource to patient and quality of that support.</p> <p>Conditions such as depression and dementia can result in patient’s inability to attend to personal appearance.</p>
<p>Clinical Decision Point Do not confuse behavioral changes with lack of available resources to maintain hygiene. Also be aware of signs and symptoms of abuse or neglect. Report suspected abuse to appropriate social service agency.</p>	
<p>8 Observe immediate home environment.</p> <p>9 If you suspect cognitive or mental status change:</p> <ul style="list-style-type: none"> a Complete Mini-Mental State Examination (e.g., Folstein’s examination) for dementia. b Complete Short Geriatric Depression Scale (SGDS) for depression. (NOTE: Other depression scales are available, such as the Beck Inventory.) <p>10 If you suspect that patient is at risk for wandering or is wandering, observe for following behaviors (family caregivers might provide information as well):</p> <ul style="list-style-type: none"> • Repeated shadowing or seeking whereabouts of caregiver • Revisiting one destination many times • Inability to locate landmarks or getting lost in familiar setting • Going into unauthorized or private places • Searching for “missing” people or places • Walking with no apparent destination or purpose • Haphazard or continuous moving, walking, or pacing • Walking that cannot easily be redirected <p>11 Assess which current environmental strategies family caregivers are using to deal with wandering (e.g., latches and alarms on doors, visual cues such as STOP signs, constant supervision, and wearing identification band).</p> <p>12 Assess caregiver for signs and symptoms of stress.</p>	<p>Behavioral changes associated with cognitive dysfunction are evident in disorderly home and inappropriate placement of objects (e.g., carton of orange juice placed inside kitchen cabinet instead of in refrigerator).</p> <p>Test screens orientation, attention and calculation, recall, language, and intelligence (Meiner, 2011).</p> <p>SGDS is recommended because it takes 5 minutes to administer and has been tested, validated, and used extensively for depression in older adults (Harvath and McKenzie, 2012).</p> <p>Alerts family and caregivers of potential safety risks. When wandering extends outside safe environment, patient is at increased risk for injury or death.</p> <p>Helps to determine level of intervention necessary. Allows for assessment of how family is dealing with issues of wandering and need for additional outside support.</p> <p>Helps to determine if caregiver is feeling burdened or overwhelmed and is in need of assistance.</p>

NURSING DIAGNOSES

- Acute confusion
- Caregiver role strain
- Impaired home maintenance
- Impaired memory
- Ineffective health maintenance
- Ineffective role performance
- Risk for injury
- Self-care deficit (feeding, toileting, bathing/hygiene, dressing/grooming)
- Wandering

Related factors are individualized based on patient’s condition or needs.

STEP

RATIONALE

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient is able to complete home management responsibilities within existing limitations.
 - Patient receives appropriate combination of medications for diagnosed conditions.
 - Patient is able to perform self-care activities or receives appropriate assistance.
 - Family caregivers describe steps to take to minimize wandering.
 - Patient experiences fewer episodes of wandering.
 - Caregiver identifies community resources for support.
- 2 If patient has difficulty with self-care skills or fine-motor skills, refer family to occupational therapy, homemaker services, or respite care as appropriate.
- 3 Offer assistive devices to make bathing, dressing, writing, and feeding easier (see illustrations).
- 4 Consider patient's level of cognitive impairment when making changes in his or her living environment. Some patients may require only minor adaptations, and others will depend more on assistance of caregivers.
- 5 Determine best time of day for approaches that result in desired response.

Modifications are made that help patient apply remaining cognitive functions.

Assistive devices enable patient to follow prescribed medication regimen.

Interventions preserve patient's autonomy and maximize patient's functionality.

Instruction prepares caregivers with wandering-management strategies.

Wandering-management strategies are effective.

Services available can include respite care, adult day care programs, and support groups.

Occupational therapists provide assistive devices and recommend self-care adaptations. Homemaker services provide added resource for meal preparation and home cleaning. Respite care provides family caregiver temporary rest away from continuous responsibilities.

Assistive eating devices have larger handles, cup handles, or plate edges to help with meals. Assistive clothing uses Velcro, large zippers, and elastic to facilitate independence when dressing.

Retention of patient's independence and autonomy is ultimate goal.

Some patients are more alert and responsive in morning versus afternoon or vice versa.

STEP 3 **A**, Assistive feeding devices. **B**, Assistive device to aid in putting on shoes. (Image used with permission ArcMate Manufacturing Corporation. All rights reserved.)

STEP

RATIONALE

IMPLEMENTATION

- | | |
|---|--|
| <p>1 If patient has difficulty remembering when to perform tasks (e.g., paying bills, taking medicines), help to create a list or post reminder notes in conspicuous location (e.g., bulletin board, front of refrigerator), provide medication container organized by days of week, recommend wristwatch with alarm to signal medication administration times.</p> | <p>Memory function in older adults tends to be preserved for relevant, well-learned material (Kazer, 2011). Lists and organizers help patient cope with memory loss and still safely perform activities.</p> |
| <p>2 When patient has difficulty completing tasks such as writing checks for bills or bringing groceries into home from store, reduce steps it takes to complete task. Consolidate steps or simplify task.</p> | <p>Prevents frustration in completing task and/or forgetting step that leads to task being unfinished.</p> |
| <p>3 Help patient and caregiver determine routine schedule for ADLs such as eating, bathing, daily exercise, home cleaning, and napping. Have large calendar posted in conspicuous area to write in appointments or special planned events.</p> | <p>Consistency creates sense of security and keeps patient oriented to daily activities. Routines are important in providing security, but patient also needs to have option of making changes as necessary (Kazer, 2011).</p> |
| <p>4 Instruct family caregiver to focus on patient's abilities rather than disabilities. Use abilities in modifying approaches to perform daily activities. (e.g., if patient has limited use of right hand, try approaches that maximize use of left hand).</p> | <p>Retains patient's autonomy and sense of self-worth.</p> |
| <p>5 Have caregiver help set up activities so patient can complete task (e.g., chopping vegetables before cooking, placing wash basin on table in bedroom for sponge bath, placing clothes to wear for day on bed, unpacking groceries on countertop for eventual storage, arranging food on plate with items in clockwise orientation [e.g., vegetables at 9, salad at 3, meat at 6]).</p> | <p>Helps patient master task even though unable either physically or cognitively to perform all steps.</p> |
| <p>6 Discuss with patient, caregiver, and health care provider options for scheduling multiple medications:</p> <ul style="list-style-type: none"> a Administer medications that are likely to cause confusion at bedtime. | <p>Drugs sometimes cause physiologic changes that create risk for injury.
Reduces risk for confusion during waking hours that contribute to disorientation and risk for falling.</p> |

Clinical Decision Point Do not recommend this if patient has nocturia, because patient will be at greater risk for falling.

- | | |
|---|--|
| <ul style="list-style-type: none"> b Space antihypertensives and antiarrhythmics at different times to minimize side effects. c When possible reduce number of pain medications used. d Have diuretics taken early in day and not at night. e Discuss with health care provider possibility of taking medications at same time. | <p>These drugs cause blood pressure changes and dizziness, thus increasing risk for falls.
Drugs create sedative effects, increasing risk for falls.
Diuretic effect occurs during day while patient is awake.
If safe and appropriate, taking medications at same time will alleviate problem of patient remembering multiple administration times.</p> |
| <ul style="list-style-type: none"> f Discuss use of medication organizer and dispenser (see illustration). | <p>Organizing medication in daily dispenser helps patient and caregiver avoid medication errors of duplicating or missing medications.</p> |
| <p>7 Teach family caregiver how to use simple and direct communication:</p> <ul style="list-style-type: none"> a Sit or stand in front of patient in full view. b Face patient with hearing impairment while speaking; do not cover mouth. c Use calm and relaxed approach. d Use eye contact and touch. | <p>Relays care and support through therapeutic communication techniques.
Promotes reception of verbal and nonverbal messages.
Patient can see speaker's lips. Prevents voice distortion.</p> <p>Helps to reinforce messages.</p> |

STEP 6f Weekly medication organizer.

STEP	RATIONALE
<ul style="list-style-type: none"> e Speak slowly, in simple words and short sentences. f Use nonverbal gestures that complement verbal messages. 	Enhances understanding of messages.
<ul style="list-style-type: none"> 8 Place clocks, calendars, and personal mementos (e.g., pictures, scrapbooks) throughout rooms within home. Enhance environment with addition of tactile boards or three-dimensional art. 	Maintaining familiar surroundings maximizes cognitive function.
<ul style="list-style-type: none"> 9 Have family caregiver routinely orient patient to who caregiver is and which activities they are going to complete. 	This strategy is useful in patients with progressive dementia. Behavioral symptoms in later stages include delusions, agitation, and hallucinations (<i>Alzheimer's Association, 2012</i>).
<ul style="list-style-type: none"> 10 Be sure that patient has regular naps or rest periods during day. 	Fatigue adds to any mental status changes. Provides patient energy to perform planned activities.
<ul style="list-style-type: none"> 11 Have caregiver encourage and support frequent visits by family and friends. Teach caregiver how to use humor and reminiscing about favorite stories to promote social interaction. 	Participation in social activities prevents boredom and restlessness.
<ul style="list-style-type: none"> 12 Provide safe place for person to wander (e.g., large family room or fenced yard). 	Reduces risk for injury and leaving residence (<i>Kazer, 2011</i>).
<ul style="list-style-type: none"> 13 Use labels to cue or remind person (<i>Alzheimer's Association, 2012</i>). 	Helps reorient patient.
<ul style="list-style-type: none"> 14 Recommend that family of wandering patient install door locks or electronic guards. 	Reduces chance of patient exiting home unsupervised.
<ul style="list-style-type: none"> 15 Create calm, safe setting that is appropriate for patient's abilities (<i>Alzheimer's Association, 2012</i>). 	Prevents falls and minimizes behavioral symptoms.
<ul style="list-style-type: none"> 16 Monitor patient for personal comfort (e.g., hunger, thirst, constipation, full bladder, and comfortable temperature) (<i>Alzheimer's Association, 2012</i>). 	Reduces stimuli that prompt wandering.
<ul style="list-style-type: none"> 17 Install motion detector near exit site, with portable alarm that can accompany caregiver. 	Alerts caregiver to patient's attempt to exit residence.
<ul style="list-style-type: none"> 18 Consider need for full-time care assistance. 	

EVALUATION

<ul style="list-style-type: none"> 1 During follow-up visits ask patient to review home-management activities completed the morning of that day and previous day. 	Determines patient's ability to recall events and evaluates if patient completed planned activities.
<ul style="list-style-type: none"> 2 Review with patient and family caregiver revised schedule for medication administration. 	Evaluates understanding of regimen.
<ul style="list-style-type: none"> 3 Have caregiver keep track of doses patient takes over a 1-week period. 	Tracking doses will confirm if patient is adherent to regimen.
<ul style="list-style-type: none"> 4 Ask caregiver to describe ways that will increase patient's success in completing home-management and self-care activities. 	Measures learning.
<ul style="list-style-type: none"> 5 Have caregiver show schedules of daily routines and review specific approaches used. Observe environment for presence of reality orientation cues. 	Determines caregiver's success in applying information and making environmental changes.
<ul style="list-style-type: none"> 6 Have family caregivers describe options for minimizing wandering. 	Measures learning.
<ul style="list-style-type: none"> 7 Have family caregivers report number of occurrences of wandering. 	Determines if reduction in wandering has occurred.

Unexpected Outcomes

- 1 Patient is unable to complete ADLs as planned.
- 2 Patient experiences drug interaction from multiple medications.
- 3 Caregiver is unable to describe/implement techniques that will improve patient's orientation and ability to complete activities.
- 4 Caregiver is unable to describe/implement strategies to decrease wandering.
- 5 Patient's wandering increases.
- 6 Patient misses medication doses or takes a wrong dosage.

Related Interventions

- Further modifications are sometimes necessary.
- Reassess what occurred when task was not completed.
- Have health care provider evaluate patient's medication regimen.
- Recommend feasibility of pharmacy consultation.
- Reinstruction and discussion are necessary.
- Support for caregiver is sometimes necessary before caregiver can learn how to support someone else.
- Consider that caregiver is not able to provide necessary support; need to analyze other options.
- Reinstruction and discussion are necessary.
- Caregiver may not have resources available to adapt environment.
- Reconsider strategies used.
- Reassess factors prompting wandering.
- Review list of medications and method for administering (e.g., medication dispenser). Reconsider strategies to organize and schedule medications.

Recording and Reporting

- Record assessment of patient's cognitive and mental status, recommended interventions, and patient's and caregiver's response in progress notes.
- Report to health care provider any change in patient's behavior that reflects a decline in cognitive or mental status.

Special Considerations

Teaching

- Instruct family caregiver in signs and symptoms of dementia and depression. If patient's functionality continues to decline, caregiver may choose to learn more ADL support skills (e.g., how to help with hygiene, dressing, transfer and turning, toileting).

Pediatric

- Children with cognitive impairment are often not aware of inherent dangers during play and other activities. Parental supervision is critical.

Gerontologic

- Early diagnosis of the cause of dementia is best for the patient and caregiver so prompt treatment can begin, the patient can be included in treatment decisions as much as possible, and the caregiver has an understanding of the behavior (*Alzheimer's Association, 2012*).
- Consider that a patient may not have a family member who is able or willing to care for him or her. Outside assistance from a professional agency may be required if available; this may also affect patient's ability to stay in his or her home and not be placed in assisted or skilled care.

SKILL 41-3 Medication and Medical Device Safety

At the first home visit, you will review and list all medications and medication bottles that a patient has in their home. It is important to note drug name, dosage, frequency, and route and compare this list with any previous lists, known medications, and discharge instructions. This process is known as medication reconciliation; the goal is to ensure that there are no errors or omissions in a patient's medication regimen, while also assessing if there is any need for change in medications (*Institute for Healthcare Improvement, 2012*).

Patients in the home frequently manage the administration of medications and the use of medical devices such as syringes, blood glucose monitoring equipment, dressing supplies, and even intravenous (IV) devices. This includes administration, storage, and disposal of medications and medical devices. It is critical that a patient administers medications correctly, uses devices properly, and cleans and removes waste from equipment. Infection control is just one safety principle that a patient and/or family caregiver must learn for the home setting. Make sure that patients know regulations regarding waste disposal and follow the procedures consistent with local and federal laws (e.g., the Environmental Protection Agency recommends placing soiled

dressings in securely fastened plastic bags before adding to regular trash).

One of the nurse's responsibilities within the home environment is to help a patient with sensory, mobility, or cognitive deficits. Patients who require special consideration include those with acute sensory or neurologic impairment; those with chronic illness such as diabetes or arthritis; and older adults, who frequently have physical limitations that make manipulating medical devices and dispensing medications difficult. For example, patients with arthritic hands are sometimes unable to open medication containers because of weakness in the hands and the pain created by pressure on the joints.

Delegation and Collaboration

The skill of assessing for and monitoring medication and medical device safety cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Make suggestions that further ensure patient safety regarding the use of basic infection control practices.
- Make suggestions as to how to dispose of sharps, needles, and contaminated supplies.

Equipment

- Colored marking pens
- Labels
- Puncture-resistant sharps container or 2-L hard plastic bottle with cap

- Duct, masking, or adhesive tape
- Assistive devices (e.g., syringe magnifier)
- Medication organizers

STEP**RATIONALE****ASSESSMENT**

- | | |
|---|---|
| <p>1 Assess patient's sensory, musculoskeletal, and neurologic function (see Chapter 6).</p> <p>2 If family caregiver provides routine assistance, assess his or her function as in Step 1.</p> <p>3 Assess patient's medication regimen and length of time that patient has been receiving each drug.</p> | <p>Reveals any deficits that will affect preparation and use of medications or medical devices.</p> <p>Determines level of assistance that caregivers can provide.</p> <p>Determines complexity of medication regimen and how familiar patient is with regimen.</p> |
|---|---|

Clinical Decision Point *Be sure that medication labels are not confusing for a patient. For example, the Spanish word for “eleven” is written as “once.” A Spanish patient could confuse a medication direction that requires them to take a medication 1 time a day as 11 times a day.*

- | | |
|--|--|
| <p>4 Ask patient to show you where medications are stored in home. Look at each container.</p> <p>5 Assess temperature of storage area.</p> <p>6 Have patient describe daily schedule for drug administration and whether there are any problems in following that schedule.</p> <p>7 If patient self-administers injections, ask to see where he or she stores supplies and what he or she uses to dispose of used syringes and needles.</p> <p>8 If patient uses glucose-monitoring device, ask to see where monitor, lancets, and glucose strips are stored. Also ask about how patient disposes of lancets.</p> | <p>Determines condition and labeling of containers.</p> <p>Medication should not be stored in extreme heat. Insulin should be kept in cool place.</p> <p>Helps to reveal patient's adherence to or misunderstanding of instructions.</p> <p>Determines sterility of equipment and whether method of disposal creates risk to patient or family for needlestick injuries.</p> <p>Allows nurse to examine cleanliness of equipment, sterility of lancets, and condition of glucose strips. Sharps should be disposed of in puncture-proof container.</p> |
|--|--|

NURSING DIAGNOSES

- | | | |
|---|---|---|
| <ul style="list-style-type: none"> • Deficient knowledge regarding medication safety | <ul style="list-style-type: none"> • Ineffective health maintenance • Noncompliance | <ul style="list-style-type: none"> • Risk for infection • Risk for injury |
|---|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient and family caregiver discuss principles of medication safety. • Patient and caregiver prepare medications independently. • Patient and caregiver identify correct conditions for storing medications, medical devices, and supplies. • Patient and caregiver dispose of used medical equipment and supplies correctly. | <p>Nurse provides knowledge base for safe medication administration.</p> <p>Adaptations successfully accommodate patient's and/or family caregiver's deficits in handling and manipulating equipment. Instruction focuses on ensuring infection control measures.</p> <p>Appropriate receptacles and methods for disposal are made available.</p> |
|--|---|

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Educate patient and family caregiver in principles to ensure that medications are safe to use:</p> <p>a Never take medicine prescribed for another member of household (Centers for Disease Control and Prevention [CDC], 2012).</p> <p>b Do not take any medicine more than a year old or past expiration date on container.</p> <p>c Do not place different medicines in same container.</p> <p>d Do not place medications in containers different than their original ones.</p> | <p>Medications must be of full strength and used for appropriate pharmacologic reason to have therapeutic benefit.</p> <p>Expired medication is sometimes toxic or no longer effective.</p> <p>Prevents accidental “mix-up” of medications and medication error. Prevents accidental “mix-up” of medications and confusion as to expiration dates.</p> |
|--|--|

STEP

RATIONALE

- e Always finish prescribed medication; do not save for future illness. Prevents underdosing or inappropriate dosing.
 - f Wash hands before and after administering/taking medication. Contaminated hands are source of infection transmission.
- 2 Recommend approaches for preparation of medications:
- a For patients with weakened grasp or pain of hands and fingers, have local pharmacist place medications in screw-top container. Tops of childproof containers are difficult to remove, especially if hand and finger grasp is weakened.

Clinical Decision Point *If patient has children or grandchildren who have easy access to medication storage area or patient's purse, be sure that medications are stored in secure place.*

- b For patients with visual alterations, have pharmacy type larger labels on all medication containers. Ensures that patient is able to read drug name and dosage schedule clearly.
- c For patients who are legally blind, have Braille labels placed on medication containers. Labels embossed with drug name, strength, and prescription numbers are easy to read for patient trained in use of Braille.
- d For patients taking multiple medications, introduce color-coding system. Use same color for drugs that patient needs to take at same time. Mark tops of bottle caps with colored marking pen. Technique helps ensure that patient takes correct drugs and doses at correct times of day.
- e Provide specially designed syringes with large numerals or syringe magnifier for patients with visual alterations (see illustration). Ensures that accurate dose of drug is prepared in syringe.
- f For patients who have difficulty manipulating syringes, offer a spring-loaded needle insertion aid. Delivers injection safely without manipulation of plunger.

Clinical Decision Point *Instruct family caregivers in knowing what to do following a needlestick injury: Wash the affected area thoroughly with soap and water and dry. If patient has acquired immunodeficiency syndrome (AIDS), hepatitis, or other communicable disease, caregivers should pursue appropriate laboratory testing.*

- g Teach caregivers how to properly draw up prescribed volume of medication into syringe. When necessary, have caregiver prepare extra prefilled syringes for patient's use when caregiver is absent. Ensures that caregiver knows proper preparation techniques. Ensures that patient has access to injections. Watch patient and/or caregiver draw up and dispense medications to determine if more teaching is needed.
- 3 Recommend approaches for medication and supply storage:
- a Store medications in safe place, preferably in kitchen. Moisture in bathroom may cause medications to decompose.
 - b Keep liquid medications and parenteral drugs, especially insulin, in cool place. Prevents decomposition of drug.

Clinical Decision Point *Although manufacturers recommend storing insulin in the refrigerator, injecting cold insulin can sometimes make the injection more painful. To avoid this, many providers suggest storing the bottle of insulin being used at room temperature. Insulin kept at room temperature will last approximately 1 month. Remember, however, to store extra bottles in the refrigerator if a patient buys more than one bottle at a time to save money (ADA, 2012). If insulin is stored in refrigerator, be sure that drug is in a bin or container, away from food.*

STEP 2e Syringe with magnifier.

STEP	RATIONALE
c Keep medical supplies such as syringes, dressing supplies, and glucose meter in airtight container (e.g., plastic storage bin) and store in cool place such as bedroom closet.	Ensures that supplies are not exposed to moisture or other contaminants.
d Instruct patient and caregiver to use new needle with each medication administration.	Multiple use of same needle puts patient at risk for infection.
4 Review for patient and caregiver proper techniques for disposal of medications, “sharps,” and disposable medical supplies:	
a Discard unused portions of drugs or outdated drugs in a bag containing coffee grounds or kitty litter.	Ensures that no one in household uses drug not prescribed for their use or drugs that will be ineffective pharmacologically. Ensures safe disposal to prevent outsider from acquiring medications.
b Obtain sharps container from medical supply store or IV equipment supplier. (If finances are limited, have patient use small-neck plastic bottle such as soda bottle.) Dispose of all needles and lancets in container.	Puncture-proof container prevents exposure to contaminated needlestick. Small-neck container makes it difficult for anyone to easily retrieve used needle or sharp.
c Caution against filling sharps container to point where needles protrude out opening. Discard when three-fourths full, securing top with duct tape or adhesive tape.	Prevents needlesticks.
d Store sharps container in area inaccessible to children.	Prevents injury to child.
e Dispose of soiled dressings, used glucose testing reagent strips, and IV tubing in separate, sealed, plastic garbage bag. Place in second plastic bag (double bagged), and discard appropriately as trash.	Prevents contamination with other items in home. Minimizes chances of caregiver being exposed to infectious waste.
f Consult local public health department or community authorities regarding proper way to dispose of waste, including some medications.	Most communities have strict guidelines for waste and medication disposal.

EVALUATION

1 Have patient and/or caregiver describe steps to take to ensure that medications are safe to use.	Demonstrates learning.
2 Observe patient and/or caregiver prepare and administer medication dose.	Evaluates ability to physically manipulate medications and necessary equipment.
3 Observe home setting for location of medications and supplies.	Evaluates patient’s and/or caregiver’s adherence to recommendations.
4 Have patient describe how sharps or medical equipment is discarded.	Demonstrates learning.
5 Do pill counts (pills remaining in containers) at successive intervals such as twice a week for 2 weeks.	Helps to verify that patient takes correct number of medications over period of time.

Unexpected Outcomes

- 1 Patient and/or family caregiver is unable to recall principles for safe use of drugs.
- 2 Patient and/or caregiver has difficulty or is unable to prepare and self-administer medication.
- 3 Medications and medical devices are not stored in secure or appropriate location.
- 4 Sharps and disposable medical equipment are not disposed of properly.
- 5 Excess or insufficient number of pills found during pill count.

Related Interventions

- Reinstruction necessary, or patient and caregiver need chance to ask more questions regarding benefit of precautions.
- Offer written, simple, and clear instructions.
- Offer further assistance in setting up equipment.
- Offer assistive aids.
- Reinstruct in steps used to prepare medication.
- Assess whether patient chooses to store items conveniently rather than safely or has limited resources.
- Reinstruction and discussion are necessary.
- Provide reinstruction.
- Arrange to provide appropriate containers.
- Review with patient and caregiver daily drug prescribed. Reevaluate use of dosage reminders.
- Notify health care provider.

Recording and Reporting

- Record instructions and recommendations to patient and caregiver and results of return demonstrations in progress notes. Notify health care provider of unsafe situation.

Special Considerations

Teaching

- Instruct patients in care of linens. If linens are contaminated with microorganisms, they should be decontaminated by washing with soap/detergent and hot water 140° F (60° C). If patient is using lower temperature washers (<113° F [45° C]),

instruct him or her to add hypochlorite bleach to effectively decontaminate linens (Reynolds, 2009).

Pediatric

- It is vital to keep medications and other equipment such as cleaning products out of the reach of children (Home Safety Council, 2011).
- All medicines and cleaning products should have child safety caps (Home Safety Council, 2011).
- If teaching self-management skills, include adult supervision and input. Never refer to medications as candy.

Critical Thinking Exercises

Mrs. James is a 79-year-old woman who lives with her 84-year-old sister in a split-level four-bedroom home. Mrs. James has a history of metastatic bone cancer and was recently diagnosed with heart failure. In addition to taking multiple oral medications, she undergoes weekly intravenous chemotherapy for progression of her cancer. Mrs. James has no other family closer than a 2-hour drive, and her older sister has advanced glaucoma and diminished hearing. Both women refuse to move from their home, even at the urging of Mrs. James' three children to move closer to one of them. Mrs. James no longer drives, nor does her sister; and she is unable to climb the few steps needed to move beyond the lower living level of the home. Because of this immobility, Mrs. James cannot reach the upstairs bathrooms, which contain showers, and she relies on her older sister to help care for her and maintain the house on a daily basis.

- Based on her medical history, offer three reasons why Mrs. James is at risk for falls.
- Mrs. James' children expressed concern that their mother is getting confused about her medication regimen. How would you approach assessing the patient's adherence to the regimen?
 - Ask her to show you where medications are stored in home.
 - Have her describe daily schedule for drug administration.
 - Determine caregiver's knowledge of medication schedule.
 - Examine the condition of storage area for medications.
- Mrs. James' children tell you that they are concerned about their mother's and aunt's safety, "We worry that they will get injured. We've tried to convince them to move to a one-level apartment near us, but they refuse." What advice might you give the family?

REVIEW QUESTIONS

- A woman found wandering in her nightclothes is also dirty, but does not appear to have any injuries. Which topics would a home care nurse include in his discussion with the patient and her family? (Select all that apply.)
 - The medications she is taking and who supervises her
 - Any decrease in cognitive function seen within the past few months
 - Whether she or someone else pays her bills
 - Any history of wandering
 - Always have a current photograph available
 - When she was last seen by her health care provider
- A 50-year-old teacher with severe rheumatoid arthritis is noting some changes in her mobility. Which simple screening examination could be used to detect difficulties with balance or gait?
 - The Mini-Mental State Examination (MMSE)
 - The Timed Get Up and Go (TUG) Test
 - The SPLATT screening tool
 - A fall diary
- A home care patient is changing a dressing daily on a foot ulcer. In what type of container should the nurse teach the patient to place the old dressing for disposal?
 - A wide-mouth plastic bottle
 - A small plastic container
 - The standard garbage can
 - A plastic garbage bag placed into a second plastic bag
- A patient has recently noticed that she has near-miss falls more often. Her health care provider recommended that she begin an exercise program. When teaching this patient, the nurse would explain that a program with which focus would be most effective for her?
 - Endurance exercises
 - Maintaining range of motion
 - Incorporating the patient's activity patterns
 - Strength, gait, and balance
- An older adult with diabetes mellitus asks the home care nurse how to maintain her diabetic supplies. The nurse knows that teaching was successful when the patient states she should: (Select all that apply.)
 - Keep the used syringes in a small-neck bottle such as a screw-top soda bottle.
 - Keep the insulin vials in the refrigerator until shortly before they are needed.
 - Keep the insulin vials on the kitchen counter until all the insulin has been used.
 - Keep the glucose meter strips in an airtight bag in the closet until they have been used.
- While visiting a patient at her home, the patient complains of many trips to the bathroom at night, which "causes her to be light-headed and very tired all day long." Which action should the nurse take first?
 - Obtain an order for a bedside commode
 - Suggest the use of night-lights throughout the house
 - Obtain a complete cultural history of the patient
 - Determine if she is taking a diuretic
- A patient with beginning dementia still wants to be independent and cook one meal per day. Which suggestion by the nurse would provide anticipatory guidance regarding safety?
 - Keep a fire extinguisher in the garage in case of fire.
 - Make sure that you have enough light in the kitchen.
 - Use a loud timer to alert you that food is ready.
 - Keep everything you need in cabinets with a lock.
- During a home visit the nurse finds one of her patients to be unusually confused and dirty. What is the most appropriate action for the nurse to take initially?
 - Observe the home environment for cleanliness and availability of supplies
 - Notify the appropriate state agency that the patient is being abused
 - Call 9-1-1 and have the patient taken to the hospital for evaluation
 - Do a brief assessment of the patient's cognitive and mental status

- 9 An older patient with hearing difficulty lives alone at home. She is taking seven different medications daily at different times of the day and states to the nurse that she is frustrated trying to remember all of her pills and is considering stopping some of the medications. The nurse helps the patient organize the medication by:
 - 1 Making a visual chart code of the medications so the patient can identify them by color and shape of pill.
 - 2 Taking the medications away from the patient and returning each day to administer them as ordered.
 - 3 Bringing the patient a medication pill organizer and helping her fill the organizer for 1 week.
 - 4 Calling the patient's daughter and instructing the daughter that it is now her responsibility to give her mother daily medication.
- 10 Both members of an older couple have visual impairments and joint stiffness and pain in their upper extremities. Which activities should the daughter, who lives nearby, suggest to help them maintain appropriate nutrition and some independence?
 - 1 Cutting up vegetables and fruits and storing in screw-top jars in the refrigerator
 - 2 Arranging the food on the plate with items in a clockwise orientation
 - 3 Placing serving-size food items in easy-to-open packages
 - 4 Taking the parents grocery shopping every week so they can plan their menus

KEY TERMS

Antipyretic	Gastrostomy feeding tube	Infusion pump	Transtracheal oxygen
Clean technique	High-Fowler's position	Nasogastric feeding tube	catheter
Dementia			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify factors that influence clients' abilities to learn and care for themselves at home.
- Discuss the collaborative nature of home care teaching.
- Assess safety factors that may impair or prohibit a client's ability to perform skills in the home setting.
- Discuss situations and conditions that require a client and/or family to learn skills that support and achieve health maintenance.
- Choose appropriate teaching strategies to use in the home setting.
- Implement and evaluate appropriate learning strategies that support clients' ability to care for themselves in the home.

The health care delivery system has changed, shifting where clients receive care from inpatient facilities to the home. Although acute and long-term care settings continue to provide inpatient services, many clients recover from or are treated for illnesses in their homes. Clients assume greater responsibility for managing their own care, resulting in a greater demand for home care nurses. A home care nurse provides information and resources by collaborating with a client or family caregiver to address the client's health needs, preferences, and values and incorporating their strengths, skills, and capacity (Wolff et al., 2009).

Client teaching is an essential part of nursing practice. All nurses, including home care nurses, have an ethical responsibility to teach their clients. Information needs to be relevant, current, and clearly presented. The Joint Commission's "Speak Up" initiative (TJC, 2011) outlines information for clients related to their rights and role in health care. Included are the rights to be informed about care they will receive, make decisions about their care, refuse care, be listened to, and be treated with courtesy and respect. The home care nurse provides information in a manner appropriate for a client to understand and clarifies information provided to the client by

other health care providers, therefore becoming the client's primary source of information.

Home care nurses thoroughly assess factors that affect a client's abilities and willingness to manage self-care. Determine what your clients want to know, how they learn, and what motivates them to learn new information (Meade, 2011). Trust must be established before teaching can begin, and you must remember that you are in their home environment and not an acute care setting. Be respectful of a client's surroundings and time. In addition, make an effort to connect the health message to the client's everyday events and real-life situations and use teach-back methods to ensure client comprehension (Meade, 2011). Teach-back is a way to confirm that you have explained to patients what they need to know in a manner that the patients understand. Patient understanding is confirmed when they explain a topic back to you. For example, after a home health nurse has completed instruction with a patient with diabetes, a teach-back method would include the question, "Now tell me what you do if your blood sugar is lower than 70."

An additional challenge facing home care nurses today is health literacy. Clients who are illiterate often have difficulty reading, writing, and speaking English. *Healthy People 2020* (US Department of Health and Human Services [USDHHS], 2012) has set an objective to improve the health literacy of Americans. To accomplish this, the USDHHS aims to increase the number of clients who report receiving easy-to-understand instructions about managing their illness or health, the rate of providers who ask their clients if they understood the instructions given, and the number of persons reporting that their health care provider always offered assistance in completing forms. It is important for you to remember that many clients have difficulty reading and understanding medical terminology. And no matter what their educational level, the health care system in general is confusing (Brown, 2009). Plan to spend a sufficient amount of time teaching your clients and ensure that they understood your teaching and the information provided. Reinforce verbal instructions with printed, culturally appropriate client education information and use other audiovisual materials when possible.

Home care nurses are creative and adapt teaching to meet each client's unique physical, psychosocial, and cultural needs. It is very important for a client to become an active partner in the plan of care. Refer him or her to community resources to help overcome barriers (e.g., lack of transportation or inadequate funds for medications) and collaborate with the client or caregivers and interdisciplinary teams (e.g., pharmacists, physical therapists, and occupational therapists). Many times a variety of other social services and health-related organizations are involved in making a client's home care plan successful. For collaboration to be successful, identify who is involved in the client's care and establish mutual trust and respect through open and honest communication. When home care nurses successfully implement individualized teaching plans, clients improve their quality of life, need fewer health care provider visits, reduce their health care expenses, and regain health or gain more control over illness.

EVIDENCE-BASED PRACTICE

Clients must understand how to manage their health and illnesses, take discharge medications correctly and safely, and perform related care at home. In discharge planning and home care you will help clients and caregivers make well-informed decisions about their health practices (Meade, 2011). As a teacher and client advocate, you can engage the client or caregiver as participants in care.

With clients discharged sooner and with more health care needs, the home care nurse is challenged to teach them and help them feel secure before and following discharge. A recent study that examined client or caregiver uncertainty surrounding discharge found three main themes: uncertainty through lack of preparation for discharge, uncertainty through lack of information, and uncertainty of "being at home" (Boughton and Halliday, 2009). Another study that examined clients' experiences of living at home on mechanical ventilation provides insight into what clients valued in their home care providers. Clients first wanted an increased quality of life and sense of control; and second, they valued competent health care providers and quality client teaching (Ballangrud et al., 2009). Several effective nursing measures facilitate a client's transition from the health care environment to home.

- Use concise, clear, and consistent information to reduce anxiety in clients and caregivers.
- Use clear written and verbal information to help lessen client or caregiver stress and anxiety and instill a sense of confidence and control when teaching clients and caregivers how to perform specific nursing skills in the home setting (Pittman, 2009).
- Offer clients an opportunity to maintain some control in their lives and health care preferences (Ballangrud et al., 2009).
- Spend quality time with clients and their caregivers and remain organized when providing direct care and client education.
- Provide routine follow-up to determine client or caregiver understanding and/or need for further education about specific home care interventions (Ballangrud et al., 2009).

CLIENT-CENTERED CARE

With appropriate and comprehensive home care teaching, clients can become empowered, resulting in better overall health outcomes. Your client is your primary concern and consideration when teaching. Involve family caregivers as appropriate to ensure their understanding and ability to provide necessary assistance.

Consider principles of cultural diversity when caring for clients in their homes. Know the unique characteristics of the community in which a person lives so you can readily access needed resources. Respect each individual's cultural background and beliefs and his or her ability to understand instructions developed outside of his or her native language. When educating clients of different ethnic groups, be aware of the distinctive aspects of each culture, being careful not to stereotype clients. Collaborate with other nurses and educators to help deal with cultural diversity and ask for help from the people in the cultural group to share values and beliefs.

Respectful communication includes addressing a client in an appropriate manner and using acceptable body language (e.g., avoid direct eye contact) (Jett, 2010). Use an interpreter if you speak a language different from that of the client or if cultural tradition prohibits the client from talking to you directly. The meanings of words can change when translated (e.g., "risk" into Spanish is "riesgo"). This word does not carry the same weight as it does in English; thus you need to explain the *concept* of "danger" for pregnant Mexican women rather than simply translating the word (Scrimshaw, 2009).

Follow ethical principles in your approach to care. Do not limit the information a client can receive, make invalid or unreliable judgments about what a client can learn, or assume that a client should learn to accommodate an unjust treatment (Redman, 2008). Consider alternative teaching methods such as role playing,

because often adults do not learn from reading brochures; they may learn by rehearsal, practice, and role playing (McKinney, 2010). Also consider different delivery approaches (e.g., Internet or DVDs) because more adults are accessing the Internet for health information.

Safety Guidelines

- 1 Assess if a client in the home setting is able to safely perform a skill. If he or she is unable to execute a skill independently,

identify a family caregiver who will help provide it safely in the home setting.

- 2 Assess and determine if the client has home medical equipment and knows how to use it properly for safe and successful self-care management.
- 3 Include teaching interventions for other persons in the household who positively or negatively influence the client's self-care management.
- 4 Provide an opportunity for client or family caregivers to demonstrate skill.

SKILL 42-1 Teaching Clients to Measure Body Temperature

An elevation in body temperature sometimes may be an early warning sign of serious health problems. Clients susceptible to temperature alterations (e.g., immunosuppressed clients) or their family caregivers need to know how to measure temperature correctly so they can seek medical attention earlier. Parents need to know how to measure their children's temperature because children can develop high fevers very quickly; older adults or their caregivers need to know the techniques for temperature measurement because older adults have impaired temperature control mechanisms. Teach clients and family caregivers the skills of measuring body temperature and technique to lower temperature when a fever occurs at home.

A variety of body temperature thermometers are currently available, including mercury, disposable single-use, electronic digital, temporal, and tympanic thermometers. The Environmental Protection Agency (EPA) discourages the use of mercury thermometers. If a mercury thermometer breaks or is not disposed of properly, the mercury vapor gets into the air, posing a major health risk in the home and community (EPA, 2011). Educate clients about the environmental hazards associated with mercury in the home and encourage them to purchase mercury-free thermometers.

Help a client choose the most appropriate thermometer to use in the home based on his or her normal dexterity, vision, and

financial resources. For example, a client with visual impairment from glaucoma or retinopathy is able to read a thermometer with a large digital display more easily. The need for an oral, rectal, or axillary temperature depends on the client's age and health status (see Chapter 5).

Delegation and Collaboration

The skill of teaching clients to measure body temperature cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Inform the nurse of client or caregiver concerns about measuring body temperature.

Equipment

- Thermometer
- Disposable probe cover (if needed)
- Water-soluble lubricant (for rectal measurements)
- Paper or logbook and pencil or pen if frequent measurements are to be taken
- Disposable clean gloves (for rectal temperature taken by a caregiver)

STEP RATIONALE

ASSESSMENT

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Assess client's or family caregiver's ability to manipulate and read thermometer. Have client put on eyeglasses if necessary. 2 Assess client's knowledge of normal temperature range, symptoms of fever and hypothermia, and client's risk for body temperature alterations. 3 Assess client's ability to determine appropriate type of thermometer to be used in varying situations (see Chapter 5). 4 Assess client's or caregiver's previous knowledge and experience in measuring temperature and maintaining thermometer. Have client or caregiver perform return demonstration if they indicate ability to measure temperature. | <p>Physical restrictions in handling or reading thermometer prevent client from being able to read thermometer and often require instructing caregiver instead of client.</p> <p>Identifies client's ability to initiate preventive health measures and recognize alterations in body temperature.</p> <p>Determines knowledge of age-related or medical conditions that determine selection of temperature.</p> <p>Allows assessment of client's or caregiver's knowledge and use of safety precautions, aseptic technique, and time period for insertion.</p> |
|---|---|

NURSING DIAGNOSES

- | | | |
|---|--------------------------------|--|
| • Deficient knowledge regarding temperature measurement skill | • Ineffective thermoregulation | • Risk for imbalanced body temperature |
| | • Risk for infection | |

Related factors are individualized based on client's condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Client or family caregiver is able to correctly measure body temperature. • Client or caregiver demonstrates proper cleaning and storage of equipment. • Client or caregiver states normal temperature range and factors that affect temperature, signs and symptoms of fever and hypothermia, and measures to take with abnormal temperatures. <p>2 Select setting in home where client is most likely to measure temperature.</p> <p>3 Discuss and demonstrate with client or caregiver normal temperature ranges; instruct caregiver to remain with client during measurement if age or physical status requires.</p> | <p>Indicates that skills are learned.</p> <p>Prevents transfer of microorganisms and maintains integrity of thermometer.</p> <p>Cognitive learning is achieved.</p> <p>Considers client's preferences; is responsive to client's needs (Romano, 2009a).</p> <p>Learning by doing; active participation is more effective than passive models (Meade, 2011).</p> |
|---|---|

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Demonstrate steps of thermometer preparation, insertion, and reading. Provide rationale for steps to client or family caregiver.</p> <p>a Instruct client to take oral temperature 20 to 30 minutes after smoking or ingesting hot or cold liquids or foods and to wait at least an hour after a hot bath or vigorous exercise. Explain indications for selecting a temperature site other than oral.</p> <p>b Perform hand hygiene. Instruct caregiver to wear clean, disposable gloves.</p> <p>c Instruct client or caregiver on proper way to position patient for a temperature measurement (see Chapter 5).</p> <p>d Demonstrate temperature measurement technique and have client or caregiver perform each step with guidance. Do not rush him or her.</p> <p>e Explain any special precautions in using thermometers: oral thermometer must be placed in sublingual pocket; rectal thermometers must be lubricated with water-soluble lubricant; use rectal thermometer only for measuring rectal temperatures; never force a rectal thermometer into rectum.</p> <p>f Discuss the typical time frame needed for a temperature to register (based on thermometer type) and how to take a reading.</p> <p>g Teach proper method for removing, cleaning, and storing thermometer (when applicable) and select suitable storage location.</p> <p>2 Discuss common symptoms of fever: warm, dry, flushed skin; feeling warm; chills; piloerection; malaise; and restlessness.</p> <p>3 Discuss common signs and symptoms of hypothermia: cool skin, uncontrolled shivering, loss of memory, and signs of poor judgment. Explain that persons with inadequate home heating, older adults, or those unaware of potential dangers of cold conditions are at risk.</p> <p>Instruct clients to dress warmly in layers, avoid extreme cold, and ingest warm liquids.</p> | <p>The eventual evaluation of psychomotor skill is measured through client's performance and ability to follow directions/instruction (Romano, 2009b). Adults learn best when they understand purpose of procedure.</p> <p>Waiting at least 15 minutes after drinking hot or cold liquids or foods improves accuracy of temperature reading (AAP, 2012).</p> <p>Client and family caregiver must be knowledgeable of infection prevention techniques.</p> <p>Improves accuracy of readings.</p> <p>Allows for correction of errors in technique as they occur and for discussion of potential consequences of errors.</p> <p>Ensures accurate reading and avoidance of injury to client.</p> <p>Ensures accurate reading.</p> <p>Prevents transmission of infection. Thermometer is stored properly so it does not break or become inaccurate when not in use.</p> <p>Client or caregiver needs to recognize onset of fever in self or family member for early detection and intervention.</p> <p>Client or caregiver needs to recognize onset of hypothermia in self or family member for early detection and intervention.</p> <p>Helps minimize risk of hypothermia by trapping body heat (McLafferty et al., 2009).</p> |
|---|---|

Clinical Decision Point Teach client to take temperature after chills/shivering subsides to obtain an accurate temperature.

STEP	RATIONALE
<p>4 Discuss importance of notifying health care provider when temperature elevations occur. Review common therapies for temperature reduction that are safe to perform at home, including when to use antipyretics, exposing skin to air, reducing room temperature, increasing air circulation, applying cool moist compresses to skin (e.g., forehead), and drinking fluids (Hockenberry and Wilson, 2011).</p> <p>5 Provide set of written guidelines for client's reference at appropriate level of health literacy.</p> <p>6 Give client or caregiver logbook or piece of paper to time and record temperature if frequent monitoring is required. Instruct client to use written record to report temperatures to health care provider.</p>	<p>Treating fever enhances client comfort. Lowering temperature can reduce risk of febrile seizures in children (Hockenberry and Wilson, 2011).</p> <p>Clients prefer written materials that are clear and concise; graphics can be used to enhance a point (Pittman, 2009).</p> <p>Keeping organized record of temperatures helps client validate and report temperature fluctuations to health care provider.</p>

EVALUATION

<p>1 Have client or family caregiver independently demonstrate technique for temperature measurement, including body placement and ability to read thermometer three separate times.</p>	<p>When psychomotor skill is performed with confidence and proficiency, it demonstrates mastery of skill (Romano, 2009a).</p>
<p>2 Ask client or caregiver to identify normal temperature range and influence of smoking and hot and cold liquids or foods on oral readings; discuss safety implications for temperature measurement.</p>	<p>Measures cognitive learning and confirms understanding of information.</p>
<p>3 Have client or caregiver describe common signs and symptoms of fever and hypothermia and methods for control.</p>	<p>Measures cognitive learning.</p>
<p>4 Watch client or caregiver clean and store equipment.</p>	<p>Proper cleaning prevents bacterial growth, and proper storage preserves accuracy of thermometer.</p>
<p>5 Watch client record temperature values and times in logbook. Review client's logbook periodically to ensure that temperatures are being recorded correctly.</p>	<p>Health care providers make changes in client care based on information provided by client. To ensure that changes are made appropriately, client needs to record accurate information.</p>

Unexpected Outcomes

- 1 Client or family caregiver is unable to measure temperature, clean and store thermometer correctly, or verbalize knowledge about fever and temperature measurement.
- 2 Client reports that mercury glass thermometer has broken.

Related Interventions

- Ask client or caregiver to describe difficulties experienced while performing temperature measurement.
- Use different teaching strategy.
- Plan for client to perform return demonstration during next scheduled home care visit or plan to teach caregiver.
- Instruct client in steps to safely dispose of thermometer (Box 42-1).

BOX 42-1 Steps to Take in the Event of a Mercury Spill

- If possible, close the room off from the rest of the house and increase ventilation in the affected room by opening windows or turning on a fan.
- Put on rubber, nitrile, or latex gloves. Do not touch mercury. Do not allow children to help clean up the spill.
- Pick up glass pieces, place them in a folded paper towel, and place glass and towel into plastic zip lock bag.
- Use a squeegee or cardboard to gather mercury beads. Use an eyedropper to collect or draw up visible mercury beads. Slowly and carefully squeeze mercury onto a damp paper towel. Place the paper towel in a zip lock bag and secure. Then put shaving cream on a small brush and "dot" the area or press duct tape in area to pick up smaller beads.
- Place mercury, material used to pick up mercury, and broken glass in a plastic zip lock bag. Triple bag the contaminated objects (place in a total of three sealed bags).
- Place gloves, mercury, and all other wastes into a trash bag. Secure and label the bag.
- Call local health department to determine where to dispose of mercury safely.
- If possible, keep windows open and room well ventilated for at least 24 hours after clean up.
- Instruct client not to use a vacuum cleaner, a broom, or household cleaners when cleaning up mercury spill. Also instruct client not to put mercury down the drain or place contaminated clothing into the washing machine.

Data from EPA: *Mercury releases and spills*, 2011, available at <http://www.epa.gov/mercury/spills/index.htm#thermometer>; accessed April 5, 2012.

Recording and Reporting

- Record information taught and client's return demonstration in home care record.
- Record temperature in home care record and home documentation system (e.g., logbook).
- Report high and low temperatures to health care provider.

Special Considerations

Teaching

- Instruct client or family caregiver to never force thermometer into rectum or use rectal thermometer after rectal surgery, when the client has a rectal disorder such as tumor or severe hemorrhoids, when the client has a low platelet count, or when it is difficult to position client for proper thermometer placement.
- Use caution in recommending aspirin or any other over-the-counter (OTC) drug or antipyretic medicine in clients whose conditions contraindicate their use (e.g., gastric ulcer, bleeding tendencies, allergic reactions, drug interactions, liver or kidney dysfunction). Encourage client to contact health care provider before using over-the-counter antipyretics.
- Instruct client to never use sponging with isopropyl alcohol to lower fever because of neurotoxic effects (Hockenberry and Wilson, 2011).
- Always leave a phone number and instructions about how to reach home care nurse if needed.

Pediatric

- Stage of growth and development of child will determine site of measurement and type of equipment used (see Chapter 5).
- Different types of thermometers are available for use with children (e.g., temporal artery, tympanic). Reliability of these different thermometers varies; ensure that parents know how to use the equipment correctly and detect the signs and symptoms of a fever (Hockenberry and Wilson, 2011).
- Teach the family to take a child's temperature whenever he or she feels warm to the touch, even if the temperature was recently normal (Hockenberry and Wilson, 2011).

Gerontologic

- Oral temperature for older adults often ranges from 35° to 36.1° C (95° to 97° F); therefore a normal temperature range for adults sometimes reflects a fever in the older adult (Ebersole et al., 2008).
- Older adults are more sensitive to temperature changes and tend to demonstrate symptoms of delirium or dementia with variations of body temperature.
- Altered internal temperature regulation or dehydration occurs frequently in frail, debilitated clients. Temperature measurement becomes very important to prevent severe states of hypothermia or hyperthermia.
- Consider common age-related sensory changes in the older adult and direct teaching strategies to compensate for any alterations (e.g., a magnifying glass to read thermometer).

SKILL 42-2 Teaching Blood Pressure and Pulse Measurement

Clients with a variety of illnesses such as cardiac, kidney, or vascular diseases are susceptible to wide variations in their blood pressure (BP) and pulse. They benefit from knowing how to assess their own BP and pulse because they are able to seek medical attention early when readings vary from their acceptable ranges. In addition, healthy people who exercise learn how their body responds to exercise and are able to determine appropriate exercise plans based on knowing what their pulse and BP are before, during, and after exercise.

Research related to home monitoring of BP has illustrated the importance of regular monitoring outside of acute care settings and medical offices so the provider can treat clients with hypertension appropriately (Powers et al., 2011). If treatment is based on single readings during an office visit, providers do not see an accurate picture of a client's health. To gather this essential information about clients living at home, you will teach them to measure their BP and pulse regularly and interpret readings that are outside of their individualized normal values. For example, teach clients about factors that affect the accuracy of BP readings such as cuff placement, movement of the tubing, speaking during measurement, and position and movement of the extremity or body.

Aneroid sphygmomanometers are available to measure BP in the home (see Chapter 5). Aneroid manometers are safe, lightweight, compact, and portable. In the home many clients choose to use commercial automatic electronic BP devices. These devices may measure pulse rate and produce a BP measurement without needing to use a stethoscope. The devices involve placing a cuff around the arm, the wrist, or a fingertip. A reading is displayed electronically for the client. Electronic BP monitors are often easier to use, but their accuracy compared to manual BP monitoring is still a focus of debate. The level of skill of the person measuring the BP has been cited as a factor that contributes to inaccurate manual readings, thus providing one potential benefit of electronic

monitors (Harvard Health Publications, 2011). It is essential for clients to keep record of all their BP readings and compare those obtained by a health care provider with their electronic monitor to assess the accuracy of readings.

Additional factors that affect the accuracy of BP monitoring are cuff size and placement (Tomlinson, 2010). Have clients learn to place a cuff directly on their skin, not over clothing. Blood pressure cuffs that are too small tend to overestimate BP, whereas cuffs that are too large tend to underestimate it (Tomlinson, 2010). Not all electronic home BP monitors come with interchangeable cuff sizes, which can complicate BP monitoring at home. Help clients and family caregivers determine cuff size, calibration, and accuracy of electronic equipment before they determine which type of BP monitor to purchase.

Delegation and Collaboration

The skill of teaching clients to measure BP and pulse cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Report concerns related to BP and measurements to the nurse.

Equipment

For Blood Pressure

- ❑ Sphygmomanometer or electronic BP reading device (Fig. 42-1) with bladder and cuff: Bladder should completely encircle arm without overlapping; cuff should be secure and fit snugly (Box 42-2).
- ❑ Stethoscope (two-headed teaching stethoscope is ideal) if using sphygmomanometer

For Pulse

- ❑ Wristwatch or clock with a second hand

For Both

- ❑ Pen or pencil and logbook or paper for recording

FIG 42-1 Home blood pressure monitoring device. (Courtesy Omron Healthcare, Bannockburn, Ill.)

BOX 42-2 Guidelines for Blood Pressure Cuff Size

Adult Sizes

- For “small adult” size: 10 × 24 cm (4 × 9.5 inches)
- For “adult” size: 13 × 30 cm (5 × 11.8 inches)
- For “large adult” size: 16 × 38 cm (6.3 × 15 inches)
- For “adult thigh” size: 20 × 42 cm (7.8 × 16.5 inches)

Pediatric Sizes*

- For newborn or premature infants, use “newborn” size: 4 × 8 cm (1.5 × 3 inches)
- For infants use “infant” size: 6 × 12 cm (2.3 × 4.7 inches)
- For older children use “child” size: 9 × 18 cm (3.5 × 7 inches)
- A standard adult cuff, a large adult cuff, and a thigh cuff for use in children with very large arms may be needed.

*Data from Hockenberry MJ, Wilson D: *Wong’s nursing care of infants and children*, ed 9, St Louis, 2011, Mosby.

STEP

RATIONALE

ASSESSMENT

- 1 Assess client’s or family caregiver’s psychomotor function: visual (see dial and a clock) and auditory (hear Korotkoff sounds) acuity, ability to manipulate BP monitoring equipment, and ability to feel pulse.
- 2 Assess client’s or caregiver’s knowledge of normal BP and pulse range for the client and symptoms and common causes of high or low readings. (Consult with health care provider regarding the normal range desired.)
- 3 Assess client’s or caregiver’s knowledge of what BP and pulse measure, specific medical issues that affect them, and why an awareness of variations is important to client’s health.
- 4 Assess client’s or caregiver’s previous knowledge and experience in measuring blood pressure and pulse. Have client or caregiver perform return demonstration if they indicate ability to measure blood pressure or pulse.
- 5 Assess home environment for favorable place to measure BP and pulse (e.g., quiet room with comfortable place to sit).

- Vision or hearing problems require use of equipment that has been adapted for these conditions (e.g., larger print) (Zaiken and Zeind, 2009). Other deficits may require caregiver to perform skills.
- Identifies client’s or caregiver’s ability to know when to initiate preventive health measures and recognize alterations in BP and pulse.
- Identifies client’s or caregiver’s understanding of potential cause-and-effect relationships between variations in BP and pulse and health status.
- Allows nurse to assess client’s or caregiver’s knowledge and skill performance.
- Ensures more accurate measurement.

NURSING DIAGNOSES

- Deficient knowledge regarding pulse/BP measurement
- Ineffective health maintenance

Related factors are individualized based on client’s condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Client or family caregiver accurately monitors BP and pulse.
 - Blood pressure and pulse are within range expected for client’s age and condition (see Chapter 5).
 - Client or caregiver explains importance of measuring BP and pulse, best time for measurement, and when to communicate with health care provider to evaluate changes in treatment regimen.
- 2 Encourage client or caregiver to perform measurements on routine schedule for long-term monitoring plan.

- Learning has occurred.
- Cardiovascular status is stable at a level that is determined for client by his or her health care provider.
- Measures cognitive learning.
- Daily activities and many extrinsic and intrinsic factors affect measurement fluctuations. A routine schedule allows for daily comparisons.

STEP	RATIONALE
3 Encourage client to avoid exercise, caffeine, and smoking for 30 minutes before assessment to avoid inaccuracy.	These factors cause elevations in BP and pulse (Vidt et al., 2010).
4 Have client or caregiver perform measurement in comfortable position, with arm supported and feet flat on floor, and in warm and quiet environment.	Maintains client's comfort during measurement. Systolic and diastolic BP increases with crossed-leg position (Frese et al., 2011).

IMPLEMENTATION

<p>1 Blood pressure measurement:</p> <p>a Explain importance of having client sit quietly for 5 minutes with back supported and feet on floor before measurement.</p> <p>b Discuss with client best sites for assessing BP. For self-measurement brachial artery is almost always used. Explain to avoid applying cuff to arm with:</p> <ul style="list-style-type: none"> • Intravenous (IV) catheter with or without fluids infusing • Arteriovenous shunt • Breast or axillary surgery • Trauma, inflammation, or disease <p>c Demonstrate steps for measuring BP (see Chapter 5):</p>	<p>Reduces anxiety that can falsely elevate BP readings (Vidt et al., 2010).</p> <p>Most accessible sites are easiest to measure for accuracy of assessment. Appropriate site selection promotes accuracy in reading and minimizes potential for trauma. Application of pressure from inflated bladder temporarily impairs blood flow and compromises circulation in extremity that already has impaired circulation.</p> <p>The eventual evaluation of a psychomotor skill is measured through client's performance and ability to follow directions/instructions (Romano, 2009b).</p>
<p>(1) Use of sphygmomanometer and stethoscope:</p> <p>(a) Teach palpating artery, positioning cuff, wrapping cuff, placing stethoscope, inflating and releasing cuff, listening for Korotkoff sounds.</p> <p>(b) Describe sounds of measurement and relationship to observation of gauge during BP reading. Caution client about level and length of time appropriate for cuff inflation.</p> <p>(c) Teach client or caregiver to routinely clean diaphragm and earpieces of stethoscope with rubbing alcohol or damp cloth.</p>	<p>Prepares client or family caregiver for measuring blood pressure.</p> <p>Ensures accurate reading. Prolonged inflation of cuff impairs circulation to extremity.</p> <p>Stethoscopes are frequently contaminated with microorganisms. Cleaning stethoscope routinely prevents transmission of microorganisms.</p>
<p>Clinical Decision Point <i>If client or caregiver needs to use stethoscope to take blood pressure, use double-headed teaching stethoscope to verify accuracy of reading or read BP 1 to 2 minutes after client's attempt to verify accuracy. If client is having difficulty hearing Korotkoff sounds, ensure that he or she is applying cuff appropriately and using the correct size cuff. Also determine correct use of equipment (e.g., cuff may have been deflated too quickly or too slowly; cuff may not have been pumped high enough for systolic readings).</i></p>	
<p>(2) Use of electronic blood pressure monitor:</p> <p>(a) Teach correct placement of cuff and use of electronic equipment for proper cuff inflation.</p>	<p>Using electronic equipment correctly helps ensure accurate BP readings.</p>
<p>2 Pulse measurement:</p> <p>a Discuss with client or caregiver best sites for assessing pulse: radial and carotid.</p>	<p>Radial and carotid sites are accessible and usually easiest to palpate.</p>

Clinical Decision Point *If carotid site is chosen, caution client against vigorously massaging neck while attempting to locate pulse or attempting to locate both arteries at the same time. Stimulation of carotid sinus leads to reflex slowing of heart rate from vagal stimulation. In addition, simultaneous occlusion of both carotid arteries decreases blood to brain, resulting in fainting.*

- | | |
|---|---|
| <p>b Demonstrate steps for palpating pulse (see Chapter 5): position of artery on wrist or neck, how to locate artery, using fingertips for palpation, compressing artery, palpating pulse before counting, counting pulse, and calculating pulse rate (see illustration).</p> | <p>The eventual evaluation of psychomotor skill is measured through client's performance and ability to follow directions/instructions (Romano, 2009b).</p> |
|---|---|

STEP	RATIONALE
(1) Instruct in use of gentle pressure; reinforce not to press hard over pulse site. (2) Instruct in use of watch or clock with second hand to count pulse. (3) Instruct to count for full 60 seconds, starting with second hand at 12:00 position.	Pressing too hard may occlude artery. Ensures correct timing of pulse. Consistent timing of procedure reduces confusion or forgetfulness about time period or starting point used for pulse measurement. A full 60-second count increases accuracy of measure.
3 Educate client about normal desired BP and pulse ranges, purposes for monitoring, and when to take measurements (e.g., before and after taking cardiac or antihypertensive medications; before, during, and after exercise).	Client needs to be able to determine when values are not in desired ranges and when measurements need to be taken.
4 Describe symptoms that indicate need to perform BP and/or pulse measurement.	Promotes understanding of health status alterations that need medical intervention.

Clinical Decision Point Discuss importance of notifying health care provider and withholding medications when abnormal values in BP or pulse occur (e.g., hypotension or bradycardia). Client needs to understand preventive measures to take and to follow health care provider's directions if alterations develop.

5 Have client or caregiver attempt each step of skill on you or family member.	You can correct any errors in technique as they occur.
6 Observe client demonstrate techniques on self. When measuring BP, do not allow multiple repetitive BP attempts on any one limb.	After developing confidence in measuring values in others, client is ready to measure own values. Making repeated BP attempts restricts circulation and alters measurement.
7 Teach client to monitor BP and pulse even if they remain in normal range.	Continuous monitoring provides important information that evaluates effectiveness of medications or other treatments.
8 Provide client with printed instructions with written or pictorial guide or with videotape/DVD demonstration of procedure if possible.	Printed and audiovisual teaching materials help stimulate client's visual and auditory senses, which enhances teaching (Pittman, 2009).
9 Give client logbook or piece of paper to record BP and pulse and time they were taken. In addition, client records whether or not medications that affect BP or pulse were taken. Instruct client to use written record to report readings to health care provider.	Keeping organized record of BP and pulse readings and medications empowers client and provides accurate information to health care providers.
10 Instruct client in proper care of equipment (e.g., storage, cleaning, and battery care).	Improper care and storage of equipment affects accuracy of measurement.

STEP 2b Nurse observing client checking radial pulse.

EVALUATION

1 Observe client or family caregiver demonstrate technique for BP and/or pulse measurement on at least three different occasions and verify that client adds information to logbook correctly.	Feedback through return demonstration of psychomotor learning is best means to evaluate learning.
2 Ask client if readings are within desired range and when to report abnormal readings to health care provider.	Determines client's ability to know when readings are within proper range and what to do when abnormal readings are obtained.

STEP

- 3 Ask client to describe reason for BP and pulse monitoring and any related medications (e.g., antihypertensives, anti-dysrhythmics) or treatment (e.g., diet and exercise).
- 4 Have client or caregiver demonstrate proper care of equipment.

RATIONALE

- Determines if client understands monitoring and related therapies.
- Demonstrates learning.

Unexpected Outcomes

- 1 Client or family caregiver is unable to measure BP or pulse (e.g., inability to manipulate equipment, visualize numbers on equipment or clock, hear BP sounds).
- 2 Client or caregiver has difficulty explaining purposes of measurement or implications of therapy.

Related Interventions

- Alter teaching plan to accommodate client's problems (e.g., use other types of equipment that are easier to manipulate, see, or hear).
- Reinforce information taught and continue return demonstrations until client is able to perform skill.
- Teach skill to a different family caregiver.
- Review and reinforce information that client or caregiver does not understand.

Recording and Reporting

- Record teaching, client responses, and demonstration in home care record.
- Record BP and pulse in home care record and home documentation system (e.g., logbook).
- Report changes in readings of BP and/or pulse.

Special Considerations

Teaching

- Educate client about risks for hypertension (see Chapter 5).
- Ensure that client understands health care provider's recommendations for treatment regimen, including potential side effects and interactions of any medication therapies (e.g., clients taking thyroid medications might need to withhold them when BP is above normal range or pulse is above 100 beats/min). Confirm specific guidelines for BP and pulse with health care provider; document information in home care record; and provide clear, written instructions for the client.
- Always leave a phone number and instructions about how to reach home care nurse if needed.

Pediatric

- Readings (BP or pulse) are often inaccurate if an infant or child is anxious and uncooperative. Blood pressure is also inaccurate when the cuff size is inappropriate. Having others divert the

child's attention or taking his or her BP or pulse while he or she is seated on the parent's lap usually helps calm the child (Hockenberry and Wilson, 2011).

- Young children will be more likely to cooperate if allowed to touch and/or play with equipment before procedure. Consider performing the procedure first on the parent or another person significant to child. This allows the child to observe that the procedure is safe.
- Use the radial pulse in children over 2 years of age. Femoral or brachial pulse is the best site for palpation of pulse for children under 2 years of age (Hockenberry and Wilson, 2011).
- In infants teach parents to observe and count the pulse on anterior fontanel. Remind parents *not* to palpate the pulse.

Gerontologic

- Musculoskeletal changes such as arthritis or other joint conditions may impair a client's ability to position limb comfortably and/or perform fine-motor skills required to measure BP and pulse (Upadhyaya, 2011).
- Older adults, especially those who are frail or who have lost upper arm mass, require a smaller BP cuff.
- Home BP monitoring is not a replacement for BP monitoring by health care professionals in older adults, but it can serve to provide more information to ensure the best treatment.

SKILL 42-3 Teaching Intermittent Self-Catheterization

Most clients urinate and empty their bladder 4 or 5 times a day (SUNA, 2010). However, some clients are not able to empty their bladder. Infections in the bladder or kidneys and damage to the kidneys sometimes result from incomplete emptying of the bladder. Clean intermittent self-catheterization (CISC) is a safe and effective way to empty the bladder. The client performs self-catheterization with clean technique, eliminating the need to wear gloves. Clients who use CISC have a variety of health problems that affect the neuromuscular control of the bladder (e.g., spinal cord injury, multiple sclerosis, spina bifida, bladder outlet obstruction, continent urinary diversion) (SUNA, 2010). Current practice supports CISC for use in the home to provide a means to completely empty the bladder, prevent urinary tract infections (UTIs), and prevent further bladder and kidney damage (NIH, 2010). Inadequate or excessive fluid intake, poor catheterization technique and catheter care, and

traumatic catheterization can cause UTIs. Teaching proper self-catheterization technique is crucial in preventing infections (Newman and Willson, 2011).

Using CISC helps clients believe that they are more in control of their daily needs, which enhances their quality of life. It also helps some clients become continent, maintain a positive body image, and experience less anxiety and embarrassment. In addition, CISC allows clients to express their sexuality and sustain satisfying relationships with significant others. However, the skill requires physical and manual dexterity, and clients must adhere to a regular schedule for it to be successful (SUNA, 2010). When the client is unable to perform CISC independently, teach his or her family caregiver how to perform the skill. For clients with certain medical conditions (e.g., immunosuppressed clients) sterile or aseptic technique is the recommended method of self-catheterization rather than CISC (Newman and Willson, 2011).

Delegation and Collaboration

The skill of teaching intermittent self-catheterization cannot be delegated to nursing assistive personnel (NAP).

Equipment

- Soap, water, and clean washcloth
- Mirror (*optional*)
- Urethral catheter (smallest size that is able to pass easily into the bladder and completely drain client's urine)

- Lubricant (e.g., water-soluble jelly)
- Container for collection of urine (e.g., urinal)—not needed for clients emptying urine directly into toilet
- Mild soap (e.g., Ivory)
- Catheter storage item or container (e.g., brown paper bag, clean towel)
- Disposable clean gloves (for family caregiver)
- Paper or logbook and pencil or pen (*optional*)

STEP **RATIONALE**

ASSESSMENT

- | | |
|--|---|
| <p>1 Review client's medical record, including order for CISC and nurses' notes. Gather information about voiding history, existing medical and surgical history, client's usual daily fluid intake, postvoid residual amounts, and daily voiding routine.</p> <p>2 Assess client's ability to perform CISC, including developmental level, level of consciousness, motor function, and psychosocial status.</p> <p>3 Assess client's or family caregiver's knowledge about CISC and observe performance of CISC if patient has performed previously.</p> | <p>Determines reason for CISC, frequency of catheterization, and previous responses to client education.</p> <p>Client must be physically able to reach urethra and move equipment as needed. Client who cannot see urethra can be taught to feel for proper location of urethral opening (NIH, 2010).</p> <p>Effective client or caregiver education builds on previous knowledge; observation is effective way to evaluate performance of psychomotor skills (Romano, 2009b).</p> |
|--|---|

NURSING DIAGNOSES

- | | | |
|---|---|--|
| <ul style="list-style-type: none"> • Impaired urinary elimination • Urinary retention | <ul style="list-style-type: none"> • Readiness for enhanced urinary elimination • Reflex urinary incontinence | <ul style="list-style-type: none"> • Deficient knowledge regarding self-catheterization |
|---|---|--|

Related factors are individualized based on client's condition or needs.

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Client or family caregiver states signs and symptoms that indicate need for CISC. • Client or caregiver correctly demonstrates how to perform CISC and clean and store equipment. • Client or caregiver verbalizes signs and symptoms of complications of CISC (e.g., UTI, urethral bleeding, urethritis, stricture, creation of a false passage) and when to contact health care provider (Newman and Willson, 2011). <p>2 Select setting in home that client or caregiver will most likely use when performing CISC.</p> <p>3 Help client or caregiver select catheter that is easiest to use, causes least amount of trauma, and is most comfortable.</p> | <p>Indicates ability to identify appropriate times to use CISC.</p> <p>Return demonstration of skill indicates learning (Romano, 2009b).</p> <p>Urinary complications are common in clients who use CISC; urethral, scrotal, and/or bladder complications can occur (Newman and Willson, 2011). Verbalization of signs and symptoms of complications helps clients or caregivers identify potential problems early and seek appropriate care.</p> <p>Respecting client's needs, values, and choices is key in client-centered care (Romano, 2009a).</p> <p>Variety of single-use and reusable catheters is currently available.</p> |
|---|---|

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Teach client or family caregiver how to perform appropriate hand hygiene using soap and water. If caregiver is performing skill, have him or her apply a pair of disposable clean gloves.</p> <p>2 Help client get into comfortable position: Some men prefer to stand, whereas others prefer to sit. Female clients often need to try different positions to decide which position is most comfortable (SUNA, 2010). Position client in place that has adequate lighting.</p> <p>3 Teach client how to clean urethral meatus:</p> <p style="margin-left: 20px;">a <i>For women:</i> Have client spread labia with one hand and clean urethral opening with warm soapy water and clean washcloth with other hand. Have female clean in direction from urethral meatus toward rectum.</p> | <p>Prevents risk for UTI and trauma, which can lead to urethral strictures (SUNA, 2010). Prevents transmission of infection.</p> <p>Client needs adequate lighting to see meatus and equipment.</p> <p>Retraction of labia allows for female urethral meatus to be cleaned, reducing risk for infection (NIH, 2010; SUNA, 2010). Reduces transmission of infection from rectal area to meatus.</p> |
|---|--|

STEP	RATIONALE
<p>b For men: If client has not been circumcised, teach him to retract foreskin to expose urethral meatus. Teach client to hold penis perpendicular to body with one hand and clean urethral opening with warm soapy water and clean washcloth with other hand. Have male clean in a circular motion from meatus outward.</p>	Ensures cleaning of meatus and reduces risk for infection (NIH 2010; SUNA 2010).
4 Teach female client how to insert catheter:	
<p>a Using mirror, help client locate meatus. Explain that it is just below clitoris and just above vaginal opening.</p>	Mirror helps female client visualize anatomy (NIH 2010; SUNA 2010).
<p>Clinical Decision Point If female client is unable to visualize anatomy or wants to learn how to find meatus while in a sitting position, teach touch technique by helping client use fingers to find her urethral opening (NIH, 2010). Teach client to put one finger over the clitoris and another finger over the vaginal opening. Then help her use these two fingers to find the urethral opening. Another method is the tunnel technique. When women sit with their hips flexed forward, the labia create a “tunnel” that leads to the urethral opening. Teach the woman to slightly separate labia near the clitoris and angle the catheter backward into the urethral opening while placing a finger over the vaginal opening.</p>	
<p>b Have client lubricate tip of catheter with water-soluble jelly by rotating tip to spread lubricant around bottom 2.5 to 5 cm (1 to 2 inches) of catheter.</p>	Lubrication reduces urethral trauma (NIH, 2010; SUNA 2010).
<p>c Place outflow end of catheter into urine collection container or let hang over toilet bowl. Slowly and gently insert tip of catheter 5 to 10 cm (2 to 4 inches) into meatus until urine begins to flow.</p>	Appearance of urine indicates that catheter tip is in bladder.
<p>Clinical Decision Point If client feels resistance at the internal sphincter, teach her to apply firm, gentle, steady pressure until muscles relax and allow catheter to pass (SUNA, 2010).</p>	
5 Teach male client how to insert catheter:	
<p>a Have client lubricate tip of catheter with water-soluble jelly by rotating tip to spread lubricant around bottom 13 to 18 cm (5 to 7 inches) of catheter.</p>	Lubrication reduces urethral trauma. Dry catheters may cause excoriations in urethra, which can lead to an entry point for bacteria contamination (Newman and Willson, 2011).
<p>b Place outflow end of catheter into urine collection container or let hang over toilet bowl. Slowly and gently insert tip of catheter 15 to 20 cm (6 to 8 inches) into meatus until urine begins to flow. Tell client that catheter often needs to be inserted all the way for urine to begin to flow.</p>	Male urethra is longer than female urethra. Flow of urine indicates that catheter tip is in bladder.
<p>Clinical Decision Point Men may experience some resistance when the catheter reaches the prostatic urethra or the neck of the bladder. If client feels resistance, teach him to apply firm, gentle, steady pressure to fatigue the external sphincter and cause muscle relaxation (SUNA, 2010).</p>	
<p>6 Instruct client to hold catheter in place while urine flows into container or toilet.</p>	Release of catheter during procedure often causes catheter to accidentally come out before bladder is completely emptied.
<p>7 When urine flow stops, teach client to slowly and gently remove catheter. Then have client perform hand hygiene.</p>	Removing catheter slowly allows pockets of urine that can accumulate at base of bladder to drain (SUNA, 2010).
<p>8 Give client logbook to record amount of urine if needed.</p>	Some clients need to keep track of their urinary output.
<p>9 Instruct client to clean catheter with mild soap (e.g., Ivory) and water immediately after use. Rinse catheter completely, allow to air dry, and store in clean dry towel or brown paper bag.</p>	Prevents UTIs.
<p>10 Teach client to replace catheter every 2 to 4 weeks (NIH, 2010) or when it becomes cracked or brittle, has any buildup of sediment, or loses its form.</p>	Appropriate disposal and replacement of equipment prevents complications of CISC (SUNA, 2010).

EVALUATION

<p>1 Observe client or family caregiver independently demonstrate technique for CISC.</p>	Feedback through return demonstration of psychomotor skill is best means of evaluating learning of skill.
<p>2 Ask client to identify plan for timing of CISC and steps to take when problems arise.</p>	Measures client’s cognitive learning and ability to problem solve.
<p>3 Review client’s logbook and observe client enter information about urine output if indicated.</p>	Confirms that client understands record keeping and importance of tracking urine output.

Unexpected Outcomes

- 1 Client is unable to easily pass catheter into bladder.
- 2 Client states he or she is having symptoms of UTI (e.g., flank or abdominal pain, malaise, fever, chills).

Related Interventions

- Teach client not to force catheter into bladder.
- Tell client to go to nearest urgent care center or emergency department if bladder is full and client is unable to insert catheter.
- Consider initiating consultation with urologist.
- Inform client's health care provider of symptoms and anticipate treatment with antibiotic.

Recording and Reporting

- Record teaching, client responses, and demonstration in home care record.
- Record urine output in home care record and home documentation system (e.g., logbook).
- Report signs and symptoms of UTIs and difficulty performing CISC.

Special Considerations

Teaching

- It is common for clients who perform CISC routinely to have an abnormal urinalysis. Clients should only be treated for UTIs if they have symptoms of an infection (e.g., back pain, pelvic tenderness, malaise, confusion, foul-smelling urine, urgency) (SUNA, 2010).
- Always leave a phone number and instructions about how to reach home care nurse if needed.

Pediatric

- Children who are motivated and physiologically and developmentally ready need to learn how to catheterize themselves.

Consult a pediatric urologist; children need special assessment and teaching (SUNA, 2010).

- When teaching children to perform CISC, use developmentally appropriate teaching strategies.
- Concerns of children and adolescents who use CISC include leakage and being wet. They also are often concerned about what their peers know. Allow children to voice their concerns and help them problem solve what they will do in a variety of situations.

Gerontologic

- CISC is very effective in older adults because it helps restore continence, decreases urinary urge and nocturia, and improves quality of life.
- Older adults may have difficulty performing CISC because of limited manual dexterity. Individualize care for a client's needs and functional abilities. Educate the client or caregivers (Ebersole et al., 2008).

SKILL 42-4 Using Home Oxygen Equipment

Medical oxygen is classified by the Food and Drug Administration (FDA) as a drug; therefore a prescription from a health care provider is required for home use (Brinkerhoff, 2009; CMS, 2008). The prescription includes the following components: drug/apparatus, dose, route of administration, and duration. The most common route of administration of oxygen in the home is by nasal cannula; however a face mask, tracheal mask, or tracheal catheter can also be used (Brinkerhoff, 2009).

Oxygen-conserving devices (OCDs) were introduced to reduce the weight of portable oxygen systems and extend operating time by not wasting oxygen through continuous flow (McCoy, 2010). There are three types of OCDs:

- 1 *Reservoir nasal cannula*: Stores oxygen in a small chamber during exhalation for subsequent delivery during early phase inhalation.
- 2 *Demand pulsing oxygen delivery systems*: Deliver a burst of oxygen at the onset of inspiration; small oxygen pulses are very effective in oxygenating the client.
- 3 *Transtracheal oxygen catheter*: Delivers oxygen directly through a catheter placed between the second and third tracheal rings (American Thoracic Society, 2011) (Table 42-1).

Oxygen sources in the home include liquid oxygen systems, compressed oxygen in tanks, or oxygen concentrators (Fig. 42-2, A) (Lewis et al., 2011). Some oxygen tanks (e.g., compressed) are large and stationary. Portable tanks are easy to move, weigh more than 10 lbs, are not designed to be carried, and deliver oxygen for about 5 hours at 2 L/min. Ambulatory tanks weigh less than 10 lb, are designed to be carried (Fig. 42-2, B), and deliver oxygen for at

least 4 hours at 2 L/min. Table 42-2 compares the different types of home oxygen delivery systems.

Compressed oxygen requires a regulator and flowmeter. The client receives delivery of several large oxygen tanks to the home. The size of the tank and flow rate determine how long compressed oxygen tanks will last (Table 42-3). Liquid systems take up less

TABLE 42-1 Oxygen Flow and Appropriate Uses for Oxygen Delivery Devices

Device	Flow (L/min)	FiO ₂ Range (%)	Uses
Nasal cannula	1-6	24-44	Clients requiring low concentrations of oxygen therapy
Simple face mask	6-12	35-50	Clients who require short-term oxygen therapy with moderate FiO ₂ needs
Oxygen-conserving cannula	Up to 8	30-50	Clients in need of long-term home therapy
Partial and nonrebreather mask	10-15	60-90	Clients in acute respiratory failure or in emergency situations

Data from Lewis et al: *Medical surgical nursing: assessment and management of clinical problems*, ed 8, St Louis, 2011, Mosby.

FIG 42-2 A, Portable oxygen concentrator for home use. B, Ambulatory tank is small enough to be carried easily. (Courtesy AirSep Corporation.)

TABLE 42-2 Home Oxygen Delivery Systems

	Advantages	Disadvantages
<p>Compressed Oxygen Oxygen is stored under pressure in a cylinder equipped with a regulator that controls the flow rate.</p>	<p>An oxygen-conserving device may be attached to the system to avoid waste; device releases gas only on inhalation and cuts it off with exhalation; does not require an electrical source; smaller tanks are available.</p>	<p>Large tanks are heavy and only suitable for stationary use. Client must know how to read regulator and understand when to call medical supplier for replacement cylinder.</p>
<p>Liquid Oxygen Systems Oxygen is stored as a very cold liquid in a vessel very similar to a thermos. When released, the liquid converts to a gas and is breathed in just like compressed gas.</p>	<p>Storage method takes up less space than the compressed gas cylinder; it can transfer the liquid to a small, portable vessel at home.</p>	<p>It is more expensive than compressed gas, and the vessel vents when it is not in use. An oxygen-conserving device may be built into the vessel to conserve the oxygen.</p>
<p>Oxygen Concentrator It separates the oxygen out of the air, concentrates it, and stores it.</p>	<p>It does not have to be resupplied and it is not as costly as liquid oxygen. Extra tubing permits the user to move around with minimal difficulty. Small, portable systems have been developed that afford even greater mobility.</p>	<p>It must have a cylinder of oxygen as a backup in the event of a power failure.</p>

space because oxygen is stored in a liquid state. Liquid oxygen is stored at or below -297°F (-183°C) and requires the use of a small ambulatory tank that is filled from a reservoir in the home (Fig. 42-3). Table 42-4 shows how long a liquid oxygen system will last, depending on the prescribed flow rate. The oxygen concentrator method extracts oxygen from room air and supplies oxygen to the client at prescribed flow rates. Oxygen concentrators deliver a lower percentage of oxygen to the flowmeter. Therefore, if a client is switched to a concentrator, the flow rate usually needs to be adjusted. The client who uses a concentrator needs to have a backup system such as a portable oxygen tank in case of power failure.

Home oxygen equipment and supplies are designated as durable medical equipment (DME) by Medicare; a certificate of medical necessity (CMN) is required for clients who receive Medicare (CMS, 2008). Governmental or private insurance often pays for home oxygen therapy if there are written orders from the health care provider.

Clients and their family caregivers need extensive teaching to use oxygen therapy correctly and safely. Instruct a client to have an all-purpose fire extinguisher close by and learn how to use it and to keep the oxygen supplier's number handy. In addition, provide client education about the safe use of oxygen in the home (Box 42-3). When initiating and managing ongoing oxygen

TABLE 42-3 Oxygen Cylinder Timetable*

L/min	Large (H-K) Tank		Small (E) Tank	
	2200 lbs Full	1000 lbs ½ Full	625 L Full	284 L ½ Full
1	115 hr	52 hr	10 hr	5 hr
2	56 hr	26 hr	5 hr	2 hr
3	37 hr	17 hr	3 hr	1 hr
4	28 hr	13 hr	3 hr	1 hr
5	22 hr	10 hr	2 hr	54 min
6	18 hr	8 hr	<2 hr	47 min

The following formulas can also be used to determine the length of time a tank will last:

For E Cylinders

Pressure on cylinder gauge (psi): 500 psi (safety factor) × 0.3 (E cylinder factor) ÷ L/min = minutes

For H Cylinders

Pressure on cylinder gauge (psi): 500 psi (safety factor) × 3.1 (H cylinder factor) ÷ L/min = minutes

EXAMPLE: If E cylinder reads 1500 psi and liter flow rate is 4 L/min:

Time left: $1500 - 500 \times 0.3 \div 4 = 1000 \times 0.3 \div 4 = 300 \div 4 = 75$ minutes (1 hr 15 min)

NOTE: Do not allow oxygen cylinder pressure to fall below 500 psi, or the client may run out of oxygen.

*All times are approximate.

FIG 42-3 Oxygen reservoir and ambulatory tank.

TABLE 42-4 Liquid Oxygen Timetable

L/min	Stationary Reservoirs		Portable Units	
	41 L	31 L	1/2 L	1 L
0.25	1400 hr	1060 hr	28 hr	44 hr
0.50	1125 hr	850 hr	18 hr	27 hr
1	560 hr	425 hr	9 hr	15 ½ hr
1.5	375 hr	283 ½ hr	6 hr	11 ½ hr
2	281 hr	213 hr	4 ½ hr	8 ½ hr
3	187 ½ hr	142 hr	3 hr	6 hr

BOX 42-3 Safe Home Oxygen Therapy

Fire Safety

Although oxygen is not flammable, it needs fire to burn, therefore:

- Use and store oxygen in a well-ventilated area.
- Keep cylinders and vessels at least 8 feet (2.4 meters) away from heaters.
- Do not use open flames (e.g., matches, fireplaces, stoves, space heaters, candles) when oxygen is in use.
- Do not allow smoking in the house. Post “No Smoking” signs inside and outside the house.
- Avoid using electrical appliances that produce sparks (e.g., electric razors).
- Install smoke detectors and have a fire extinguisher available in the home. Test smoke detectors twice a month.
- Help client or family caregiver plan a fire evacuation route. Have two routes out of every room and an outside meeting place.

Oxygen Storage and Handling

- Store oxygen tanks upright in carts or stands to prevent tipping or falling or place tanks flat on the floor when not in use.
- Do not store oxygen tanks in the trunk of a car.
- When transporting oxygen in a vehicle, ensure that tanks are secured properly in the passenger area with the windows opened 2 to 3 inches (5 to 7.5 cm) to allow adequate ventilation.

Concentrator Safety

- Plug concentrators into properly grounded outlets.
- Do not use extension cords, power strips, or multioutlet adapters with concentrators.
- Ensure that power supply or circuit meets or exceeds the amperage requirements of the concentrator.

Liquid Oxygen Safety

- Avoid direct contact with liquid oxygen because it can cause frostbite. The vapors are also extremely cold; can damage delicate tissues such as eyes.
- Do not touch connectors that are frosted or icy.
- Keep ambulatory tanks upright; do not lay them down or place on their side.

Adapted from Lewis et al: *Medical surgical nursing: assessment and management of clinical problems*, ed 8, St Louis, 2011, Mosby; *National Fire Protection Association, 2008*, available at <http://www.nfpa.org/assets/files/pdf/os.oxygen.pdf>, accessed April 5, 2012.

therapy, collaborate with the client, health care provider, family caregivers, DME provider, and payer.

Delegation and Collaboration

The skill of teaching clients how to use home oxygen equipment cannot be delegated to nursing assistive personnel (NAP).

Equipment

- ❑ Nasal cannula, oxygen mask (see Chapter 23), OCD, or other prescribed delivery device
- ❑ Oxygen tubing
- ❑ Home oxygen delivery system (compressed oxygen, oxygen concentrator, or liquid oxygen) with all required equipment (varies with supplier and system used)
- ❑ “No Smoking/Oxygen in Use” sign for each entrance to the home

STEP

RATIONALE

ASSESSMENT

- | | |
|---|--|
| <p>1 While client is still in hospital, determine client’s or family caregiver’s ability to use oxygen equipment correctly. In home setting reassess for appropriate use of equipment.</p> <p>2 Assess home environment for adequate electrical service if oxygen concentrator is used.</p> <p>3 Assess client’s or family caregiver’s knowledge of purpose of oxygen and ability to observe for signs and symptoms of hypoxia, including apprehension, anxiety, decreased ability to concentrate, decreased levels of consciousness, increased fatigue, dizziness, behavioral changes, increased pulse, increased respiratory rate, pallor, and cyanosis.</p> <p>4 Determine appropriate resources in community for equipment and assistance, including maintenance and repair services and medical equipment supplier.</p> <p>5 Determine appropriate backup systems for compressor in event of power failure (e.g., notify local emergency medical services [EMS]). Have spare oxygen tank available for emergency use.</p> | <p>Physical or cognitive impairments indicate need to teach caregiver how to operate home oxygen equipment. Determines specific components of skill that client and family caregiver are able to complete easily.</p> <p>Oxygen concentrators require electricity to work (American Thoracic Society, 2011). Continuous oxygen therapy must not be interrupted.</p> <p>Hypoxia sometimes occurs at home when client uses oxygen. Possible causes of hypoxia include poor tubing connections; use of long oxygen tubing; or worsening of client’s physical problem, with change in respiratory status.</p> <p>Ensures readily available assistance for clients with home oxygen systems.</p> <p>Many municipalities require that clients who have home oxygen equipment notify EMS before putting equipment in the home. In case of power outage, EMS will call the home, and in some cases the home is on priority list for having power restored.</p> |
|---|--|

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding oxygen therapy
- Ineffective health maintenance

Related factors are individualized based on client’s condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Client receives oxygen at prescribed rate. • Client or family caregiver verbalizes purpose and correct use of home oxygen. • Client or caregiver demonstrates how to maintain oxygen system. • Client or caregiver states indications for calling DME provider to replenish oxygen supply and reorder oxygen delivery supplies. • Client or caregiver verbalizes safety guidelines for oxygen use (e.g., place “No Smoking/Oxygen in Use” signs at entrances to home) (Lewis et al., 2011). • Client or caregiver verbalizes emergency plan of care (Lewis et al., 2011). <p>2 Select setting in home where client is most likely to use oxygen equipment.</p> | <p>Oxygen system set up correctly.</p> <p>Provides measurable criteria to determine level of understanding.</p> <p>Indicates learning has occurred.</p> <p>Client needs constant supply of oxygen at home.</p> <p>Provides measure of understanding of oxygen use.</p> <p>Ensures safe, continuous delivery of home oxygen.</p> <p>Practicing in same environment where skill is routinely performed facilitates comprehension and learning.</p> |
|---|--|

STEP

RATIONALE

IMPLEMENTATION

- | | | |
|---|--|--|
| 1 | Instruct client or family caregiver on how to perform hand hygiene before handling oxygen equipment. | Reduces transmission of microorganisms. |
| 2 | Place oxygen delivery system in clutter-free environment that is well ventilated; away from walls, drapes, curtains, bedding, and combustible materials; and at least 8 feet (2.4 meters) from heat sources. | Keeps system balanced and prevents injury. |

Clinical Decision Point Do not place oxygen delivery system in a closet.

- | | | |
|---|--|---|
| 3 | Demonstrate steps for preparation and maintenance of oxygen therapy: | Demonstration is reliable technique for teaching psychomotor skill and enables client to ask questions. |
| | a Compressed oxygen system: | |
| | (1) Turn cylinder valve counterclockwise two to three turns with wrench. | Turns on oxygen. |
| | (2) Check cylinders by reading amount on pressure gauge. | Verifies adequate oxygen supply for client use. |
| | (3) Store wrench with oxygen tank or in other safe place. | Storing wrench in safe place ensures that it is available whenever needed. |
| | b Oxygen concentrator system: | |
| | (1) Plug concentrator into appropriate outlet. | Provides power safely to concentrator. |
| | (2) Turn on power switch. | Starts concentrator motor. |
| | (3) Alarm will sound for few seconds. | Alarm turns off when desired pressure inside concentrator is reached. |
| | c Liquid oxygen system: | |
| | (1) Check liquid system by depressing button at lower right corner and reading dial on stationary oxygen reservoir or ambulatory tank. | Verifies adequate oxygen supply for client use. |
| | (2) Collaborate with DME provider to provide instruction in refilling ambulatory tank when it becomes empty. | Ensures continuous oxygen therapy is not interrupted. |

Clinical Decision Point Only fill ambulatory tanks when they are empty. Liquid oxygen is stored at or below -297°F (-183°C) inside reservoir, and the temperature inside the ambulatory tank is warmer. If cold oxygen from the reservoir mixes with warmer oxygen left in the ambulatory tank, the ambulatory tank malfunctions.

- | | | |
|-----|---|--|
| (3) | To refill liquid oxygen tank: | |
| | (a) Wipe both filling connectors with clean, dry, lint-free cloth. | Removes dust and moisture from system. |
| | (b) Turn off flow selector of ambulatory unit. | |
| | (c) Attach ambulatory unit to stationary reservoir by inserting female adapter from ambulatory tank into male adapter of stationary reservoir (see illustration). | Secures connection between oxygen reservoir and ambulatory tank. |

STEP 3c(3)(c) Top view of stationary reservoir.

STEP

- (d) Open fill valve on ambulatory tank (e.g., lever, button, key) and apply firm pressure to top of stationary reservoir (see illustration). Stay with unit while it is filling. You will hear loud hissing noise. Tank should be filled in about 2 minutes.
- (e) Disconnect ambulatory unit from stationary reservoir when hissing noise changes and vapor cloud begins to form from stationary unit.

Clinical Decision Point *If ambulatory unit does not separate easily, valves from reservoir and ambulatory unit are frozen together. Wait until valves warm to disengage (about 5 to 10 minutes). Do not touch any frosted areas because contact with skin causes skin damage from frostbite.*

- (f) Wipe both filling connectors with clean, dry, lint-free cloth.
- 4 Connect oxygen delivery device (e.g., nasal cannula) to oxygen delivery system (see Chapter 23) (see illustration).
 - 5 Adjust oxygen flow rate (L/min).
 - 6 Have client or caregiver apply oxygen delivery device (e.g., nasal cannula) correctly (see Chapter 23). Ensure that client has two sets of oxygen delivery devices and tubing.
 - 7 Instruct client not to change oxygen flow rate.
- 8 Have client or caregiver perform each step with guidance. Provide written material for reinforcement and review.
 - 9 Instruct client or caregiver to notify health care provider if signs or symptoms of hypoxia or respiratory tract infection occur (e.g., fever, increased sputum, change in color of sputum, foul sputum odor).
 - 10 Discuss emergency plans for power loss, natural disaster, and acute respiratory distress. Have client or caregiver call 9-1-1 and notify health care provider and home care agency.

RATIONALE

Prevents leakage of oxygen during filling process. If oxygen leaks during filling process, connection between ambulatory tank and reservoir potentially ices up, and ambulatory and reservoir tanks stick together.

Overfilling causes ambulatory unit to malfunction as result of high pressure in tank.

Ice often forms during filling process. Removes moisture from oxygen system.

Connects oxygen source to delivery method.

Ensures ordered oxygen dose is delivered.

Delivers oxygen to client. Extra set of equipment is used when equipment is cleaned or in case of equipment malfunction.

Provides prescribed amount of oxygen. Exceeding prescribed amount of oxygen is sometimes harmful (e.g., client with chronic obstructive pulmonary disease [COPD]).

Allows for correction of any errors in technique and discussion of their implications.

Respiratory tract infections increase oxygen demand and often affect oxygen transfer from lungs to blood, creating exacerbation of client's pulmonary disease.

Ensures appropriate response and can prevent worsening of client's condition.

STEP 3c(3)(d) Fill valve on ambulatory tank is opened while applying firm pressure to top of ambulatory tank.

STEP 4 Oxygen delivery device (nasal cannulas) and tubing attached to ambulatory oxygen tanks.

STEP

RATIONALE

- 11 Instruct client in safe home oxygen practices, including placing “No Smoking/Oxygen in Use” signs at each entrance to home, not allowing smoking in house, keeping oxygen tanks 8 feet (2.4 meters) away from open flames, and storing oxygen tanks upright.

Ensures safe use of oxygen in home and prevents injury to client and family (Lewis et al., 2011).

EVALUATION

- 1 Monitor rate at which oxygen is being delivered during each home visit.
- 2 Ask client or family caregiver about ease or problems associated with home oxygen.
- 3 Ask client or caregiver to state safety guidelines, emergency precautions, and emergency plan.

Determines if client or caregiver is regulating oxygen at prescribed rate.
 Determines ability of client or caregiver to deal with stressors associated with home oxygen use. Also indicates client’s risk for inappropriate oxygen use.
 Determines client’s or caregiver’s knowledge of what to do if power fails, there is a failure in equipment, or client’s status worsens.

Unexpected Outcomes

- 1 Client has signs and symptoms associated with hypoxia (see Assessment, Step 3).
- 2 Client uses unsafe practices with oxygen therapy, uses oxygen around fire or cigarette smoking, or sets incorrect flow rate.
- 3 Client is unable to fill ambulatory system.

Related Interventions

- Determine if oxygen delivery device and oxygen source are delivering oxygen properly.
- Determine if prescribed oxygen flow rate is set properly.
- Assess client for change in respiratory status such as airway plugging, respiratory tract infection, or bronchospasm.
- Instruct client or family caregiver when to notify health care provider or activate EMS because of signs of hypoxia.
- Reinforce client education and perform follow-up reassessment (see Box 42-3).
- Include caregiver in instruction and set up problem-solving exercises with client.
- Identify and instruct family caregiver who can help client fill tank.

Recording and Reporting

- Record teaching plan, information provided to client, and client’s or family caregiver’s ability to discuss information in home care record.
- Communicate client’s or caregiver’s learning progress to other health care providers involved in client’s care.
- Record oxygen delivery system, related supplies, and prescribed oxygen flow rate in home care record.
- Report respiratory complications/concerns to health care provider.

that mask is not too tight; tight mask often leaves marks on skin. Apply cotton or gauze sponge at pressure points.

- Always leave a phone number and instructions about how to reach home care nurse if needed.

Special Considerations

Teaching

- Potential for oxygen desaturation and decreased oxygen delivery to brain impairs client’s ability to remember previous learning. Provide frequent teaching sessions and written or pictorial instructions to reinforce previous learning of teaching plan.
- Instruct client or caregiver in appropriate cleaning, disinfecting, and maintaining all oxygen delivery systems and supplies. Verify instructions with manufacturer guidelines and DME provider’s instructions.
- Instruct client or caregiver to check mask and tubing by placing hands or face over mask or cannula to feel airflow and check

Pediatric

- Keep equipment out of reach of any children in home. Do not allow children to handle or operate home oxygen equipment.
- Oxygen is not flammable, but fire needs it to burn. Keep children away from fire and flames at all times; as appropriate, educate about dangers of oxygen coming into contact with fire (National Fire Protection Association, 2008).

Gerontologic

- Older adults have less efficient respiratory systems and less surface area for gas exchange; thus they are at greater risk for cerebral anoxia and confusion when they experience decreased oxygen levels. They may be unable to recognize respiratory problems or problems with their oxygen delivery system; therefore they need frequent contact with a designated caregiver.

SKILL 42-5 Teaching Home Tracheostomy Care and Suctioning

Performing tracheostomy care and suctioning in the home is similar to performing them in the hospital except for one key variable: the use of *medical asepsis* or *clean technique*. The home environment has fewer germs than hospitals; therefore clean technique can be used. Aseptic technique is used in the hospital because the client is more susceptible to infection and more virulent or pathogenic microorganisms are usually present. In the home setting the majority of clients use clean technique. Use judgment in choosing the correct technique for each client (e.g., use aseptic technique with clients who are immunocompromised; are infected [not colonized]; or have family caregivers infected with viral, bacterial, or fungal microorganisms). Clients living in unclean conditions also need to be suctioned using aseptic technique whenever possible to try to prevent infection. All caregivers need to use standard precautions when suctioning with either clean or aseptic technique.

Caring for a tracheostomy at home begins in the hospital (see Chapter 25) with teaching and return demonstration. The client or family caregiver usually learns better when instruction in less invasive techniques such as tracheal stoma care precedes more invasive techniques such as inner cannula care and suctioning. Continually develop, implement, and evaluate the teaching plan based on client performance. It is imperative that clients and their caregivers have the ability to practice suctioning frequently before discharge to develop confidence with skill performance; otherwise arrangements to provide 24-hour care are necessary before discharge.

Delegation and Collaboration

The skill of teaching home tracheostomy care and suctioning cannot be delegated to nursing assistive personnel (NAP).

Equipment

- Suction machine with connecting tube
- Clean or sterile gloves
- Three small basins
- Mild, soapy water or solution of 3% hydrogen peroxide
- Normal saline
- Appropriate-size sterile or clean and disinfected suction catheter (diameter no greater than half the diameter of the tracheostomy tube [e.g., if tracheostomy tube is 8 mm (0.3 inches), then use 16-Fr or smaller suction catheter])
- Tracheostomy care kit or clean 4 × 4-inch gauze pads (nonshredding)
- Small nylon bottle brush or pipe cleaners or disposable inner cannula
- Cotton-tipped applicators
- Tracheostomy ties (twill tape [$\frac{3}{8}$ -inch preferably] or Velcro-type tie holders)
- Mirror
- Wet washcloth or paper towel (*optional*)
- Dry cloth, towel, or paper towel (*optional*)
- Protective eyewear (*optional*)
- Trash bag (plastic, leakproof preferred)
- Disposable apron (*optional*)
- Bag-valve-mask (BVM) with oxygen supply (*optional*)

STEP

RATIONALE

ASSESSMENT

- 1 Assess client's or family caregiver's ability to measure a pulse and to perform tracheostomy care and suctioning properly. Also assess client's level of consciousness, ability to attend and problem solve, and fine-motor function.
- 2 Assess client's or caregiver's knowledge of indications for the need to perform:
 - a Tracheostomy care, including presence of excess peristomal secretions, excess intratracheal secretions, soiled or damp tracheostomy dressing/ties, and diminished airway through tracheostomy tube.
 - b Suctioning, including presence of gurgling, wheezes on inspiration or expiration, restlessness, ineffective coughing, tachypnea, cyanosis, acutely decreased level of consciousness, tachycardia or bradycardia, acutely shallow respirations, or acute dyspnea.
- 3 Observe client or caregiver perform complete tracheostomy tube care and suctioning.

Instructing caregiver is essential if client's physical and cognitive impairment prevents ability to perform tracheostomy care and suctioning. Emergency situations usually require family caregiver or significant other to suction.

Knowledge needed for client or caregiver to accurately assess need to provide tracheostomy care. Signs and symptoms are related to presence of secretions at stoma site or within tracheostomy tube.

Knowledge allows client or caregiver to accurately determine need to perform tracheostomy tube suctioning. Physical signs and symptoms result from lower airway obstruction and tissue hypoxia.

Determines which specific components of skill that client or caregiver can complete easily and which are more difficult and require reinforcement.

NURSING DIAGNOSES

- Deficient knowledge regarding tracheostomy care
- Ineffective breathing pattern
- Ineffective health maintenance
- Risk for caregiver role strain
- Risk for infection

Related factors are individualized based on client's condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Client or family caregiver identifies signs and symptoms indicating need for tracheostomy care and suctioning. • Client or caregiver states factors that influence tracheostomy airway functioning. • Client or caregiver correctly demonstrates complete tracheostomy tube care and suctioning in controlled setting. • Client or caregiver identifies signs of stoma inflammation or respiratory tract infection and when to notify health care provider. • Lower and upper airways are cleared of secretions, as evidenced by absent or diminished wheezes and gurgles in large airways, normalization of pulse and respiratory rate, increased depth of respirations, absence of cyanosis, improved color, and decreased dyspnea. • Stoma site is clean and free of infection and transesophageal fistula; inner cannula is free of secretions. <p>2 Select setting in home that client or caregiver is most likely to use when completing tracheostomy tube care.</p> <p>3 Discuss and demonstrate with client or caregiver proper position for procedure (high-Fowler's position in front of mirror).</p> | <p>Client or caregiver is able to institute preventive means to maintain airway.</p> <p>Tracheostomy often impairs normal airway clearance, humidification, and gas exchange.</p> <p>Provides validation of ability to perform procedure.</p> <p>Measures cognitive learning.</p> <p>Suctioning by client or caregiver is successful.</p> <p>Tracheostomy care is successful.</p> <p>Practicing skill in same setting where skill will be routinely performed facilitates comprehension and learning.</p> <p>Promotes understanding of comfort and safety principles and facilitates visibility.</p> |
|---|--|

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Suctioning:</p> <ul style="list-style-type: none"> a Verify health care provider's orders for suctioning. b Instruct client or caregiver on techniques for hand hygiene and application of clean gloves. c Explain and demonstrate step-by-step preparation and completion of tracheostomy tube suctioning using either open or closed suctioning (see Chapter 25) (see illustration). | <p>Invasive procedure requires an order.</p> <p>Reduces transmission of microorganisms.</p> <p>Demonstration is reliable technique for teaching psychomotor skill and enables client or caregiver to ask questions throughout procedure. Steps used to suction clients in hospital are also used in home.</p> |
|--|---|

Clinical Decision Point *Instillation of normal saline before suctioning, once a common practice, is no longer recommended. Use of normal saline adversely affects arterial and global tissue oxygenation and dislodges bacterial colonies; therefore this can contribute to lower airway contamination (Halm and Krisko-Hagel, 2008).*

- | | |
|---|--|
| <p>d After client or caregiver suction tracheostomy, teach how to suction nasal and oral pharynx and perform mouth care. Encourage client or caregiver to brush teeth with small soft toothbrush 2 times a day and use mouth moisturizer and moisturize lips every 2 to 4 hours.</p> | <p>Dental plaque harbors microorganisms.</p> <p>Suctioning removes secretions from trachea and lower airway that clients are not able to clear by coughing (Cleveland Clinic, 2009).</p> |
|---|--|

STEP 1c Insertion of suction catheter into tracheostomy tube.

STEP

RATIONALE

- e At conclusion of procedure, have client take two to three deep breaths; reassess status of breathing.
 - f Demonstrate how to disconnect suction catheter; coil and discard catheter in appropriate receptacle. If catheter is to be cleaned and disinfected, set aside. Have client or caregiver remove soiled gloves and dispose in appropriate container; perform hand hygiene.
- 2 Tracheostomy care:
- a Have client sit at a table with mirror. Teach skills of tracheostomy care, including cleaning stoma and tracheostomy tube and changing tracheostomy ties and dressing (see illustrations and [Chapter 25](#)).

Deep breathing reduces oxygen loss and prevents hypoxia. Expect client's respiratory status to improve following suctioning. Prevents transmission of microorganisms.

Steps used to provide tracheostomy care in hospital are also used in home. *Exception:* Mild soap and water can be used to clean a tracheostomy tube ([Cleveland Clinic, 2009](#)). Use hydrogen peroxide solution only to remove heavy secretions.

Clinical Decision Point During tracheostomy care a client is at risk for the tracheostomy tube coming out. Instruct client or caregiver to never remove the old tracheostomy tube ties until the new ties are secured properly. Keep two tracheostomy tubes, one the same size as the client's and one a size smaller, at the client's bedside so he or she can insert a new tube if the tube comes out.

- b Instruct client or caregiver to apply clean gloves. Demonstrate technique for cleaning reusable supplies in warm soapy water. Rinse thoroughly and dry between two layers of clean paper towels. Store supplies in loosely closed clear plastic bag; label bag.
 - c Have client or caregiver remove and discard gloves. Perform hand hygiene.
 - d Explain the procedure for disinfecting reusable supplies. This needs to be done at least weekly. To disinfect supplies use one of the following methods:
 - (1) *Method 1:* Boil reusable (boilable) supplies for 15 minutes. Allow to cool and dry.
 - (2) *Method 2:* Soak reusable supplies in equal parts of vinegar and water for 30 minutes. Remove, rinse thoroughly, and dry.
 - (3) *Method 3:* Soak reusable supplies in prepared solutions of quaternary ammonium chloride compounds according to manufacturer instructions. Rinse and dry.
- 3 Have client or caregiver perform each step with guidance from you.

Prevents transmission of microorganisms. Air must circulate, or humidity in bag can promote microorganism growth.

Reduces transmission of microorganisms.

Removes organisms and reduces risk for infection.

Adults learn psychomotor skills best by active participation, and you can correct any errors in technique as they occur and discuss their implications.

STEP 2a A, Cleaning area around tracheal stoma. B, Applying clean tracheostomy dressing.

STEP

RATIONALE

- 4 Teach client or caregiver signs and symptoms of the following:
- a Stoma infection (redness, tenderness, drainage)
 - b Respiratory tract infection (fever, increased sputum, change in color of sputum, foul sputum odor, increased cough, chills, night sweats)
 - c Transesophageal fistula (air leaking through stoma, nose, or mouth with cuff properly inflated; more air needed to inflate cuff; aspiration of food or liquid during suctioning; excessive belching; coughing when swallowing)

Client or caregiver must be able to recognize onset of complications associated with long-term tracheostomy use early so medical treatment can begin, reducing risk for more serious negative outcomes. Emphasize importance of notifying health care provider when signs and symptoms of complications occur.

EVALUATION

- 1 Ask client or family caregiver to state signs of stoma or respiratory tract complications.
- 2 Observe client or caregiver demonstrate technique for tracheostomy tube care and suctioning.

Prompt identification of symptoms results in early treatment and decreases risk for complications that may lead to hospital readmission.
Feedback through independent demonstration of psychomotor skill is reliable method to evaluate learning.

Unexpected Outcomes

- 1 Stoma site is reddened or hard, with or without drainage.
- 2 Copious colored secretions are present around stoma or when client or caregiver suction tracheostomy.
- 3 Bloody secretions are suctioned.
- 4 No secretions are suctioned.
- 5 Tracheostomy tube comes out during a home visit.
- 6 Skin breakdown is present at stoma site.

Related Interventions

- Evaluate client's or family caregiver's technique.
- Increase frequency of tracheostomy care.
- Have client use sterile technique for suctioning and tracheostomy care.
- Secretions may be pink, rust colored, or blood tinged, depending on problem; documenting color helps health care provider diagnose problem.
- Evaluate for adequate humidity (use room humidifier or tracheostomy collar humidity, if needed) (see Chapter 25).
- Notify health care provider.
- Evaluate suctioning technique, suctioning frequency, and size of catheter used.
- Usual length to insert catheter is length of tracheostomy tube plus $\frac{1}{4}$ inch.
- Assess for signs of infection.
- Evaluate client's fluid status, need for increased humidity.
- Determine if appropriate size of suction catheter is used.
- Reassess need to suction.
- Replace tracheostomy tube to maintain an airway.
- Activate emergency medical system (EMS) if needed.
- Assess site for pressure areas or site infection.
- Remove pressure source.

Recording and Reporting

- Record client instruction and client's or family caregiver's ability to demonstrate tracheostomy care and suctioning in home health record.
- Develop a system of recording home care for client or caregiver to document and keep track of tracheostomy care provided.

Special Considerations

Teaching

- Some clients benefit by using a mirror to visualize stoma area.
- Tracheostomy tubes are changed every 3 to 4 weeks in adults and every 1 to 2 weeks in children. Two people are required to change the tracheostomy tube. Procedural Guideline 42-1 provides guidelines for changing a tracheostomy tube at home.
- Always leave a phone number and instructions about how to reach home care nurse if needed.

Pediatric

- Encourage parents to give tracheostomy care as soon as child is stable in the hospital. The more time they have to practice these skills, the more comfortable they become in caring for the child at home.
- Children with tracheostomies need to socialize and play with other children who are close to their own age. Encourage parents to take children out of the home. However, an additional adult needs to travel in the car with the child to help if problems arise while in the car (Hockenberry and Wilson, 2011).
- To prevent hypoxia, teach parents that suctioning needs to last no more than 5 seconds. Allow the child to rest for at least 30 to 60 seconds between suctioning passes and do not suction more than 3 times (Hockenberry and Wilson, 2011).
- Teach families and caregivers pediatric cardiopulmonary resuscitation, including use of BVM or mouth-to-tracheostomy technique. They also need to notify the local EMS of the child's

condition and the presence of a tracheostomy and provide EMS with a list of equipment in the home (Hockenberry and Wilson, 2011).

- Encourage parents to have a cool-mist humidifier in same room as child; humidity helps keep secretions thin and decreases the likelihood of mucus plugging (Hockenberry and Wilson, 2011).
- Caring for a child with a tracheostomy often disrupts parents' ability to socialize and can cause sleep deprivation. Develop a plan that includes respite care to allow parents time to meet their own needs (Zia et al., 2010).
- Teach families and caregivers to avoid dressing the child in clothes that could cover the tracheostomy opening such as turtlenecks and clothes that have a tight-fitting collar. Avoid

clothing, toys, and pets that shed fine hair or lint because they could get into the tracheostomy and cause breathing problems (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults lose some properties of elastic recoil and often have greater difficulty in clearing airway secretions through cough. As a result they require more suctioning and airway care and have increased risk for infection (Ebersole et al., 2008).
- Assess for cognitive, mobility, or sensory impairments that impair ability to manage artificial airway at home and teach caregiver if client is unable to manage airway independently.
- Anxiety accompanies decreased ability to breathe and may cause the older adult to become too nervous to perform suctioning independently.

PROCEDURAL GUIDELINE 42-1 Changing a Tracheostomy Tube at Home

To change a tracheostomy tube in the home, it is best to have two people present in case of emergency. Before beginning, ensure that all necessary supplies have been gathered and the client and family caregiver are in a place in the home that is comfortable for the procedure. The client or family caregiver is observed by a home care health professional the first time the caregiver changes a tracheostomy in the home setting.

Delegation and Collaboration

The skill of changing a tracheostomy tube cannot be delegated to nursing assistive personnel (NAP).

Equipment

- Clean gloves
- Suction catheter
- Suction machine
- Bag-valve-mask
- Face mask
- New sterile tracheostomy tube (Fig. 42-4)
- Gauze tracheostomy dressing

Procedural Steps

- 1 Do not allow client to have anything by mouth (NPO) or hold tube feedings for at least 1 hour before procedure.
- 2 Explain procedure to client before tracheostomy is changed to alleviate anxiety. Have family caregiver assist.
- 3 Have caregiver perform hand hygiene and apply clean gloves.
- 4 Remove new tracheostomy tube from sterile container. If the tube has a cuff, be sure it is deflated. Remove inner cannula and insert obturator into outer cannula. Attach clean tracheostomy ties or tracheostomy tube holder to neck plate, checking integrity of cuff.
- 5 Suction existing tracheostomy tube and have bag-valve-mask and face mask available.

- 6 Have family caregiver use fingers to hold tracheostomy faceplate in place. Loosen tracheostomy ties and deflate tracheostomy tube cuff (if tracheostomy has one).
- 7 Have patient take a deep breath, relax, and then direct caregiver to pull out old tracheostomy tube with a gentle, steady pressure in same direction as an inner cannula would be removed. Be sure patient is breathing without distress. Remove gloves and perform hand hygiene.
- 8 Apply sterile gloves. Insert new tracheostomy through stoma with gentle force, then push back and then down, following direction of the airway. Remove obturator. Allow air to flow in; insert inner cannula and lock in place.
- 9 Secure new tracheostomy ties or tube holder, inflate cuff (if present), and place new gauze dressing around stoma if necessary.
- 10 Evaluate patient's ease of breathing, respiratory rate.

FIG 42-4 Tracheostomy tube. (Courtesy Mallinckrodt, Inc. Shiley Tracheostomy Products, St. Louis, MO.)

SKILL 42-6 Teaching Medication Self-Administration

The National Institute for Health and Clinical Excellence (NICE, 2009) found that approximately 50% of prescribed medications are used incorrectly and that some clients do not choose to take their prescribed medication. The goals of NICE include identifying and addressing issues that can influence clients' adherence to their medication regimen. You will be involved in teaching clients how to correctly administer medications, but first you must seek to identify and address any issues that are of concern to your clients.

Compliance was used in the past to describe if clients' behaviors matched that of health care providers' recommendations when it came to taking prescribed medications or adhering to prescribed treatments (Kaufman and Birks, 2009). Recent literature supports the term *adherence* since this emphasizes a client's role in decision making, taking into account freedom of choice (Kaufman and Birks, 2009). One method that has been identified to increase adherence is to support clients' decisions in how to take their medications. Use teaching methods that incorporate active listening so you can adapt clients' needs and concerns into their medication regimen.

Some barriers to medication adherence include fear of adverse reactions from medications, belief that a medication does not help, inconvenience of taking medication, cost of medication, inadequate knowledge, forgetfulness, and lack of social support (Santhosh and Naveen, 2011). Considering these potential

barriers, you can provide information and support to ensure that a client or family caregiver is making a well-informed decision when it comes to whether or not to take a medication. Once a client has mastered the skill of administering medications, you must continue to validate that the skill is being performed correctly and assess for new issues and concerns.

Delegation and Collaboration

The skill of teaching clients medication self-administration cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Communicate to the nurse problems that clients report having with medication self-administration.

Equipment

- Medication
- Liquid to take with medication
- Medication administration record or other up-to-date list of current medications from health care provider
- Diary or medication log
- Container for daily or weekly preparation
- Measuring devices as needed (e.g., medicine cup, teaspoon)
- Teaching tools (e.g., charts, written instructions, color codes for medicine containers)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Assess client's cognitive, sensory, and motor function; level of consciousness, sight, hearing, touch, health literacy level, swallowing ability, mobility, activity tolerance, social support, and willingness to cooperate. 2 Assess resources client has to obtain medications when needed (e.g., finances, social support, and transportation). 3 Assess client's learning readiness and ability to concentrate; consider presence of pain, nausea, or fatigue and client interest in instruction. 4 Assess client's and family caregiver's knowledge regarding medication therapy: names of drugs, how to administer, purpose or action, daily doses and times to be taken, side effects to expect, and what to do if problems occur. 5 Assess client's belief in need for medication therapy. Consider prior experiences, ethnic values, religious beliefs, personal experiences with medications, and significant others' values about medications. 6 Assess client's prescribed and over-the-counter (OTC) medications, including use of herbal supplements: Has more than one health care provider prescribed medications? Are labels clearly marked? Are time schedules confusing? Do different drugs look alike? Does client store medications together or out of original containers? Are expiration dates on bottles still current? 7 Assess client's understanding of effects and interactions between prescribed medications and ingestion of certain foods, OTC drugs, and herbal supplements. 8 Be sure family caregiver knows client's drug allergies. | <p>Cognitive, sensory, and motor deficits frequently influence client's ability to take or prepare prescribed medication correctly and participate in instruction.</p> <p>Lack of resources is a major factor that will negatively affect adherence with medication self-administration regimen (Santhosh and Naveen, 2011).</p> <p>Presence of significant illness, frailty, or confusion affects person's ability to attend to teaching plan. Indicates need to rely on family caregiver for learning and implementation (if available) on short- or long-term basis.</p> <p>Clients need to be able to understand information about their medications and remember it (Kaufman and Birks, 2009).</p> <p>Caregivers' self-confidence in administering medication influences their ability to manage medication for client (Lau et al., 2010).</p> <p>Many factors influence client's willingness to follow drug regimen.</p> <p>Determines sources of confusion affecting client's adherence. Adherence with medication therapy (especially in older adults) is often complicated by polypharmacy (multiple chronic conditions are often treated with multiple medications sometimes prescribed by more than one health care provider). Adherence is more complicated when medication regimens are complex.</p> <p>Medication interactions, including those with OTC drugs, herbals, and certain foods, can seriously affect medication effectiveness and/or create negative side effects (Santhosh and Naveen, 2011).</p> <p>As new drugs are prescribed, the family caregiver often becomes the one to monitor for inappropriate drug prescription.</p> |
|---|---|

STEP

RATIONALE

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding medication self-administration
- Readiness for enhanced knowledge
- Ineffective health maintenance
- Ineffective individual or family therapeutic regimen management

Related factors are individualized based on client's condition or needs.

PLANNING

- Expected outcomes following completion of procedure:
 - Client or family caregiver is able to state purpose of each medication and why it is beneficial. Demonstrates cognitive learning.
 - Client identifies common adverse effects and relief measures. Enhances adherence to medication therapy. Empowers client to participate in care.
 - Client or caregiver is able to state when to notify health care provider about medication problems. Prevents medication administration errors.
 - Client reads each label and explains when each medication should be taken. Demonstrates skill achieved.
 - Client or caregiver demonstrates self-administration of medication by prescribed route.
- Prepare environment for teaching session:
 - Select room that is well lit.
 - Provide comfortable seating.
 - Be sure that client is close and can see nurse clearly.
 - Control sources of noise and distractions.

Room environment needs to minimize existing sensory alterations. Comfortable environment free of distractions promotes client's attention.
- Prepare teaching materials:
 - Use an approach that matches client's learning preference:
 - Written materials printed in large bold letters (set in 14-point or larger type).
 - DVD or Internet instructional programs.
 - Illustrations of medication safety guidelines.
 - Give written schedules or individualized instruction sheets.

Client-centered care focuses on working in partnership with clients to provide high-quality, appropriate, and cost-effective health care (Kaufman and Birks, 2009).

Makes teaching patient-centered.
- Ensure that client is wearing glasses or hearing aids if needed during teaching session.

Use of glasses or hearing aids increases client's sensory perception and likelihood of attending to teaching session and understanding content.
- Consult with health care provider to review medications that client is receiving and simplify regimen if possible.

Review of medications helps minimize risk for drug interactions from multiple medications and ensures accuracy of medication regimen. Simplification of regimen improves adherence, particularly related to daily frequency of prescribed doses.

Caregiver can serve as positive resource to client and often reinforce information provided (Lau et al., 2010).
- Arrange teaching time to allow participation of family members (see illustration).

STEP 6 Client and family member participate in medication self-administration teaching program.

STEP

RATIONALE

IMPLEMENTATION

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Instruct client or family caregiver on importance of performing hand hygiene before medication self-administration. 2 Present information clearly and concisely: <ol style="list-style-type: none"> a Face learner in well-lit room. b Use short sentences and speak in slow, low-pitched voice. c Provide descriptions in understandable terms. 3 Provide frequent pauses so client or caregiver can ask questions and express understanding of content. 4 Instruct client or caregiver on the following content: purpose of regularly scheduled and prn (as needed) medications and their desired effects, how medication works and why it helps, dosage schedules and rationale, common side effects, what to do to relieve side effects, what to do if dose is missed, when to call health care provider with problems, who to call with problems, medication safety guidelines, and implications when medications are not taken. 5 Instruct client in appropriate route of medication delivery, including oral, subcutaneous, intramuscular, inhalation, and topical. 6 Provide frequent, short teaching sessions. Plan to have several teaching sessions, especially if client needs to take multiple medications. Leave instruction aids in home for client to review if possible. 7 Provide teaching about OTC medications and herbal supplements. 8 Provide client with special charts, diagrams, learning aids, written information, and Internet/Intranet resources (see illustration). | <p>Reduces transmission of microorganisms.</p> <p>Improves client's ability to attend and understand (Kaufman and Birks, 2009).
Allows visualization of client's nonverbal responses to education. Client with hearing loss or visual problem is able to see your expressions, read written information, and hear your voice more clearly.
Enhances understanding of information.
Prevents confusion of terminology. Clients learn more quickly when you present information at level of learner (Kaufman and Birks, 2009).</p> <p>Increases learner participation. Ongoing feedback ensures that client is acquiring information.</p> <p>Provides client or caregiver with sufficient information to understand and take medications safely at home.</p> <p>Client needs to be proficient in all routes of medication administration. Adverse effects often occur if medications are administered incorrectly.</p> <p>Frequent sessions improve client's attention and retention of information discussed. Reference to charts, written information, and other teaching tools as resources enhances learning (Kaufman and Birks, 2009).</p> <p>Clients may not understand effects of OTC and herbal supplements (Santhosh and Naveen, 2011).</p> <p>Clear written information, charts, and other resources such as the Internet/Intranet enhance client learning and allow for reinforcement of information.</p> |
|---|---|

STEP 8 Examples of aids for client medication self-administration.

STEP	RATIONALE
9 Offer assistance as client practices preparing medication (e.g., “Let’s prepare the medications you will take with your meals or the medicines you take first in the morning”).	Allows for observation of client’s ability to read labels correctly and prepare all medications for prescribed times.
10 Have pharmacy provide clear, large-print labels for medication bottles and medication teaching handouts if appropriate.	Improves client’s ability to read and follow directions.
11 Have pharmacy provide containers that client can open independently if manual dexterity is limited.	Most pharmacies dispense pills in “childproof” containers, which client with limited mobility of fingers/hands often finds difficult to manipulate or open.
<p>Clinical Decision Point <i>If there are pets or small children in the home or children who frequently visit the home, help client establish a “safe place” for medication storage to reduce risk for accidental ingestion by pets or children.</i></p>	
12 Facilitate arrangements for pharmacy to receive written prescriptions in timely fashion if required for dispensing. Arrange for pharmacy to deliver medications to home if client is unable to arrange for transportation to pharmacy.	Availability of drugs influences adherence.

EVALUATION

1 Ask client or family caregiver to explain information about each drug: purpose; actions; routes; timing of medications and maximum frequency of use of either prescribed or OTC medications; side effects and interactions; and foods, herbals, or OTC medications to avoid.	Clients and caregivers need to be able to understand medication information they are given and remember this information (Kaufman and Birks, 2009).
2 Identify client’s problem-solving abilities (e.g., when to call health care provider or refer to printed information for resources).	Developing techniques to gain information and solve problems assists in client adherence and reduces potential problems from medication regimen (Kaufman and Birks, 2009).
3 Have client or caregiver prepare doses for all prescribed medications.	Indicates understanding of medication dosages and schedules.
4 Ask client to verbalize any remaining questions regarding medication management.	Offers opportunity for clarification and minimizes any remaining confusion or misunderstanding.

Unexpected Outcomes

- 1 Client or family caregiver makes errors in preparing medications or is unable to recall and/or explain information discussed in teaching sessions.
- 2 Medication self-administration plan is not possible because of client’s self-care deficits. This is very common when client develops cognitive changes.
- 3 Client refuses to take medications as prescribed.

Related Interventions

- Provide additional instruction and/or teaching materials for consultation when information is forgotten or unclear.
- Ensure that written instructions are at client’s level of understanding. Some commercially prepared booklets contain instructions that are too complex or contain medical jargon that is difficult to understand.
- Consider use of pictures, color coding, diagrams, and tape-recorded instructions for reading or sight impaired.
- Periodically observe client or caregiver prepare and administer medications.
- Develop alternative plan, which often relies on family caregivers to provide safe administration of home medication regimen.
- Explore and identify reasons for noncompliance, which often include the following: cost, side effects, complexity of regimen, problems with swallowing or other side effects, and cultural preferences.
- See [Box 42-4](#).

Recording and Reporting

- Document instruction provided and learning outcomes achieved by client in home care record.
- Develop a system of recording (patient diary) for client or family caregiver to use to document adherence to dosage schedules and self-monitoring of any problems.
- Always leave a phone number and instructions about how to reach home care nurse if needed.

Special Considerations

Teaching

- See [Chapter 41](#) for guidelines for medication safety.
- If it is difficult to plan a separate teaching session, instruct client while administering medications.
- Examples of learning aids include homemade calendars for each week that contain plastic bags containing medications to take at specific times, egg cartons divided into color-coded sections

BOX 42-4 Evidence-Based Nursing Interventions to Enhance Adherence to Medication Therapy

- Involve clients as partners in collaboration. Encourage them to express their views and share in the decision making with you.
- Urge clients to take medications.
- Be empathetic regarding clients' feelings.
- Encourage a sense of control for the client by providing information about diagnosis and treatment.
- Recognize caregiver needs and provide information and support. Understand that caregiver may have competing responsibilities (e.g., employment, other dependents).
- Client's attitude will affect his or her willingness to work with health care providers and be compliant with treatments.

Modified from Kaufman G, Birks Y: Strategies to improve clients' adherence to medication, *Nurs Stand* 23(49):51, 2009; Lau DT et al.: Exploring factors that influence informal caregiving in medication management for home hospice clients, *J Palliat Med* 13(9):1085, 2010; Santhosh YL, Naveen MR: Medication adherence behavior in chronic diseases like asthma and diabetes mellitus, *Int J Pharm Pharm Sci* 3(3):238, 2011.

with medications for the day, clock faces for clients who cannot read or see clearly, color coding for drug types (e.g., blue for sedative, red for pain pill), and pillboxes that identify days of the week and times of day.

Pediatric

- Instruct adults to keep all medications locked and securely out of reach of children.
- Encourage caregivers not to tell children that medications are treats because this increases the risk for child overdosing by mistaking medicine for candy.

- Successful medication teaching involves the child's parents or other caregivers and the child and siblings whenever possible. To provide effective medication teaching to children, take the child's developmental and cognitive abilities into consideration when planning teaching sessions (Hockenberry and Wilson, 2011).
- Parents need to supervise older children as they begin taking responsibility for their own treatment.

Gerontologic

- Capacity for learning new information remains as people age (in the absence of dementia); however, older clients often need additional time to accomplish learning. Allow adequate time and number of teaching sessions to support successful learning. Effective teaching strategies for older adults include memory aids, information written in large letters (14 point is recommended), involvement of caregiver, follow-up teaching sessions either over the telephone or in person, and computer-assisted teaching guides (Ebersole et al., 2008).
- Cognition problems coupled with complexity of medication regimens have a negative effect on safe medication self-administration in older adults. Attempt to decrease the complexity of medication regimens in clients with cognitive deficits whenever possible to promote safe medication self-administration practices.
- Older adults often have to take medications in multiple routes (e.g., oral, inhaled, injections). Many times problems with physical dexterity, eyesight, cognitive skills, and memory negatively affect adherence to medication schedules. Establish a therapeutic nurse-client relationship to help clients overcome these barriers to adherence.

SKILL 42-7 Managing Feeding Tubes in the Home

Enteral nutrition therapy in the home setting is usually effective when a client tolerates at least 70% of feeding intake without complications and is medically stable, the client or family caregiver is able to administer feedings, and there is sufficient time in a controlled environment to learn the skill. A recent study revealed that the majority of clients requiring home enteral nutrition are adults over the age of 60 years (Hitchings et al., 2010). Clients benefit when they are able to see tube feeding equipment and devices when learning how to administer home enteral nutrition. Provide hands-on experience and client involvement with decision making about home enteral nutrition whenever possible.

This procedure in the home setting follows the guidelines and skills described in Chapter 31 (see Skills 31-1, 31-2, 31-3, and 31-4 and Procedural Guideline 31-1). Most patients who receive enteral nutrition in the home have either gastrostomy or jejunostomy tubes. This skill focuses on teaching the client or caregiver in the home. Frequently in this setting the nurse is responsible for

reinsertion of gastrostomy feeding tubes, and the health care provider is responsible for reinsertion of jejunostomy tubes.

Delegation and Collaboration

The skill of management of feeding tubes in the home cannot be delegated to nursing assistive personnel (NAP). The nurse inserts feeding tubes, verifies tube placement, assesses for residual volume, and administers medications through feeding tubes. Administration of enteral tube feeding via syringe is sometimes delegated to NAP (verify agency policy). The nurse directs the NAP to:

- Report when client has difficulty with feeding, coughing, gagging, respiratory distress, discomfort, or vomiting.

Equipment

See Skills 31-1, 31-2, 31-3, and 31-4 and Procedural Guideline 31-1 for list of equipment

- ☐ Paper or log book to record daily weights, intake and output (I&O), temperature, feeding residuals

STEP

RATIONALE

ASSESSMENT

- 1 Assess client's health status, including presence of discomfort and fatigue and ability to successfully manage enteral feedings in home.
- 2 Assess client's and family caregiver's physical, emotional, financial, and community resources.

Increases successful home management with fewer complications.

Availability of resources increases ability for self-care home management.

STEP	RATIONALE
3 Assess environmental conditions of home (sanitation, storage of equipment, work area, supplies, and power source).	Ensures safe environment and decreases risks of infection and complications.
4 Assess client's and caregiver's understanding of purpose of enteral feedings and positive expected outcomes.	Understanding rationale of treatment is critical to enhancing participation and cooperation in care.
5 Assess client's and caregiver's understanding of storage and management of equipment and supplies and where and how to obtain supplies.	Ensures safe home management and decreases risk for complications. Home care delivery companies usually deliver a month's supply at a time. If client stores feeding containers in garage, it must be brought into the house a couple hours before using in colder months to warm to room temperature (Best and Hitchings, 2010). The garage is not a good storage place during hot weather; use a basement if possible.
6 Assess client's and caregiver's ability to manipulate feeding equipment.	Sometimes caregiver needs to administer enteral feedings.

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding tube feeding self-administration
- Feeding self-care deficit
- Imbalanced nutrition: less than body requirements
- Risk for aspiration
- Ineffective health maintenance

Related factors are individualized based on client's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Client or family caregiver verbalizes purpose of enteral feedings and enhanced nutritional health. • Client or caregiver demonstrates proper use of equipment and handling of formulas. • Client or caregiver demonstrates accurate administration of enteral feedings and medications. • Client or caregiver verbalizes understanding of signs and symptoms and management of complications of feeding. | <p>Provides measurable criteria to determine level of cognitive understanding.</p> <p>Provides demonstration of skills needed to manage home enteral nutrition.</p> <p>Provides demonstration of skills needed to administer home enteral nutrition.</p> <p>Confirms that client or caregiver has knowledge needed to respond when problems with feedings develop.</p> |
|---|--|

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Have client or family caregiver perform hand hygiene.</p> <p>2 Discuss with client or family caregiver purpose of enteral feeding and enhanced nutritional health.</p> <p>3 Help client or caregiver determine a feeding schedule that will maintain nutritional requirements and fit within client's or family's schedule.</p> | <p>Reduces transmission of microorganisms.</p> <p>Reinforces importance of regular feedings.</p> <p>Promotes adherence to enteral nutrition therapy.</p> <p>A patient-centered approach increases client confidence in managing his or her own feedings (Best and Hitchings, 2010).</p> |
|--|---|

Clinical Decision Point Explain that caregiver needs to communicate to home health or health care provider any changes in feeding schedules made to fit daily routine.

- | | |
|---|--|
| <p>4 Have client or caregiver apply clean gloves. Demonstrate how to identify placement of feeding tube: aspiration of gastric fluid, checking pH of gastric fluid, and acceptable pH range (see Skill 31-2).</p> | <p>Some nasally placed tubes are inadvertently placed in respiratory system and migrate to esophagus or into respiratory tract. Check pH periodically (Best and Hitchings, 2010). Aspirated secretions with low pH are strong indicator of gastric placement. However, high pH cannot differentiate between aspirated secretions obtained from respiratory and intestinal tube placements.</p> |
|---|--|

Clinical Decision Point Instruct client to avoid administration of all feedings, flushes, or medications if there is any doubt as to placement of enteral feeding tube.

- | | |
|--|---|
| <p>5 Observe client or caregiver determine placement of nasally placed tube.</p> <p>6 Observe client or caregiver check for gastric residual volume by aspirating gastric contents. Instruct to return aspirated contents to stomach unless volume exceeds 250 mL (Bankhead et al., 2009).</p> | <p>Identifies if there are areas for further teaching.</p> <p>Aspirates more than 250 mL indicate need to initiate interventions such as changing from intermittent to continuous feedings, evaluating possibility of decreasing opioid analgesics, and starting medication that enhances gastric motility (e.g., metoclopramide [Reglan]) to reduce aspiration risk.</p> |
|--|---|

STEP

RATIONALE

Clinical Decision Point *If gastric aspirates are more than 250 mL and there is no abdominal pain, instruct client or caregiver to return gastric contents and recheck in 1 hour. If aspirates remain more than 250 mL after an hour, instruct the client or caregiver not to stop the infusion for 4 hours and recheck (Bankhead et al., 2009). If the residual is still more than 250 mL, instruct client or caregiver to contact home care nurse or health care provider (Kenny and Goodman, 2010).*

- | | | |
|----|---|---|
| 7 | Discuss use of medical asepsis in setting up and changing administration sets, mixing formulas (do not add formula to hanging bag), refrigerating unused formula, limiting amount of formula “hung” at one time to amount that can be infused in 4- to 6-hour period (less time in warmer weather), and maintaining and caring for bag. | Medical aseptic technique minimizes risk for microorganism contamination. Refrigeration and limiting “hang” time reduce microorganisms. Changing administration sets every 24 hours reduces microorganism growth. |
| 8 | Instruct client or caregiver that client needs to sit up in chair or have head of bed elevated at least 30 to 45 degrees while receiving feedings or medications or when tube is flushed. If this is not possible, place client in reverse Trendelenburg’s position. | Decreases risk for aspiration. Aspiration is indicated by increased coughing, difficulty in breathing, or increased sputum (Hitchings et al., 2010). |
| 9 | Observe client or caregiver mixing, administering, and storing formulas. Discuss flushing of tube after administration of feedings or medications. | Identifies competence and need for further teaching. Regular flushing of tube prevents clogging. |
| 10 | Observe client or caregiver changing administration sets; and cleaning bags. Then have them dispose of supplies, remove gloves and perform hand hygiene. | Reduces transmission of infection. |
| 11 | Observe client or caregiver administering medications and flushing tube (see Skill 21-2). | Ensures that medications are given correctly. |

Clinical Decision Point *Verify that medications do not include any sublingual, enteric-coated, or sustained-release medications.*

- | | | |
|----|---|--|
| 12 | Discuss and observe use of infusion pump if client is receiving continuous feeding (see Chapter 31). | Use of tube-feeding infusion pumps is complex and requires reinforcement. |
| 13 | Discuss measures to stabilize feeding tube in clients with abdominal tubes and to cleanse and protect skin insertion site. | Prevents tube from dislodging and prevents skin breakdown. |
| 14 | Provide contact information for ordering equipment and supplies or who to call in case of equipment failure. | Ensures that caregiver is able to respond in an emergency. |
| 15 | Discuss emergency plan and actions to take for signs and symptoms of aspiration such as elevating head of bed, oral suctioning, and calling health care provider. | Ensures understanding of management of equipment, supplies, emergency plan, and collaboration. |
| 16 | Discuss who to contact and when for signs of diarrhea, constipation, or weight loss. | Provides support to client or caregiver. |

EVALUATION

- | | | |
|---|---|--|
| 1 | Ask client or family caregiver to state purpose of home enteral nutrition therapy. | Demonstrates cognitive learning. |
| 2 | Observe client or caregiver performing medical asepsis techniques, checking tube placement, aspirating residuals, administering medications and solutions, and using/cleaning equipment. | Demonstrates psychomotor learning. |
| 3 | Ask client or caregiver to state measures used to prevent complications (e.g., verification of tube position before each feeding, elevation of client’s head during feeding, stabilization and flushing of tubing). | Ensures safe home management and identification of areas for teaching. |
| 4 | Ask client or caregiver how to care for open formula cans. | Ensures safe home management for preventing foodborne illness. |
| 5 | Ask client or caregiver about ways to manage complications (e.g., signs of intolerance: nausea, abdominal distention, diarrhea, skin problems, and fluid deficit). | Ensures safe home management and identification of areas of teaching (Hitchings et al., 2010). |

Unexpected Outcomes

- 1 Feeding tube becomes displaced.
- 2 Signs and symptoms of aspiration are present.
- 3 Client develops diarrhea.
- 4 Skin surrounding stoma breaks down, or drainage around insertion site develops.

Related Interventions

- Instruct family caregiver to notify home care nurse whenever this happens and stop feeding.
- Nurse will reposition feeding tube and verify placement before initiating any enteral feeding.
- Stop feeding. Raise head of bed.
- Verify tube position.
- Notify health care provider.
- Notify health care provider.
- Consider change in strength, type, or rate of enteral feeding or administration of antidiarrheal agents (Hitchings et al., 2010).
- Clean stoma area more frequently.
- Apply antibiotic ointment around stoma as ordered.
- Contact health care provider.

Recording and Reporting

- Record instructions given to client or family caregivers and their response in home care record.
- Record specifics of enteral feeding plan, including type and size of tube in home, formula, and amounts to be administered in specific time frames.
- Client or caregivers need to document I&O, daily weights, amount of gastric fluid aspirated before each feeding (or every 4 hours if receiving continuous feeding), date and time of feedings, amount and type of formula, any additives, and date and time that administration sets are changed.

Special Considerations

Teaching

- Performing skill without nurse in attendance provokes anxiety. Always leave a phone number and instructions about how to reach home care nurse if needed.

Pediatric

- Children are at risk for aspiration and fluid and electrolyte imbalance; thus teach parent to monitor child carefully (Hockenberry and Wilson, 2011).
- Children who receive long-term home enteral feedings often experience developmental and growth delays. Other common

problems include sleep disturbance, tube blockages, problems with delivery of equipment, and equipment malfunction. Therefore these children require close follow-up and frequent nutritional monitoring.

- Teach parents or caregiver to position children who cannot sit up during or after a tube feeding on their right side during the tube feeding and for approximately 1 hour after the feeding (Hockenberry and Wilson, 2011).

Gerontologic

- Assess for changes and limitations in sensory function, mobility, or dexterity that indicate a need to teach a caregiver how to administer feedings.
- Day enteral tube feeding is best choice because overnight feeding has an increased risk of aspiration in clients with an incompetent swallow. Feeding increases the need for urination; client may forget to disconnect before getting out of bed, get tangled in the tubing, and/or experience urinary/fecal incontinence because he or she cannot get to the toilet quickly enough (Hitchings et al., 2010).
- Elderly are especially at risk for drug interactions with nutrients because of increased number of different medications (polypharmacy) (Hitchings et al., 2010).

SKILL 42-8 Managing Parenteral Nutrition in the Home

Parenteral nutrition (PN) in the home is indicated for clients who cannot take adequate nutrition by mouth and when enteral feedings are contraindicated (e.g., cancer, renal failure, motor neuron disorders, cardiac disease, chronic respiratory or gastrointestinal disorders) (Holmes, 2011). In the home PN is often called *total nutrient admixture (TNA)*. Nurses who manage PN in the home collaborate frequently with registered dietitians and other health care providers to ensure that clients receive sufficient calories, protein, and fluid. PN is administered through a long-term central venous catheter (CVC) such as a tunneled CVC (e.g., Groshong or Hickman catheter), an implantable port, or a peripherally inserted central catheter (PICC) (see Chapter 28). There are risks of complications for infusion, including intravenous (IV)-related blood clots and blood stream infection.

PN is an individually formulated and complete supplement that includes a mixture of amino acids, dextrose, fat emulsions, vitamins, electrolytes, minerals, and trace elements. Administering PN

in the home is time consuming, placing a burden on the family caregiver (Smith and Ross, 2010).

Usually administration of PN in the home takes about 12 hours; thus many clients choose to receive their PN during the night. Because of the risks involved with PN and because management in the home is very complex, clients receive their first infusion of PN in an acute care setting. After discharge a home care nurse visits frequently. Carefully assess the reaction of the client or caregiver to the use of the technology needed to administer PN at home and provide emotional support. Although administering PN in the home increases clients' autonomy, it often interferes with their ability to maintain their normal routines. Work with the client or caregiver to stress the benefits and offer support in dealing with related issues.

Delegation and Collaboration

The skill of managing parenteral nutrition in the home cannot be delegated to nursing assistive personnel (NAP).

Equipment

- IV solution of PN or TNA
- IV tubing with optional filter (0.2 µm for dextrose/amino acids, 1.2 µm for TNA)
- Electronic IV infusion pump with alarms and protection from free flow

- Home blood glucose monitoring equipment
- Alcohol swabs
- Clean gloves
- Paper or logbook and pencil or pen

STEP	RATIONALE
------	-----------

ASSESSMENT

<p>1 Assess client’s nutritional status and risk for malnutrition by using a nutrition screening tool (see Chapter 30) and performing a physical examination. Identify signs and symptoms of malnutrition (e.g., weight loss or weight below ideal level; muscle atrophy, wasting, or weakness; lethargy; unable to eat for more than 6 days). Include measurement of vital signs.</p> <p>2 Assess client’s fluid and electrolyte levels, serum albumin, total protein, transferrin, prealbumin, triglycerides, and glucose levels.</p> <p>3 Assess client’s venous access device for edema, drainage, tenderness, and signs of inflammation (see Chapter 28). Measure circumference of upper arm if client has PICC; mark place on arm where measurement was taken.</p> <p>4 Verify health care provider’s order for nutrients, vitamins, minerals, trace elements, electrolytes, and flow rate.</p> <p>5 Assess client’s or family caregiver’s anxiety level and readiness to learn.</p> <p>6 Assess client’s or caregiver’s previous knowledge and experience in managing PN in the home. Have client or caregiver perform return demonstration if able to perform skill.</p>	<p>Nutritional assessment helps to identify clients who are malnourished or vulnerable to nutritional decline (Holmes, 2011).</p> <p>Provides baseline assessment data (Holmes, 2011).</p> <p>Infection is a common complication when client has venous access device. Measurement of arm helps detect infiltration of PICC. Mark on arm ensures consistent measurements over time.</p> <p>Ensures safe and accurate PN administration.</p> <p>Anxiety prevents learning. Skill is highly complex, and client needs to be ready to learn.</p> <p>Determines level of understanding before beginning teaching session.</p>
--	---

NURSING DIAGNOSES

- | | | |
|--|--|--|
| <ul style="list-style-type: none"> • Adult failure to thrive • Anxiety • Caregiver role strain • Fatigue | <ul style="list-style-type: none"> • Imbalanced nutrition: less than body requirements • Deficient knowledge regarding TPN | <ul style="list-style-type: none"> • Readiness for enhanced nutrition • Risk for infection • Social isolation |
|--|--|--|

Related factors are individualized based on client’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Client or family caregiver is able to administer PN correctly. • Client or caregiver demonstrates proper care of CVC. • Client or caregiver states signs and symptoms that need to be reported to health care provider. <p>2 Select setting in home where client is most likely to administer PN.</p>	<p>Indicates that skills are effectively learned.</p> <p>Prevents infection and ensures patency of venous access device.</p> <p>Ensures safe administration of PN in home.</p> <p>Practicing in same environment where skill is routinely performed facilitates comprehension and learning.</p>
---	---

IMPLEMENTATION

<p>1 Provide name and phone number of persons or resources available 24 hours a day, 7 days a week in case problems arise.</p> <p>2 Explain type/name of infusion, dosage, expected outcomes, and components of PN. Explain that PN needs to be stored in refrigerator.</p> <p>3 Have client or caregiver perform each step with guidance from nurse. Do not rush client.</p> <p>4 Instruct client or caregiver to inspect bag label, ensure that client’s name is on label, ensure that bag has not expired, and check bag for leaks.</p> <p>5 Suggest taking PN solution out of refrigerator for 30 to 60 minutes before scheduled infusion time.</p> <p>6 Explain need to inspect fluid in bag for color and precipitates.</p>	<p>Provides assurance and allows client or family caregiver to troubleshoot problems and answer questions.</p> <p>Allows client or caregiver to verify that correct PN is infused and client or caregiver understands expected outcomes of care. Refrigeration maintains integrity of PN.</p> <p>Allows you to correct errors in technique as they occur and discuss implications.</p> <p>Ensures that right client receives right PN. Bag needs to be intact to maintain closed system and ensure that client receives all prescribed nutrients.</p> <p>Chilled solution often causes discomfort; allowing solution to warm enhances comfort during infusion.</p> <p>Changes in color or precipitates in bag indicate disruption in PN.</p>
---	--

STEP

RATIONALE

Clinical Decision Point *If precipitate appears, components of mixture are separated, or color changes, explain that solution needs to be discarded.*

- | | |
|---|---|
| <p>7 Perform hand hygiene and apply clean gloves. Demonstrate how to attach IV tubing to bag, how to attach filter to IV tubing (<i>optional</i>), how to prime IV tubing, and how to load IV tubing into electronic infusion pump (see Chapter 28).</p> <p>8 Wipe CVC port with alcohol and show how to flush CVC and connect IV tubing to port (see Chapter 28). Use needleless system whenever possible.</p> <p>9 Explain how to determine appropriate rate of infusion and program infusion pump (see Skill 28-2). Caution patient and caregiver against changing rate to “catch up.”</p> <p>10 Remove and dispose of gloves; perform hand hygiene.</p> <p>11 When infusion is completed, explain how to disconnect IV tubing and flush CVC (see Chapter 28). Ensure that client or caregiver performs hand hygiene before and after disconnecting line.</p> <p>12 Describe appropriate use and storage of infusion pump and supplies. Explain appropriate tubing replacement schedules (e.g., every 24 hours for TNA, 72 hours for three-in-one solutions).</p> <p>13 Help to develop plan for appropriate disposal of supplies, including needles, syringes, and unused medications or solutions, using principles of standard precautions.</p> <p>14 Demonstrate appropriate care of CVC site; discuss how to change dressings, frequency of dressing changes, and signs of infection (see Skill 28-6).</p> <p>15 Teach client and/or caregiver about signs and symptoms that indicate potential complications from PN therapy (e.g., infection and phlebitis at CVC site, refeeding syndrome, hyperglycemia, hyponatremia, hypophosphatemia, hypokalemia, hypomagnesemia) and when to call for help.</p> <p>16 Demonstrate use of self-blood glucose monitor. Explain frequency of testing, normal glucose values, and what to do if values fall outside of expected range (see Chapter 43).</p> <p>17 Provide client with logbook to record administration of PN, weights, intake and output, and blood glucose levels.</p> <p>18 Help client develop a plan to reorder supplies, PN fluid, and prescribed additives; for emergencies (e.g., what to do if electricity goes out); and for a home safety plan (e.g., how to get to bathroom without tripping over IV tubing).</p> | <p>Prepares PN solution for IV administration.</p> <p>CVC needs to be patent, and IV tubing needs to connect to CVC to allow PN to be administered. Needleless systems prevent needlestick injuries.</p> <p>Ensures that PN is administered at appropriate rate.</p> <p>Prevents spread of microorganisms.</p> <p>Flushing CVC following infusion maintains patency of vascular access device. Meticulous hand hygiene prevents infection.</p> <p>Maintains integrity of equipment; appropriate timing of tubing changes prevents infection.</p> <p>Implementation of standard precautions is necessary to prevent transmission of communicable diseases and needlestick injuries.</p> <p>Prevents infection at CVC insertion site.</p> <p>Knowledge of complications of PN therapy allows for early detection and appropriate action.</p> <p>PN increases blood glucose levels, which negatively affects client outcomes. Frequent monitoring of glucose level helps detect problems early. Expect testing frequency to decrease as client’s condition and response to PN stabilizes.</p> <p>Allows health care providers and clients to evaluate outcomes and detect adverse effects of nutritional therapy.</p> <p>Plans allow for continuous, safe, and effective administration of PN.</p> |
|---|---|

EVALUATION

- | | |
|--|--|
| <p>1 Have client or family caregiver independently demonstrate initiation, infusion, and discontinuation of PN infusion and CVC site care.</p> <p>2 Watch client clean and store PN, equipment, and supplies.</p> <p>3 Ask client or caregiver to identify expected outcomes of nutritional therapy.</p> <p>4 Have client or caregiver describe common signs and symptoms of infection and other complications of PN.</p> <p>5 Watch client record information in logbook. Review client’s or caregiver’s log book periodically to ensure that information is being recorded correctly.</p> | <p>Feedback through return demonstration of psychomotor skill is best means of evaluating mastery of skill.</p> <p>Proper cleaning and storage prevents bacterial growth.</p> <p>Measures client cognitive learning and confirms understanding of information.</p> <p>Measures cognitive learning.</p> <p>Health care providers make changes in client care based on information provided by client. To ensure that changes are made appropriately, client needs to record accurate information.</p> |
|--|--|

Unexpected Outcomes

- 1 Client or family caregiver is unable to manage home PN therapy or verbalize information that was taught.
- 2 Client or caregiver reports signs and symptoms of complications from PN or CVC.

Related Interventions

- Ask client or caregiver to describe difficulties experienced while performing skill.
- Use different teaching strategy.
- Teach caregiver further and evaluate need to increase frequency of home visits to ensure safe administration of PN at home.
- Inform health care provider.
- Tell client or caregiver to call EMS if signs and symptoms are severe.

Recording and Reporting

- Record information taught, client's response, and outcomes of PN therapy (e.g., weight, electrolyte and glucose levels, physical assessment findings) in home care record.
- Record appearance of CVC site, infusions, glucose monitoring results, client's weight in home documentation system (e.g., logbook).

Special Considerations

Teaching

- Assess client's psychosocial status while providing information. Many clients experience a decrease in the quality of life when PN feedings are started in the home, which often increases anxiety and decreases comprehension of information.
- Eating is often a social event. When clients do not eat, they tend to feel socially isolated. Teach clients and family caregivers the importance of maintaining social relationships and enhancing social support during PN therapy. Refer client to support

groups and other resources such as the Oley Foundation (<http://oley.org/index.html>) (Hockenberry and Wilson, 2011).

- Always leave a phone number and instructions about how to reach home care nurse if needed.

Pediatric

- The risk for displacement of the CVC increases as the child grows. Ensure that the placement of the venous access device is confirmed with x-ray film examination as the child grows.
- Teach the caregiver to socialize child with other children to enhance development (Hockenberry and Wilson, 2011).

Gerontologic

- Frail older adults are at high risk for electrolyte disturbances. Frequently assess and monitor their response to PN and their laboratory values.
- Carefully assess client's ability to perform skill. Management of PN at home is complex and requires manual dexterity, visual acuity, and high-level critical thinking and decision-making skills. Include caregiver or other family members in teaching plan to help with management of home PN.

Critical Thinking Exercises

You are scheduled to visit an 80-year-old retired banker who lives in a private home with his 77-year-old wife. The client was recently hospitalized for atrial fibrillation, an abnormal heart rhythm, and was sent home on digoxin, a cardiac glycoside, to control his arrhythmia. The client has impaired visual acuity and is hard of hearing. When you call him to set up the home visit, you find that, in addition to his recent arrhythmia, he has an elevated temperature. This is your first home visit.

- 1 What information would you like to have about the client before you go to his home to help him with safely managing his new medical condition and medication and address the temperature?
- 2 You teach the client how to take his pulse before he takes his digoxin. For how long do you tell him to take his pulse? Explain your choice.
 - 1 For 15 seconds and then multiply by 4
 - 2 For 30 seconds and then multiply by 2
 - 3 For a full minute
 - 4 For 2 minutes
- 3 The client tells you that he cannot feel his radial pulse after repeated attempts. What is your next step?
- 4 Describe three teaching strategies you could use to enhance client's ability to learn how to take medications correctly.
- 5 The client informs you that his temperature has been 100° F (37.7° C) for the past 2 days. However, his wife is concerned that he is not checking his temperature accurately and that it is actually much higher. What will you do to assess if the client is checking his temperature correctly?

REVIEW QUESTIONS

- 1 A client has purchased a new electronic blood pressure monitoring device. Which nursing action will verify the accuracy of her blood pressure monitor?
 - 1 Calling the client after 2 weeks of monitoring and asking for the readings obtained
 - 2 Having her check her neighbor's blood pressure with the new monitor
 - 3 Checking her blood pressure with a manual aneroid sphygmomanometer 1 to 2 minutes after she checks it with her monitor
 - 4 Asking her to describe when and how she should take her blood pressure with her new monitor
- 2 A client is being discharged from the hospital with home oxygen therapy. What should be included in the nurse's teaching session with him and his family? (Select all that apply.)
 - 1 He should not allow people in the home to smoke.
 - 2 He should be able to attend his son's Boy Scout campfire.
 - 3 He should use an electric razor when shaving.
 - 4 He should have two complete sets of oxygen delivery devices.
 - 5 The oxygenation delivery systems can be placed behind the bedroom curtains so the room looks neat and uncluttered.
 - 6 When filling an ambulatory liquid tank from the stationary reservoir, the first thing to do is to wipe the connectors of both tanks with a lint-free cloth.

- 3 A client's family is being taught how to suction the client's tracheostomy in preparation for her discharge home. What information should be included in the teaching session?
 - 1 Instill normal saline to help prevent hypoxia during suctioning.
 - 2 Set the suction pressure on the suction machine between 160 and 180 mm Hg.
 - 3 Teach how to perform oral suction after tracheostomy suction.
 - 4 Place client in a supine position.
 - 5 Grasp the suction catheter with the nondominant hand.
- 4 An 83-year-old client cares for himself at home. Which nursing intervention will enhance adherence to his medication regimen?
 - 1 Teach him everything he needs to know in 1 day and return in 2 weeks.
 - 2 Include him in deciding the system used to help him remember to take his medications.
 - 3 Provide large-print instructions that are written in dark blue ink.
 - 4 Provide medication information when his daughter and infant grandchild are visiting him.
- 5 An older adult had a recent stroke and is receiving home enteral nutrition. Which action(s) should the nurse have instructed the family caregiver to take if the client begins to have difficulty breathing and coughing? (Select all that apply.)
 - 1 Call the health care provider.
 - 2 Raise the head of the bed.
 - 3 Verify tube placement.
 - 4 Stop the feeding.
- 6 The home care nurse receives a call from the wife of an elderly couple, who says that her frail husband doesn't feel well at all and his temperature is 99.2° F (37.3° C) orally. Which response by the nurse would be most appropriate?
 - 1 "How much liquid has he had to drink since yesterday?"
 - 2 "Take him to the emergency department because he needs care."
 - 3 "Which specific symptoms is your husband experiencing?"
 - 4 "When did he beginning noticing a change in his health?"
- 7 A client who is monitoring his blood pressure at home is consistently getting much higher readings than the readings taken when he visits his health care provider's office. Which question is most important for the home health nurse to ask?
 - 1 "What time of day are you checking your blood pressure?"
 - 2 "How tight is the blood pressure cuff before you inflate it?"
 - 3 "Are you concerned about the difference in the readings?"
 - 4 "How long ago did the difference in the readings begin?"
- 8 The nurse is teaching a client how to perform clean, intermittent catheterization. Which statement by the client reflects accurate teaching by the nurse?
 - 1 "I need to clean the urethral opening with three betadine wipes."
 - 2 "I should use a sterile catheter each time I catheterize myself."
 - 3 "I should have an extra catheter washed and ready to use."
 - 4 "I should use sterile gloves to prevent contamination of the urine."
- 9 The daughter of an older client asks why her mother periodically becomes more confused when she is trying to cough up thick mucus than she did several years ago. Which response by the nurse is most accurate?
 - 1 "Your mother is becoming weaker, which is causing the problem."
 - 2 "As your mother ages, she is losing some of the elastic recoil."
 - 3 "Oxygen levels decrease with forceful coughing more as aging occurs."
 - 4 "Her anxiety is causing her to not to cough as effectively as before."

- 10 A mother of a school-age child with a newly diagnosed chronic illness is receiving education about the new medication regimen from the nurse. Which statement by the mother requires that the nurse provide additional information?
 - 1 "I'm not sure why my child needs all these medications."
 - 2 "Medications need to be stored in a locked area so my 3-year-old can't get them."
 - 3 "I need to make a chart outlining when to give the medications."
 - 4 "I need to call the pharmacy when I notice that only a few doses of medication are left."

Double-voided specimen	Ketones	Reagent	Void
Dysuria			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Explain the rationale for the collection of each specimen.
- Identify special conditions necessary for collection of each specimen.
- Explain instructions to encourage patient cooperation for successful collection of each specimen.
- Recognize the impact of patient-centered issues on patient's cooperation with collection of specimens.
- Identify measures to minimize anxiety and promote safety during specimen collection.
- Discuss nursing responsibilities for processing a specimen after collection.
- Chart appropriate information in a patient's electronic health record (EHR) or written record after collection of a specimen.
- Use correct technique for collecting clean-voided, timed, and catheterized urine specimens.
- Use correct technique for collecting specimens and cultures for blood and other body fluids.
- Use correct technique to perform venipuncture.
- Use infection control practices during specimen collection techniques.
- Use correct technique to perform arterial puncture for blood gas measurement.

Laboratory test results aid in the diagnosis of health care problems, provide information about the stage and activity of a disease process, and measure a patient's response to therapy. Proficiency in performing point-of-care (POC) tests, assistance with diagnostic testing, and specimen collection and analysis are nursing responsibilities. Skill and judgment in obtaining specimens affect patient comfort and safety and ensure accuracy and quality of diagnostic procedures. Accountability, attention to monitoring patient outcomes, and current health care economics increase the demand for accurate and timely laboratory tests.

When there are questions about laboratory tests, consult reference books or the agency procedure manual or laboratory. Each agency may establish its own values for each test, which are printed on the agency laboratory slips. It is important that you know the significance of any abnormal finding. Discuss any major deviations immediately with the health care provider.

EVIDENCE-BASED PRACTICE

Evidence-based research specific to nursing practices of specimen collection techniques needs further exploration to provide and ensure safety, quality care, and best practices. Blood cultures are one type of specimen collection obtained by venipuncture to confirm the diagnosis of infection. Blood cultures are usually incubated to examine for bacterial growth, but early test results are available within 48 hours. If results are negative, antibiotics are unnecessary, and the health care provider can seek alternative diagnoses. When results are positive and bacteria grow in the blood culture, the health care provider needs to ensure that the growth was not caused by contamination from the skin but by a true bacterium. During this time unnecessary testing may occur, hospital stays are extended, and unneeded antibiotics may be administered. Studies have indicated that in the adult population blood cultures are contaminated 1% to 6% of the time (Weddle et al., 2010). In the pediatric population these contamination rates can be 9% or higher. There are interventions that can reduce the contamination of blood cultures during venipuncture.

- Use skin preparations such as iodine, chlorhexidine, or alcohol before venipuncture.
- Obtain culture only through percutaneous venipuncture.
- Obtain two different culture specimens at the same time.
- Developing a dedicated phlebotomy team has been shown to reduce contamination rates.

PATIENT-CENTERED CARE

Nurses and other health care providers support patient-centered care by assessing and adapting for patient's psychosocial and physiologic factors before, during, and after specimen collection. During phlebotomy physiologic factors such as discomfort, pain, or dehydration may affect your ability to collect a specimen. Psychosocial factors to consider include age, gender, anxiety, embarrassment, fear, ethnicity, and patients' values and beliefs (Pagana and Pagana, 2011).

Patients often experience embarrassment or discomfort when giving a sample of body excretions or secretions. It is important to handle excretions or secretions discretely and provide a patient

with as much privacy as possible. Given clear instructions, patients are able to obtain their own specimens of urine, stool, and sputum without unnecessary exposure. Choose words that are clearly understood; many patients, especially children, do not understand the terms *void*, *urine*, or *stool*.

Cultural considerations are important when collecting specimens and performing diagnostic procedures. Culture and beliefs may affect a patient's response and willingness to participate in specimen collection. Southeast Asians consider blood to be a vital life force that is irreplaceable. They may become anxious about a needle penetrating the skin, allowing blood to seep out. The insertion of a foreign object into the mouth (e.g., swab, tongue blade) to collect specimens may be threatening to Southeast Asians who believe that diseases can be introduced through the mouth and the head is the seat of one's life force (Stuart, Stuart, and Cherry, 2011).

Consider both cultural and language barriers when delegating specimen collection to patients and family members. For example, Muslims and Hindus designate which hand is to be used for clean and dirty tasks. Collecting their own stool and urine specimens may be difficult because only the left hand can be used for "dirty" activities. Language barriers make it difficult to explain the purpose of tests and collection techniques. Be sure to provide repeated return demonstrations to ensure that patient or family member understands how to perform a procedure.

Whenever possible, use gender-congruent caregivers when collecting vaginal, rectal, and urinary specimens from patients whose cultural values demand modesty and distinct separation of gender roles. Provide privacy when giving instructions and during specimen collection.

Safety Guidelines

- 1 Adapt to a patient's need and ability to safely perform and/or participate in specimen collection procedures.
- 2 Verify the type of procedure scheduled and the procedure site with the patient.
- 3 Follow standard precautions (see Chapter 7) when collecting specimens of blood or body fluids.
- 4 Properly label all specimens with patient's identification, date and time the specimen is obtained, name of the test, and source of the specimen/culture for each container (TJC, 2012).
- 5 Deliver specimens to the laboratory within the recommended time or ensure that they are stored properly for later transport.
- 6 Follow procedures for special conditions (e.g., iced specimens, special containers with preservatives) required for transport of specimens. Specific required prerequisite conditions include fasting and nothing by mouth (NPO) and may need to be completed before the collection of a specimen (Pagana and Pagana, 2011).
- 7 Know agency policy regarding infection control practices for transportation of all specimen containers of body substances.
- 8 Follow procedures for medications or dietary intake that may result in some deviations from normal values.
- 9 Follow precautions for collecting specimens from patients who are in protective isolation.

SKILL 43-1 Urine Specimen Collection: Midstream (Clean-Voided) Urine; Sterile Urinary Catheter

NSO Specimen Collection Module / Lessons 1 and 2

A urinalysis provides information about kidney or metabolic function, nutrition, and systemic diseases. Urine collection uses a variety of methods, depending on the purpose of the urinalysis and the presence or absence of a urinary catheter. Guidelines for assessment, planning, and evaluation are similar, regardless of the method of collection. Routine urinalysis includes measurement of nine or more elements, including urine pH, protein and glucose levels, ketones, specific gravity, white blood cell (WBC) count, and presence of bacteria and/or blood (Pagana and Pagana, 2011).

Types of Urine Tests and Specimens

A *random urine specimen for routine urinalysis* is collected using a specimen “hat” (Fig. 43-1), which you place under a toilet seat to collect voided urine. You then place approximately 120 mL of urine in a specimen container, properly labeled, and send to the laboratory.

A *culture and sensitivity (C&S) of urine* is performed to identify if bacteria are present (culture) and determine the most effective antibiotic for treatment (sensitivity). Use sterile technique to ensure that any microorganisms present originate in the urine and not from the patient’s skin, the hands, or the environment. You collect specimens for C&S either as a clean-voided midstream specimen or under sterile technique from a urinary catheter. Urine collected by this method may also be analyzed for the same components as a routine urinalysis.

A *timed urine specimen for quantitative analysis* requires urine to be collected over 2 to 72 hours. The 24-hour timed collection (see [Procedural Guideline 43-1](#)) is most common and allows for measurement and quantitative analysis of elements such as amino acids, creatinine, hormones, glucose, and adrenocorticosteroid excretion.

Chemical properties of urine are tested by immersing a specially prepared test strip of paper (Chemostrip) into a clean urine specimen. The test detects the presence of glucose, ketones, protein, or blood not normally present in the urine (see [Procedural Guideline 43-2](#)). When the screening test for the presence of substances in the urine is positive, additional laboratory tests are used to determine a patient’s diagnosis or measure the effectiveness of treatment.

FIG 43-1 Specimen hat.

Video Clip

Delegation and Collaboration

The skill of collecting urine specimens can be delegated to nursing assistive personnel (NAP). The nurse informs the NAP about:

- When to obtain the specimens.
- Patient mobility restrictions that will affect collection technique.
- Reporting to the nurse if the urine is not clear (e.g., contains blood, cloudiness, or excess sediment).
- Reporting when a patient is unable to initiate a stream or has pain or burning on urination.

Equipment

- ❑ Completed identification labels with appropriate patient identifiers
- ❑ Completed laboratory requisition, including patient identification, date, time, name of test, and source of culture
- ❑ Small plastic biohazard bag for delivery of specimen to laboratory (or container specified by agency)

Clean-Voided Urine Specimen

- ❑ Commercial kit for clean-voided urine (Fig. 43-2) containing:
 - Sterile cotton balls or antiseptic towelettes
 - Antiseptic solution (chlorhexidine or povidone-iodine solution)
 - Sterile water or normal saline
 - Sterile specimen container
 - Urine cup
- ❑ Clean gloves
- ❑ Soap, water, washcloth, and towel
- ❑ Bedpan (for nonambulatory patient), specimen hat (see Fig. 43-1) (for ambulatory patient)

Sterile Urine Specimen from Urinary Catheter

- ❑ 20-mL Luer-Lok for routine urinalysis or 3-mL safety Luer-Lok syringe for culture
- ❑ Alcohol, chlorhexidine, or other disinfectant swab
- ❑ Clamp or rubber band
- ❑ Specimen container (nonsterile for routine urinalysis; sterile for culture)
- ❑ Clean gloves

FIG 43-2 Clean-voided specimen collection kit.

STEP

RATIONALE

ASSESSMENT

1 Assess patient's or family members' understanding of purpose of test and method of collection.	Information allows you to clarify misunderstanding; promotes patient cooperation.
2 Assess patient's ability to help with urine specimen collection; able to position self and hold container.	This determines degree of assistance patient requires.
3 Assess for signs and symptoms of urinary tract infection (UTI) (frequency, urgency, dysuria, hematuria, flank pain, fever; cloudy, malodorous urine).	These are indicators of UTI.
4 Refer to agency procedures for specimen collection methods.	Agency policies may vary regarding collection and/or handling of specimens.

NURSING DIAGNOSES

- Acute pain
- Anxiety
- Deficient knowledge regarding specimen collection
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Specimen free of contaminants is collected. • Patient discusses procedure for specimen collection. • Patient discusses purpose and benefits of specimen collection. 	<p>Proper collection technique prevents substances from changing normal characteristics of urine.</p> <p>Procedure is safely performed.</p> <p>Evaluates patient's learning.</p>
--	--

IMPLEMENTATION

1 Perform hand hygiene, check labels, and complete laboratory requisition for specimen container.	Reduces transfer of microorganisms. Organizes procedure.
2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
3 Provide privacy for patient; close curtains around bed or close room door. Allow mobile patients to collect specimen in bathroom.	Privacy allows patient to relax and produce specimen more easily.
4 Collect clean-voided urine specimen. <ul style="list-style-type: none"> a Apply clean gloves. Give patient cleaning towelette or towel, washcloth, and soap to clean perineum or help with cleaning perineum. Help bedridden patient onto bedpan to facilitate access to perineum. Remove and dispose of gloves. b Using surgical asepsis, open outer package of commercial specimen kit. c Apply clean gloves. d Pour antiseptic solution over cotton balls (unless kit contains prepared antiseptic towelettes). e Open specimen container, maintaining sterility of inside specimen container, and place cap with sterile inside up. Do not touch inside of cap or container. f Use aseptic technique to help patient or allow patient to independently clean perineum and collect specimen. Amount of assistance needed varies with each patient. Inform patient that antiseptic solution will feel cold. 	<p>Patients prefer to wash their own perineal areas when possible. Cleaning prevents contamination of specimen after urine passes from urethra.</p> <p>Maintains sterility of equipment.</p> <p>Prevents contact of microorganisms on your hands. Cotton ball or towelette is used to clean perineum.</p> <p>Contaminated specimen is most frequent reason for inaccurate reporting of urine C&S.</p> <p>Maintains patient's dignity and comfort.</p>

STEP

RATIONALE

(1) *Male:*

- (a) Hold penis with one hand; using circular motion and antiseptic towelette, clean meatus, moving from center to outside 3 times with different towelettes (see illustration). Have uncircumcised male patient retract foreskin for effective cleaning of urinary meatus and keep retracted during voiding. Return foreskin when done.
- (b) If agency procedure indicates, rinse area with sterile water and dry with cotton balls or gauze pad.
- (c) After patient initiates urine stream into toilet or bedpan, have him pass urine specimen container into stream and collect 90 to 120 mL of urine (Pagana and Pagana, 2011) (see illustration).

Reduces number of microorganisms at urethral meatus and moves from areas of least to most contamination. Return of foreskin prevents stricture of penis.

Prevents contamination of specimen with antiseptic solution.

Initial urine flushes out microorganisms that normally accumulate at urinary meatus and prevents transfer into specimen.

(2) *Female:*

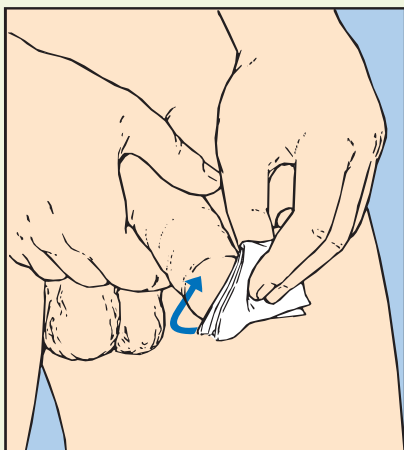

- (a) Either nurse or patient spreads labia minora with fingers of nondominant hand.
- (b) With dominant hand clean urethral area with antiseptic swab (cotton ball or gauze). Move from front (above urethral orifice) to back (toward anus). Use fresh swab each time; clean 3 times; begin with labial fold farthest from you, then labial fold closest, and then down center (see illustration).
- (c) If agency procedure indicates, rinse area with sterile water and dry with cotton ball.
- (d) While continuing to hold labia apart, patient initiates urine stream into toilet or bedpan; after stream is achieved, pass specimen container into stream and collect 90 to 120 mL of urine (Pagana and Pagana, 2011) (see illustration).

Provides access to urethral meatus.

Prevents contamination of urinary meatus with fecal material. Cleaning down center last decreases contamination from labia.

Prevents contamination of specimen with antiseptic solution.

Initial stream flushes out resident microorganisms that accumulate at urethral meatus and prevents transfer into specimen.

STEP 4f(1)(a) Cleaning technique (male).

STEP 4f(1)(c) Collecting midstream urine specimen (male).

STEP 4f(2)(b) Clean from front to back, holding labia apart.

STEP 4f(2)(d) Collection of midstream urine specimen (female).

STEP

RATIONALE

- g** Remove specimen container before flow of urine stops and before releasing labia or penis. Patient finishes voiding into bedpan or toilet. Offer to help with personal hygiene as appropriate.
- h** Replace cap securely on specimen container, touching only outside.
- i** Clean urine from exterior surface of container.
- 5 Collect urine from indwelling urinary catheter.**
- a** Explain that you will use syringe without need to remove urine through catheter port and that patient will not experience any discomfort.
- b** Explain that you will need to clamp catheter for 10 to 15 minutes before obtaining urine specimen and that urine cannot be obtained from drainage bag.
- c** Apply clean gloves. Clamp drainage tubing with clamp or rubber band for as long as 15 minutes below site chosen for withdrawal (see illustration).
- d** After 15 minutes position patient so catheter sampling port is easily accessible. Location of port is where catheter attaches to drainage bag tube (see illustration). Clean port for 15 seconds with disinfectant swab and allow to dry.
- e** Attach needleless Luer-Lok syringe to built-in catheter sampling port (see illustration). Some needleless ports use blunt plastic valve or slip-tip syringe inserted into port diaphragm.

- Prevents contamination of specimen with skin flora. Prevents sediment from bladder getting into specimen.
- Retains sterility of inside of container and prevents spillage of urine.
- Prevents transfer of microorganisms to others.
- Minimizes anxiety when you manipulate catheter and aspirate urine with syringe from catheter port.
- Allows urine to accumulate in catheter. Urine in drainage bag is not considered sterile.
- Permits collection of fresh sterile urine in catheter tubing rather than draining into bag.
- Prevents entry of microorganisms into catheter.
- Guideline recommends use of Luer-Lok needleless system. Needleless system prevents injury by needlestick.

STEP 5c Rubber band used to clamp catheter drainage tube.

STEP 5d Port with syringe attached.

STEP 5e Access urinary catheter port with Luer-Lok syringe or syringe with blunt plastic valve.

STEP	RATIONALE
f Withdraw 3 mL for culture or 20 mL for routine urinalysis.	Allows collection of urine without contamination. Proper volume is needed to perform test.
g Transfer urine from syringe into clean urine container for routine urinalysis or into sterile urine container for culture.	Prevents contamination of urine during transfer procedure.
h Place lid tightly on container.	Prevents contamination of specimen by air and loss by spillage.
i Unclamp catheter and allow urine to flow into drainage bag. Ensure that urine flows freely.	Allows urine to drain by gravity and prevents stasis of urine in bladder.
6 Securely attach label to container (not lid). In patient's presence, confirm label identifiers (two identifiers, specimen source, and collection date and time). If patient is female, indicate if she is menstruating.	Ensures that specimen is identified correctly for proper diagnosis (TJC, 2012).
7 Dispose of soiled supplies. Remove and dispose of gloves and perform hand hygiene.	Prevents transmission of microorganisms.
8 Send specimen and completed requisition to laboratory within 20 minutes. Refrigerate specimen if delay cannot be avoided.	Delay of analysis may significantly alter test results (Pagana and Pagana, 2011).

EVALUATION

1 Inspect clean-voided specimen for contamination with toilet paper or stool.	Contaminants prevent specimen from being used.
2 Evaluate patient's urine C&S report for bacterial growth.	Routine cultures identify organism(s), and sensitivity study identifies antimicrobial medications that may be effective against pathogen.
3 Observe urinary drainage system in catheterized patient to ensure that it is intact and patent.	System must remain closed to remain sterile.
4 Ask patient to describe midstream urine collection procedure.	Validates patient's understanding.

Unexpected Outcomes

- 1 Urine specimen is contaminated with stool or toilet paper.
- 2 Patient is unable to void, or urine does not collect in drainage tube.
- 3 Urine culture reveals bacterial growth (determined by colony count of more than 10,000 organisms per milliliter).
- 4 Lumen leading to balloon that holds catheter in bladder is punctured.

Related Interventions

- Repeat patient instruction and specimen collection. If unable to obtain specimen through clean voiding, patient may need catheterization (see Skill 33-1).
- Offer fluids if permitted to enhance urine production.
- Report findings to health care provider.
- Administer medications as ordered.
- Monitor patient for fever and dysuria.
- Notify health care provider.
- Prepare for removal and insertion of new catheter.
- Collect specimen.

Recording and Reporting

- Record collection of specimen in nurses' notes and electronic health record (EHR) or per agency policy; note method used to obtain specimen, date and time collected, type of test ordered, appearance, odor and color of urine, and disposition to laboratory.
- Report any abnormal findings to health care provider.

Special Considerations

Teaching

- Discuss signs and symptoms of UTI with patient and family member.
- Explain significance of cleaning genital area before collecting specimen.

Pediatric

- Use a sterile plastic urine-collecting bag (Fig. 43-3) that adheres to the perineum of an infant or a non-toilet-trained child (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults may need assistance in positioning to obtain specimen.

Home Care

- Specimens for culture should not be collected at home because time delay before laboratory culture could greatly enhance bacterial growth. If patient collects the urine specimen, he or she should keep it on ice until it reaches the laboratory for testing.

FIG 43-3 Application of urine collection bag. (From Warekois RS, Robinson R: *Phlebotomy worktext and procedures manual, ed 3, St Louis, 2012, Mosby.*)

PROCEDURAL GUIDELINE 43-1 Collecting a Timed Urine Specimen

Some tests of renal function and urine composition require urine to be collected over 2 to 72 hours. The 24-hour timed collection is used most often and measures elements such as amino acids, creatinine, hormones, glucose, and adrenocorticosteroids, the levels of which fluctuate throughout the day. A timed urine collection provides a means to measure the concentration or dilution of urine.

Timed urine collections begin after a patient urinates. Discard the first specimen and then collect every successive specimen until the time period has ended. Transfer each specimen immediately to a large collection bottle with or without preservative, kept in the patient's bathroom. Any missed specimens make test results inaccurate. The patient should always provide the last specimen as close as possible to the end of the collection period. The specimen may be placed on ice to prevent deterioration.

Delegation and Collaboration

The skill of collecting a timed urine specimen can be delegated to nursing assistive personnel (NAP). The nurse informs the NAP about:

- When timed collection begins, proper method to store the collected urine, where to place signs that a timed urine collection is in progress, and saving all urine.
- Reporting when blood, mucus, or foul odors are present in the urine specimen or if there is a break in the collection procedure.

Equipment

- ❑ Large collection bottle with cap that usually contains a chemical preservative
- ❑ Bedpan, urinal, specimen hat, bedside commode, or pediatric potty-chair
- ❑ Graduated measuring container for intake and output (I&O) measurement
- ❑ Large basin to hold collection bottle surrounded by ice if immediate refrigeration is required
- ❑ Specimen identification label and completed laboratory requisition (with appropriate patient identifiers and specimen information)
- ❑ Instructional signs that remind patient and staff of timed urine collection

- ❑ Clean gloves
- ❑ Plastic biohazard plastic bag or container (see agency policy)

Procedural Steps

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers on MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 2 Explain the reason for specimen collection, how patient can help, and that urine must be free of feces and toilet tissue.
- 3 Place specimen collection container in the bathroom and, if indicated, in a pan of ice. Post signs to remind staff, family and visitors, and patient of timed urine collection on patient's door and toileting area. If patient leaves unit, be sure that personnel in receiving area collect and save all urine.
- 4 If possible, have patient drink two to four glasses of water about 30 minutes before times of collection to facilitate ability to void at the appropriate time for test to begin.
- 5 Perform hand hygiene and apply clean gloves. Discard the first voided specimen as the test begins. Indicate time test began on laboratory requisition. For accurate results the patient must begin the test with an empty bladder. Begin collecting all urine for designated time.
- 6 Measure volume of each voiding if I&O are to be recorded. Place all voided urine in labeled specimen bottle with appropriate additives.
- 7 Unless instructed otherwise, keep specimen bottle in specimen refrigerator or container of ice in bathroom to prevent decomposition of urine.
- 8 Encourage patient to drink two glasses of water 1 hour before timed urine collection ends. Encourage patient to empty bladder during last 15 minutes of urine collection period.
- 9 Perform hand hygiene and apply clean gloves. Collect final specimen at end of collection period. Label specimen (two identifiers, specimen source, collection date and time, number of bottle) in patient's presence, attach appropriate requisition, and send to laboratory. Remove gloves and perform hand hygiene.
- 10 Remove signs. Tell patient that specimen collection period is completed.

PROCEDURAL GUIDELINE 43-2 Urine Screening for Glucose, Ketones, Protein, Blood, and pH

Video Clip

Tests for chemical properties of urine are part of the routine urinalysis completed in the laboratory or as a point-of-care test performed at the bedside or in the home. The use of a Multistix reagent test strip may simultaneously assess for up to nine chemical properties, specific gravity, pH, protein, glucose, ketones, blood bilirubin, urobilinogen, leukocytes, and nitrates. The test is easy to perform and causes no pain. This type of screening is used when more detailed laboratory testing is not available (e.g., health care provider's office, clinic, or long-term care setting). The use of urine testing for managing blood glucose is no longer recommended. Capillary blood monitoring is an accurate assessment of serum glucose levels (Pagana and Pagana, 2011).

Delegation and Collaboration

The skill of urine screening for chemical properties can be delegated to nursing assistive personnel (NAP). The nurse informs the NAP to:

- Obtain the specimen correctly (e.g., before meals, following a “double-voided” specimen).
- Report the results of the test or any odor, blood, or mucus in the urine specimen.

Equipment

- Bedpan, urinal, specimen hat, bedside commode, or pediatric potty-chair
- Container for urine from catheter
- Watch with second hand or digital counter
- Reagent test strip (check expiration date on container)
- Test strip color chart
- Paper towel
- Clean gloves
- Small biohazard plastic bag for delivery of specimen to laboratory (or container specified by agency)

Procedural Steps

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers on MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 2 Determine if double-voided specimen is needed for glucose testing. If required, ask patient to void, discard, and then drink a glass of water.
- 3 Perform hand hygiene and apply clean gloves. Ask patient to collect a fresh, random urine specimen. If patient is catheterized, remove a 5-mL specimen from the catheter port (see Skill 43-1).

- 4 Immerse end of reagent strip into urine container. Remove the strip immediately and tap it gently against the side of the container to remove excess urine.
- 5 Hold strip in horizontal position to prevent mixing of chemical reagents (see illustration).

STEP 5 Testing urine using reagent strip.

- 6 Precisely time the number of seconds specified on container and compare color of strip with color chart on container (Table 43-1).
- 7 When appropriate, discuss test results with patient. Discard urine. Remove and discard gloves; perform hand hygiene.
- 8 Record results immediately on appropriate testing flow sheet. Report reading to health care provider.

TABLE 43-1 Color Chart for Reagent Strip

Test	When to Read	Range of Results
pH	Anytime	4.6-8.0
Protein	Anytime	None or up to 8 mg/100 mL
Glucose	10 seconds (qualitative) 30 seconds (quantitative)	(-) to +4 (-) to +4 (270)
Ketones	15 seconds	(-) to +3 (large)
Blood	25 seconds	(-) to +3 (large)

SKILL 43-2 Measuring Occult Blood in Stool

NSO Specimen Collection Module / Lesson 4

Hemoccult testing is useful for screening for the presence of occult (invisible) blood in the stool for conditions such as colon cancer, bleeding gastrointestinal (GI) ulcers, and localized gastric or intestinal irritation. Use caution; a false-positive result may occur if a patient has ingested red meat within 3 days of testing or is taking certain medications (e.g., iron). A false-negative may result if that patient is taking vitamin C (Pagana and Pagana, 2011). The test measures microscopic amounts of blood in the stool. Normally a person loses small amounts of blood daily in the feces as a result of minor abrasions of the nasopharyngeal or oral mucosa. If greater than 50 mL of blood enters the feces from the upper GI tract, the blood causes melena (darkening of feces). When blood is present, further testing is indicated to determine the source of the bleeding.

Patients are often instructed on how to collect stool specimens for the test in the home. Only a small amount of stool is needed to perform the test successfully. The most common guaiac tests are the Hemoccult slides and the Hematest tablets. A new deoxyribonucleic acid (DNA) stool sample test promises to be twice as sensitive as the current guaiac testing for precancerous benign and malignant tumors. The DNA stool sample test identifies nonbleeding polyps with abnormal DNA (Pagana and Pagana, 2011).

Delegation and Collaboration

The skill of testing stool for occult blood can be delegated to nursing assistive personnel (NAP). The nurse informs the NAP to:

- Report immediately if blood is detected and not to discard stool from a positive test so the nurse may repeat the testing.

Equipment

- Soap, water, washcloth, and towel
- Paper towel
- Clean gloves

Video Clip

- Wooden applicators

Hemoccult Test

- Cardboard Hemoccult slide (Fig. 43-4)
- Hemoccult developing solution

Hematest

- Hematest tablets (must be protected from moisture, heat, and light)
- Guaiac paper
- Clean container of tap water

FIG 43-4 Hemoccult testing kit for measuring occult blood.

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's or family member's understanding of need for stool test.
- 2 Assess patient's ability to cooperate with procedure and collect specimen.
- 3 Assess patient's medical history for GI disorders (e.g., history of bleeding, colitis, or hemorrhoids).
- 4 Review patient's medications for drugs that contribute to GI bleeding.
- 5 Refer to health care provider's orders for medication or dietary modifications or restrictions before test.

Provides information on which to base necessary health teaching.

To avoid embarrassment, patients often prefer to collect own stool specimen. Some patients require assistance.

You can institute routine screening. Hemorrhoids can cause bleeding that may be misinterpreted as upper GI bleeding.

Anticoagulants increase risk for bleeding in GI tract, even from minor trauma to mucosa. Long-term use of steroids, nonsteroidal antiinflammatory drugs (NSAIDs), and acetylsalicylic acid (aspirin) can irritate mucosa and result in bleeding (Pagana and Pagana, 2011).

Specimens will be positive if contaminated by menstrual blood, hemorrhoid blood, or povidone-iodine. Diets rich in meats, green leafy vegetables, poultry, and fish may produce false-positive results.

NURSING DIAGNOSES

- Anxiety
- Bowel incontinence
- Constipation
- Deficient knowledge regarding collection and testing of stool specimen
- Diarrhea

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Test for occult blood is negative.
 - Patient discusses purpose and benefits of testing stool for blood.
- 2 Explain procedure to patient and/or family member. Discuss reason for specimen collection and how patient can help. Explain that feces must be free of urine and toilet tissue.
- 3 Arrange for any needed dietary or medication restrictions.

Patient has only small amount of blood in feces because of normal nasopharyngeal and oral mucosa abrasions.
Validates learning.

Patient who understands procedure is more likely to cooperate and may be able to obtain specimen independently. Also prevents accidental disposal of specimen.
Ensures accuracy of test results.

IMPLEMENTATION

- 1 Perform hand hygiene
- 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers on MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 3 Apply clean gloves. Obtain uncontaminated stool specimen and place in clean, dry container not contaminated with urine, water, or toilet tissue.
- 4 Use tip of wooden applicator to obtain small portion of feces.
- 5 Measure for occult blood.
 - a Perform Hemocult slide test:
 - (1) Open flap of Hemocult slide. Apply thin smear of stool on paper in first box.
 - (2) Obtain second fecal specimen from different portion of stool and apply thinly to second box of slide (see illustration).
 - (3) Close slide cover and turn slide over to reverse side. Open cardboard flap and apply 2 drops of Hemocult developing solution on each box of guaiac paper (see illustration).
 - (4) Read results of test after 30 to 60 seconds. Note color changes.
 - (5) Dispose of test slide in proper receptacle.
 - b Perform test using Hematest tablets:
 - (1) Place stool on guaiac paper. Then place Hematest tablet on top of stool specimen. Apply 2 to 3 drops of tap water to tablet, allowing water to flow onto guaiac paper.

Reduces transmission of microorganisms.
Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

Prevents transmission of microorganisms. Allows for accurate testing when specimen is not contaminated with other products.

Small specimen is sufficient for measuring blood content.

Guaiac paper inside box is sensitive to fecal blood content.

Occult blood from upper GI tract is not always equally dispersed throughout stool. Findings of occult blood are more conclusive for GI bleeding when entire specimen is found to contain blood. Developing solution penetrates underlying fecal specimen. Change in color of guaiac paper indicates blood.

Ensures correct results. Bluish discoloration indicates occult blood (guaiac positive). No change in color of guaiac paper indicates negative results.

Reduces transfer of microorganisms.
Tablet contains solid form of developing solution.
Tap water dissolves Hematest tablet and thus dispenses developing solution over specimen and guaiac paper.

STEP 5a(2) Application of stool specimen to both spots on Hemocult slide.

STEP 5a(3) Application of developing solution.

STEP	RATIONALE
(2) Observe color of guaiac paper within 2 minutes.	Bluish discoloration is guaiac positive. Do not read color after 2 minutes. False findings may occur.
(3) Dispose of tablet and paper in proper receptacle.	Reduces transfer of microorganisms.
6 Wrap wooden applicator in paper towel, grasp in nondominant hand, remove gloves over wrapped applicator. Discard in proper receptacle. Perform hand hygiene.	Reduces transfer of microorganisms.

EVALUATION

1 Ask patient to explain collection procedure.	Documents level of learning.
2 Note color changes in guaiac paper.	Reveals blood in feces.

Clinical Decision Point *Single positive test result does not confirm bleeding or indicate colorectal cancer. To confirm positive results, test must be repeated while patient is on meat-free, high-residue diet with more in-depth diagnosis (Van Leeuwen et al., 2011).*

3 Note character of stool specimen.	Certain abnormal constituents of stool may be visible.
-------------------------------------	--

Unexpected Outcomes

- 1 Test for occult blood is positive.

Related Interventions

- Continue to monitor patient.
- Notify health care provider.

Recording and Reporting

- Record results of test and include stool characteristics in nurses' notes.
- Report positive test results to health care provider.

Special Considerations

Teaching

- Explain rationale regarding why patient needs to obtain specimens from two different areas of stool specimen.
- If patient has been on long-term steroid or anticoagulant drug therapy, explain how these drugs may result in occult blood in stools.
- If health care provider orders meat-free diet before test, explain its significance to test results (red meats can cause false-positive results).
- Discuss reason for multiple testing of stool for occult blood. Patients are usually requested to obtain specimen every day for 3 days.

Pediatric

- Children of school age and older are concrete thinkers and often very curious. They may ask many questions about the test. Answer questions honestly and at child's level of understanding. Allow child to watch, if desired, while performing test.
- Testing reagent is often poisonous; thus keep it out of reach of the small child.

Home Care

- Many patients or family caregivers are instructed to collect specimens at home and return them to clinic or health care provider's office. Be sure they know infection control principles.
- Alert patient that presence of chemical home products such as toilet bowl cleaner in the stool specimen will interfere with the results (Fischbach and Dunning, 2009).

SKILL 43-3 Measuring Occult Blood in Gastric Secretions (Gastroccult)

NSO Specimen Collection Module / Lesson 3

Analysis of gastric secretions or emesis can detect blood that is not always visible. Gastroccult testing helps to reveal bleeding in the esophagus or stomach. The test can verify the presence of blood when red or black coloration of the gastric contents is noted or when the gastric contents or emesis has the appearance of coffee grounds. The test measures microscopic amounts of blood in the gastric secretions. It is a useful diagnostic tool for conditions such as upper gastrointestinal (GI) ulcers or bleeding. Because the test is easy to perform, patients are often instructed in how to test emesis in the home.

Delegation and Collaboration

The skill of Gastroccult testing can be delegated to nursing assistive personnel (NAP) for test on emesis. You cannot delegate the skill of Gastroccult testing to NAP if the specimen is collected from a nasogastric (NG) or nasoenteral tube. The nurse informs the NAP to:

- Report immediately if blood or coffee-ground emesis is visible in NG or NI tube secretions.
- Save specimen for repeat testing.

Equipment

- Facial tissues
- Emesis basin
- Wooden applicator or 3-mL syringe
- Bulb or catheter tip syringe
- Cardboard Gastrocult test slide
- Gastrocult developing solution
- Clean gloves

STEP**RATIONALE****ASSESSMENT**

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Assess patient's or family members' understanding of need for test. 2 Assess patient's medical history for bleeding or GI disorders. 3 Assess patient's medical history for GI disorders (e.g., history of bleeding, colitis). | <p>Provides nurse with information on which to base necessary health teaching.</p> <p>You can institute routine screening.</p> <p>Anticoagulants increase risk for bleeding in GI tract, even from minor trauma to mucosa. Long-term use of steroids, nonsteroidal antiinflammatory drugs (NSAIDs), and acetylsalicylic acid (aspirin) can irritate mucosa.</p> |
|--|---|

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding occult blood testing
- Fear

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Test for occult blood is negative. • Patient discusses purpose and benefits of testing gastric contents for blood. 2 Explain procedure to patient and/or family member. Discuss why specimen collection is necessary. | <p>Patient has only small or no amount of blood in gastric secretions. Validates learning.</p> <p>Patient who understands procedure is more likely to be less anxious and more cooperative.</p> |
|---|---|

IMPLEMENTATION

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Perform hand hygiene. 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name. 3 Verify NG tube placement (see Chapter 34). 4 Obtain specimen by disconnecting suction or gravity drainage tube from NG or nasoenteral tube. Using a bulb or catheter tip syringe, aspirate 5 to 10 mL of fluid from NG or nasoenteral tube. | <p>Reduces transmission of microorganisms.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Ensures aspiration of gastric contents.</p> <p>Only small amount of specimen is needed for testing.</p> |
|--|---|

Clinical Decision Point *Observe specimen. If you find red blood or coffee-ground material, report these findings immediately to health care provider.*

- | | |
|---|--|
| <ol style="list-style-type: none"> 5 To obtain sample of emesis, use 3-mL syringe or wooden applicator to obtain sample from emesis basin. 6 Perform Gastrocult test: <ol style="list-style-type: none"> a Using wooden applicator or syringe, apply 1 drop of gastric sample to Gastrocult blood test slide. b Apply 2 drops of commercial developer solution over sample and 1 drop between positive and negative performance monitors (see illustration). c Verify that performance monitor turns blue in 30 seconds. d After 60 seconds compare color of gastric sample with that of performance monitor. e Dispose of test slide, wooden applicator, and syringe in proper receptacle. If needed, reconnect enteral tube to drainage system or suction. Remove gloves. Perform hand hygiene. | <p>Small specimen is sufficient for measuring blood content.</p> <p>Sample must cover test paper for test reaction to occur.</p> <p>Indicates proper function of testing paper.</p> <p>If sample turns blue, test is positive for occult blood. If sample turns green, it is negative for occult blood.</p> <p>Reduces transmission of microorganisms.</p> |
|---|--|

STEP

RATIONALE

STEP 6b Applying developing solution to Gastroculti test area.

EVALUATION

- 1 Ask patient to explain reason for procedure.
- 2 Note color changes in guaiac paper.
- 3 Note character of gastric secretions.

Validates level of understanding.
Reveals blood in gastric secretions.
Blood may be visible, or coffee-ground material denoting blood may be observed.

Unexpected Outcomes

- 1 Test for occult blood is positive.

Related Interventions

- Continue to monitor patient.
- Notify health care provider.

Recording and Reporting

- Record results of test and presence of any unusual characteristics of gastric contents in nurses' notes.
- Report positive test results to health care provider.

Pediatric

- Children of school age and older are concrete thinkers, are often very curious, and may ask many questions about test. Answer questions honestly and at child's level of understanding. Allow child to watch, if desired, while test is performed.

Special Considerations

Teaching

- Explain that long-term steroids cause increase risk for bruising, skin is more fragile, and anticoagulants increase risk for bleeding.

Home Care

- Many patients or family caregivers can perform the Gastroculti test on emesis. Be sure they know infection control principles.

SKILL 43-4 Collecting Nose and Throat Specimens for Culture

When patients have signs and symptoms of upper respiratory or sinus infection, a nose or throat culture is a simple diagnostic tool to identify the presence and type of microorganisms. You should obtain cultures before antibiotic therapy is initiated because antibiotics may interrupt the growth of the organisms in the laboratory. If a patient is receiving antibiotics, notify the laboratory and identify which specific antibiotics he or she is receiving (Pagana and Pagana, 2011).

Collection of a specimen from the nose and throat can cause discomfort and gagging because of sensitive mucosal membranes.

It is important to collect a throat culture before mealtime or at least 1 hour after eating or drinking to decrease the chance of inducing vomiting. A patient's clear understanding of the specimen collection technique minimizes anxiety or discomfort.

Delegation and Collaboration

The skill of obtaining specimens from the nose and throat cannot be delegated to nursing assistive personnel (NAP). The nurse informs the NAP to:

- Report any complaint of shortness of breath, difficulty breathing, and other signs of respiratory distress.

Equipment

- Two sterile swabs in sterile culture tubes (flexible wire swab with cotton tip may be used for nose cultures)
- Nasal speculum (*optional*)
- Emesis basin or clean container (*optional*)

- Tongue blades and penlight
- Facial tissues/gauze
- Clean gloves
- Completed identification labels with proper patient identifiers
- Completed laboratory requisition (date, time, name of test, patient identification, source of culture)
- Small biohazard plastic bag for delivery of specimen to laboratory (or container specified by agency)

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's understanding of purpose for procedure and ability to cooperate. You may need assistance to obtain throat cultures from confused, combative, or unconscious patients.
- 2 Inspect condition of nares and drainage from nasal mucosa and sinuses.
- 3 Determine if patient experiences postnasal drip, sinus headache or tenderness, nasal congestion, sore throat, or exposure to others with similar symptoms.
- 4 Apply clean gloves. Assess condition of posterior pharynx (see Chapter 6).
- 5 Assess patient for signs of infection, including fever, chills, and/or fatigue.
- 6 Review health care provider's orders to determine if nose, throat, or both cultures are needed.

- Provides basis to determine need for health teaching and assistance.
- Reveals physical signs that indicate infection or allergic irritation. Clear drainage usually indicates allergy. Yellow, green, or brown drainage usually indicates infection. Symptoms help reveal nature of problem.
- Reveals local inflammation or lesions of pharynx.
- Infection originating within nasopharynx can become systemic, requiring antibiotic therapy.
- Prevents exposing patient to unnecessary discomfort of repeated cultures.

NURSING DIAGNOSES

- Acute pain
- Chronic pain
- Deficient knowledge regarding specimen collection
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - There is no bacterial growth in specimens.
 - Patient does not experience bleeding of nasal mucosa.
 - Specimen is not contaminated.
 - Patient discusses purpose of nose and throat cultures.
- 2 Plan to do culture before mealtime or at least 1 hour after eating.
- 3 Explain procedure to patient and/or family member. Discuss reason for specimen collection and how patient can help.
- 4 Explain that patient may have tickling sensation or gagging during swabbing of throat. Nasal swab may create urge to sneeze. Each procedure only takes a few seconds to complete.

- Absence of bacterial infection.
- Procedure is atraumatic.
- Evidenced by results of laboratory analysis.
- Validates learning.
- Procedure often induces gagging; timing decreases patient's chances of vomiting.
- Understanding procedure usually decreases anxiety and promotes cooperation.
- Helps patient relax.

IMPLEMENTATION

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 2 Ask patient to sit erect in bed or chair facing you. Acutely ill patient or young child may lie back against bed with head of bed raised to 45-degree angle in semi-Fowler's position.
- 3 Perform hand hygiene. Have swab in tube ready for use. Loosen top so swab can be removed easily.

- Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
- Provides easy access to nasal or oral structures.
- Reduces transmission of microorganisms. Allows you to grasp swab easily without danger of contamination. Most commercial tubes have tops that fit securely over end of swab. Allows touching outer tops without contaminating swab stick.

STEP

RATIONALE

4 Collect throat culture.

- a Apply clean gloves.
- b Instruct patient to tilt head backward. For patients in bed, place pillow behind shoulders.
- c Ask patient to open mouth and say “ah.” To visualize pharynx, depress tongue with tongue blade and note inflamed areas of pharynx or tonsils. Depress anterior third of tongue only and illuminate with penlight as needed.

Reduces transmission of microorganisms.
Facilitates visualization of pharynx.

Permits exposure of pharynx, relaxes throat muscles, and minimizes gag reflex.
Area to be swabbed should be visualized clearly.

Clinical Decision Point Placement of tongue blade along back of tongue more likely initiates gag reflex. If patient gags, remove tongue blade and allow him or her to relax before reinserting.

- d Insert swab without touching lips, teeth, tongue, cheeks, or uvula.
- e Gently but quickly swab tonsillar area side to side, making contact with inflamed or purulent sites (see illustration).
- f Carefully withdraw swab without touching oral structures.

Prevents contamination with organisms from oral cavity (Pagana and Pagana, 2011).
These areas contain most microorganisms.

Collects microorganisms from throat tissues without contamination from mouth and tongue.

5 Collect nasal culture.

- a Apply clean gloves.
 - b Encourage patient to blow nose and then check nostrils for patency with penlight. Select nostril with greatest patency.
 - c In sitting position have patient tilt head backward. Patients in bed should have small pillow behind shoulders.
 - d Gently insert nasal speculum in one nostril (*optional*).
 - e Carefully pass swab into nostril until it reaches that portion of mucosa that is inflamed or containing exudate. Rotate swab quickly. **NOTE:** If you need to obtain nasopharyngeal culture, use special swab on flexible wire that can be flexed downward to reach nasopharynx.
 - f Remove swab without touching sides of speculum or nasal canal.
 - g Carefully remove nasal speculum (if used) and place in basin. Offer patient facial tissue.
- 6** Insert swab into culture tube. Use gauze to protect your fingers while crushing ampule at bottom of tube to release culture medium (see illustrations).
- 7** Place tip of swab into liquid medium and place top securely on top of tube.
- 8** Securely attach completed identification label and laboratory requisition to culture tube and confirm identifiers, specimen source, and collection date and time in front of patient (see agency policy). Note on laboratory requisition if patient is taking antibiotic or if specific organism is suspected (e.g., *Bordetella pertussis*).

Reduces transmission of microorganisms.
Clears nasal passages of mucus containing resident bacteria.

Provides access to nasal passages and facilitates visualization of nasal septum and sinuses.
Allows retraction of mucosa for easier swab insertion.
Swab should remain sterile until it reaches area to be cultured.
Rotating swab covers all surfaces where exudate is present.

Prevents contamination of swab by resident bacteria.

Minimizes period of time that patient experiences discomfort.

Placing tip within culture medium maintains life of bacteria for testing.

Preserves specimen for testing.

Incorrect identification of specimen could result in diagnostic or therapeutic errors.

STEP 4e Collection of specimen from posterior pharynx.

STEP

- 9 Enclose specimen in plastic biohazard bag (according to agency policy) and send immediately to laboratory.
- 10 Return patient to position of comfort. Remove and dispose of gloves and perform hand hygiene.

RATIONALE

Specimen not sent to laboratory immediately or refrigerated allows growth of organisms and inaccurate results.
Provides for patient comfort. Reduces transmission of microorganisms.

STEP 6 Activating culture tube. **A**, Place swab into tube. **B**, Crush end of tube to release liquid medium.

EVALUATION

- 1 Check laboratory record for results of culture test.
- 2 Ask patient to explain purpose of culture.

Results reveal type of organisms in nose or pharynx and antibiotics most likely to be effective.
Demonstrates learning.

Unexpected Outcomes

- 1 Nose and throat cultures reveal bacterial growth.
- 2 Patient experiences minor nasal bleeding.
- 3 Specimen is contaminated.

Related Interventions

- Notify health care provider of findings.
- Administer medications as ordered.
- Apply mild pressure and ice pack over bridge of nose.
- Notify health care provider of patient's condition.
- Repeat specimen collection.

Recording and Reporting

- Describe appearance of nasal and oral mucosal structure and record specimen collection, date, time, and disposition in nurses' notes.
- Report unusual test results to health care provider.

Special Considerations

Teaching

- Instruct patient that procedure may cause slight discomfort and gagging is common.
- Discuss patient's role in collecting specimen.
- Discuss reason for time delay in receiving culture results.

Pediatric

- Allowing young children to visualize and examine speculum decreases their fear.
- Immobilization of child's head and arms is important when obtaining specimen. You should do this in a firm, gentle, kind manner. Ask another nurse to help if necessary.
- Ask parents to act as coach and suggest that they hold their child on their lap. Do not ask parents to restrain child.

- Showing tongue blade and penlight to child and demonstrating how to say "ah" helps to decrease anxiety.
- School-age child will be more cooperative if given opportunity to ask questions about procedure and results.
- Nasal and nasopharyngeal specimen screening may be done for actual infection or nonsymptomatic carriers in respiratory infections, including respiratory syncytial virus (RSV) (Pagana and Pagana, 2011).
- Do not attempt throat culture if you suspect acute epiglottitis because trauma from swab might cause increase in edema, resulting in occlusion of airway (Hockenberry and Wilson, 2011).

Gerontologic

- Some older adults need help in keeping mouth open to obtain specimen.
- Some older adults have poor dentition. Take care not to break a tooth and consider removal of dentures.
- In confused patients someone may need to hold patient's hands while you collect the sample.

SKILL 43-5 Obtaining Vaginal or Urethral Discharge Specimens

Normally drainage from the vagina or urethra is thin, nonpurulent, whitish or clear, and small in amount. Factors such as poor hygiene practices can cause an accumulation of discharge. If a patient develops an increased amount of discharge or if there is a change in the character of discharge from the vagina or urethra, medical follow-up is necessary.

Patients most commonly requiring cultures of vaginal or urethral discharge have signs and symptoms of sexually transmitted disease (STD) or urinary tract infection. Patients suspected of having an STD may be embarrassed by their condition. Show respect and understanding toward a patient. When collecting vaginal or urethral specimens, work quickly and calmly, maintaining the patient's privacy at all times.

Delegation and Collaboration

The skill of obtaining vaginal or urethral discharge specimens cannot be delegated to nursing assistive personnel (NAP).

Equipment

- ❑ Sterile swab in sterile culture tube (commercially available culture tubes have swab and tube with ampule containing special transport medium)
- ❑ Sheet, blanket, or paper drape
- ❑ Clean gloves
- ❑ Penlight or gooseneck lamp
- ❑ Completed identification labels with proper patient identifiers
- ❑ Completed laboratory requisition (date, time, name of test, patient identification, source of culture)
- ❑ Small biohazard plastic bag for delivery of specimen to laboratory (or container specified by agency)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Assess patient's understanding of need for culture and ability to cooperate with procedure. 2 Perform hand hygiene and apply clean gloves. Assess condition of external genitalia and urethra, meatus, and vaginal orifice. Observe for redness; swelling; complaint of tenderness; and discharge that is whitish, mucoid, or purulent or a whitish discharge like cottage cheese. Remove and discard gloves and perform hand hygiene. NOTE: This step may be done during collection. 3 Ask patient about dysuria, localized pruritus of genitalia, or lower abdominal pain. 4 If symptoms suggest STD, gather and record patient's sexual history. 5 Refer to health care provider's order to determine if culture is to be vaginal or urethral. | <p>Provides you with information on which to base necessary health teaching.</p> <p>Reduces transmission of microorganisms. Assessment findings and specimen test results reveal nature of problem.</p> <p>Symptoms of urinary tract or vaginal infection.</p> <p>Determines sexual activity and if there has been sexual contact with a person known to have an STD. If culture results are positive, tell patient to receive treatment and have sexual partners evaluated (Pagana and Pagana, 2011).</p> <p>Patient may require one or both types of cultures.</p> |
|--|--|

NURSING DIAGNOSES

- Acute pain
- Deficient knowledge regarding specimen collection
- Risk for infection
- Anxiety

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Specimen is not contaminated. • Vaginal or urethral cultures do not reveal growth of microorganisms. 2 Explain procedure to patient and/or family member. Discuss reason for specimen collection and how patient can help. Instruct female patient not to douche 24 hours before culture is obtained. Male is not to urinate 1 hour before urethral culture is obtained. | <p>Results on laboratory test will reveal whether skin cells or mucosal cells have contaminated specimen.</p> <p>Evidence of absence of infection.</p> <p>Patient who understands procedure is less anxious and more likely to cooperate. Douching of vaginal canal would remove discharge containing pathogens. Urinating by male washes secretions out of urethra (Pagana and Pagana, 2011).</p> |
|--|--|

STEP

RATIONALE

IMPLEMENTATION

1 Perform hand hygiene. Apply clean gloves.	Reduces transmission of microorganisms.
2 Draw bedside curtains or close room door. Place “Do Not Enter” sign on door (if available).	Provides privacy for patient and demonstrates respect for patient’s well-being.
3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient’s identification bracelet and/or ask patient to state name.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
4 Help patient to proper position, raise gown, and drape body parts to be exposed: <ul style="list-style-type: none"> a Female: Dorsal recumbent position with sheet draped over each leg and genitalia. b Male: Sitting on chair or bed or lying supine with sheet draped across lower trunk and genitalia. 	Provides easy access to perineal area. Draping minimizes exposure of body parts, minimizing anxiety.
5 Direct light source onto perineum (may not be needed for male patient).	Allows better visualization of external urethral or vaginal structures.
6 Open culture tube and hold swab in dominant hand.	Provides for easier manipulation of swab during culture collection.
7 Instruct patient to deep breathe slowly.	Helps patient to relax. Tensing of muscles around pelvic floor may cause discomfort during swabbing.
8 Obtain specimens. <ul style="list-style-type: none"> a Female: <ul style="list-style-type: none"> (1) With nondominant hand fully separate labia to expose vaginal orifice. (2) Touch tip of swab into discharge pool, being careful not to touch skin or mucosa along perineum or vaginal canal. If no discharge is visible, gently insert swab 1 to 2.5 cm ($\frac{1}{2}$ to 1 inch) into vaginal orifice and rotate before removal. (3) To expose urethral meatus use nondominant hand to pull gently on labia minora upward and back to separate. (4) Use clean swab; gently apply to tip of meatus where discharge is visible. Avoid touching labia. 	Exposes perineum and ensures that specimen is of vaginal discharge. Discharge contains greatest concentration of microorganisms. Allows better visualization of urethral orifice. Discharge contains greatest concentration of microorganisms.
<p>Clinical Decision Point <i>If discharge near vagina appears different from discharge along perineum, collect separate specimens from each area because, if two organisms are present, they could be cross-contaminated on a single swab. Label specimen with area of patient’s body that you swabbed.</i></p>	
<ul style="list-style-type: none"> b Male: <ul style="list-style-type: none"> (1) Grasp patient’s penis proximal to glans with nondominant hand; if male is uncircumcised, gently retract foreskin. (2) Use dominant hand to hold swab. Apply gently to area of discharge at urinary meatus. (3) If no discharge is apparent, health care provider may order swab to be introduced into urinary meatus. Hold male genitalia firmly but gently. (4) Return foreskin to natural position. 	Provides clear exposure of urethral meatus. Discharge contains greatest number of microorganisms. Excess manipulation can cause erection. Tightening of foreskin around shaft of penis can cause localized discomfort, edema, and potential necrosis.
9 Return each swab to culture tube and secure top.	Retains microorganisms within tube.
10 If using commercial culture tube, wrap ampule with gauze to prevent injury to your fingers while crushing. Immediately squeeze end of tube to crush ampule (see Skill 43-4). Push tip of swab into fluid medium.	Medium supports life of microorganisms until culture is analyzed.
11 Remove and discard gloves. Perform hand hygiene.	Reduces transmission of microorganisms.
12 Label each culture tube with identification label, affix completed requisition, and confirm identifiers in front of patient (TJC, 2012).	Incorrect specimen identification could lead to diagnostic or therapeutic error.

STEP	RATIONALE
13 Send specimen to laboratory immediately or refrigerate.	Bacteria multiply quickly. Prompt analysis ensures accurate results.
14 Help patient to comfortable position, assist with personal hygiene, and remove and discard drape.	Reinforces patient's sense of self-esteem. Reduces transmission of microorganisms.

EVALUATION

1 Review laboratory results for evidence of pathogens.	Results will reveal type of organisms present. Certain organisms are common to vaginal tract. Urethra should be free of microorganisms.
2 Continue to monitor whether discharge is present; if so, observe color and amount.	Characteristics of discharge indicate specific type of infection.
3 Observe specimen for presence of feces.	Need to obtain another specimen if it contains feces.

Unexpected Outcomes

- 1 Vaginal or urethral cultures reveal growth of pathogenic microorganisms.
- 2 Specimen is contaminated with epidermal cells.

Related Interventions

- Notify health care provider of findings and follow new orders.
- Continue to monitor patient.
- Repeat specimen collection.

Recording and Reporting

- Record types of cultures obtained and date and time sent to laboratory in nurses' notes and EHR.
- Report laboratory results to nurse in charge or health care provider.

Special Considerations

Teaching

- Discuss sexuality and safe sex practices with patient if appropriate.
- Patients with urethral or vaginal discharge often require instruction about perineal hygiene measures.
- If topical treatments (e.g., suppositories) are ordered, instruct patient in proper administration of medication (see Chapter 21).

Pediatric

- A second nurse can help with specimen collection from an infant or young child by gently holding child's legs apart

in froglike position. Have parent present to encourage cooperation.

- Parents should understand that obtaining vaginal specimen will not affect virginity of child.
- Be sensitive to cultural variations and beliefs pertaining to genitalia (i.e., female circumcisions).
- In addition to collecting the specimen on adolescent patients, this may also open up the possibility of discussions related to sexuality during which they may have questions but are not comfortable initiating on their own.

Gerontologic

- Clear explanation regarding importance of obtaining sample is extremely helpful to alleviate or diminish anxiety and gain cooperation.

PROCEDURAL GUIDELINE 43-3 Collecting a Sputum Specimen by Expectoration

Sputum is mucus secretions produced by cells of the lungs, bronchi, and trachea. You collect a specimen either by having a patient cough and expectorate into a sterile specimen container or by suctioning into a sterile sputum trap (see Skill 43-6). In a healthy state sputum production is minimal; a disease state can increase the amount and character of sputum. Sputum specimens are collected to identify cancer cells, for culture and sensitivity (C&S) to identify pathogens and determine the antibiotics to which they are sensitive, and for acid-fast bacillus to diagnose pulmonary tuberculosis.

Delegation and Collaboration

The skill of collecting a sputum specimen by expectoration can be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Immediately report the presence of blood in the sputum or changes in the patient's vital signs.

Equipment

- Completed identification labels with appropriate patient identifiers
- Completed laboratory requisition, including appropriate patient identification, date, time, name of test, and source of culture
- Small biohazard plastic bag for delivery of specimen to laboratory (or container as specified by agency)
- Sterile specimen container with cover
- Clean gloves
- Facial tissues
- Emesis basin (*optional*)
- Toothbrush (*optional*)
- Disinfectant swab (*optional*)

Procedural Steps

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy.

PROCEDURAL GUIDELINE 43-3 Collecting a Sputum Specimen by Expectoration—cont'd

- Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 2 Provide opportunity to clean or rinse mouth with water. Patient should not use mouthwash or toothpaste because the products may alter culture results.
 - 3 Perform hand hygiene and apply clean gloves. Provide sputum cup and instruct patient not to touch the inside of the container.
 - 4 Have the patient take three-to-four deep slow breaths with full exhalation. Then take full inhalation followed immediately by a forceful cough, expectorating sputum directly into specimen container.
 - 5 Repeat until 5 to 10 mL of sputum (not saliva) has been collected.
 - 6 Secure lid on container tightly. If any sputum is present on outside of container, wipe it off with disinfectant.
 - 7 Offer patient tissues after patient expectorates, dispose of tissues, and offer mouth care.
 - 8 Remove and dispose of gloves. Perform hand hygiene.
 - 9 Securely attach properly completed identification label and laboratory requisition to side of specimen container (not lid). Confirm identifiers in patient's presence.
 - 10 Enclose specimen in a plastic biohazard bag.
 - 11 Send specimen to laboratory immediately.

SKILL 43-6 Collecting a Sputum Specimen by Suction

Video Clip

Sputum is produced by cells lining the respiratory tract. Although production is minimal in the healthy state, disease states can increase the amount or change the character of sputum. Examination of sputum aids in the diagnosis and treatment of several conditions, ranging from simple bronchitis to lung cancer.

Suctioning is often indicated to collect sputum from patients unable to spontaneously expectorate a sample for laboratory analysis. Sometimes suctioning provokes violent coughing, which can induce vomiting and constriction of pharyngeal, laryngeal, and bronchial muscles. In addition, it may cause hypoxemia or vagal overload, causing cardiopulmonary compromise and increased intracranial pressure.

Delegation and Collaboration

The skill of collecting sputum specimens by suction cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Notify the nurse if the patient expectorates bloody sputum.

Equipment**Suctioned Specimen**

- Completed identification labels with proper patient identifiers
- Completed laboratory requisition, including patient identification, date, time, name of test, and source of culture
- Suction device (wall or portable)
- Sterile suction catheter (size 14, 16, or 18 Fr [not large enough to cause trauma to nasal mucosa]) or suction catheter with sleeve
- Sterile gloves and clean gloves
- Sterile water in container
- In-line specimen container or sputum trap
- Small plastic bag for delivery of specimen to laboratory (or a container as specified by agency)
- Oxygen therapy equipment if indicated
- Protective eyewear
- Disinfectant wipe

STEP**RATIONALE****ASSESSMENT**

- 1 Check health care provider's orders for type of sputum analysis and specifications (e.g., amount of sputum, number of specimens, time of collection, method to obtain). Specimens for acid-fast bacillus (AFB) require three consecutive morning samples.
 - 2 Assess patient's level of understanding of procedure and its purpose.
 - 3 Assess when patient last ate meal (or had tube feeding).
 - 4 Determine type of assistance needed by patient to obtain specimen.
 - 5 Assess patient's respiratory status, including respiratory rate, depth, pattern, and color of mucous membranes.
- Specific test dictates when or how frequently specimens are collected. Ideal time to collect sputum is early morning because bronchial secretions tend to accumulate during the night. Bacteria also accumulate as secretions pool.
- Provides baseline to establish teaching plan.
- It is best to obtain specimen 1 to 2 hours after or 1 hour before meal to minimize gagging, which can cause vomiting and aspiration.
- Positioning, postural drainage, and deep breathing and coughing exercises may improve ability to cough productively. Suctioning is often indicated when patient is unable to cough and expectorate.
- Active coughing may alter respiratory status. Respiratory status can depend on amount of sputum in tracheobronchial tree.

STEP

RATIONALE

NURSING DIAGNOSES

- Deficient knowledge regarding specimen collection procedures
- Ineffective airway clearance
- Ineffective breathing pattern
- Risk for aspiration
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- Expected outcomes following completion of procedure:
 - Patient's respirations are same rate and character before and after procedure. Specimen collection did not alter respiratory status.
 - Patient maintains comfort level and experiences minimal anxiety. Suctioning tends to cause anxiety.
 - Sputum is not contaminated by saliva or oropharyngeal flora. Sputum must originate from tracheobronchial tree for accurate results.
 - Laboratory tests do not reveal abnormal cells or microorganisms. Absence of infection or abnormal cells.
 - Patient discusses purpose and benefit of sputum collection. Validates learning.
- Explain steps of procedure and purpose. Instruct patient to breathe normally during suctioning to prevent hyperventilation. Promotes understanding and cooperation.

IMPLEMENTATION

- Close curtains or room door. Provides privacy.
- Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name. Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
- Position patient in high- or semi-Fowler's position for suctioning. Promotes full lung expansion and facilitates ability to cough.

Clinical Decision Point *If patient has surgical incision or localized area of discomfort, have him or her place pillow or hands firmly over affected area. Splinting of painful area minimizes muscular stretching and discomfort during coughing and thus makes cough more productive.*

- Perform hand hygiene and apply clean glove to nondominant hand. Prepare suction machine or device and determine if it functions properly. Adequate amount of suction is necessary to aspirate sputum.
- Connect suction tube to adapter on sputum trap. Open sterile water. Establishes suction that passes through sputum trap to aspirate specimen.
- Using sterile technique, apply sterile glove to dominant hand or use clean glove if suction catheter has plastic sleeve. Tracheobronchial tree is sterile body cavity. Allows you to manipulate suction catheter without contamination.
- With gloved hand connect sterile suction catheter to rubber tubing on sputum trap. Aspirated sputum will go directly to trap instead of to suction tubing.
- Lubricate suction catheter tip with sterile water (*with suction off*). Lubrication allows for easier insertion of catheter.
- Gently insert tip of suction catheter through nasopharynx, endotracheal tube, or tracheostomy tube without applying suction (see Chapter 25). Minimizes trauma to airway as catheter is inserted.
- Gently and quickly advance catheter into trachea. Warn patient to expect to cough. Entrance of catheter into larynx and trachea triggers cough reflex.
- As patient coughs, apply suction for 5 to 10 seconds, collecting 2 to 10 mL of sputum. Ensures collection of sputum from deep within tracheobronchial tree. Suctioning longer than 10 seconds can cause hypoxia and mucosal damage.
- Release suction and remove catheter; turn off suction. Suction can damage mucosa if applied during withdrawal.
- Detach catheter from specimen trap and dispose of catheter in appropriate receptacle. Decreases risk for spreading microorganisms.
- Secure top on specimen container tightly. For sputum trap, detach suction tubing and connect rubber tubing on sputum trap to plastic adapter (see illustration). Contains microorganisms within container, preventing exposure to personnel handling specimen.

STEP	RATIONALE
15 If any sputum is present on outside of container, wipe it off with disinfectant.	Prevents spread of infection to people handling specimen.
16 Offer patient tissues after suctioning. Dispose of tissues in emesis basin or appropriate container.	Maintains cleanliness and comfort.
17 Remove and dispose of gloves. Perform hand hygiene.	Reduces transmission of microorganisms.
18 Label specimen with identification label on side of specimen container (not lid). Confirm identifiers in front of patient (TJC, 2012). Place specimen in small plastic bag (or container specified by agency) and attach requisition.	Incorrect identification could lead to diagnostic or therapeutic error. Plastic bag or container reduces risk for health care worker's exposure to sputum.
19 Send specimen immediately to laboratory or refrigerate.	Bacteria multiply quickly. Prompt analysis ensures accurate results.
20 Offer patient mouth care if desired.	Promotes comfort.

STEP 14 Closing sputum specimen trap.

EVALUATION

1 Observe patient's respiratory status throughout procedure, especially during suctioning. If under distress, measure oxygen saturation with pulse oximeter.	Excessive coughing or prolonged suctioning can alter respiratory pattern and cause hypoxia. Determines oxygenation status.
2 Note anxiety or discomfort in patient.	Procedure can be uncomfortable. If patient becomes short of breath, anxiety will develop.
3 Observe character of sputum: color, consistency, odor, volume, viscosity, and/or presence of blood.	Characteristics may indicate disease entities.
4 Refer to laboratory reports for test results.	Indicates if abnormal cells or microorganisms are present in sputum.
5 Evaluate patient's ability to describe/demonstrate sputum collection process.	Reinforces patient's ability to collect future expectorated specimens.

Unexpected Outcomes

- 1 Patient becomes hypoxic with increased respiratory rate and effort and shortness of breath.
- 2 Patient remains anxious or complains of discomfort from suction catheter.
- 3 Inadequate amount of sputum collected.
- 4 Patient complains of pain when coughing to produce sputum.

Related Interventions

- Discontinue suctioning immediately.
- Administer oxygen (if ordered).
- Notify health care provider of patient's condition.
- Continue to monitor patient's vital signs and pulse oximetry.
- Discontinue procedure until stable.
- Administer oxygen (if ordered).
- Notify health care provider of patient's change in condition.
- Continue to monitor patient's vital signs and pulse oximetry.
- Repeat specimen collection after patient takes several deep breaths.
- Encourage patient who is recovering from surgical procedure to splint incision before coughing.
- Obtain order for pain medication as needed (prn).
- Inform health care provider of changes in patient's condition.

Recording and Reporting

- Record method used to obtain specimen, date and time collected, type of test ordered, and transport to laboratory in nurses' notes. Describe characteristics of sputum specimen. Describe patient's tolerance of procedure.
- Report unusual sputum characteristics to nurse in charge or health care provider.
- When laboratory reports are available, report abnormal findings to health care provider. If AFB sputum culture is positive, initiate appropriate isolation techniques.
- Most agencies require nurses to note on specimen requisition if patient is receiving antibiotics.

Special Considerations

Teaching

- Demonstrate proper splinting technique for postoperative patients.

- If aerosol treatment is indicated, teach patient purpose of procedure, explaining that it will stimulate coughing and sputum expectoration.

Pediatric

- Children need very clear instructions or demonstration for deep breathing. Infants and young children will be unable to cooperate; aerosol treatment may be indicated.
- You may need help to restrain a young child's head and arms during suctioning; parent may help by providing support.
- Use smaller catheter size for young children. It may be possible to elicit a cough by tickling the back of the throat with the suction catheter.

SKILL 43-7 Obtaining Wound Drainage Specimens

NSO Specimen Collection Module / Lesson 5

When caring for a patient with a wound, assess the condition of the wound and observe for the development of infection. Localized inflammation, tenderness, and warmth at the wound site and purulent drainage are signs and symptoms of wound infection. Identification of the causative organism confirms an infection and provides guidelines for accurate treatment. A specimen of wound drainage is analyzed to determine the type and number of pathogenic microorganisms.

Always collect a wound culture sample from fresh exudate from the center of a wound after removing old drainage. Resident colonies of bacteria on the skin grow in wound exudate and may not be the true causative organisms of infection. Use separate techniques to collect specimens for measuring aerobic versus anaerobic microorganisms. Aerobic organisms grow in superficial wounds exposed to the air. Anaerobic organisms grow deep within body cavities, where oxygen is not normally present.

Delegation and Collaboration

The skill of obtaining wound drainage specimens cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Report foul odor, increase in drainage, and increase in temperature or patient complaint of discomfort.

Equipment

- Culture tube with swab and transport medium for aerobic culture
- Anaerobic culture tube with swab (tubes contain carbon dioxide or nitrogen gas)
- 5- to 10-mL syringe and 19-gauge needle
- Two pairs of clean gloves and sterile gloves
- Protective eyewear
- Antiseptic swab
- Sterile dressing materials (determined by type of dressing)
- Paper or plastic disposable bag
- Completed specimen identification label with proper patient identifiers
- Completed laboratory requisition (date, time, name of test, patient identification, and source of culture)
- Small plastic biohazard bag for delivery of specimen to laboratory (or container specified by agency)

STEP **RATIONALE**

ASSESSMENT

- 1 Assess patient's understanding of need for wound culture and ability to cooperate with procedure.
- 2 Assess patient for signs of fever, chills, or excessive thirst. Note in medical record laboratory results if white blood cell (WBC) count is elevated.
- 3 Ask patient about extent and type of pain at wound site using a scale of 0 to 10. If patient requires analgesic before dressing changes, give medication 30 minutes before beginning procedure to reach peak effect.
- 4 Determine when dressing change is scheduled (see Chapter 39). Perform wound assessment as part of actual procedure.
- 5 Review health care provider's orders for aerobic or anaerobic culture.

- Use data to develop teaching plan. Wound is painful site. Collection of specimen may cause anxiety or fear.
- Signs and symptoms indicate systemic infection.
- Pain at wound site often increases with infection.
- Specimens are taken from different sites and placed in different containers, depending on type of culture.

STEP	RATIONALE
<p>6 Perform hand hygiene and apply clean gloves. Remove old dressings covering wound. Fold soiled sides of dressing together and dispose properly. Remove gloves. Apply sterile gloves to palpate wound. Observe for swelling, separation of wound edges, inflammation, and drainage. Palpate gently along wound edges and note tenderness or drainage. Remove and discard gloves.</p>	<p>Gloves minimize exposure to microorganisms Signs indicate wound infection.</p>
NURSING DIAGNOSES	
<ul style="list-style-type: none"> • Acute pain • Anxiety • Chronic pain 	<ul style="list-style-type: none"> • Deficient knowledge regarding wound drainage culture procedure • Impaired tissue integrity • Risk for infection • Risk for injury
<p><i>Related factors are individualized based on patient's condition or needs.</i></p>	
PLANNING	
<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Wound culture does not reveal bacterial growth. • Culture swab is not contaminated by bacteria from skin. • Patient discusses purpose and procedure for specimen collection. <p>2 Determine if analgesia is necessary. Administer analgesic 30 minutes before dressing change and/or specimen collection.</p> <p>3 Explain reason for wound culture and how it will be collected.</p> <p>4 Explain that patient may feel tickling sensation when wound is swabbed.</p>	<p>Wound remains free of pathogenic microorganisms. Test results indicate type of cells present. Validates learning.</p> <p>Minimizes discomfort during procedure. Provides patient-centered care.</p> <p>Promotes understanding and cooperation and eases anxiety. Anticipation of expected sensations minimizes anxiety.</p>
IMPLEMENTATION	
<p>1 Close bedside curtains or door to room.</p> <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> <p>3 Perform hand hygiene and apply clean gloves.</p> <p>4 Clean area around wound edges with antiseptic swab. Wipe from edges outward. Remove old exudate.</p> <p>5 Discard swab and remove and dispose of soiled gloves in appropriate receptacle. Perform hand hygiene.</p> <p>6 Open packages containing sterile culture tube and dressing supplies. <i>Apply sterile gloves.</i></p> <p>7 Obtain cultures.</p> <p>a Aerobic culture:</p> <p>(1) Take swab from culture tube, insert tip into wound in area of drainage, and rotate swab gently. Remove swab and return to culture tube (wrap outside of ampule with gauze to prevent injury to your fingers). Crush ampule of medium and push swab into fluid.</p> <p>b Anaerobic culture:</p> <p>(1) Take swab from special anaerobic culture tube, swab deeply into draining body cavity, and rotate gently. Remove swab and return to culture tube.</p> <p>Or</p> <p>(2) Insert tip of syringe (without needle) into wound and aspirate 5 to 10 mL of exudate. Attach 19-gauge needle, expel all air, and inject drainage into special culture tube.</p> <p>8 Remove and dispose of gloves. Perform hand hygiene.</p>	<p>Provides privacy.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Provides baseline for condition of wound. Removes skin flora, preventing possible contamination of specimen.</p> <p>Reduces spread of infection.</p> <p>Provides sterile field for picking up and handling sterile supplies.</p> <p>Swab should be coated with fresh secretions from within wound. Medium keeps bacteria alive until analysis is complete.</p> <p>Specimen is taken from deep cavity where oxygen is not present. Carbon dioxide or nitrogen gas keeps organisms alive until analysis is complete. Air injected into tube would cause organisms to die.</p> <p>Sterile large-bore needle (19-gauge) allows exudate to be transferred from sterile syringe into special culture tube without contamination.</p> <p>Reduces transfer of microorganisms.</p>

STEP	RATIONALE
9 Place correct specimen label on each culture tube. Verify identifiers in front of patient (TJC, 2012). <i>NOTE:</i> Indicate on specimen if patient is receiving antibiotics.	Ensures correct results for correct patient.
10 Send specimens to laboratory immediately.	Bacteria multiply rapidly. Prompt analysis ensures accurate results.
11 Clean wound per health care provider's order. Apply new sterile dressing (see Chapter 39) using aseptic technique. Secure dressing with tape or ties.	Protects wound from further contamination; aids in absorbing drainage and debridement of wound.
12 Remove and dispose of gloves and soiled supplies in appropriate receptacle according to agency policy. Perform hand hygiene.	Reduces transmission of microorganisms.
13 Help patient to comfortable position.	Promotes patient's ability to relax.

EVALUATION

1 Obtain laboratory report for results of cultures.	Report indicates if pathogenic organisms are identified.
2 Observe character of wound drainage.	Characteristics can reveal abnormal status and infection.
3 Observe edges of wound for redness and bleeding.	Indicates trauma to healing tissue.
4 Ask patient about purpose of wound culture.	Validates learning.

Unexpected Outcomes

- 1 Wound cultures reveal heavy bacterial growth.
- 2 Wound culture is contaminated from superficial skin cells.
- 3 Patient describes increased pain.

Related Interventions

- Monitor patient for fever, chills, or excessive thirst, which indicate systemic infection.
- Inform health care provider of findings.
- Monitor patient for fever and pain.
- Inform health care provider of findings.
- Repeat collection of specimen as ordered.
- Provide analgesia.
- Notify health care provider.

Recording and Reporting

- Record types of specimens obtained, source, and time and date sent to laboratory and describe appearance of wound and characteristics of drainage in nurses' notes.
- Report any evidence of infection to charge nurse and health care provider.
- Record patient's tolerance of procedure and response to analgesics.

Special Considerations

Teaching

- Instruct patient to inform you if procedure causes pain or if you need to stop because unable to tolerate pain.

- Teach patient to assess status of wound for changes and signs and symptoms of infection.

Pediatric

- If procedure is to be performed on a child and is anticipated to be painful, some agencies prefer performing it in area other than child's room, thus maintaining feeling that child's room is safe place (Hockenberry and Wilson, 2011).
- It is often helpful to have an additional nurse or other adult available to help with a specimen collection in a young child or infant.

Home Care

- Teach patient antiseptic practices (e.g., handwashing, disposal of dressings, and clean technique for applying dressing).

SKILL 43-8 Collecting Blood Specimens and Culture by Venipuncture (Syringe and Vacutainer Method)

NSO Vascular Access / Drawing Blood and Administering Fluid Module

Blood tests are one of the most commonly used diagnostic aids in the care and evaluation of patients. In any health care setting they can yield valuable information about a patient's nutritional, hematologic, metabolic, immune, and biochemical status. Tests allow health care providers to screen patients for early signs of physical illness, monitor changes in acute or chronic diseases, and evaluate responses to therapies.

You are often responsible for collecting blood specimens; however, many agencies have specially trained phlebotomists

who are responsible for drawing venous blood. Be familiar with your agency policies and procedures and your state Nurse Practice Act regarding guidelines for drawing blood samples.

The three methods of obtaining blood specimens are (1) skin puncture, (2) venipuncture, and (3) arterial puncture. All procedures require sterile technique. Anticipate a patient's anxiety because the procedures are painful; and often just the appearance of a needle is frightening, especially to children. A calm approach and skilled technique help to limit anxiety.

Venipuncture is the most common method of obtaining blood specimens. This method involves inserting a hollow-bore needle

into the lumen of a large vein to obtain a specimen using either a needle and syringe or a Vacutainer device that allows the drawing of multiple samples. Because veins are major sources of blood for laboratory testing and routes for intravenous (IV) fluid or blood replacement, maintaining their integrity is essential. You need to be skilled in venipuncture to avoid unnecessary injury to veins.

Skin puncture, also called *capillary puncture*, is the least traumatic method of obtaining a blood specimen. A sterile lancet or needle is used to puncture a vascular area on a finger or earlobe in an adult or child. You place a drop of blood on a test slide, wick a drop of blood to a test slide, or collect it within a thin glass capillary tube for laboratory analysis. Changes in health care economics and delivery result in the increased use of skin puncture. Point-of-care (POC) clinical laboratory tests at the bedside most frequently use skin puncture (Pagana and Pagana, 2011).

Blood cultures aid in detection of bacteria in the blood. It is important that at least two culture specimens be drawn from two different sites. Because bacteremia may be accompanied by fever and chills, blood cultures should be drawn when these symptoms are present (Pagana and Pagana, 2011). Bacteremia exists when both cultures grow the infectious agent. Only one culture growing bacteria is considered contamination. Draw all cultures before antibiotic therapy begins because the antibiotic may interrupt the growth of an organism in the laboratory. If the patient is receiving antibiotics, notify the laboratory and inform them of specific antibiotics the patient is receiving (Pagana and Pagana, 2011).

Delegation and Collaboration

The skill of collecting blood specimens by venipuncture can be delegated to specially trained nursing assistive personnel (NAP). In some agencies, phlebotomists obtain the venipuncture samples. Agency and government regulations and policies differ regarding personnel who may draw blood specimens. The nurse informs the NAP to:

- Report any patient discomfort or signs of excessive bleeding from the puncture site to the nurse.

Equipment

All Procedures

- Chlorhexidine or antiseptic swab (check agency policy for use of 70% alcohol)
- Clean gloves
- Small pillow or folded towel
- Sterile 2 × 2-inch gauze pads
- Tourniquet
- Adhesive bandage or adhesive tape
- Completed identification labels with proper patient identifiers
- Completed laboratory requisition (appropriate patient identification, date, time, name of test, and source of culture)
- Small plastic biohazard bag for delivery of specimen to laboratory (or container specified by agency)
- Sharps container

Venipuncture with Syringe

- Sterile safety needles (20- to 21-gauge for adults; 23- to 25-gauge for children)
- Sterile 10- to 20-mL Luer-Lok safety syringes
- Needle-free blood transfer device
- Appropriate blood specimen tubes

Venipuncture with Vacutainer

- Vacutainer and safety access device with Luer-Lok adapter
- Sterile double-ended needles (20- to 21-gauge for adults; 23- to 25-gauge for children)
- Appropriate blood specimen tubes

Blood Cultures

- Sterile double needles (20- to 21-gauge for adults; 23- to 25-gauge for children)
- Two 20-mL sterile syringes
- Anaerobic and aerobic culture bottles (check agency policy)

Central Venous Catheter Collection

- Two empty 10-mL sterile syringes
- Sterile 10-mL normal saline flushes
- Vacutainer and safety access device Luer-Lok adapter
- Appropriate blood specimen tubes

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <p>1 Determine whether patient understands purpose of procedure and ability to cooperate.</p> | <p>Provides data for you to establish teaching plan and provides emotional support. Some patients' past experiences increase anxiety.</p> |
| <p>2 Determine if special conditions need to be met before specimen collection (e.g., patient allowed nothing by mouth [NPO], specific time for collection in relation to medication given, need to ice specimen).</p> | <p>Some tests require meeting specific conditions to obtain accurate measurement of blood elements (e.g., fasting blood sugar, drug peak and trough level, timed endocrine hormone levels).</p> |
| <p>3 Assess patient for possible risks associated with venipuncture: anticoagulant therapy, low platelet count, bleeding disorders (history of hemophilia). Review medication history.</p> | <p>Patient history may include abnormal clotting abilities caused by low platelet count, hemophilia, or medications that increase risk for bleeding and hematoma formation.</p> |
| <p>4 Assess patient for contraindicated sites for venipuncture: presence of IV infusion, hematoma at potential site, arm on side of mastectomy, or hemodialysis shunt.</p> | <p>Drawing specimens from such sites can result in false test results or may injure patient. Samples taken from vein near IV infusion may be diluted or contain concentrations of IV fluids. Postmastectomy patient may have reduced lymphatic drainage in arm on operative side, increasing risk for infection from needlesticks. Never use arteriovenous shunt to obtain specimens because of risks for clotting and bleeding. Hematoma indicates existing injury to vessel wall.</p> |
| <p>5 Review health care provider's orders for type of tests.</p> | <p>Multiple samples are often needed. Health care provider's order is required.</p> |

STEP

RATIONALE

Clinical Decision Point *Some specimens have special collection requirements before or after specimen collection; examples follow:*

- Cryoglobulin levels: Use prewarmed test tubes.
- Ammonia and ionized calcium levels: Place tube in ice for delivery to laboratory.
- Lactic acid levels: Do not use tourniquet.
- Vitamin levels: Avoid exposure of test tube to light.

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding blood specimen collection process
- Fear
- Risk for infection
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Venipuncture site shows no evidence of continued bleeding or hematoma at venipuncture site after specimen collection. • Patient denies anxiety or discomfort. <p>• An adequate sample is collected for testing (see agency policy or laboratory manual).</p> <p>• Patient discusses purpose, procedure, and benefits of venipuncture.</p> | <p>Indicates that hemostasis is achieved.</p> <p>Explanation relieves anxiety; procedure is performed quickly. Removal of painful stimulus lessens anxiety. Appropriate laboratory analysis can be conducted.</p> <p>Validates learning.</p> |
| <p>2 Explain procedure to patient: describe purpose of tests; explain how sensation of tourniquet, alcohol swab, and needlestick will feel.</p> | <p>Anticipatory guidance helps to reduce anxiety.</p> |

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Bring equipment to bedside and organize.</p> | <p>Facilitates procedure.</p> |
| <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> |
| <p>3 Close bedside curtain or room door. Perform hand hygiene.</p> | <p>Provides for privacy. Reduces transmission of infection.</p> |
| <p>4 Raise or lower bed to comfortable working height.</p> | <p>Reduces strain on your back muscles and improves access to venipuncture site.</p> |
| <p>5 Help patient to supine or semi-Fowler's position with arms extended to form straight line from shoulders to wrists. Place small pillow or towel under upper arm. (<i>Option:</i> Lower arm briefly so it fills veins in hand and lower arm with blood.)</p> | <p>Helps to stabilize extremity because arms are most common sites of venipuncture. Supported position in bed reduces chance of injury to patient if fainting occurs.</p> |
| <p>6 Apply tourniquet so it can be removed by pulling an end with single motion.</p> <p>a Position tourniquet 5 to 10 cm (2 to 4 inches) above venipuncture site selected (antecubital fossa site is most often used).</p> <p>b Cross tourniquet over patient's arm (see illustration). May place tourniquet over gown sleeve to protect skin.</p> <p>c Hold tourniquet between your fingers close to arm. Tuck loop between patient's arm and tourniquet so you can grasp free end easily (see illustration).</p> | <p>Tourniquet blocks venous return to heart from extremity, causing veins to dilate for easier visibility.</p> <p>Older adult's skin is very fragile.</p> <p>Pull free end to release tourniquet after venipuncture.</p> |

Clinical Decision Point *Palpate distal pulse (e.g., radial) below tourniquet. If pulse is not palpable, remove tourniquet, wait 60 seconds, and reapply it more loosely. If tourniquet is too tight, pressure will impede arterial blood flow.*

- | | |
|---|--|
| <p>7 Do not keep tourniquet on patient longer than 1 minute.</p> | <p>Prolonged tourniquet application causes stasis, localized acidemia, and hemoconcentration (Pagana and Pagana, 2011).</p> |
| <p>8 Ask patient to gently open and close fist several times, finally leaving fist clenched.</p> | <p>Facilitates distention of veins by forcing blood up from distal veins. Vigorous open and close may cause erroneous laboratory results from hemoconcentration (Pagana and Pagana, 2011).</p> |

STEP

- 9 Quickly inspect extremity for best venipuncture site, looking for straight, prominent vein without swelling or hematoma. Of three veins located in antecubital area, median cubital vein is preferred (see illustration).
- 10 Apply clean gloves. Palpate selected vein with finger (see illustration). Note if vein is firm and rebounds when palpated or if it feels rigid or cordlike and rolls when palpated. Avoid vigorously slapping vein, which can cause vasospasm.
- 11 Obtain blood specimen.
 - a **Syringe method:**
 - (1) Have syringe with appropriate needle securely attached.
 - (2) Clean venipuncture site with antiseptic swab, with first swab moving back and forth on horizontal plane, another swab on vertical plane, and last in circular motion from site outward for about 5 cm (2 inches) for 30 seconds. Allow to dry.
 - (a) If drawing sample for blood alcohol level or blood cultures, use only antiseptic swab, not alcohol swab.
 - (3) Remove needle cover and inform patient that “stick” lasts only a few seconds.

RATIONALE

- Straight and intact veins are easiest to puncture.
- Patent, healthy vein is elastic and rebounds on palpation. Thrombosed vein is rigid, rolls easily, and is difficult to puncture.
- Needle must not dislodge from syringe during venipuncture.
- Antimicrobial agent cleans skin surface of resident bacteria so organisms do not enter puncture site. Allowing antiseptic to dry completes its antimicrobial task and reduces “sting” of venipuncture. Alcohol left on skin can cause hemolysis of sample and retraction of tissue away from puncture site. Ensures accurate test results.
- Patient has better control over anxiety when prepared for what to expect.

Clinical Decision Point Observe needle for defects such as burrs, which can cause increased discomfort and damage to patient's vein (McCall and Tankersley, 2012).

STEP 6b Cross tourniquet over arm.

STEP 6c Tuck loop between patient's arm and tourniquet.

STEP 9 Location of antecubital veins.

STEP 10 Palpate vein.

STEP

RATIONALE

- | | |
|--|---|
| <p>(4) Place thumb or forefinger of nondominant hand 2.5 cm (1 inch) below site and gently pull skin taut. Stretch skin steadily until vein is stabilized.</p> <p>(5) Hold syringe and needle at 15- to 30-degree angle from patient's arm with bevel up.</p> <p>(6) Slowly insert needle into vein, stopping when "pop" is felt as needle enters vein (see illustration).</p> <p>(7) Hold syringe securely and pull back gently on plunger.</p> <p>(8) Observe for blood return (see illustration).</p> <p>(9) Obtain desired amount of blood, keeping needle stabilized.</p> <p>(10) After obtaining specimen, release tourniquet.</p> <p>(11) Apply 2 × 2-inch gauze pad without applying pressure. Quickly but carefully withdraw needle from vein and apply pressure following removal of needle (see illustration). Check for hematoma.</p> <p>(12) Activate safety cover and immediately discard needle in appropriate container.</p> | <p>Stabilizes vein and prevents rolling during needle insertion.</p> <p>Reduces chance of penetrating both sides of vein during insertion. Bevel up decreases chance of contamination by not dragging bevel opening over skin and allows point of needle to first puncture skin, reducing trauma.</p> <p>Prevents puncture through vein to opposite side.</p> <p>Syringe held securely prevents needle from advancing. Pulling on plunger creates vacuum needed to draw blood into syringe. If plunger is pulled back too quickly, pressure may collapse vein. If blood flow fails to appear, needle may not be in vein.</p> <p>Test results are more accurate when required amount of blood is obtained. You cannot perform some tests without minimal blood requirement. Movement of needle increases discomfort.</p> <p>Reduces bleeding at site when needle is withdrawn.</p> <p>Pressure over needle can cause discomfort. Careful removal of needle minimizes discomfort and vein trauma.</p> <p>Hematoma may cause compression injury (McCall and Tankersley, 2012).</p> <p>Prevents needlestick injury.</p> |
|--|---|

STEP 11a(6) Inserting needle into vein.

STEP 11a(8) Observe for blood return.

STEP 11a(11) Application of gauze to puncture site.

STEP

- (13) Attach blood-filled syringe to needle-free blood transfer device. Attach tube and allow vacuum to fill tube to specified level. Remove and fill other tubes as appropriate (see illustration). Gently rotate each tube back and forth 8 to 10 times.

b Vacutainer system method:

- (1) Attach double-ended needle to Vacutainer tube (see illustration).
- (2) Have proper blood specimen tube resting inside Vacutainer device but do not puncture rubber stopper.
- (3) Clean venipuncture site by following Steps 11a(2) and 11a(2)(a) for antiseptic swab. Allow to dry.
- (4) Remove needle cover and inform patient that “stick” will occur, lasting only a few seconds.
- (5) Place thumb or forefinger of nondominant hand 2.5 cm (1 inch) *below* site and gently pull skin taut. Stretch skin down until vein stabilizes.
- (6) Hold Vacutainer needle at 15- to 30-degree angle from arm with bevel up.
- (7) Slowly insert needle into vein (see illustration).
- (8) Grasp Vacutainer securely and advance specimen tube into needle of holder (do not advance needle in vein).
- (9) Note flow of blood into tube, which should be fairly rapid (see illustration).

STEP 11a(13) Attach blood filled syringe to needle-free blood transfer device.

RATIONALE

Additives prevent clotting. Shaking can cause hemolysis of red blood cells (RBCs).

Long end of needle is used to puncture vein. Short end fits into blood tubes.

Puncturing causes loss of tube vacuum.

Cleans skin surface of resident bacteria so organisms do not enter puncture site. Drying maximizes effect of antiseptic.

Patient has better control over anxiety when prepared about what to expect.

Helps to stabilize vein and prevent rolling during needle insertion.

Smallest and sharpest point of needle will puncture skin first. Reduces chance of penetrating sides of vein during insertion. Keeping bevel up causes less trauma to vein.

Prevents puncture on opposite side.

Pushing needle through stopper breaks vacuum and causes flow of blood into tube. If needle in vein advances, vein may become punctured on other side.

Failure of blood to appear indicates that vacuum in tube is lost or needle is not in vein.

STEP 11b(1) Attaching double-ended needle to Vacutainer tube.

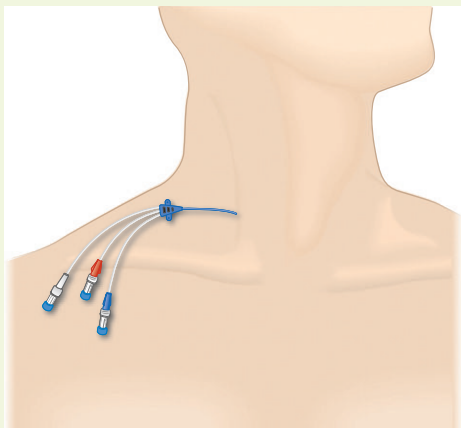

STEP 11b(7) Inserting Vacutainer needle into vein.

STEP 11b(9) Blood flowing into tube.

STEP	RATIONALE
(10) After filling specimen tube, grasp Vacutainer firmly and remove tube. Insert additional specimen tubes as needed. Gently rotate each tube back and forth 8 to 10 times.	Vacuum in tube stops flow at amount to be collected. Grasping prevents needle from advancing or dislodging. Tube should fill completely because additives in certain tubes are measured in proportion to filled tube. Ensures proper mixing with additive to prevent clotting.
(11) After last tube is filled and removed from Vacutainer, release tourniquet.	Reduces bleeding at site when needle is withdrawn.
(12) Apply 2 × 2-inch gauze pad over puncture site without applying pressure and quickly but carefully withdraw needle with Vacutainer from vein.	Pressure over needle can cause discomfort. Careful removal of needle minimizes discomfort and vein trauma.
(13) Immediately apply pressure over venipuncture site with gauze or antiseptic pad for 2 to 3 minutes or until bleeding stops. Observe for hematoma. Tape gauze dressing securely.	Direct pressure minimizes bleeding and prevents hematoma formation. Hematoma may cause compression and nerve injury. Pressure dressing controls bleeding.
(14) Dispose of syringe, needle, gauze, and other supplies in appropriate containers.	Safe disposal of supplies exposed to body fluids prevents transfer of microorganisms.
c Blood culture:	
(1) Clean venipuncture site as in Step 11a(2) with antiseptic swab or follow agency policy. Allow to dry.	Antimicrobial agent cleans skin surface so organisms do not enter puncture site or contaminate culture. Drying ensures complete antimicrobial action and decreases stinging.
(2) Clean bottle tops of culture bottles for 15 seconds with agency-approved cleaning solution. Allow to dry.	Ensures that bottle top is sterile.
(3) Collect 10 to 15 mL of venous blood using syringe method (see Step 11a) in 20-mL syringe from two different venipuncture sites.	Two blood cultures must be collected from two different sites to confirm culture growth (Pagana and Pagana, 2011).
(4) With each specimen activate safety guard and discard needle. Replace with new sterile needle before injecting each blood sample into culture bottle.	Maintains sterile technique and prevents contamination of specimen.
(5) If both aerobic and anaerobic cultures are needed, fill anaerobic bottle first.	Anaerobic organisms may take longer to grow (Pagana and Pagana, 2011).
(6) Gently mix blood in each culture bottle.	Mixes medium and blood.
d Central venous catheter (CVC) collection:	
(1) Select appropriate port on IV catheter (see illustration). Turn off all IV pumps and clamp lumens.	If more than one lumen, select distal lumen if possible (Alexander et al., 2010). Prevents dilution of sample with medication or total parenteral nutrition (TPN).
(2) Wipe all Luer-Lok caps with alcohol-wipe antiseptic solution or remove Luer-Lok alcohol-impregnated cap (DualCap System) (see illustration). Attach 10-mL saline prefilled syringe to selected port. Release clamp. Aspirate gently for blood return. Flush with 5 to 10 mL normal saline (NS) (check agency policy). Do not use syringe smaller than 10 mL. Remove syringe.	Luer-Lok-impregnated caps recommended by INS (2011). 70% isopropyl alcohol impregnated Luer-Lok cap (DualCap System) eliminates issue of wiping CVC ports adequately (Buchman et al., 2009). Aspirating and flushing ensures patency of selected lumen and catheter in vein.
	Pressure from small syringe may damage catheter.

STEP 11d(1) Triple-lumen central venous catheter; select appropriate distal lumen port.

STEP 11d(2) DualCap System. Disinfects and protects both IV catheter needleless Luer access and end of IV tubing.

STEP

- (3) Wipe port with alcohol wipe. For **syringe method** attach syringe to selected port, aspirate 5 mL of blood, and discard. Reclamp catheter. Wipe port, attach 10- to 20-mL Luer-Lok syringe, unclamp catheter, and aspirate desired amount of blood. Reclamp catheter and remove syringe. Clean catheter port with alcohol. To transfer blood from syringe to specimen tube, use a Vacutainer holder with Luer-Lok attachment. Insert appropriate specimen tube into Vacutainer holder. Attach syringe to Luer-Lok attachment and fill desired tubes.
 - (4) For **Vacutainer method**, clamp catheter and attach needleless connector to Vacutainer holder. Place blood tube into Vacutainer holder. Disinfect injection or access cap with alcohol. Insert Vacutainer needleless connection into injection or access cap, unclamp catheter, and advance blood tube into holder to activate blood flow. Allow blood to fill tube, clamp catheter, and discard first tube in appropriate biohazard container. Attach specimen tubes to Vacutainer with Luer-Lok adapter, unclamp catheter, and obtain blood specimens (see illustration).
 - (5) After all specimens are collected, clamp catheter. Remove Vacutainer holder and needleless connection from injection or access cap and disinfect with alcohol.
 - (6) Attach 10-mL prefilled NS syringe and flush with 5 to 10 mL NS using push, pause method. Ensure positive pressure for lumen. Cap with spring automatically has positive pressure; thus syringe can be removed, and lumen locked (see illustration). For caps without positive pressure, hold syringe plunger steady at completion of flush, lock off lumen with slide clamp, and remove syringe. Reattach alcohol-impregnated cap.
 - (7) Blood tubes contain additives; gently rotate back and forth 8 to 10 times.
- 12 Check tubes for any sign of external contamination with blood. Decontaminate with 70% alcohol if necessary.
 - 13 Remove gloves and perform hand hygiene after specimen is obtained and any spillage is cleaned.
 - 14 Help patient to comfortable position.

STEP 11d(4) Male Luer-Lok Vacutainer adapter attaches to port; blood draws directly into specimen tubes. (Courtesy and copyright © Becton Dickinson.)

RATIONALE

Discard ensures that blood sample is not contaminated with IV fluids, medication, or other products.
Tubes have vacuum and automatically fill to necessary amount.

Tubes have vacuum and automatically fill to necessary amount.

Reduces risk for contamination by bloodborne pathogens.

Push, pause creates turbulence that helps to clear lumen. Positive pressure prevents blood from flowing into tip of catheter and forming clot.

Additives mix with blood to prevent clotting. Shaking can cause hemolysis of RBCs producing inaccurate test results.

Prevents cross-contamination. Reduces risk for exposure to pathogens present in blood.

Reduces risk for exposure to bloodborne pathogens.

STEP 11d(6) Positive-pressure cap helps maintain patency of vascular access device. (With permission, courtesy ICU Medical, San Clemente, Calif.)

STEP	RATIONALE
15 Securely attach properly completed identification label to each tube and affix proper requisition. Verify identifiers in front of patient (TJC, 2012).	Incorrect identification of specimen could result in diagnostic or therapeutic errors.
16 Place specimens in plastic biohazard bag and send to laboratory. Cultures must be sent to laboratory within 30 minutes (Pagana and Pagana, 2011).	Minimizes spread of microorganisms.
17 Perform hand hygiene.	Reduces transfer of microorganisms.

EVALUATION

1 Reinspect venipuncture site for homeostasis.	Determines if bleeding has stopped or hematoma has formed.
2 Determine if patient remains anxious or fearful.	Some patients require more blood tests in future. Address concerns and let patient express anxiety.
3 Check laboratory report for test results.	Reveals constituents of blood specimen.
4 Ask patient to explain purposes of tests.	Validates learning.

Unexpected Outcomes

- Hematoma forms at venipuncture site.
- Bleeding at site continues.
- Signs and symptoms of infection at venipuncture site occur.
- Laboratory tests reveal abnormal blood results.

Related Interventions

- Apply pressure using 2 × 2-inch gauze dressing.
- Continue to monitor patient for pain and discomfort.
- Apply pressure to site; patient may also apply pressure.
- Monitor patient.
- Notify health care provider.
- Notify health care provider.
- Apply moist heat to site (see Chapter 40).
- Notify health care provider.

Recording and Reporting

- Record method used to obtain blood specimen, date and time collected, type of test ordered, disposition of specimen, and description of venipuncture site.
- Report any STAT or abnormal test results to health care provider.

Special Considerations

Teaching

- Instruct patient to briefly apply pressure to venipuncture site. Patients with bleeding disorders or those undergoing anticoagulant therapy should apply pressure for at least 5 minutes.
- Instruct patient to notify nurse or health care provider if persistent or recurrent bleeding or expanding hematoma develops at venipuncture site.

Pediatric

- Explain procedure to child at developmentally appropriate age and provide atraumatic care (Hockenberry and Wilson, 2011).
- Because children often fear that loss of their blood is a threat to their lives, explain to them that their blood is continually being produced. An adhesive bandage gives them assurance that

their blood will not leak out through puncture site (Hockenberry and Wilson, 2011).

- At times it is advantageous to draw children's blood specimens in a treatment room instead of in bed or room to maintain feeling that their room is a safe place (Hockenberry and Wilson, 2011).
- When performing venipuncture on children, explore sources for vein access: scalp, antecubital fossa, saphenous, and hand veins.
- Application of EMLA cream to the venipuncture site may be ordered before the stick to reduce pain in infants and young children (Hockenberry and Wilson, 2011).
- Vacutainers are not recommended in children under 2 years of age because of possible vein collapse with their use.

Gerontologic

- Older adults have fragile veins that are easily traumatized during venipuncture. Sometimes application of warm compresses may help to obtain samples. Using small-bore catheter may be beneficial.

Home Care

- In home care setting a blood pressure cuff rather than a tourniquet can be used for venipuncture.

SKILL 43-9 Blood Glucose Monitoring

Blood glucose monitoring allows patients with diabetes mellitus to self-manage their disease. Obtaining capillary blood by skin puncture is an alternative to reduce the frequency of needlesticks when you cannot perform venipuncture. The procedure is less painful than venipuncture, and the ease of the skin puncture method makes it possible for patients to

perform this procedure. The development of reagent strips, home glucose monitors, and the skin puncture method has revolutionized home management care of patients with diabetes mellitus.

Glucose levels can be evaluated by performing a skin puncture and using either a visually read test (e.g., Chemstrip bG, Glucostix)

or a reflectance meter. The visually read test does not require an expensive machine, but the patient must be able to visually interpret the results. A single drop of blood is applied to a specifically prepared reagent strip; the strip is read, and the results are compared to the color chart on the container. Measurement by a visually read test may not be accurate but can be useful for screening.

Blood glucose reflectance meters are lightweight and run on batteries (e.g., AccuChek III, OneTouch) (Fig. 43-5). After a drop of blood from the skin puncture is dropped or wicked onto a reagent strip, the meter provides an accurate measurement of blood glucose level in 5 to 50 seconds. Point-of-care (POC) blood glucose testing meters should be dedicated for single-patient use. If single-patient use is not possible, meters must be cleaned and disinfected (US FDA, 2011).

Reflectance meters use a wet-wash or dry-wipe method of testing. To perform a wet wash, the user flushes the blood-coated reagent strip with water before inserting the strip into the glucose meter. The dry-wipe method requires the user to wipe off the blood-coated reagent strip with a dry cotton ball before making a reading. Some products do not require blood to be flushed or wiped before a reading. The various methods allow measurement of blood glucose between 20 and 800 mg/dL, thus providing a sensitive measurement of blood glucose level.

The meters differ in several ways, including amount of blood needed for each test, testing speed, overall size, ability to store test results in memory, cost of the meter, and cost of test strips (ADA, 2011). Some larger meters are voice activated, which provides support for the older adult or patient with visual impairments. The amount of time to complete the glucose testing with the current glucose meters varies from 5 to 50 seconds. You can program some meters to monitor the glucose levels for a continuous 72 hours.

Improved technology introduced two methods for glucose measurement now available on the market. A minimally invasive glucose meter uses a very small, fine plastic sensor inserted through the abdomen and provides continuous readings of blood glucose levels (Fig. 43-6, A). A biosensor is taped on the external abdomen. Using a handheld wireless meter, a patient activates the biosensor to transmit the blood glucose level at any time without puncturing

the skin (Fig. 43-6, B). Another model, considered a noninvasive glucose meter, does not prick the skin with a needle but uses precise laser technology or light beam to puncture the skin, resulting in less damage to tissue. For the patient with diabetes mellitus who requires assessment of trends and patterns, these systems are ideal.

Testing of glycosylated hemoglobin (HbA_{1c}) evaluates the amount of glucose available in the bloodstream over the 120-day life span of a red blood cell. HbA_{1c} provides an accurate long-term index of a patient's average blood glucose level drawn by venous puncture (Pagana and Pagana, 2011).

Delegation and Collaboration

Assessment of a patient's condition cannot be delegated to nursing assistive personnel (NAP). When the patient's condition is stable, the skill of obtaining and testing a sample of blood for blood glucose level can be delegated to NAP. The nurse informs the NAP by:

- Explaining appropriate sites to use for puncture and when to obtain glucose levels.
- Reviewing expected blood glucose levels and when to report unexpected glucose levels to the nurse.

FIG 43-5 Blood glucose monitor. (Courtesy LifeScan, Milpitas, Calif.)

FIG 43-6 A, Tiny sensor implanted under skin transmits continuous reading to receiver. B, Monitor displays and stores readings. (Courtesy DexCom.)

Equipment

- Antiseptic swab
- Cotton ball
- Lancet device, either self-activating or button activated

- Blood glucose meter (e.g., Accucheck III, OneTouch)
- Blood glucose test strips appropriate for meter brand used
- Clean gloves
- Paper towel

STEP	RATIONALE
------	-----------

ASSESSMENT

<p>1 Assess patient’s understanding of procedure and purpose of blood glucose monitoring. Determine if patient understands how to perform test and its importance in glucose control.</p>	<p>Provides baseline for developing teaching plan.</p>
<p>2 Determine if specific conditions need to be met before or after sample collection (e.g., fasting, postprandial, after certain medications, before insulin doses).</p>	<p>Dietary intake of carbohydrates and ingestion of concentrated glucose preparations alter blood glucose levels.</p>
<p>3 Determine if risks exist for performing skin puncture (e.g., low platelet count, anticoagulant therapy, bleeding disorders).</p>	<p>Abnormal clotting mechanisms increase risk for local ecchymosis and bleeding.</p>
<p>4 Assess area of skin to be used as puncture site. Inspect fingers or forearms for edema, inflammation, cuts, or sores. Avoid areas of bruising and open lesions. Avoid using the hand on the side of a mastectomy.</p>	<p>Sides of fingers are commonly selected because they have fewer nerve endings.</p> <p>Measurements from alternative sites are meter specific and may be different from those at traditional sites (Corbett, 2008). The puncture site should not be edematous, inflamed, or recently punctured because these factors cause increased interstitial fluid and blood to mix and also increase risk for infection.</p>
<p>5 Review health care provider’s order for time or frequency of measurement.</p>	<p>Health care provider determines test schedule on basis of patient’s physiologic status and risk for glucose imbalance.</p>
<p>6 For patient with diabetes who performs test at home, assess ability to handle skin-puncturing device. Patient may choose to continue self-testing while in hospital.</p>	<p>Patient’s physical health may change (e.g., vision disturbance, fatigue, pain, disease process), preventing him or her from performing test.</p>

NURSING DIAGNOSES

- | | | |
|---|--|--|
| <ul style="list-style-type: none"> • Anxiety • Deficient knowledge regarding blood glucose monitoring | <ul style="list-style-type: none"> • Ineffective health maintenance | <ul style="list-style-type: none"> • Ineffective therapeutic regimen management |
|---|--|--|

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Puncture site shows no evidence of bleeding or tissue damage. • Blood glucose measurements are accurate. • Patient can verbalize procedure for self-monitoring blood glucose. • Patient explains test results. 	<p>Hemostasis is achieved. Lancet or needle did not puncture skin too deeply.</p> <p>Normal fasting glucose is 70 to 110 mg/dL, indicating good metabolic control (Pagana and Pagana, 2011).</p> <p>Demonstrates psychomotor learning.</p>
<p>2 Explain procedure and purpose to patient and/or family. Offer patient and family opportunity to practice testing procedures. Provide resources/teaching aids for patient and family caregiver.</p>	<p>Validates knowledge.</p> <p>Promotes understanding and cooperation.</p>

IMPLEMENTATION

<p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient’s identification bracelet and/or have patient state name.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p>
<p>2 Perform hand hygiene. Instruct adult to perform hand hygiene, including forearm (if applicable) with soap and water. Rinse and dry.</p>	<p>Promotes skin cleansing and vasodilation at selected puncture site.</p> <p>Reduces transmission of microorganisms.</p>
<p>3 Position patient comfortably in chair or in semi-Fowler’s position in bed.</p>	<p>Ensures easy accessibility to puncture site. Patient will assume position when self-testing.</p>

STEP	RATIONALE
<p>4 Remove reagent strip from vial and tightly seal cap. Check code on test strip vial. Use only test strips recommended for glucose meter. Some newer meters do not require code and/or have disk or drum with 10 or more test strips.</p>	<p>Protects strips from accidental discoloration caused by exposure to air or light. Code on test strip vial must match code entered into glucose meter.</p>
<p>5 Insert strip into meter (refer to manufacturer directions (see illustration). Do not bend strip. Meter turns on automatically.</p>	<p>Some machines must be calibrated; others require zeroing of timer. Each meter is adjusted differently.</p>
<p>6 Remove unused reagent strip from meter and place on paper towel or clean, dry surface with test pad facing up (see manufacturer directions).</p>	<p>Moisture on strip can alter accuracy of final test results.</p>
<p>7 Meter displays code on screen that must match code from test strip vial. Press proper button on meter to confirm matching codes. Meter is ready for use.</p>	<p>Codes must match for meter to operate. Meters have different messages that confirm that meter is ready for testing and blood can be applied.</p>
<p>8 Perform hand hygiene and apply clean gloves. Prepare single-use lancet or multiple-use lancet device. NOTE: Some meters recommend that this step be completed before preparing test strip. Remove cap from lancet device; insert new lancet. Some lancet devices have disk or cylinder that rotates to new lancet.</p> <p>a Twist off protective cover on tip of lancet. Replace cap of lancet device.</p> <p>b Cock lancet device, adjusting for proper puncture depth.</p>	<p>Reduces transmission of microorganisms. Never reuse a lancet because of risk of infection.</p>
<p>9 Obtain blood sample.</p>	<p>Each patient varies as to depth of insertion needed for lancet to produce blood drop.</p>
<p>a Wipe patient's finger or forearm lightly with antiseptic swab. Choose vascular area for puncture site. In stable adults select lateral side of finger. Avoid central tip of finger, which has denser nerve supply (Pagana and Pagana, 2011).</p>	<p>Removes microorganisms from skin surface. Side of finger is less sensitive to pain.</p>
<p>b Hold area to be punctured in dependent position. Do not milk or massage finger site.</p>	<p>Increases blood flow to area before puncture. Milking may hemolyze specimen and introduce excess tissue fluid (Pagana and Pagana, 2011).</p>
<p>c Hold tip of lancet device against area of skin chosen for test site (see illustration). Press release button on device. Some devices allow you to see blood sample forming. Remove device.</p>	<p>Placement ensures that lancet enters skin properly.</p>
<p>d With some devices a blood sample begins to appear. Otherwise gently squeeze or massage fingertip until round drop of blood forms (see illustration).</p>	<p>Adequate-size blood sample is needed to test glucose.</p>
<p>10 Obtain test results.</p>	<p>Exposure of blood to test strip for prescribed time ensures proper results.</p>

STEP 5 Load test strip into meter. (Courtesy Accucheck Glucometer.)

STEP 9c Prick side of finger with lancet. (Courtesy Accucheck Glucometer.)

STEP

RATIONALE

Clinical Decision Point Some meters (e.g., OneTouch [LifeScan]) require blood sample to be applied to test strip already in the meter. Once the drop of blood is applied, the meter automatically calculates the reading.

- a Be sure that meter is still on. Bring test strip in meter to drop of blood. Blood will be wicked onto test strip (see illustration). Follow specific meter instructions to be sure that you obtain adequate sample. Blood enters strip, and glucose device shows message on screen to signal that enough blood is obtained.

Clinical Decision Point Do not scrape blood onto the test strips or apply it to wrong side of test strip. This prevents accurate glucose measurement.

- b Blood glucose test result will appear on screen (see illustration). Some devices “beep” when completed.

STEP 9d Gently squeeze puncture site until drop of blood forms.

STEP 10a Touch test strip to blood drop. Blood wicks into test strip. (Courtesy Accucheck Glucometer.)

STEP 10b Results appear on meter screen. (Courtesy Accucheck Glucometer.)

STEP	RATIONALE
11 Turn meter off. Some meters turn off automatically. Dispose of test strip, lancet, and gloves in proper receptacles.	Meter is battery powered. Proper disposal reduces risk for needlestick injury and spread of infection.
12 Perform hand hygiene.	Reduces transmission of microorganisms.
13 Discuss test results with patient and encourage questions and eventual participation in care if this is a new diabetes mellitus diagnosis.	Promotes participation and compliance with therapy.

EVALUATION

1 Reinspect puncture site for bleeding or tissue injury.	Site can be source of discomfort and infection.
2 Compare glucose meter reading with normal blood glucose levels and previous test results.	Determines if glucose level is normal.
3 Ask patient to discuss procedure.	Validates level of learning.
4 Ask patient to explain test results and perform next reading.	Results of test may cause anxiety. Patient may misunderstand specific step of procedure. Return demonstration reinforces learning.

Unexpected Outcomes

- 1 Puncture site is bruised or continues to bleed.
- 2 Blood glucose level is above or below target range.
- 3 Glucose meter malfunctions.
- 4 Patient expresses misunderstanding of procedure and results.

Related Interventions

- Apply pressure.
- Notify health care provider if bleeding continues.
- Continue to monitor patient.
- Check if there are medication orders for deviations in glucose level.
- Notify health care provider.
- Administer insulin or carbohydrate source as ordered, depending on glucose level.
- Review instructions for troubleshooting glucose meter.
- Repeat test.
- Repeat instructions to patient.
- Have patient demonstrate procedure.

Recording and Reporting

- Record procedure and glucose level in nurses' notes or special flow sheet and action taken for abnormal range.
- Describe patient response, including appearance of puncture site, in nurses' notes.
- Describe explanations or teaching provided in nurses' notes.
- Record and report abnormal blood glucose levels.

Special Considerations

Teaching

- Provide information on where patient with diabetes mellitus can obtain testing supplies. When possible, teach with the same meter that patient will use at home.
- Provide patient with information on where to obtain assistance if glucose meter has malfunctioned.
- Stress importance of the timing of blood glucose levels, particularly in patients with diabetes mellitus.

Pediatric

- Allow young children to choose puncture site; heel and great toe are common puncture sites in infants.

- Heel warming helps to obtain specimen from a neonate.
- Infection or abscess of the heel and necrotizing osteochondritis are the most serious complications of heelstick puncture in infants. To avoid osteochondritis make sure that puncture is not deeper than 2 mm and is made at the outer aspect of the heel (Hockenberry and Wilson, 2011).
- Allow young child with parent to demonstrate technique; incorporate a play activity for further understanding.

Gerontologic

- Warming fingertips may facilitate obtaining specimen.
- Some older adults have vision or dexterity problems that interfere with performing self-fingersticks.

Home Care

- Provide information on correct disposal of sharps in nonpermeable and puncture-resistant container.
- Suggest that patient attend diabetic support group if needed.
- Be sure that patient's family caregiver can perform test when patient is ill or is unable to manipulate devices.

SKILL 43-10 Obtaining an Arterial Specimen for Blood Gas Measurement

You assess effectiveness of oxygenation and ventilation by measuring arterial blood gases (ABGs). Measurement of ABGs provides valuable information in assessing and managing a patient's respiratory and metabolic disturbances (Pagana and Pagana, 2011). The parameters measured in an ABG include arterial blood pH, partial pressure of oxygen (PaO₂), partial pressure of carbon dioxide (PaCO₂), and arterial oxygen saturation (SaO₂). The ABG sample is easy to obtain and analyze to provide a clear picture of acid-base balance, oxygenation, and ventilation.

Each agency has a policy regarding who is allowed to obtain ABG samples. Many agencies allow nurses in specialty areas (e.g., critical care) to obtain them; others specify a certified respiratory therapist, and some require institutional certification of this skill. A decision to draw ABG samples may be a direct result of your physical assessment (see Chapter 6).

Delegation and Collaboration

The skill of obtaining an arterial blood gas sample cannot be delegated to nursing assistive personnel (NAP). The nurse informs the NAP to:

- Report any bleeding from arterial puncture site.
- Report any changes in patient vital signs, level of consciousness, or restlessness.

Equipment

- Commercial blood gas kit or individual supplies, including:
 - 3-mL heparinized syringe
 - 23- or 25-gauge needle with safety guard
 - Filter cap (allows expelling of air and retains blood)
 - Alcohol swabs (2)
 - 2 × 2-inch gauze pad
 - Tape
 - Heparin (1:1000 solution)
 - Cup or plastic bag with crushed ice
 - Clean gloves
 - Protective eyewear
- Completed identification labels with proper patient identifiers
- Completed laboratory requisition with date, time, name of test, patient identification, and source of specimen
- Small plastic biohazard bag for delivery of specimen to laboratory (or container specified by agency)

STEP

RATIONALE

ASSESSMENT

1 Assess for factors that influence ABG measurements:

- a** Hypoventilation or hyperventilation
- b** Body temperature

2 Identify medications that may influence ABG measurement (e.g., anticoagulants, diuretics).

3 Assess respiratory status, including rate, depth, rhythm, adventitious sounds, use of accessory muscles.

4 Review criteria for choosing site for ABG sample.

Allows you to eliminate factors that interfere with accurate measurement.

Hypoventilation can cause retention of CO₂, and hyperventilation can cause decreased CO₂ levels (Hockenberry and Wilson, 2011).

Change in body temperature as little as 1° F can alter blood gas values (Hockenberry and Wilson, 2011).

Certain medications increase risk for bleeding at puncture site or may cause hemoconcentration.

Physical signs and symptoms may indicate need for ABG sample.

Prevents causing compromised circulation from puncture.

Clinical Decision Point Factors that contraindicate use of arterial site include amputation, contractures, localized infection, dressing or cast, mastectomy, or arteriovenous shunts.

a Assess collateral blood flow. Perform Allen test.

- (1) Have patient make tight fist and raise hand above heart.
- (2) Apply direct pressure to both radial and ulnar arteries (see illustration).
- (3) Have patient lower and open hand (see illustration).
- (4) Release pressure over ulnar artery; observe color of fingers, thumbs, and hand (see illustration).

Allen test assesses collateral circulation before performing arterial puncture on radial artery. Positive Allen test ensures that there is collateral circulation to hand in case thrombosis of radial artery occurs following puncture (Pagana and Pagana, 2011).

Removes as much blood from hand as possible. Obstructs arterial blood flow to hand.

Fingers and hand should be pale and blanched, indicating lack of arterial blood flow.

Flushing identifies that circulation through ulnar artery is good and that ulnar artery alone is capable of providing blood supply to entire hand. Therefore you can use radial artery for puncture.

Clinical Decision Point If there is no flushing in 15 seconds, Allen test is negative and should be repeated on the other arm or choose another artery for puncture (Pagana and Pagana, 2011).

STEP	RATIONALE
b Assess accessibility of vessel.	Palpating, stabilizing, and performing venipuncture of superficial artery is easier. Superficial arteries are located at distal ends of extremities.
c Assess tissue surrounding artery.	Muscle, tendon, and fat have decreased sensation to pain. Bony periosteum and nerves are highly sensitive to pain.
d Assess that arteries are not directly adjacent to veins.	Helps reduce chance of venous puncture and possibility of inaccurate samples.
5 Assess arterial sites for use in obtaining specimen.	Arterial blood may be obtained from areas where strong pulses are palpable (i.e., radial, brachial, or femoral artery) (Pagana and Pagana, 2011).

Clinical Decision Point Previous puncture sites or preexisting conditions may eliminate potential sites (see agency policy). Artery should be easily accessible.

a Radial artery

Safest, most accessible site for puncture; is superficial, is not adjacent to large veins, usually has adequate collateral circulation by ulnar artery, and is relatively painless if periosteum is avoided. Used when Allen's test is positive.

b Brachial artery

Has reasonable collateral blood flow, is less superficial, is more difficult to palpate and stabilize, carries increased risk for venous puncture, and results in increased discomfort for patient if brachial nerve is punctured. Used when radial artery is inaccessible or Allen's test is negative.

c Femoral artery

Nurses without specialized training should not use this artery. Has no adequate collateral flow if obstructed below inguinal ligament, is difficult to stabilize, is deep, and is directly adjacent to femoral vein. Is best artery to use in emergency (e.g., cardiac arrest or hypovolemic shock when pulses are difficult to palpate).

STEP 4a(2) Applying pressure to radial and ulnar arteries.

STEP 4a(3) Patient opening hand; note color.

STEP 4a(4) Releasing pressure over ulnar artery, and noting color of hand.

STEP	RATIONALE
6 Review baseline ABG values for patient.	Provides baseline for comparison and evaluation of therapies.
7 Determine patient's knowledge about ABG procedure.	Obtaining blood specimen is painful. Patient who is knowledgeable will be more cooperative.

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding arterial blood gases
- Impaired gas exchange
- Ineffective airway clearance
- Ineffective breathing pattern
- Ineffective peripheral tissue perfusion
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient's ABG values are within normal range. • Patient's extremity distal to puncture remains warm and pink, has adequate capillary refill, and is free of pain. • Patient denies anxiety, and respiratory rate remains within baseline. • Patient correctly discusses ABG procedure. 	Indicates adequate oxygenation. Indicates adequate arterial circulation to extremity.
2 Prepare heparinized syringe (if not in commercial kit). <ul style="list-style-type: none"> a Aspirate 0.5 mL sodium heparin (1000 units/mL) into syringe from vial or ampule. b Withdraw plunger entire length of syringe. Maintain asepsis. c Eject all heparin in barrel out of syringe. 	Anxiety increase respiratory rate, which can alter ABG results. Indicates learning. Heparin mixes with specimen to prevent clotting. Prevents blood sample from clotting before reaching laboratory. Excessive heparin can affect pH of arterial sample. Coats inside of barrel of syringe with heparin. In hub of syringe 0.15 to 0.25 mL of sodium heparin remains; 0.05 mL of sodium heparin adequately anticoagulates 1 mL of blood; 0.15 mL adequately anticoagulates 3 mL without affecting pH level.
3 Explain steps and purpose of procedure to patient.	Reduces anxiety and promotes understanding and cooperation.

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2 Perform hand hygiene.	Reduces transmission of infection.
3 Palpate selected radial, femoral, or brachial site with fingertips.	Determines area of maximal impulse for puncture site.
4 Using radial artery, elevate patient's wrist with small pillow and ask him or her to extend fingers downward. Stabilize artery by slight hyperextension of wrist.	This flexes wrist and positions radial artery closer to surface (Fischbach and Dunning, 2009). Reduces mobility of artery and makes insertion of needle easier.
5 Apply clean gloves. Clean area of maximal impulse with alcohol swab or antiseptic swab (check agency or manufacturer recommendation). Wipe in circular motion away from site or use back-and-forth strokes. Allow to dry.	Reduces number of resident bacteria on surface of skin. Drying maximizes antibacterial effects.
6 Hold 2 × 2 inch-gauze pad with same fingers used to palpate artery.	Keeps gauze pad accessible for covering puncture site when necessary.
7 Use corner of sterile gauze pad or alcohol wipe to point to chosen site.	Maintaining location of artery improves likelihood of successful puncture.
8 Hold needle bevel up and insert at 45-degree angle into artery. Prepare patient for needlestick because radial sticks are painful.	Angle allows for better arterial flow into needle. Prepared patient will be less likely to withdraw arm.
9 Stop advancing needle when blood is noted returning into hub of needle or syringe.	Quick return of blood indicates that arterial flow is obtained. Prevents puncturing through both sides of artery.
10 Allow arterial pulsations to pump 2 to 3 mL of blood into heparinized syringe slowly (see illustration).	Allowing pulsations to assist in filling syringe reduces presence of air bubbles in sample. Bubbles alter ABG results.
11 When sampling is complete, hold 2 × 2-inch gauze pad over puncture site, withdraw syringe and needle, and activate safety guard over needle.	Pad minimizes pulling of skin as needle is withdrawn. Decreases contamination from blood and accidental needlestick.
12 Apply pressure over and just proximal to puncture site with pad (see illustration).	Insertion of needle into artery is just proximal to insertion site through skin. Gauze absorbs any blood that might ooze from site.

STEP

- 13 Maintain continuous pressure on and proximal to site for 3 to 5 minutes (approximately 15 minutes if patient is undergoing anticoagulant therapy or has bleeding disorder) (Pagana and Pagana, 2011). Have another nurse perform Step 16 if prolonged pressure is needed.
- 14 Visually inspect site for signs of bleeding or hematoma formation.
- 15 Palpate artery below or distal to puncture site.
- 16 Take syringe, remove safety needle, and discard needle in appropriate biohazard container. Attach filter cap to syringe (available in kit) to expel air or cover tip of syringe with 2 × 2-inch sterile gauze to expel air (see agency procedure). Some kits may have all supplies, including syringe with heparin, needle with safety needle cap, and filter cap that allows air to vent and not blood (see illustration).
- 17 Prepare syringe for laboratory analysis (according to agency policy). Common principles include:
 - Place patient identification label on syringe in front of patient (TJC, 2012), confirming identifiers.
 - Place syringe in cup of crushed ice.

RATIONALE

- To avoid hematoma formation, apply and hold pressure or apply a pressure dressing to arterial puncture site for 3 to 5 minutes (Pagana and Pagana, 2011). Prevents delay in preparing syringe in ice.
- Determines if continued need exists to exert pressure. Because artery rather than vein has been accessed, monitor puncture site for bleeding.
- Determines if pulse quality has changed, indicating alteration in arterial flow.
- Decreases chance of contamination from room air. Air bubbles in specimen can falsely elevate or decrease results, depending on patient's blood gas concentration (Hockenberry and Wilson 2009; Van Leeuwen et al., 2011).
- Permits proper identification of sample for laboratory.
- Failure to place ABG sample in ice bath may affect results of pH, PaO₂, and PaCO₂ (Van Leeuwen et al., 2011).

STEP 10 Blood flowing into syringe.

STEP 12 Applying firm pressure to arterial puncture site.

STEP 16 Filter-Pro Air Bubble Removal Device expels air safely from syringe without accidentally expelling blood and aerosolizing sample. (With permission from Smiths Medical, Carlsbad, Calif.)

STEP

RATIONALE

- Attach properly labeled requisition to blood gas sample, including most recent hemoglobin, mode and flow of oxygen, and patient's temperature.
- 18 Place cup and sample in biohazard bag. Send sample to laboratory immediately.
- 19 Remove gloves and perform hand hygiene.

Prevents mislabeled specimens in laboratory. Ensures that correct results are received for correct patient.

Hyperthermia and hypothermia influence oxygen release from hemoglobin at tissue level (Fischbach and Dunning, 2009). Temperature affects amount of gas in solution. Fever increases actual PaO₂ and PaCO₂ (Van Leeuwen et al., 2011).

Prevents alteration in gas tensions resulting from metabolic processes that continue after blood is drawn (Fischbach and Dunning, 2009).

Reduces transmission of microorganisms.

EVALUATION

- 1 Inspect puncture site and area distal to puncture site for complications.
- 2 Review results of sample as soon as possible.

An artery can be obstructed, or important structures anatomically juxtaposed to an artery can be penetrated (Pagana and Pagana, 2011).

Identifies any abnormality and expedites initiation of treatment.

Unexpected Outcomes

- 1 Patient has abnormal ABG values.
- 2 Patient has hematoma formation at puncture site.
- 3 Puncture site is bruised or continues to bleed.

Related Interventions

- Continue to monitor patient.
- Notify health care provider of findings and obtain further orders.
- Apply warm compresses to enhance absorption of blood (see Chapter 40).
- Continue to monitor patient.
- Notify health care provider.
- Apply pressure.
- Notify health care provider if bleeding continues.

Recording and Reporting

- Record results of Allen test, location and condition of puncture site, patient's tolerance of procedure, and disposition of specimen to laboratory in nurses' notes.
- Report ABG results to health care provider as soon as available.
- Report patient's FiO₂ and any ventilator settings (e.g., tidal volume [V_T], respiratory frequency [RF], mode of ventilation).
- Record results of test in nurses notes.

Pediatric

- In neonatal and pediatric patients you can use capillary blood gas. Procedures are similar to those for obtaining heelsticks.
- When dealing with neonatal patients, especially premature infants, normal values for ABGs often differ from those of adults.
- Arterial blood samples from punctures are painful and cause crying and breath holding that affect the accuracy of blood gas values (decreases PaO₂) (Hockenberry and Wilson, 2011).

Special Considerations

Teaching

- Teach patient to report numbness, burning, and/or tingling during and after in hand that had radial artery puncture.

Gerontologic

- Pay special attention during interpretation of ABGs for patients with chronic pulmonary conditions. In these patients compensatory mechanisms may allow normal pH in face of markedly elevated PaCO₂.

 Critical Thinking Exercises

Mrs. Yamamoto is a 76-year-old who was admitted with pneumonia today. She has a productive cough. She also has a history of diabetes mellitus. Her blood glucose level on admission is 208 mg/dL. She speaks and understands minimal English. Her daughter translates for her and states that her blood glucose level is normally well controlled with oral hypoglycemic medication.

- 1 Which test(s) would you expect to be ordered? (Select all that apply.)
 - 1 Sputum specimen today
 - 2 Throat culture in morning
 - 3 Midstream urine culture at noon
 - 4 Fingertick for blood glucose levels before meals and at bedtime
- 2 Immediate results will be available for which of the tests?
- 3 Briefly describe how you would teach Mrs. Yamamoto about providing a sputum specimen.
- 4 What do you need to assess to determine Mrs. Yamamoto's ability to test her own blood glucose levels at home?

 REVIEW QUESTIONS

- 1 A urine specimen for culture and sensitivity is being collected from a male patient. Which steps would be used to obtain an accurate specimen? (Select all that apply.)
 - 1 Two patient identifiers are checked.
 - 2 Help patient to perform pericare before the sterile part of the procedure.
 - 3 Wipe the head of the penis back and forth 3 times with each swab.
 - 4 Collect 10 to 20 mL for the sample.
 - 5 Have the patient initially void into a bedpan or clean container.
 - 6 Have patient hold penis above the sterile specimen cup without touching the container.
- 2 A 24-hour urine (timed urine collection) is being started. Which step is essential to have an accurate collection?
 - 1 Discarding the first urine specimen
 - 2 Including the first specimen for the test
 - 3 Discarding both the first and last specimen
 - 4 Discarding the last specimen

- 3 A patient is scheduled to obtain a stool sample for occult blood several days from now. Which food should be avoided before the stool sample is obtained because it can alter the results of the test?
- 1 Potatoes
 - 2 Tomatoes
 - 3 Bananas
 - 4 Apples
- 4 The nurse is preparing to obtain a throat culture. Which step(s) would facilitate obtaining an accurate specimen? (Select all that apply.)
- 1 Placing patient in a sitting position or with head elevated at a 45-degree angle
 - 2 Having patient lean her head forward
 - 3 Having patient swallow a small amount of water to rinse away food from the culture site before swabbing the area
 - 4 Swabbing the tonsillar area
 - 5 Swabbing the uvula
 - 6 Having patient blow her nose
- 5 The nurse is preparing to obtain a culture from a male patient with a urethral discharge. Which objective data should the nurse observe for in the genital area before obtaining the culture?
- 1 Redness
 - 2 Lower abdominal discomfort
 - 3 Urethral stinging
 - 4 Itching
- 6 Place the steps for collecting a wound culture specimen in the correct order.
- 1 Open packages containing sterile culture tubes and dressing supplies.
 - 2 Identify patient using two identifiers.
 - 3 Clean area around wound edges.
 - 4 Apply clean gloves. Remove old dressings and dispose of in appropriate receptacle.
 - 5 Apply sterile gloves. Obtain culture.
- 7 Place the following steps for collecting a sterile urine specimen from a Luer-Lok catheter port in the correct order.
- 1 Attach a Luer-Lok syringe to the Luer-Lok port.
 - 2 Clamp the drainage tube with a clamp or rubber band for 15 minutes.
 - 3 Clean catheter entry port and wait for disinfectant to dry.
 - 4 Unclamp catheter and allow urine to flow into drainage bag.
 - 5 Aspirate 3 mL of urine into the syringe attached to the Luer-Lok.
- 8 Place in order the steps for performing a skin puncture for blood glucose monitoring.
- 1 Instruct adult patient to perform hand hygiene.
 - 2 Apply clean gloves.
 - 3 Compare code on glucose meter screen to code on test strip vial.
 - 4 Drop or wick blood on to reagent strip.
 - 5 Clean site with an antiseptic swab or wipe
- 9 A nursing assistive personnel (NAP) received instructions from the nurse to collect a sterile urine specimen from the Luer-Lok port of an indwelling catheter. The nurse identifies that the NAP needs further instruction when he or she states:
- 1 "It's not my role to collect a specimen from the port of an indwelling catheter."
 - 2 "I'll use an 18-gauge needle to draw out the urine for the specimen."
 - 3 "I'll use a 20-mL Luer-Lok syringe to collect urine for a routine urinalysis."
 - 4 "I'll use a Luer-Lok syringe to draw the urine specimen."
- 10 Which sites are most often used for the Allen test before the collection of an arterial blood gas?
- 1 Radial and ulnar pulses
 - 2 Radial and brachial pulses
 - 3 Radial and carotid pulses
 - 4 Popliteal and posterior tibial pulses

Capnography	Intestinal obstruction	Moderate sedation	Trocar
Cerebrospinal fluid (CSF)	Intravenous conscious sedation (IV sedation)	Modified Ramsay sedation scale	
Cytology			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify the physiologic indications for diagnostic procedures.
- Describe the health care team collaboration and teamwork required before, during, and after procedures, including delegation to nursing assistive personnel.
- Perform appropriate physical and psychosocial assessments before, during, and after diagnostic procedures.
- Effectively assist health care providers with angiogram, cardiac catheterization, intravenous (IV) pyelogram, bone marrow aspiration/biopsy, lumbar puncture, paracentesis, thoracentesis, bronchoscopy, and endoscopy.
- Demonstrate understanding of nursing responsibilities related to the use of intravenous sedation during diagnostic/surgical procedures.

Diagnostic procedures are performed at patients' bedsides or in specially equipped rooms within a hospital or outpatient care setting. As a nurse you are responsible for assessing a patient's knowledge of a procedure; preparing the patient; providing a safe environment and emotional support throughout the procedure; providing preprocedure and postprocedure assessment, care, and documentation; and providing discharge teaching. In addition, you are responsible for the oversight of

any nursing care delegated to nursing assistive personnel (NAP). When procedures are completed in outpatient settings, it is the discharge nurse's responsibility to provide detailed printed home care instructions for postprocedure care, provide a complete reconciliation and instructions for all medications taken by a patient before the procedure and after discharge, and teach postprocedure care to the patient or caregiver. The health care provider is responsible for providing

the patient with an explanation of the test/procedure, risks, benefits, treatment options, and outcomes before the procedure as part of the *informed consent* process.

EVIDENCE-BASED PRACTICE

Patients have diagnostic procedures in a variety of settings: inpatient, outpatient, and specialty diagnostic imaging centers. It is a challenge for nurses working in these settings to ensure that patients requiring diagnostic testing understand their testing and postprocedural care requirements. Some tests require intravenous (IV) sedation along with the diagnostic procedure, such as a gastrointestinal endoscopy; others require contrast media or aspirations; and some diagnostic tests that are noninvasive. Diagnostic procedures are not without risk. It is important that you understand your patients' diagnostic procedures, including why the procedure is needed, which preprocedural assessments are needed, expected outcomes, your role during the procedure, and appropriate postprocedural nursing care, to help ensure patient safety.

IV sedation is used for diagnostic or surgical procedures that do not require complete or general anesthesia. It is performed in acute care, surgical care, and outpatient care settings. Sedation classifications include "minimal," "moderate," or "deep" sedation/analgesia, depending on the depth of sedation (ASA, 2009). Based on current evidence-based practice, health care agencies maintain standards for preassessment, preparation, and monitoring of patients who will receive IV procedural sedation. Objective scales such as the American Society of Anesthesiologists (ASA) physical status classification system are used to determine if patients are at risk for undesirable outcomes. Use of an objective scale helps to reduce the risk for complications by determining when it is prudent to involve an anesthesiologist to help manage the care of a complicated patient condition (ASA, 2009). These objective scales incorporate evidence-based guidelines to reduce the risk for sedation-induced complications such as cardiac arrhythmias, respiratory failure, renal failure, neurologic disorders related to the use of paralytic agents, or bleeding disorders resulting from hepatic failure.

The use of vascular closure devices (VCDs) is common after procedures involving an arteriotomy or opening in an artery. VCDs are designed to reduce the time to hemostasis at the access (puncture) site and allow for earlier sheath removal. The use of VCDs contributes to earlier postprocedural resumption of normal activities and decreased treatment costs. A recent meta-analysis noted the effectiveness of the VCDs in obtaining prompt hemostasis over manual compression in the adult (Biancari et al., 2010). However, the researchers also noted an increased risk for lower limb ischemia, arterial stenosis, and other arterial complications (Biancari et al., 2010). They also leave behind foreign material, resulting in an increased risk for site infection (Hermanides et al., 2011; Hon et al., 2009).

- Timely and complete neurovascular checks are critical to identify postprocedure limb ischemia or other arterial complications.
- Instruct patient and caregiver to notify the nurse if the extremity feels moist, cold, tingling, or burning.

Patients undergoing lumbar puncture (LP) are at risk for experiencing postpuncture headaches as a side effect of the procedure. The symptoms range from a dull ache with a stiff neck to nausea. These symptoms can last several days and are incapacitating at times. Although an epidural blood patch may be effective in treating postpuncture headaches in some patients, it is not effective in preventing these headaches (Boonmak and Boonmak, 2010).

- In children the early use of a topical anesthetic EMLA before the puncture is showing some clinical effects in preventing postpuncture headaches but needs further testing (Fein et al., 2010).
- Rest, fluids (including caffeinated beverages), and analgesics are effective measures for managing this headache pain (Stannard, 2011).

PATIENT-CENTERED CARE

Any diagnostic procedure can create a sense of powerlessness for patients. The unknown (i.e., not knowing what a test may reveal or not completely understanding what a test involves or feels like) can also create fear and anxiety. It is important to involve patients in a discussion of what a test involves and giving them opportunity to ask questions. Learn what their fears are because you may have the opportunity to alleviate them. For example, if a patient worries about being physically exposed during a procedure, communicate with procedure staff to see if there is a way to minimize exposure and use more draping.

When a patient is chronically ill or fatigued or has decreased functional status, plan the diagnostic testing schedule to provide rest periods between multiple tests performed on the same day. Provide reassurance to a patient throughout a procedure. Most of these procedures cause moderate discomfort, and the patient tolerates them better if you remain at the side and explain each step.

Safety Guidelines

Before a procedure:

- 1 It is essential to patient safety to be sure that patient undergoes the correct procedure. Ensure proper identification of a patient by using a minimum of two identifiers, verifying the correct procedure (and site, when applicable). This includes verbal verification and written/computerized documentation of the preceding information on patient arrival, again in the procedure room, and just before starting a procedure (TJC, 2012) (see agency policy).
- 2 Assess for completion of relevant documentation (e.g., history and physical, signed procedure consent form, nursing assessment, and preanesthesia assessment) necessary for performing a safe procedure.
- 3 Identify any medications for which uninterrupted dosing is required (e.g., anticonvulsants, antibiotics, and certain cardiac medications). If the procedure requires a patient to have nothing by mouth (NPO), discuss medications with the health care provider to decide if the patient should take any medications before the procedure. When insulin or oral hypoglycemic medications are given to patients before procedures, arrange to have either the patient's meal or other nutritional support available on completion of the procedure.
- 4 Verify that informed consent was obtained before administering any sedatives. The health care provider performing the procedure is responsible for obtaining informed consent from a patient. In some agencies after the health care provider discusses the procedure and obtains verbal consent, the registered nurse obtains the patient's signature on the consent form. (Check agency policy to determine if a consent form is required and the expectations of the nurse in this process.) *When there is no evidence of informed consent in the patient medical record, hold any preprocedure medications that may alter the patient's level of consciousness and notify the health care provider performing the procedure and staff in any receiving area.*

During a procedure:

- 1 If a procedure involves the use of radiation:
 - a Minimize the amount of radiation exposure by using protective shielding devices such as a lead apron and goggles, radioprotective gloves, and/or thyroid shield.
 - b Monitoring staff radiation exposure may require the use of a dosimeter (see agency policy).
 - c Remain positioned as far away from the radiographic equipment as possible while still performing required patient care.
- 2 Monitor physiologic parameters indicated by the procedure.
- 3 Position patients carefully to avoid musculoskeletal or neurologic injury.
- 4 Label any specimens obtained during a procedure properly.

After the procedure:

- 1 Know possible procedural complications and conduct appropriate assessments for early detection.
- 2 Monitor oxygen saturation and vital signs to detect sedation failure and adverse effects (e.g., vomiting, hypoxic events) (AHRQ, 2010).
- 3 Know the use, side effects, and complications of the sedative agent(s) and reversal agents to be administered.
- 4 Be able to recognize cardiac dysrhythmias.
- 5 Institute fall precautions until patient has recovered from effects of sedatives.

SKILL 44-1 Intravenous Moderate Sedation During a Diagnostic Procedure

Certain diagnostic or therapeutic procedures require patients to receive intravenous (IV) moderate sedation. Moderate sedation/analgesia produces a minimally depressed level of consciousness induced by the administration of pharmacologic agents in which a patient retains a continuous and independent ability to maintain protective reflexes and a patent airway and is aroused by physical or verbal stimulation. Moderate sedation improves a patient's cooperation with a procedure, allows a rapid return to his or her preprocedure status, and minimizes the risk for injury. It often raises a patient's pain threshold and provides amnesia concerning the actual procedural events. In addition, no interventions are required during a procedure to maintain a patent airway, and spontaneous ventilation is adequate (ASA, 2009).

Deep sedation is one risk associated with moderate sedation when a patient's level of consciousness depresses past the point at which he or she cannot maintain a patent airway. Because of this risk, the use of IV moderate sedation is closely controlled and normally restricted to physicians and registered nurses (RNs) who receive specialized training or credentialing (AORN, 2011). Know the agency policy for recommended and maximum doses of medications and monitoring and documentation requirements when using IV sedation.

The most common types of medications used to achieve moderate sedation include benzodiazepines and opiates. Benzodiazepines reduce anxiety and promote muscle relaxation. Midazolam (Versed) also produces an amnesic effect. Opiates such as morphine sulphate or fentanyl (Sublimaze, Duragesic) help control pain while achieving sedation. Propofol (Diprivan), a safe, rapid-acting hypnotic, is also commonly used and may offer a faster recovery time than the combination of benzodiazepines and opiates (Ellett, 2010; Muller and Wehrmann, 2011).

Patient risks during IV sedation include hypoventilation, airway compromise, hemodynamic instability, and/or altered levels of consciousness that include an overly depressed level of consciousness or agitation and combativeness. Emergency equipment appropriate for the patient's age and size (see Chapter 27) and a staff competent in airway management, oxygen delivery, and use of resuscitation equipment are essential. During a procedure

patients need continuous monitoring (recorded at least every 5 minutes) of heart and respiratory rate and rhythm, blood pressure, oxygen saturation, and level of consciousness (see agency policy) (AHRQ, 2010). End-tidal CO₂ is also becoming a common parameter for monitoring sedation tolerance. Monitoring continues after the procedure (see agency policy).

Delegation and Collaboration

The skill of assisting with IV moderate sedation, including the preprocedure assessment, cannot be delegated to nursing assistive personnel (NAP). In most agencies an RN or health care provider assesses and monitors a patient's level of sedation, airway patency, and level of consciousness. Roles in monitoring depend on scope-of-practice guidelines as determined by state regulations (see agency policy).

Equipment

- ❑ Personal protective equipment (PPE): Gloves, mask, gown, eye protection
- ❑ Sedation as prescribed: Benzodiazepines (e.g., midazolam [Versed], opiates, and propofol [Diprivan], fentanyl [Sublimaze])
- ❑ Emergency equipment: Crash cart, cardiac monitor/defibrillator, and endotracheal intubation/airway management equipment in various sizes and appropriate for patient's age
- ❑ Equipment for insertion of a peripheral IV catheter (CDC, 2011) (see Chapter 28)
- ❑ Oxygen and airway supplies: Bag and mask device, oral/nasopharyngeal airways
- ❑ Suction equipment (see Chapter 25)
- ❑ Sphygmomanometer or noninvasive blood pressure monitor
- ❑ Pulse oximeter or end-tidal CO₂ monitor
- ❑ Electrocardiogram (ECG) monitor
- ❑ Appropriate reversal drugs (e.g., flumazenil [Romazicon] for reversal of benzodiazepines, naloxone [Narcan] for reversal of opiates) and labels for each
- ❑ Pain medication (opioids) for procedures anticipated to cause discomfort

STEP

RATIONALE

ASSESSMENT

1	Verify type of procedure scheduled and procedure site with patient.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2	Verify that a preprocedure medication reconciliation and history and physical (H&P) examination were completed.	Accrediting agencies such as The Joint Commission require a documented preprocedure medication history and H&P before administration of procedural IV sedation.
3	Verify that informed consent was obtained before administering any sedatives.	Federal regulations, many state laws, and accreditation agencies require informed consent for procedure.
4	Assess patient's past history of adverse reaction to IV sedation (e.g., hemodynamic instability, nausea or vomiting, airway compromise, altered level of consciousness).	Patients with history of these reactions are at higher risk for procedural complications if IV sedation is used.
5	Verify patient's ASA Physical Status Classification (Box 44-1).	ASA recommends that patients receiving classification of 3 or higher have anesthesia consultation before receiving IV sedation (ASA, 2009).

Critical Decision Point Consultation with an anesthesiologist is often required by the agency if a patient has an ASA classification of 3 to 6 or history of or evidence for difficult intubation, sleep apnea, or complications related to sedation/anesthesia.

6	Assess patient for history of airway abnormalities, liver failure, lung disease, heart failure, hypotonia, morbid obesity, severe gastroesophageal reflux, and history of adverse reaction to sedatives (AHRQ, 2010).	Risk factors that increase likelihood of adverse event (AHRQ, 2010).
7	Assess patient's current or past history for substance abuse or liver/kidney disease.	A history of substance abuse and/or liver/kidney disease usually requires dose adjustment of sedative agents.
8	Verify that patient has not ingested food or fluids, except for oral medications, for at least 4 hours (check specific agency requirements).	Because risk of moderate sedation is loss of airway protection, empty stomach reduces risk for aspiration.
9	Determine if patient is allergic to latex, antiseptic, tape, or anesthetic solutions.	Allergic reactions to latex or tape range from mild skin reaction to anaphylaxis. Common allergic reactions to local anesthetic agents include central nervous system (CNS) depression, respiratory difficulty, and hypotension.
10	Assess patient's level of understanding of procedure, including any concerns.	Determines extent of instruction or level of support required.
11	Assess baseline heart rate, breath sounds, respiratory rate, blood pressure, level of consciousness, pain level, and oxygen saturation (SpO ₂).	Establishes baseline for comparison during and after procedure.
12	Determine patient's height and weight.	Needed to calculate drug dosages.
13	Assess patient's baseline status via agency's designated scoring system. Many agencies use an "Aldrete score" (Aldrete, 2007; Table 44-1).	Establishes baseline for comparison after procedure.

NURSING DIAGNOSES

- Acute pain
- Anxiety
- Deficient knowledge regarding procedure
- Risk for aspiration
- Risk for injury

Related factors are individualized based on patient's condition or needs.

BOX 44-1 ASA Physical Status Classification System

ASA 1 = Normal healthy patient
 ASA 2 = Patient with mild systemic disease
 ASA 3 = Patient with severe systemic disease
 ASA 4 = Patient with severe systemic disease that is a constant threat to life
 ASA 5 = Moribund patient who is not expected to survive without the operation
 ASA 6 = Declared brain-dead patient whose organs are being removed for donor purposes
 "E" is added if the procedure is performed as an emergency.

STEP **RATIONALE**

PLANNING

|---|---|
| <ol style="list-style-type: none"> 1 Expected outcomes following completion of procedures: <ul style="list-style-type: none"> • Adhere to Universal Protocol (Box 44-2) • Patient's airway remains patent. • Patient's level of comfort is equivalent to score of 4 or less on pain scale of 0 to 10. 2 Explain to patient that IV sedation will cause relaxation and amnesia but that he or she will be awake during procedure. If patient will not be able to verbalize because of nature of procedure, teach him or her agreed-on nonverbal signals such as "yes," "no," and "pain." 3 Explain that close monitoring of vital signs and frequent checks to determine that patient is awake are normal and do not mean that there are problems. 4 Explain to patient major steps of procedure. 5 Position patient as needed for procedure. | <p>Maintains patient safety (TJC, 2012).
 Moderate sedation is monitored successfully without progression to deep sedation.
 Procedure managed to minimize patient's pain.</p> <p>Encourages cooperation and minimizes risks and anxiety about procedure.</p> <p>Reduces patient anxiety during procedure.</p> <p>Reduces patient anxiety during procedure.</p> |
|---|---|

IMPLEMENTATION

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name. 2 Establish peripheral IV access (CDC, 2011) (see also Chapter 28). 3 Implement Universal Protocol in presence of appropriate health care team members (as applicable) and in accordance with agency policy (see Box 44-2). | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Provides access for administration of sedation and any emergency medications (as needed).</p> <p>Ensures patient safety by correctly identifying correct patient to correct procedure.</p> |
|---|---|

TABLE 44-1 Aldrete Scoring System		
		Score
Activity (moving voluntarily on command)	4 extremities	2
	2 extremities	1
	0 extremities	0
Respiration	Able to deep breathe and cough freely	2
	Dyspnea, shallow or limited breathing	1
	Apneic	0
Circulation	BP ± 20 mm Hg of presedation level	2
	BP ± 20-50 mm Hg of presedation level	1
	BP ± 50 mm Hg of presedation level	0
Consciousness	Fully awake	2
	Arousable on having name called	1
	Not responding	0
Color	Normal	2
	Pale, dusky, blotchy, jaundiced, or other change	1
	Cyanotic	0

From Aldrete JA: The post-anesthesia recovery score revisited, *J Clin Anesth* 7:89, 1995; Aldrete JA: Post-anesthetic recovery score, *J Am Coll Surg* 205(5):3, 2007.
 BP, Blood pressure.

BOX 44-2	The Joint Commission Universal Protocol
<ul style="list-style-type: none"> • Verification of correct person, correct site, and correct procedure occurs. • Procedure site is marked before moving to procedure area. • A "Time-Out" is performed immediately before starting procedures. • When patient is in preprocedure area (immediately before moving him or her to procedure room), a checklist (e.g., paper, electronic, or other medium such as a wall-mounted white board) is used to review and verify that required items are available and are accurately matched to the patient. 	

From The Joint Commission: *National Patient Safety Goals*, 2012, TJC, http://www.jointcommission.org/assets/1/18/UP_Poster1.PDF, accessed August 23, 2012.

STEP	RATIONALE
4 During the diagnostic procedure, monitor heart rate and oxygen saturation (SpO ₂) continuously via pulse oximetry equipment. Some agencies also use end-tidal CO ₂ monitoring (capnography). Monitor patient's airway patency, respiratory rate and depth, blood pressure, and level of consciousness and responsiveness every 5 minutes (AHRQ, 2010). Keep oxygen and suction equipment nearby.	Vital signs, oximetry, and capnography provide comparison with patient's baseline status. Oxygen and suction equipment may be required in an emergent situation.
5 Observe for verbal or nonverbal evidence of pain, facial grimacing, and eye opening.	Physical responses indicate level of sedation.
6 Assess level of sedation using Modified Ramsay Sedation Scale (Table 44-2) or other criteria adopted by agency.	Determines patient's level of sedation. Numeric rating scale offers consistent assessment and accurate judgment of patient's changing status and verbal/physical stimulation.
Critical Decision Point Report a Ramsay sedation score higher than 3 (responsive to commands only) to the health care provider.	
7 Reposition patient as needed without interrupting diagnostic procedure.	Prevents pressure- and position-related injuries (AHRQ, 2010).

EVALUATION

1 Monitor patient throughout procedure using the Modified Ramsay Sedation Scale (or other criteria adopted by the agency).	Provides data to verify patient's expected return to baseline status.
2 After procedure: Use Aldrete score (see Table 44-1) and monitor level of consciousness, respiratory rate, SpO ₂ , blood pressure, heart rate and rhythm, and pain score according to agency policy (AHRQ, 2010) (e.g., every 5 minutes for at least 30 minutes, then every 15 minutes for an hour, and then every 30 minutes until patient meets discharge criteria).	Enables prompt detection of any airway compromise or protective reflexes caused by delayed action of medications.
3 Ask patient to repeat back what he or she understands regarding procedure or any postprocedure patient instructions, including medication orders and instructions.	Verifies patient understanding of procedure or discharge education.
4 Have patient's "designated driver" explain any postprocedure education and sign appropriate documents.	Patients who receive conscious sedation are restricted from driving for 24 to 48 hours, depending on procedure, type of sedation, and postprocedure restrictions.

Unexpected Outcomes

- 1 Oversedation, evidenced by decreasing SpO₂ (cyanosis, slow shallow respirations with periods of apnea), tachycardia, sedation score of 4 (exhibiting brisk response to light glabellar tap or loud auditory stimulus) or higher on Modified Ramsay Sedation Scale or less than 8 on Aldrete scale.

Clinical Decision Point If reversal agents are used, level of consciousness and vital signs should return to acceptable levels for a period of 2 hours from time of administration of reversal agent before monitoring ends (AHRQ, 2010).

- 2 Patient develops cardiac instability evidenced by irregular heart rate, change in pulse rate, or change in blood pressure.

Related Interventions

- Support patient's breathing via positioning and manual bagging.
- Immediately notify health care provider.
- Be prepared to administer reversal agents. Naloxone (Narcan) is for reversal of opioids, and flumazenil (Romazicon) is for reversal of benzodiazepines.

- Initiate oxygen therapy, ensure IV access, and obtain ECG as ordered.
- Immediately notify health care provider.

TABLE 44-2 Modified Ramsay Sedation Scale

Minimal sedation (anxiolysis)	1	Anxious and agitated or restless or both
	2	Cooperative, oriented, and tranquil
Moderate sedation/analgesia (conscious sedation)	3	Responds to commands spoken in a normal voice
Deep sedation/analgesia	4	Brisk response to a light forehead tap or loud auditory stimulus
	5	Sluggish response to a light forehead tap or loud auditory stimulus
	6	No response to a light forehead tap or loud auditory stimulus

Data from American Society of Anesthesiologists: *Continuum of depth of sedation: definition of general anesthesia and levels of sedation/analgesia*, The Society, October 2009, available at <http://www.asahq.org/For-Members/Standards-Guidelines-and-Statements.aspx>, accessed August 23, 2012; and Sessler C et al: Evaluating and monitoring analgesia and sedation in the critical care unit, *Crit Care* 12(suppl 3):S2, 2008.

Recording and Reporting

- Document vital signs, SpO₂, end-tidal CO₂, and sedation level at baseline, then every 5 minutes during the procedure, and every 15 minutes for at least 30 minutes after the procedure according to agency policy.
- Record dosage, route, and time of administration for drugs given during and after the procedure, including reversal agents. Record significant patient reactions during the procedure. Include IV fluids and blood products if administered.
- Immediately report to patient's health care provider any respiratory distress, cardiac compromise, or unexpected altered mental status.
- Document discharge teaching, medication reconciliation, discontinuation of IV access, final/discharge assessment, and to whom/how discharged (e.g., designated driver, ambulance/transporter, nursing home).

Special Considerations

Teaching

- Explain that it is unlikely for patients to remember the procedure because of the amnesic effect of the sedative(s).
- Before the procedure, instruct patient to arrange for transportation home after the procedure because (at most agencies) patient will not be permitted to drive for 24 hours after receiving sedation.
- Provide patients and family caregivers with discharge instructions that include complications that may occur; how to manage complications; and physical signs and symptoms to report to the

health care provider, including contact information and post-procedure medication reconciliation and instructions.

Pediatric

- Children are more likely than adults to sustain a serious complication resulting from anesthesia. Such complications are often linked to either the cardiovascular or respiratory system. For this reason the American Academy of Pediatrics recommend that personnel who are able to manage a child's airway be present for the procedure (AAP, 2012).
- A preprocedure medical evaluation is required. To safely administer sedation to a pediatric patient, consider anatomic and physiologic variations, preprocedure assessments, and pharmacologic techniques (AAP, 2012).
- During the preprocedure assessment answer the parent's questions in a relaxed and confident manner. When communicating with children, take into account the child's developmental stage.

Gerontologic

- Closely monitor the effects of medications on patient's respiratory status and pulse. These drugs interfere with breathing or increase or decrease heart rate as a result of reduced drug clearance through the kidneys or liver (Lewis et al., 2011).
- Physical limitations of the patient, including hearing and vision loss, contribute to frustration and confusion, compounding the sense of loss of control.

Home Care

- Instruct the patient to avoid making any legally binding decisions until at least 24 hours after the procedure.

SKILL 44-2 Contrast Media Studies: Arteriogram (Angiogram), Cardiac Catheterization, and Intravenous Pyelogram

Contrast media studies involve visualization of blood vessels and internal organs by intravascular injection of a radiopaque medium. An arteriogram (angiogram) permits visualization of the vasculature and arterial system of an organ (Fig. 44-1). Arteriography is usually performed by an interventional radiologist to diagnose arterial or venous occlusions; stenosis; emboli; thromboses; aneurysms; tumors; congenital malformations; or trauma to the brain, heart, lung, kidneys, or lower extremities.

FIG 44-1 Pulmonary arteriogram shows obstruction (arrows) of right pulmonary artery. (From Eisenberg R, Johnson N: *Comprehensive radiographic pathology*, ed 4, St Louis, 2007, Mosby.)

Cardiac catheterization is a specialized form of angiography performed by an interventional cardiologist. An intravenous or intraarterial catheter introducer is inserted into the left or right side of the heart via a major peripheral vessel, usually the femoral artery and/or vein. The test studies pressures within the heart, cardiac volumes, valvular function, and patency of coronary arteries. Cardiac catheterizations are performed in specially equipped laboratories (Fig. 44-2). A contrast medium is injected, and the structures and functions of the heart and lungs are assessed.

FIG 44-2 Cardiac catheterization laboratory. (Image used with permission, Flagstaff Medical Center, Northern Arizona Healthcare. All rights reserved.)

Cardiac catheterizations are contraindicated in patients who would refuse needed surgery, are allergic to iodine contrast media, are uncooperative or cannot lie still during the entire procedure, or are susceptible to dye-induced renal failure. Precautions to help prevent dye-induced renal failure are controversial and include ensuring that the patient is well-hydrated using bicarbonate solution or sodium chloride with or without prophylactic *N*-acetylcysteine (Mucomyst) (Lewis et al., 2011). Intravenous pyelography (IVP) is a venographic examination of the flow of radiopaque contrast medium through the kidneys, ureters, and bladder to identify obstruction, hematuria, stones, bladder injury, or renal artery occlusion. Dye is injected into a peripheral vein, and serial radiographs are taken over the subsequent 30 minutes.

Delegation and Collaboration

The skill of assisting with angiography and IVP can be delegated to nursing assistive personnel (NAP) if the patient is stable and no intravenous (IV) sedation is used. The registered nurse (RN) directs the NAP about:

- When to obtain and report vital signs, urinary output, and weight.
- Which signs and symptoms to report to the nurse.

- Accompanying the patient to the procedure room and assisting specially trained and licensed radiology personnel with the specific angiography procedure.

The skill of assisting with cardiac catheterization can be delegated to specially trained NAP with a nurse continuously present. The nurse provides continuous patient assessment and monitoring for serious complications. The NAP helps with patient transport, positioning, and obtaining supplies.

Equipment

- ❑ Protective supplies: Mask, goggles, sterile gown, and sterile gloves
- ❑ Sterile packs containing catheters/equipment for performing procedures
- ❑ Equipment for peripheral IV access
- ❑ Medications such as sedatives (e.g., diazepam [Valium], midazolam [Versed], propofol [Diprivan]) for IV sedation or analgesics for relaxation and pain control
- ❑ Emergency equipment: Oxygen, endotracheal intubation/airway management equipment, emergency cart, cardiac monitor/defibrillator, sedative reversal agents
- ❑ Pulse oximeter, end-tidal CO₂ monitor, blood pressure (BP) equipment

STEP

RATIONALE

ASSESSMENT

- 1 Verify type of procedure scheduled and procedure site with patient.
- 2 Verify that informed consent was obtained before administering any sedatives.
- 3 Determine if patient is taking anticoagulants, aspirin, or any nonsteroidal medication.
- 4 Assess patient for history of any allergies to iodine dye, shellfish, or latex and whether patient has had previous reaction to contrast agent (Schabelman and Witting, 2010). If so, notify cardiologist or radiologist.
- 5 Review medical record for contraindications:
 - a *All contrast media*: Pregnancy unless benefits of test outweigh risks to fetus.
 - b *Angiography*: Anticoagulant therapy, bleeding disorders, thrombocytopenia, dehydration, uncontrolled hypertension, renal insufficiency, and pregnancy.
 - c *Cardiac catheterization*: History of severe cardiomyopathy, severe dysrhythmias, uncontrolled heart failure (HF).
 - d *IVP*: History of dehydration, known renal insufficiency (with blood urea nitrogen [BUN] level >40 mg/100 mL, or creatinine >2 mg/dl) (Pagana and Pagana, 2010).
 - e Determine whether patient took metformin hydrochloride (Glucophage) within previous 48 hours. If so, notify health care provider immediately.
- 6 Assess patient's bleeding and coagulation status (e.g., complete blood count [CBC], platelets, prothrombin time [PT], activated partial thromboplastin time [aPTT], and international normalized ratio [INR]) and assess patient's renal function (e.g., BUN, creatinine levels) before procedure. Assess electrolytes (sodium and potassium).

- Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
- Federal regulations, many state laws, and accreditation agencies require informed consent for procedure.
- Medication increases risk for bleeding and is often stopped before procedure.
- Allergic individuals in general are at mildly increased risk for developing adverse reactions to radiocontrast media (Beatty et al., 2008). Hypoallergenic contrast medium is sometimes used.
- Radioactive iodinated contrast media crosses blood-placental barrier.
- Anticoagulants and bleeding disorders interfere with patient's blood clotting abilities and may cause blood loss.
- Dehydration and renal insufficiency are contraindications to use of ionic radiographic contrast media because patient has impaired ability to excrete contrast media via kidneys.
- Introduction of catheter into myocardium increases risk for dysrhythmias (Pagana and Pagana, 2010).
- Iodinated dye is sometimes nephrotoxic and worsens existing renal disease.
- Taking metformin hydrochloride 48 hours before receiving iodinated contrast media can lead to acute renal failure and lactic acidosis (Ott, 2008).
- Abnormal laboratory findings may contraindicate procedure because of potential complications of hemorrhage and/or renal failure. Report elevated BUN or creatinine levels because such patients are at risk for renal failure induced by contrast media (Pagana and Pagana, 2010). Abnormal electrolytes may reveal possible electromechanical problems.

STEP	RATIONALE
7 Obtain vital signs and peripheral pulses. For arterial procedures mark patient's peripheral pulses before procedure. For cardiac catheterization also auscultate heart and lungs and obtain weight.	Provides baseline data and locations for comparison with findings during and after procedure.
8 Assess patient's hydration status, including condition of mucous membranes, and recent 24-hour intake.	Severe dehydration can lead to renal failure (Pagana and Pagana, 2010).
9 Assess patient's level of understanding of procedure, including any concerns.	Determines extent of instruction or level of support required.
10 Determine type of arteriogram scheduled (e.g., carotid, femoral, brachial). If cardiac catheterization, verify if test is for right or left heart or both. For IVP ask if study is for one or both kidneys.	Enables you to anticipate patient teaching needs and postprocedure interventions.
11 Determine and document last time of ingested food, drink, or medications.	Prevents possible aspiration because patient is sedated. Excessive hydration causes dilution of contrast medium, making structures more difficult to visualize. Patients should be NPO for 6 to 8 hours before procedure.

Clinical Decision Point *Exceptions occur for patients at risk for contrast media–induced renal impairment who are specifically instructed to drink increased fluids in the hours before the procedure or those instructed by the health care provider to take medications before the procedure. Good preprocedure hydration reduces the risk for renal impairment caused by contrast media (Pagana and Pagana, 2010).*

12 Review health care provider's orders for preprocedure medications, hydration, antihistamines, and IV sedation:	Increased sedation is necessary in anxious or confused patients. Increased hydration is often required for renal insufficiency, and antihistamines for possible allergic reaction.
a Atropine	Decreases salivary secretions and increases heart rate when bradycardia is present.
b Diphenhydramine (Benadryl)	Used prophylactically to block histamine and decrease allergic response.
c Preprocedural sedative	Decreases anxiety and promotes relaxation.

NURSING DIAGNOSES

- | | | |
|---|---|---|
| <ul style="list-style-type: none"> • Acute pain • Anxiety • Decreased cardiac output | <ul style="list-style-type: none"> • Deficient knowledge regarding procedure • Fear | <ul style="list-style-type: none"> • Risk for infection • Risk for injury |
|---|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:	
• Patient does not experience any procedure or postprocedure complications such as significant changes in vital signs, diminished or absent peripheral pulses, allergic response, or decreased or absent urine output.	Procedure performed without complication.
• Patient's level of comfort is equal to score of 4 or less on pain scale of 0 to 10. Expected discomfort includes soreness at catheter insertion site and possible backache.	Patient tolerates procedure.
• Patient tolerates increased fluid intake and urinates sufficiently (at least 30 mL/hr or 0.5 mL/kg/hr) to excrete radiographic dye.	Adequate renal function.
• Patient recovers from IV sedation without respiratory complications or change in level of consciousness.	Appropriate level of sedation.
2 Explain to patient purpose of procedure and what will happen during it.	Helps to minimize patient's anxiety.
3 Remove all of patient's jewelry, metal objects, and body piercings.	Eliminates objects that interfere with radiography visualization of vessels and could be conductive material during electrocautery.
4 Preprocedure preparation:	
a For IVP: Verify that patient has completed necessary bowel preparation of orally administered evacuation preparation 24 hours before test and evacuation enema 8 hours before test (check agency policy).	An evacuated lower intestine and bowel improves visualization of urinary structures.

STEP	RATIONALE
<p>b For cardiac catheterization: Determine whether hair at site of catheter insertion needs clipping or preparation with antiseptic just before procedure. Allow antiseptic to dry. Do not shave site.</p>	<p>Reduces risk for site-related infection. Drying promotes maximal antibacterial activity. Shaving results in increased chance for infection.</p>
<p>5 For cardiac catheterization it is common to verify availability of emergent cardiac surgery because of risk for complete coronary artery occlusion from dislodged plaque or inadvertent perforation of vasculature (check agency policy). Also verify patient's ASA classification before procedure.</p>	<p>Prepares backup plan for possible procedural outcomes that would require emergency surgery.</p>

IMPLEMENTATION

<p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. Verify type of procedure scheduled and procedure site with patient.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p>
<p>2 Have patient empty bladder or bowels before procedure.</p>	<p>Ensures that patient will not need to void during procedure.</p>
<p>3 Prepare cardiac monitor, pulse oximeter, and/or end-tidal CO₂ monitor.</p>	<p>Provides easy access to equipment for monitoring patient status during and after procedure.</p>
<p>4 Perform hand hygiene and apply appropriate protective equipment.</p>	<p>Reduces transmission of microorganisms.</p>
<p>5 Provide IV access using large-bore cannula. Remove gloves.</p>	<p>Provides access for delivery of IV fluids and/or drugs.</p>
<p>6 Assist patient in assuming a comfortable supine position on x-ray table. Some patients undergoing IVP may be in supine or in a slight Trendelenburg's position. Immobilize extremity that will be injected. Pad any bony prominences.</p>	<p>For arterial procedures, patient may need to maintain position for 1 to 3 hours. Padding the bony prominences reduces the risk for impaired skin integrity.</p>
<p>7 Take "Time-Out" to verify patient's name, type of procedure to be performed, and procedure site with patient.</p>	<p>"Time-Out" verification just before starting an invasive procedure includes health care provider and all involved personnel and is a safety precaution to prevent wrong patient, wrong site, and wrong procedure errors (TJC, 2012).</p>
<p>8 Monitor vital signs, pulse oximetry (SpO₂), end-tidal CO₂ and, for arterial procedures, palpate peripheral pulses.</p>	<p>Data provides comparison with baseline to determine patient's response to procedure.</p>
<p>9 Inform patient that during injection of dye it is common to experience some chest pain and severe hot flash that is quite uncomfortable but lasts only a few seconds.</p>	<p>Dye causes feeling of warmth, flushing, or metallic taste shortly after injection.</p>
<p>10 Physician cleanses arterial puncture site for catheter insertion (femoral, radial, carotid, or brachial) with antiseptic.</p>	<p>Reduces transmission of microorganisms.</p>
<p>11 All members of the team apply mask and goggles, sterile gown, head cover, and sterile gloves. Drape patient with sterile drapes, leaving puncture site exposed.</p>	<p>Maintains surgical asepsis.</p>
<p>12 Physician anesthetizes skin overlying arterial puncture site.</p>	<p>Provides local anesthetic to area of incision or puncture.</p>
<p>13 For arterial procedures, the physician does the following:</p> <p>a Punctures artery; inserts introducer (think plastic tube) into artery. Guidewire is inserted through introducer and advanced; flexible catheter is inserted over guidewire and advanced into heart. Introducers allow for use of various procedure catheters, depending on need (e.g., balloon angioplasty, stent placement, ablation).</p>	<p>Permits access to artery and coiling of catheter in artery.</p>
<p>b Advances catheter to desired artery or cardiac chamber, removes guidewire, and injects contrast medium through catheter.</p>	<p>Permits radiographic visualization of structures, aneurysms, occlusions, or anomalies.</p>
<p>14 During dye injection, specialized machinery takes rapid sequence of x-ray films.</p>	<p>Permits radiographic records of visualization of dye through artery and any abnormalities present.</p>
<p>15 If iodinated dye is used, observe patient for signs of anaphylaxis, including respiratory distress, palpitation, itching, and diaphoresis.</p>	<p>Allergic reactions can be life threatening.</p>
<p>16 During cardiac catheterization the nurse assists with measuring cardiac volumes and pressure.</p>	<p>Provides data related to cardiac output, central venous pressure (CVP), ventricular pressures, and pulmonary artery pressure.</p>

STEP

RATIONALE

Clinical Decision Point *Be prepared to end the cardiac catheterization procedure early in the event of severe unrelieved chest pain, neurologic symptoms of a cerebrovascular accident, cardiac dysrhythmias, or hemodynamic changes (Pagana and Pagana, 2010).*

- | | |
|---|---|
| <p>17 Nurse administering IV sedation monitors levels of sedation, level of consciousness, and vital signs (see Skill 44-1).</p> <p>18 Physician withdraws catheter and applies manual pressure to puncture site until homeostasis occurs (5 to 15 minutes or longer).</p> <p>a <i>Option:</i> Physician may choose to use an arteriotomy closure device (ACD), which can be categorized as either passive-closure device (helps with compression such as clamps/tamping devices, assisted or enhanced coagulation, and sealants) or active-closure devices (immediate closure with suture devices, clips, and collagen plug devices).</p> | <p>Proper IV sedation does not cause loss of consciousness.</p> <p>Five to fifteen minutes of manual pressure is often enough to stop active site bleeding. However, certain amount of bed rest is needed to achieve reliable hemostasis. Check agency policy for postprocedure bed rest requirements. This may vary from 2 to 6 hours when no arteriotomy closure device is used.</p> <p>Use of ACDs is reasonable after invasive cardiovascular procedures performed via femoral artery to achieve faster hemostasis, shorter duration of bed rest, and possibly improved patient comfort. Use of devices should be weighed against risk of complications (Patel et al., 2010).</p> |
|---|---|

Clinical Decision Point *Before removing catheter sheath, check for health care provider's orders for instructions for treating a vasovagal reaction. Manual pressure applied to the groin/femoral area can stimulate the baroreceptors and cause a vasovagal reaction in which the patient becomes bradycardic and hypotensive. Vasovagal reactions are usually brief and self-limiting. When applying pressure to the groin after sheath removal, be alert for a vasovagal reaction and prepared to treat it by lowering the head of the bed to the flat position and giving a bolus of IV fluids.*

- | | |
|--|---|
| <p>19 If a percutaneous coronary intervention (PCI) such as a percutaneous transluminal coronary angioplasty (PTCA) or directional coronary atherectomy (DCA) was performed during cardiac catheterization, a femoral introducer/sheath is often left in place and removed in several hours.</p> <p>20 Remove and discard gloves. Perform hand hygiene.</p> <p>21 Postprocedure:</p> <p>a For arterial procedures:</p> <p>(1) Keep affected extremity immobilized for 2 to 6 hours after removal of sheath (see agency policy). Use orthopedic bedpan for female patient as needed for bowel or bladder evacuation while on bed rest.</p> <p>(2) Emphasize need to lay flat for 6 to 12 hours (and possibly overnight if sheath is left in groin).</p> <p>b Encourage patient to drink 1 to 2 L of fluid after procedure.</p> | <p>Postinterventional sheaths provide emergency access to vasculature in event that coronary artery becomes occluded, allowing time for anticoagulants to wear off.</p> <p>Reduces transmission of microorganisms.</p> <p>There is evidence of no benefit relating to bleeding and hematoma formation in patients who have more than 3 hours of bed rest following transfemoral diagnostic cardiac catheterization. There is evidence of benefit relating to decreased incidence and severity of back pain after 3 hours of bed rest. Inconclusive evidence suggests that bed rest for 2 hours following transfemoral cardiac catheterization may be sufficient (Chair and Fernandez, 2008).</p> <p>Helps to prevent disruption of hemostasis.</p> <p>Facilitates elimination of contrast material and prevents renal damage (Pagana and Pagana, 2010).</p> |
|--|---|

EVALUATION

- | | |
|--|---|
| <p>1 Evaluate patient's body position and comfort during procedure.</p> <p>2 Monitor vital signs and oxygen saturation and assess for signs of cardiac complications every 15 minutes for 1 hour, every 30 minutes for 2 hours, or until vital signs are stable.</p> <p>3 Monitor for complications:</p> <p>a Perform neurovascular checks by palpating peripheral pulses on affected extremity and comparing right and left extremities for skin color, temperature, and sensation. Use Doppler ultrasonic stethoscope to locate pulses that are not palpable (see Chapter 6).</p> <p>b With vital signs assess vascular access site for bleeding and hematoma.</p> <p>c Auscultate heart and lungs and compare with preprocedure findings.</p> | <p>Position can cause stress on insertion site and patient's musculoskeletal structures.</p> <p>Verifies patient's physiologic status and evaluates effect of procedure. Signs of cardiac complications include chest pain or pressure, new dysrhythmias, and/or shortness of breath.</p> <p>Enables prompt detection of circulatory impairment caused by intravascular clotting or bleeding at procedure site. Signs of reduced circulation include diminishing distal pulses and/or coolness, mottling, pallor, pain, numbness, and tingling in affected extremity.</p> <p>Verifies expected sealing of puncture.</p> <p>Evaluates patient response to procedure.</p> |
|--|---|

STEP	RATIONALE
d Observe patient for possible delayed reaction to iodine dye (if used)—dyspnea, hives, tachycardia, and rash (Pagana and Pagana, 2010).	Reaction may occur up to 6 hours after injection of dye.
4 Evaluate level of sedation, level of consciousness, and SpO ₂ . Use Aldrete scale (see Skill 44-1).	Determines patient's response to IV sedation.
5 Assess postprocedure laboratory values—CBC, prothrombin time, aPTT, INR, electrolytes, BUN/creatinine.	Detects changes in laboratory values that indicate onset of complications such as bleeding.
6 Have patient rate discomfort on pain scale of 0 to 10.	Pain is early sign of complications.

Unexpected Outcomes

- Vasovagal response occurs (at time of femoral puncture or after procedure with femoral pressure). Symptoms include feeling faint, dizzy, and light-headed and possible momentary loss of consciousness. Bradycardia is caused by stimulation of vagus nerve via baroreceptors.
- Evidence of oversedation:
 - Prolonged reduced level of consciousness.
- Pedal pulses are nonpalpable bilaterally 2 hours after arteriogram with change in skin color and temperature.
- Hematoma or hemorrhage is present at catheter insertion site.
- Patient has allergic reaction to contrast medium with symptoms of flushing, itching, and urticaria.
- Renal toxicity from contrast medium occurs:
 - Urine output less than 30 mL/hr or 0.5 mL/kg/hr.
- Patient experiences retroperitoneal bleeding (when femoral access site is used):
 - Low back pain radiating to both sides of body (hallmark sign).
 - Tachycardia.

Related Interventions

- Support airway (through positioning).
- Lower table or head of bed to flat position or to Trendelenburg's position if ordered.
- Be prepared to administer bolus of IV fluid (normal saline).
- See Skill 44-1.
- Assess pulse with Doppler.
- Immediately notify health care provider.
- Apply pressure over insertion site.
- Monitor catheter site every 15 to 30 minutes for 2 to 3 hours; follow agency protocol.
- Notify health care provider if interventions do not stop bleeding or if patient has symptoms of acute blood loss (hypotension, tachycardia, decreased level of consciousness).
- Monitor vital signs and observe for symptoms of anaphylaxis.
- Notify health care provider.
- Follow specific postprocedure orders related to findings.
- Prepare to administer antihistamine or epinephrine if ordered.
- Place on strict intake and output (I&O) monitoring.
- Monitor closely for signs of fluid overload.
- Review electrolyte, urea nitrogen, and creatinine levels.
- Prepare patient for emergency surgery.
- Monitor vital signs every 5 to 15 minutes.
- Monitor distal pulses hourly.

Recording and Reporting

- Record patient's status: vital signs, SpO₂/end-tidal CO₂, status of peripheral pulses for equality and symmetry, blood pressure for hypotension, temperature and color of catheterized extremity, condition of IV site, and level of patient responsiveness. Record any drainage from puncture site, appearance of dressing, and condition of puncture site.
- Report to health care provider any vital sign change, excessive bleeding or increasing hematoma at puncture site, decreased or absent peripheral pulses, persistent pain, altered neurologic status, dysrhythmias, decreased SpO₂ or increased end-tidal CO₂, or decreased responsiveness after sedation.

Special Considerations

Teaching

- See Skill 44-1, Teaching Considerations.
- Prepare patient to stay in the hospital if complications occur or if an intervention necessitates prolonged postprocedure vascular checks.
- Because the dye can transfer to breast milk, teach women who are breast-feeding to substitute formula or previously pumped

breast milk for infant feedings, disposing of any pumped breast milk for 24 hours after the procedure (Pagana and Pagana, 2010).

Pediatric

- Infants and children are particularly susceptible to the diuretic effects of radiocontrast dyes because of their small body size and immature renal/hepatic systems. In addition, those with congenital cardiac anomalies develop compensatory erythrocytosis and thus experience complications from dehydration very quickly. Emphasize to the parent(s) or caregiver the importance of fluid intake with the child after the procedure. Urinary output should exceed 1 mL/kg/hr (Hockenberry and Wilson, 2011).

Gerontologic

- Physical exposure and low room temperature contribute to hypothermia in frail older adults who are unable to communicate that they are cold. Use heated blankets or forced-air heat to maintain core temperature at comfortable, safe levels (Lewis et al., 2011).
- In older adults slight alterations in vital signs or behavior are signs for impending problems; therefore close monitoring is important.

Home Care

- On discharge, provide patient with written instructions to contact the health care provider (or affiliated emergency department) if the following occur after arteriogram or cardiac catheterization:
 - Bleeding from the catheterization puncture site; apply gentle pressure with a clean gauze or cloth
 - Formation of a knot or lump under the skin that increases in size
 - Worsening of a bruise or its movement down the extremity rather than disappearing
 - Pain at puncture site or in the extremity used for the catheterization
 - Extremity is pale and cool to the touch where arterial puncture is made
- Appearance of redness, swelling, or warmth of the affected extremity
- After arteriogram or cardiac catheterization, instruct patient not to drive or climb stairs for 24 hours; to avoid sports, strenuous activity/housework, and lifting (e.g., groceries, children) for 3 days; and to avoid taking baths until wound is healed.
- On discharge after an IVP, instruct patient to:
 - Drink at least 64 ounces (1 to 2 liters) of water to help flush the contrast media through the kidneys.
 - Watch for signs of a delayed reaction to the contrast medium for 24 hours after the procedure and call the health care provider or go to the nearest emergency department.

SKILL 44-3 Assisting with Aspirations: Bone Marrow Aspiration/Biopsy, Lumbar Puncture, Paracentesis, and Thoracentesis

Aspirations are sterile invasive procedures involving the removal of body fluids or tissue for diagnostic procedures (Table 44-3). The nurse assists the health care provider during an aspiration procedure. Informed consent is required for these invasive procedures.

Bone marrow aspiration is the removal of a small amount of the liquid organic material in the medullary canals of selected bones. The sternum and the posterior superior iliac crests are the most common in adults. In children the anterior or posterior iliac crests are used, and in infants the proximal tibia is used (Hockenberry and Wilson, 2011; Pagana and Pagana, 2010). A biopsy is the removal of a core of marrow cells for laboratory analysis. Both aspiration and biopsy diagnose and differentiate leukemia, certain malignancies, anemia, and thrombocytopenia. The marrow is examined in a laboratory to reveal the number, size, shape, and development of red blood cells (RBCs) and megakaryocytes (platelet precursors). Bone marrow cultures help differentiate infectious diseases such as tuberculosis (TB) or histoplasmosis. This procedure takes approximately 20 minutes to perform. Potential complications of bone marrow aspiration or biopsy include bleeding, especially if coagulopathy is present; infection; and, less commonly, organ puncture.

A lumbar puncture (LP), called a *spinal puncture* or *tap*, involves the introduction of a needle into the subarachnoid space of the spinal column. The purpose of the test is to measure pressure in the subarachnoid space; obtain cerebrospinal fluid (CSF) for visualization and laboratory examination; and inject anesthetic, diagnostic, or therapeutic agents. CSF is examined in a laboratory to help diagnose spinal cord tumors, central nervous system (CNS) infections, hemorrhage, and degenerative brain disease. The procedure takes approximately 30 minutes to perform.

The major contraindication for LP is evidence of increased intracranial pressure (ICP). The LP causes a sudden release of pressure and possible herniation of the brain structures through the foramen magnum. This herniation compresses the brainstem, which contains the vital cardiac, respiratory, and vasomotor centers; and sudden death results. In elective LP preprocedure computed tomography results are reviewed for evidence of brain shift to rule out ICP.

Abdominal paracentesis involves aspiration of peritoneal fluid from the abdomen. Cytologic analysis of the aspirate determines presence of bacteria, blood, glucose, and protein to help diagnose the causes of an abdominal effusion. Paracentesis may also be a

TABLE 44-3 Summary of Aspiration Procedures

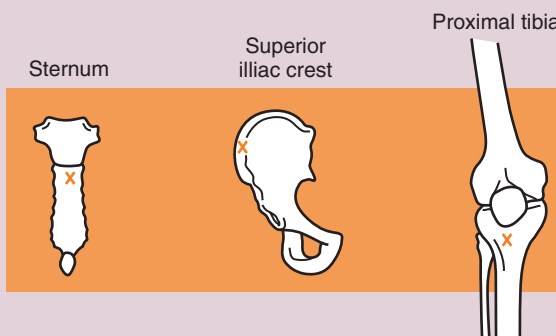

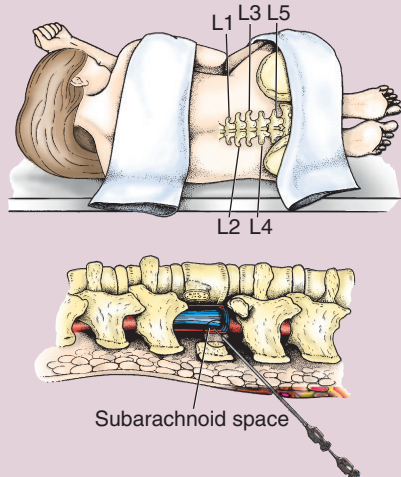

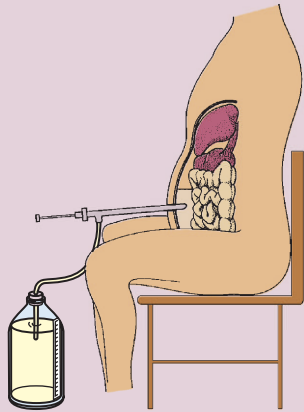

Aspiration Procedure	Preparation/Assessment Specific to Test	Position and Site	Special Considerations
Bone marrow aspiration	Assess complete blood count for abnormalities.	<p>Sternum Superior iliac crest Proximal tibia</p>  <p>“X” marks site of aspiration. (From Ignatavicius DD, Workman ML: Medical-surgical nursing: Patient-centered collaborative care, St Louis, ed 6, 2010, Saunders.)</p>	<p>Patients with arthritis or orthopnea may have difficulty assuming the positions.</p> <p>Pressure is applied to the site following procedure.</p>

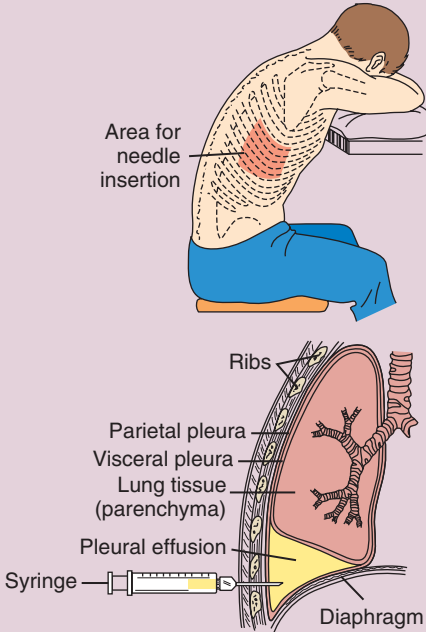

TABLE 44-3 Summary of Aspiration Procedures—cont'd

Aspiration Procedure	Preparation/Assessment Specific to Test	Position and Site	Special Considerations
Lumbar puncture	Assess neurologic status, including movement, sensation, and muscle strength of legs to provide a baseline for comparison.	<p>Lateral decubitus position</p> 	<p><i>Risk for spinal headache:</i> Instruct patient to remain flat and logroll according to health care provider's orders.</p> <p>Observe for excessive drainage at site. Fluid loss at site can predispose patient to headache and infection.</p>

(From Ignatavicius DD, Workman ML: Medical-surgical nursing: Patient-centered collaborative care, ed 7, St Louis, 2013, Saunders.)

Paracentesis	Assess bladder for distention and determine last voiding. Weigh patient, inspect and palpate abdomen, and measure abdominal girth at largest point. Mark location.		<p>After fluid is removed, pressure on diaphragm is released, and breathing becomes much easier.</p> <p><i>Risk for trauma:</i> Have patient empty urinary bladder before procedure.</p>
--------------	--	--	--

(From Pagana KD, Pagana TJ: Mosby's manual of diagnostic and laboratory tests, ed 4, St Louis, 2010, Mosby.)

Thoracentesis	Assess respiratory rate and depth, symmetry of chest on inspiration and expiration, cough, and sputum. Help patient remain still during procedure to prevent trauma to visceral pleura. Patient will need to hold breath and avoid coughing during procedure.		<p>Monitor blood pressure for hypotension if large quantity of fluid is removed.</p> <p><i>Risk for pneumothorax:</i> Observe for sudden shortness of breath, tracheal deviation, anxiety, altered vital signs, and decreased oxygen saturation.</p>
---------------	---	---	--

palliative measure to provide temporary relief of abdominal and respiratory discomfort caused by severe ascites. Lavage paracentesis, in which a lavage of solution is instilled and then withdrawn, is done to detect the presence of bleeding, as in cases of blunt abdominal trauma or tumor cells when cancer is suspected. Although not contraindicated, paracentesis is performed with caution in patients with coagulopathies, with portal hypertension accompanied with abdominal collateral circulation, and in those who are pregnant. The procedure takes approximately 30 minutes to perform.

Thoracentesis is performed to analyze or remove pleural fluid or instill medications intrapleurally. Cytologic studies of specimens reveal presence of blood, glucose, amylase, lactate dehydrogenase (LD), and cellular composition. Cytologic specimens are also examined for malignancy, differentiated between transudative and exudative characteristics, and cultured for pathogens. The following cause transudate in the pleural space: ascites, cirrhosis (hepatic), heart failure, hypertension (pulmonary, systemic), nephritis, and nephrosis. Therapeutic thoracentesis relieves pain, dyspnea, and signs of pleural pressure. The test takes approximately 30 minutes to perform.

Delegation and Collaboration

The skill of assisting with aspirations can be delegated to nursing assistive personnel (NAP) if the patient is stable (check agency policy). However, assessment of the patient's condition must be completed by the nurse and cannot be delegated. The nurse directs the NAP about:

- How to properly position the patient during the procedure.
- When to take and report vital signs.
- Which signs and symptoms experienced by the patient to immediately report to the RN.

Equipment

- ❑ Protective equipment: Masks, goggles, gowns, head cover, sterile gloves for all health care personnel performing the procedure
- ❑ Test tubes, sterile specimen containers, laboratory requisitions, and labels
- ❑ Analgesia (if ordered)
- ❑ Antiseptic solution
- ❑ 4 × 4-inch sterile gauze pads, tape, Band-Aid
- ❑ Sphygmomanometer, pulse oximeter/end-tidal CO₂ monitor
- ❑ Aspiration tray: Most agencies provide trays specific to the aspiration procedure. Standard tray includes antiseptic solution

FIG 44-3 Bone marrow biopsy needle showing shape and size. (From Monahan F et al: Phipps' medical-surgical nursing: health and illness perspectives, ed 8, St Louis, 2007, Mosby.)

(e.g., povidone-iodine; chlorhexidine); gauze sponges (4 × 4 inch); sterile towels; local anesthetic solution (e.g., lidocaine 1%); two 3-mL sterile syringes with 16- to 27-gauge needles. Additional equipment for specific aspirations includes:

- Bone marrow aspiration: Two bone marrow needles with inner stylet (Fig. 44-3)
- LP: Manometer to measure spinal pressure and at least four test tubes
- Paracentesis: Intravenous (IV) fluids as ordered, vacuum bottles to collect fluid, stopcock with extension tubing, sterile collection containers, measuring tape
- Thoracentesis: Vacuum bottles to collect fluid, stopcock with extension tubing

STEP

RATIONALE

ASSESSMENT

- 1 Verify type of procedure scheduled, purpose, and procedure site with patient and medical record.
- 2 Verify that informed consent was obtained before administering any analgesia or antianxiety agents.
- 3 Review medical record for contraindications.
 - a LP: Increased intracranial pressure (IICP), spinal deformities, and clotting disorders
 - b Paracentesis: Clotting disorders, intestinal obstructions, and pregnancy
 - c Bone marrow biopsy: Patient cannot maintain position during procedure.
 - d Thoracentesis: Patient cannot maintain position during procedure.

Ensures correct patient. Complies with The Joint Commission (2012) requirements and improves procedure safety. Federal regulations, many state laws, and accreditation agencies require informed consent for procedures.

Factors can cause hemorrhage, and ICP may cause brainstem herniation.

Paracentesis in pregnant woman may injure fetus.

STEP	RATIONALE
4 Determine patient's ability to assume position required for procedure and ability to remain still (see Table 44-3). Discuss with health care provider need for premedication for anxious patients.	Movement during procedure can cause complications such as bleeding and injury to nerves or tissue. Required position depends on site used for aspiration.
5 Before procedure: Obtain vital signs, oxygen saturation (SpO ₂)/end-tidal CO ₂ value, and weight. For paracentesis obtain abdominal girth measurement. (Use ink pen to mark measurement location for abdominal girth measurement.) For LP assess lower extremity movement, sensation, and muscle strength.	Provides baseline for comparison with vital signs during and after procedure. Patients will have decreased abdominal girth and lose weight after paracentesis.
6 Instruct patient to empty bladder.	Reduces risk for bladder trauma during paracentesis. Promotes patient comfort.
7 Assess patient's coagulation status: use of anticoagulants, complete blood count (CBC), platelet count, clotting factors, activated partial thromboplastin time (aPTT), international normalized ratio (INR), and prothrombin time (PT).	Invasive procedures are contraindicated in patients with coagulation disorders because of risk for bleeding (Pagana and Pagana, 2010).
8 Determine whether patient is allergic to antiseptic, latex, or anesthetic solutions.	Precautions can be taken to decrease chance of allergic reactions.
9 Assess patient's level of understanding of procedure, including any concerns.	Determines extent of instruction and level of support required.
10 Assess baseline pain level, using scale of 0 to 10.	Determines need for preprocedure analgesia. Pain control helps patients maintain proper position and tolerate aspiration procedure.

NURSING DIAGNOSES

- Acute pain
- Anxiety
- Deficient knowledge regarding procedure
- Fear
- Impaired gas exchange
- Impaired mobility
- Ineffective breathing pattern
- Risk for infection
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:	Demonstrates understanding and improves likelihood of cooperation.
<ul style="list-style-type: none"> • Patient describes purpose of procedure. • Patient assumes and maintains required position and remains still throughout procedure. • There is no bleeding at needle insertion site. • Amount of aspirate is sufficient to perform laboratory testing. • Patient's level of comfort equals score of 4 or less on pain scale of 0 to 10. • Vital signs, SpO₂, and end-tidal CO₂ remain within normal limits during and after aspiration procedure. • Patient undergoing paracentesis has reduced abdominal girth and improved respirations. 	Correct position facilitates safe and timely completion of the procedure. Precautions during procedure prevent bleeding.
2 Explain steps of skin preparation, anesthetic injection, needle insertion, position required.	Procedure performed with minimal discomfort to patient.
3 If ordered, premedicate for pain 30 minutes before procedure. <i>Option:</i> In some cases patients will receive anti-anxiety medications.	Removal of abdominal (ascites) or pleural fluid increases lung expansion and improves gas exchange. Fluid successfully removed from peritoneal space.
4 Before thoracentesis verify recent chest x-ray film examination.	Anticipation of expected sensations and procedural activities reduces anxiety. Pain and anxiety control helps patient to remain in position, minimizes discomfort from needle insertion, and decreases anxiety. Provides preprocedure baseline to determine location of pleural fluid.

IMPLEMENTATION

- | | |
|--|---|
| 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (2012). |
| 2 Perform hand hygiene. | Reduces transmission of microorganisms. |

STEP	RATIONALE
3 Set up sterile tray or open supplies to make accessible for health care provider.	Maintains integrity of sterile field and promotes prompt completion of procedure.
4 Take “Time-Out” to verify patient’s name, type of procedure scheduled, and procedure site with patient and health care team.	“Time-Out” verification just before starting procedure includes physician and all personnel and is safety precaution to prevent wrong patient, wrong site, and wrong procedure errors (TJC, 2012).
5 Help patient maintain correct position. Reassure patient while explaining procedure.	Decreases chance of complications occurring during procedure. Explanations increase patient comfort and relaxation.
<p>a Bone marrow:</p> <ul style="list-style-type: none"> • <i>Adults:</i> For sternal biopsy place in supine position. For iliac crest biopsy place in prone or lateral recumbent position. • <i>Children:</i> For iliac crest biopsy place in prone or lateral recumbent position. 	Provides best access to bone containing marrow.
<p>b LP:</p> <p>Position in lateral recumbent (fetal) position with head and neck flexed (see Table 44-3).</p>	Provides full curvature and flexion of spinal column to allow maximal space between vertebrae.
<p>c Paracentesis:</p> <p>Position in bed in semi-Fowler’s position or sitting upright on side of bed or in chair with feet supported (see Table 44-3).</p>	Position uses gravity to cause fluid to accumulate in lower abdominal cavity, where it is drained more easily.
<p>d Thoracentesis:</p> <p>Place in orthopneic position (upright position with arms and shoulders raised and supported on padded over-bed table) (see Table 44-3). If patient is unable to tolerate, help to side-lying position with affected lung positioned upward.</p>	Expands intercostal space for needle insertions.

Clinical Decision Point *Emphasize the importance of remaining immobile during procedure to prevent trauma, especially with the LP. Sudden movement is a risk for spinal cord nerve root damage. Sudden movement during paracentesis or thoracentesis risks damage of the abdominal or pulmonary structures. Also instruct patient not to cough, sneeze, or breathe deeply during the procedures because these actions increase the risk for needle displacement and damage of other structures.*

6 Explain to patient that pain may occur when lidocaine (local anesthetic) is injected into tissues. Pressure may also occur when tissue or fluid is aspirated.	Aspiration is painful but lasts for only a few moments. If patient is having bone marrow aspirate, deep pressure feeling is frequently experienced as bone marrow is withdrawn (Pagana and Pagana, 2010).
7 Physician applies sterile gloves, mask, gown, and goggles; cleans patient’s skin with antiseptic solution; and drapes site with sterile drape.	Removes surface bacteria from skin at area of puncture site. Creates sterile field.
8 Physician injects local anesthetic and allows time for anesthesia to occur.	Provides optimal effect of local anesthesia.
9 Physician inserts needle or trocar into spinal space or body cavity involved (see Table 44-3). To aspirate tissue or body fluids for specimen analysis, syringe is attached to trocar or needle, and aspirate is placed into specimen container.	Success depends on positioning, accurate insertion site, and patient remaining still.
10 Nurse assesses patient’s condition during procedure, including respiratory status, vital signs if indicated, and any complaints of pain.	Identifies any changes that indicate complication.

Clinical Decision Point *Increased or worsening abdominal or thoracic pain is significant in paracentesis and thoracentesis. Severe abdominal pain indicates a possible bowel perforation following a paracentesis. Following a thoracentesis abdominal pain results from diaphragmatic, liver, or spleen perforation. Inspiratory chest pain results from perforation of the lung.*

<p>11 Note characteristics of aspirate:</p> <p>a Bone marrow aspirate: Marrow may appear red or yellow.</p> <p>b LP: Record opening pressure; observe fluid for color, cloudiness, or blood.</p> <p>c Paracentesis: Fluid may appear yellow, cloudy, bile-stained green, or blood tinged. Peritoneal lavage fluid may appear bright red.</p>	<p>Normal marrow.</p> <p>Normal CSF is clear and colorless.</p> <p>Cloudiness is result of protein, which indicates an infection.</p> <p>Blood-tinged fluid is caused by traumatic tap. In patient with abdominal trauma bloody lavage identifies active bleeding.</p>
---	--

STEP	RATIONALE
d <i>Thoracentesis</i> : Pleural fluid may appear clear yellow, puslike, or cloudy.	Clear yellow is normal. Transudate and exudates are typically yellow, straw color.
12 Properly label specimens in presence of patient and transport to laboratory in proper containers. Label specimens in order of collection.	Blood-tinged fluid indicates malignancy, pulmonary infarction, or severe inflammation. Puslike fluid indicates infection (empyema); milky fluid indicates chylothorax (i.e., leak from thoracic duct resulting in lymphatic drainage in pleural cavity).
13 Physician removes needle/trocar and applies pressure over insertion site until drainage ceases. If necessary, help with direct pressure and application of gauze dressing.	Ensures that correct laboratory results are assigned to right patient. Test tubes are numbered in sequence of collection (e.g., 1 through 4).
14 All team members in procedure remove protective equipment, discard in appropriate receptacle, and perform hand hygiene.	Assists in homeostasis and secures insertion site. Reduces transmission of infection.

EVALUATION

1 Monitor level of consciousness, vital signs, and SpO ₂ /end-tidal CO ₂ . Check agency policy; sometimes vital signs are obtained every 15 minutes for 2 hours.	Verifies patient's physiologic status in response to procedure or any potential complications.
2 Inspect dressing over puncture site for bleeding, swelling, tenderness, and erythema. Inspect area under patient for bleeding. Avoid disrupting healing clot at site if pressure dressing is present.	Determines further blood loss from puncture site. Infection is potential complication, especially if patient is leukopenic (Pagana and Pagana, 2010).
3 Evaluate pain score to determine if patient's level of comfort is equivalent to a score of 4 or less on pain scale of 0 to 10.	Determines if patient is having increased pain to warrant postprocedure analgesia.
4 Following paracentesis, measure abdominal girth and respirations and compare to preprocedure measurements.	Determines amount of change in abdominal size and ability to ventilate.

Unexpected Outcomes

- 1 Oversedation occurs.
- 2 Site complications occur:
 - a *Bone marrow*: Tenderness or erythema at site.
 - b *LP*:
 - (1) Postprocedure headache (PPHD) is evidenced by headache, blurred vision, and tinnitus.
 - (2) Excess loss of CSF is indicated by decreased level of consciousness, hearing loss, dilated pupils, and decreased ICP.
 - c *Paracentesis*: Leakage of fluid from site and acute abdominal pain occur.
 - d *Thoracentesis*: Pneumothorax is evidenced by sudden dyspnea, tachypnea, and asymmetric chest excursion.

Related Interventions

- See Skill 44-1.
- Notify health care provider and obtain further orders.
- Administer analgesic as ordered.
- Continue to monitor site.
- Monitor fluid loss.
- Physician may inject blood patch into epidural space.
- Medicate for pain as ordered.
- Maintain airway.
- Transfer to intensive care unit (ICU) per physician order.
- Reinforce dressing; may also be instructed to place sterile collection bag over site.
- Monitor vital signs and SpO₂.
- Assess abdomen for bowel sounds.
- Administer oxygen.
- Monitor vital signs and SpO₂.
- Anticipate chest x-ray film examination and possible chest tube insertion.

Recording and Reporting

- Record in patient's chart name of procedure; preprocedure preparation; location of puncture site; amount, consistency, and color of fluid drained or specimen obtained; duration of procedure; patient's tolerance (e.g., vital signs, SpO₂) and comfort level; laboratory tests ordered and specimen sent; type of dressing; postprocedure activities (e.g., chest x-ray film examination); and other procedure-specific assessments (e.g., extremity assessment, abdominal girth, level of consciousness).
- Immediately report to health care provider any change in vital signs and SpO₂, unexpected pain/discomfort, and any excessive drainage from dressing over puncture site.

Special Considerations

Teaching

- Instruct patient that some people experience tenderness at the puncture site for several days after the study and that mild analgesia often helps to relieve some of the discomfort.

Pediatric

- Conscious or unconscious sedation is commonly used. If using unconscious sedation, an anesthesiologist or nurse anesthetist will be needed for the procedure.
- Prepare preschool children before the procedure; make a game out of having child recall the next procedural step, which can serve as a distraction (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults with arthritis need help to stay in the required position.

- Older adults have reduced elastic lung recoil, weaker cough efficiency, and decreased chest expansion. Restlessness may indicate hypoxia following thoracentesis.
- Be aware that older adults may have specific fears and anxiety related to postprocedure falling and fatigue.

Home Care

- Teach patients and family caregivers about specific postprocedure complications and when to report them to the health care provider.
- If patient is transferred to long-term care facility, ensure thorough communication between agencies regarding results of procedure and patient condition.

SKILL 44-4 Assisting with Bronchoscopy

Bronchoscopy is the examination of the tracheobronchial tree through a lighted tube containing mirrors. A flexible fiberoptic bronchoscope has lumens that allow both visualization and simultaneous administration of oxygen (Fig. 44-4). The fiberoptic bronchoscope is used for obtaining sputum, foreign bodies, and biopsy specimens. Laser ablation of endotracheal lesions may also be performed through the bronchoscope.

Bronchoscopy may be an emergency or elective procedure and may be performed for diagnostic or therapeutic reasons. The main purposes of this procedure include aspirating excessive sputum or

mucus plugs that airway suctioning cannot remove; visualizing the tracheobronchial tree for assessment of abnormalities of the mucosa, abscesses, aspiration pneumonia, strictures, and tumors; obtaining deep tissue biopsy and sputum specimens; and/or removing foreign bodies. This procedure is contraindicated in patients who cannot tolerate interruption of high-flow oxygen unless intubated. Potential complications of bronchoscopy include fever, infection, hypoxemia, bronchospasm and/or laryngospasm, pneumothorax, aspiration, dysrhythmias and hypotension, hemorrhage (after biopsy), and cardiac arrest.

The procedure is performed at the bedside or in a specially equipped endoscopy room. Usually a pulmonary specialist or surgeon performs the procedure in approximately 30 to 45 minutes.

Delegation and Collaboration

The skill of assisting with bronchoscopy cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Measure follow-up postprocedure vital signs (after RN's initial assessment).
- Position the patient appropriately (based on procedure and patient limitations).
- Immediately report to the nurse if the patient has possible respiratory distress or is coughing up blood.

Equipment

- Bronchoscopy tray, if available from central supply, which includes flexible fiberoptic bronchoscope (see Fig. 44-4); 4 × 4-inch gauze sponges; local anesthetic spray (lidocaine); sterile tracheal suction catheters; diazepam (Valium), midazolam (Versed), or other sedative for intravenous (IV) sedation
- Oxygen, resuscitative equipment
- Pulse oximeter/end-tidal CO₂ monitor, cardiac monitor
- Sterile gloves
- Sterile water-soluble lubricating jelly (NOTE: Petroleum-based lubricants are not used because of the hazard of aspiration and subsequent pneumonia.)
- Protective equipment: Mask, gown, gloves, head cover, and goggles for all health care providers
- Emesis basin
- Suction machine and connecting tube
- Blood pressure equipment

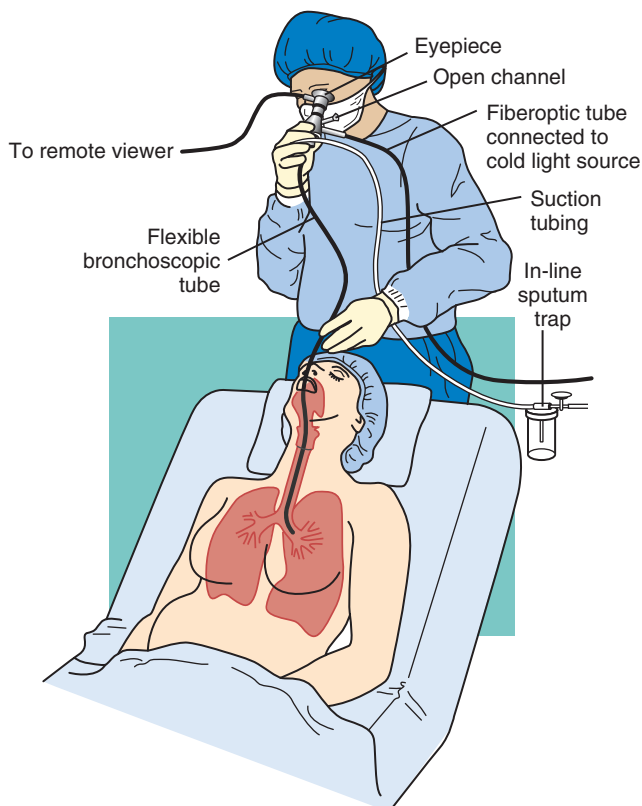

FIG 44-4 Flexible fiberoptic bronchoscopy.

STEP

RATIONALE

ASSESSMENT

1	Verify type of procedure scheduled and procedure site with patient.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2	Verify that informed consent was obtained before administration of any sedatives.	Federal regulations, many state laws, and accreditation agencies such as The Joint Commission require informed consent for procedure.
3	Assess patient's history for inability to tolerate interruption of high-flow oxygen unless intubated.	Determines need for oxygen administration during procedure.
4	Obtain baseline vital signs, pulse oximetry (SpO ₂) and end-tidal CO ₂ values.	Baseline data provide for comparison with findings during and after procedure.
5	Assess type of cough, sputum produced, heart and lung sounds.	Provides for comparison with respiratory status during and after procedure.
6	Determine purpose of procedure: for sputum aspiration, assessment, tissue biopsy, or removal of foreign body.	Anticipates equipment needs of physician and type of information to convey to patient during teaching.
7	Determine whether patient is allergic to local anesthetic used for spraying throat (usually lidocaine).	Allergy causes laryngeal edema or laryngospasm.
8	Assess need for preprocedure medication (usually atropine and opioid or sedative).	Atropine decreases secretions and inhibits vagally stimulated bradycardia; opioids or sedatives relieve anxiety and decrease discomfort.
9	Assess time patient last ingested food/fluids or medications. Patient must be NPO for at least 8 hours before a bronchoscopy; however, some medications may be taken before procedure by physician order.	Reduces risk for aspiration.
10	Assess patient's level of understanding of procedure, including any concerns.	Determines extent of instruction and level of support required.

NURSING DIAGNOSIS

- | | | |
|---|---------------------------------|-----------------------|
| • Anxiety | • Impaired gas exchange | • Risk for aspiration |
| • Deficient knowledge regarding procedure | • Ineffective airway clearance | • Risk for infection |
| • Fear | • Ineffective breathing pattern | • Risk for injury |

Related factors are individualized based on patient's condition or needs.

PLANNING

1	Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient recovers from sedation without respiratory complications or change in level of consciousness. • Patient's level of comfort is equivalent to score of 4 or less on pain scale of 0 to 10. • Physician is able to observe, suction, and obtain specimens from tracheobronchial tree. • Patient explains procedure and assumes appropriate position. 	Sedation adequate, and patient tolerates procedure.
2	Administer atropine, opioid, or antianxiety agent 30 minutes before procedure.	Minimal trauma caused by bronchoscope.
3	Explain procedure to patient.	Indicates that purpose of procedure was achieved.
4	Remove and safely store patient's dentures and/or eyeglasses.	Demonstrates patient's understanding. Ensures that medication takes effect before procedure.
		Reduces anxiety and increases cooperation. Minimizes chance of airway obstruction.

IMPLEMENTATION

1	Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2	Assess current IV access or establish new IV access with large-bore cannula (see Chapter 28).	Provides immediate access for IV fluids or medications if emergency occurs.
3	Help patient assume position desired by physician: usually semi-Fowler's.	Provides maximal visualization of lower airway and adequate lung expansion.

STEP	RATIONALE
4 Take “Time-Out” to verify patient’s name, type of procedure scheduled, and procedure site with patient and health care team.	“Time-Out” verification just before starting procedure includes physician and all personnel and is safety precaution to prevent wrong patient, wrong site, and wrong procedure errors (TJC, 2012).
5 Perform hand hygiene and apply protective equipment. Position tip of suction catheter for easy access to patient’s mouth.	Reduces transmission of microorganisms. Removes secretions to reduce risk for aspiration.
6 Physician usually sprays nasopharynx and oropharynx with topical anesthetic. Lidocaine is commonly used 10 to 15 minutes before procedure. When a patient is intubated or has tracheostomy, anesthetic spray is usually not needed.	Provides swift anesthesia of oropharynx.
7 Instruct patient not to swallow local anesthetic; provide emesis basin for expectorating it.	Reduces unintended anesthesia of esophagus.
8 Another physician or staff member attaches bronchoscope to machine light source.	Enhances visualization during procedure.
9 Physician applies goggles, mask, and sterile gloves; introduces bronchoscope into mouth to pharynx; passes through glottis and into trachea and bronchi (see Fig. 44-4). More anesthetic spray may be used at glottis to prevent cough reflex. For intubated patients the flexible bronchoscope is introduced through their endotracheal tube.	Bronchoscope must be passed through upper airway structures to promote visualization of lower airways. Trachea and bronchi are observed for lesions and obstructions. Adaptor accompanies bronchoscope and is used for bag-valve-mask or ventilator use.
10 Physician suctions mucus and performs bronchial washing with cytologic specimens taken with wire brush or curette. Biopsy specimens may also be obtained.	Cytologic specimens are obtained to diagnose carcinoma.
11 Help patient through procedure by providing explanations, verbal reassurance, and support.	Although premedicated and drowsy, remind patient not to change position and to cooperate. Reinforce that patient will be able to breathe during procedure.
12 Assess patient’s pulse, blood pressure, respirations, SpO ₂ , end-tidal CO ₂ , and breathing capacity during procedure: observe degree of restlessness, capillary refill, and color of nail beds.	Bronchoscope can cause feelings of suffocation and vasovagal response and laryngospasm. Because airway is partially occluded, patient can develop hypoxia during procedure.
13 Note characteristics of suctioned material. Expect small amount of blood mixed with aspirate because of tissue trauma.	Information used to record and report and make further patient observations.
14 Using gloved hand, wipe patient’s mouth and nose to remove lubricant after bronchoscope is removed.	Promotes hygiene and comfort.
15 Instruct patient not to eat or drink until tracheobronchial anesthesia has worn off and gag reflex has returned, usually 2 hours. Use tongue depressor to touch pharynx to test for presence of gag reflex.	Prevents aspiration.
16 Remove protective equipment, discard, and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Monitor vital signs, SpO ₂ , and end-tidal CO ₂ .	Verifies physiologic response to procedure.
2 Observe character and amount of sputum. Physician may order serial sputum collection for 24 hours for cytologic examination.	Evaluates for complication of bronchial perforation, indicated by severe hemoptysis.
3 Observe respiratory status closely; palpate for facial or neck crepitus.	Slight blood-tinged sputum is normal after this procedure.
4 Assess for return of gag reflex. It usually returns in approximately 2 hours.	Detects early sign of bronchial perforation (Chernecky and Berger, 2008).
5 Ask patient to describe postprocedure normal and abnormal symptoms.	Helps prevent aspiration pneumonia, which is risk until gag reflex returns. Evaluates patient’s understanding.

Unexpected Outcomes

- 1 Vasovagal response caused by stimulation of baroreceptors during bronchoscope insertion, causing symptoms of:
 - Feeling nauseous, faint, dizzy, and/or light-headed.
 - Diaphoresis with slow, steady pulse.
 - Unconsciousness for few seconds.
- 2 Laryngospasm and bronchospasm as evidenced by:
 - Sudden, severe shortness of breath.
- 3 Hypoxemia as evidenced by:
 - Gradual shortness of breath.
 - Decreasing level of consciousness.
- 4 Hemorrhage as evidenced by:
 - Acute blood loss
 - Hypotension and tachycardia
 - Decreasing level of consciousness
- 5 Oversedation (see Skill 44-1)

Related Interventions

- Lower head of table.
 - Continue vital signs monitoring.
 - Lower head of table.
 - Support airway (positioning/suctioning).
-
- Call physician immediately.
 - Support airway (positioning).
 - Prepare emergency resuscitation equipment.
 - Anticipate possible cricothyrotomy.
-
- Monitor SpO₂.
 - Maintain airway and breathing.
 - Notify physician immediately.
-
- Notify physician immediately.
 - Monitor vital signs.
 - Be prepared to administer IV fluids.

Recording and Reporting

- Record procedure(s) performed (e.g., biopsy), character of sputum, duration of procedure, patient's tolerance and if any complications, and the collection and disposition of specimen(s). Document time of gag reflex return.
- Report bleeding or respiratory distress following the procedure or any changes in vital signs beyond patient's normal limits to physician immediately. Report results of procedure to appropriate health care personnel.

Special Considerations

Teaching

- Before the procedure instruct patient to perform good mouth care to decrease risk for introducing bacteria into lungs during the procedure.
- In some cases patients may receive IV sedation (refer to Skill 44-1, Teaching Considerations).
- If ordered, teach patient how to perform controlled coughing techniques for obtaining serial sputum samples (see Chapter 43).

Pediatric

- In children the procedure is most frequently performed under general anesthesia to remove foreign bodies from the larynx or

trachea. Follow-up care after the foreign body is removed includes chest physiotherapy, monitoring for respiratory distress, and education of parents.

- Children are at higher risk for hypoxemia than adults because their bronchus is smaller and the bronchoscope decreases the available breathing space (Pagana and Pagana, 2010).

Gerontologic

- Physical exposure and room temperature contribute to hypothermia in frail older adults who are unable to communicate that they are cold. Use warmed blankets or forced-air heat to maintain core temperature at comfortable, safe levels (Lewis et al., 2011).
- Postprocedure restlessness often indicates hypoxemia or pain. Thoroughly assess pulmonary capacity before administering opioids, which may depress the respiratory centers.

Home Care

- Instruct ambulatory care patients to notify the physician if the following symptoms develop: fever, chest pain or discomfort, dyspnea, wheezing, or hemoptysis.
- Throat discomfort is managed with throat lozenges or warm saline gargles.

SKILL 44-5 Assisting with Gastrointestinal Endoscopy

Endoscopy allows direct visualization of an internal organ or structure by means of a long, flexible fiberoptic scope. The tip of the scope has a light source and camera lens that allows visualization of the lining of the gastrointestinal (GI) structures on a large display screen (Fig. 44-5). For visualization of the upper GI tract, esophagoscopy, gastroscopy, gastroduodenoscopy (GDJ), or duodenoscopy is performed; or more frequently esophagogastroduodenoscopy (EGD), which permits visualization of the esophagus, stomach (Fig. 44-6), and duodenum in one examination. Besides direct observation, endoscopy enables biopsy of suspicious tissue, polyp removal, and performance of many other procedures such as direct visual guidance for fine-needle aspiration biopsies

and dilation and stenting of strictures. For visualization of the hepatobiliary tree and pancreatic ducts, an endoscopic retrograde cholangiopancreatography (ERCP) is performed. For visual examination of the lower GI tract, proctoscopy, sigmoidoscopy, or colonoscopy is performed. Typically these patients receive intravenous (IV) moderate sedation.

Risks of endoscopic procedures include intestinal perforation, hemorrhage, peritonitis, aspiration, respiratory depression, and/or myocardial infarction secondary to vasovagal response. Both upper and lower GI endoscopic examinations may be performed in a specially equipped endoscopic unit or at the patient's bedside.

FIG 44-5 A, Scope view of healthy colon. B, Overview of colonoscopy process. C, Path of scope through colon.

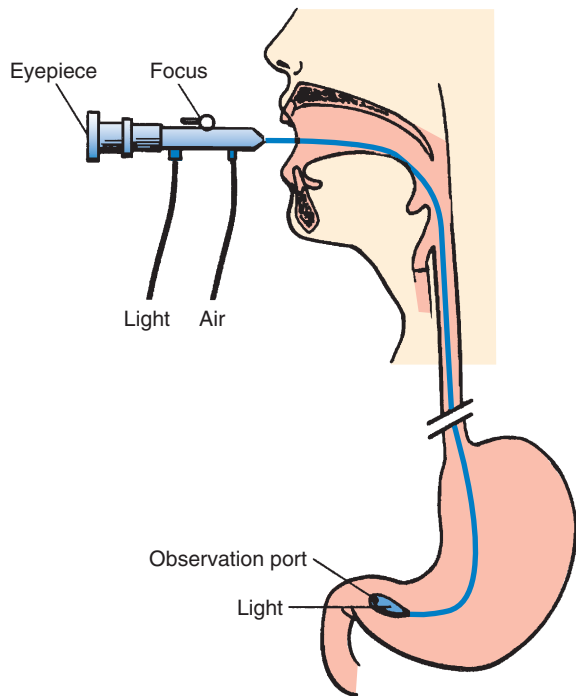

FIG 44-6 Stomach may be visualized by means of a fiberscope.

Delegation and Collaboration

The skill of assisting with endoscopy cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- How to assist with patient positioning.

Equipment

- Protective equipment: Mask, gown, gloves, head cover, goggles for all health care personnel
- Endoscopy tray
- Fiberoptic endoscope and camera (see Fig. 44-5)
- Solutions for biopsy specimens
- Local anesthetic spray
- Tracheal suction equipment (see Chapter 25)
- Blood pressure equipment
- Sterile water-soluble jelly
- Sterile gloves for physician
- Emesis basin
- IV fluid and equipment for IV start (*optional*)
- Diazepam (Valium), midazolam (Versed), or other sedative for IV sedation (*optional*)
- Sedative reversal agents
- Carbon dioxide source to inflate colon (for lower GI procedures)
- Oxygen, resuscitative equipment, pulse oximeter/end-tidal CO₂ monitor

STEP

RATIONALE

ASSESSMENT

- | | |
|---|--|
| <ol style="list-style-type: none"> 1 Verify type of procedure scheduled and procedure site with patient. 2 Verify that informed consent was obtained before administering sedation. 3 Determine if GI bleeding is present. Observe character of emesis, stool, and nasogastric (NG) tube drainage for frank blood or material that looks like coffee grounds. 4 Obtain vital signs and oxygen saturation/end-tidal CO₂ values. | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Federal regulations, many state laws, and accreditation agencies such as The Joint Commission require informed consent for procedure.</p> <p>Test is contraindicated in patients with severe upper GI bleeding because viewing lens becomes covered with blood clots, preventing visualization (Pagana and Pagana, 2010).</p> <p>Baseline data provide for comparison with findings during and after procedure.</p> |
|---|--|

Clinical Decision Point If patient is bleeding actively, physician may order lavage of the stomach and aspiration to clear clots before procedure is attempted.

STEP	RATIONALE
5 Determine purpose of procedure: biopsy, examination, or coagulation of bleeding sites.	Anticipates appropriate equipment needs.
6 Verify that patient was NPO for at least 8 hours for endoscopy of upper GI tract.	Introduction of endoscope increases risk for vomiting resulting from stimulation of gag reflex. Empty stomach reduces risk for aspiration of stomach contents.
7 For lower GI studies (proctoscopy, sigmoidoscopy, or colonoscopy), verify that patient followed clear liquid diet for 2 days and has completed any ordered bowel-cleansing regimen.	An empty intestinal tract promotes endoscopic insertion and good visualization of interior walls.
8 Assess patient's level of understanding and previous experience with procedure, including any concerns.	Determines extent of instruction and level of support required.

NURSING DIAGNOSES

- | | | |
|---|---------------------------------|-----------------------|
| • Anxiety | • Fear | • Risk for aspiration |
| • Deficient knowledge regarding procedure | • Impaired gas exchange | • Risk for infection |
| | • Ineffective breathing pattern | • Risk for injury |

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient does not aspirate and has no postprocedure bleeding. • Patient's level of comfort is equivalent to score of 4 or less on pain scale of 0 to 10. • Patient is without respiratory complications or change in level of consciousness. • Patient describes purposes and steps of procedure. | Indicates absence of complications and tolerance of procedure.
Provides reliable detection of increasing pain so postprocedure analgesia is given.
Recovers from sedation. |
| 2 Prepare patient: <ul style="list-style-type: none"> a Explain steps of procedure, including sensations to expect. b Administer pain medication or preprocedure medication. | Documents patient understanding.
Relieves anxiety and answers patient's questions.
Promotes relaxation and reduces anxiety. |

IMPLEMENTATION

- | | |
|--|--|
| 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information in patient's identification bracelet. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). |
| 2 Perform hand hygiene and apply protective equipment. | Reduces transmission of microorganisms. |
| 3 Remove patient's eyeglasses, dentures, or other dental appliances. | Prevents damage to eyeglasses or damage/dislodgement of dental structures during intubation phase. |
| 4 Take "Time-Out" to verify patient's name, type of procedure scheduled, and procedure site with patient and health care team. | "Time-Out" verification just before starting procedure includes physician and all personnel and is safety precaution to prevent wrong patient, wrong site, and wrong procedure errors (TJC, 2012). |
| 5 Ensure that IV line is patent and administer IV sedation as ordered (see Skill 44-1). | Provides route for emergency medications and creates immediate conscious sedation. |
| 6 Help patient assume proper position for procedure and apply appropriate drape. <ul style="list-style-type: none"> a <i>Upper GI procedures:</i> Assist patient in maintaining left lateral Sims' position. b <i>Lower GI procedures:</i> Assist patient in maintaining left lateral decubitus position. Drape patient for privacy. | Improves efficiency of procedure and ability of physician to visualize site. Drape provides comfort and minimizes exposure.
Sims' position allows easy passage of upper or lower endoscope.
Provides airway clearance if patient gags and vomits gastric contents.
Left lateral decubitus position provides access to lower GI tract. |
| 7 Physician performs hand hygiene and puts on protective equipment. | Reduces transmission of microorganisms. |
| 8 Upper GI procedures: <ul style="list-style-type: none"> a Help physician spray nasopharynx and oropharynx with local anesthetic. b Administer atropine if ordered. c Position tip of suction cannula for easy access in patient's mouth. | Topical anesthetic decreases gag reflex caused by passage of endoscope, thus improving safety and comfort.
Reduces quantity of secretions, therefore reducing risk for aspiration.
Drains oral secretions to reduce risk for aspiration. |

STEP	RATIONALE
9 Lower GI procedures:	
a Prepare lubricant for fiberoptic endoscope.	Facilitates passage of tubing.
10 Physician slowly passes endoscope into mouth or through anus to view esophagus, stomach, colon, or rectum and advances to desired depth while visualizing lining of structures.	Provides visualization of all structures to detect polyps, cancerous lesions, or areas of inflammation and stricture.
11 Physician insufflates air through endoscope into upper GI tract or carbon dioxide into lower GI tract in case of colonoscopy.	Distends GI structures for better visualization. Carbon dioxide insufflation produces less postprocedure abdominal cramping than air insufflation because it is more readily absorbed (Chernecky and Berger, 2008).
12 Help patient throughout procedure:	
a Anticipate needs and promote comfort.	Patient is unable to speak after tube is passed into throat.
b Tell patient what is happening as each portion of procedure is carried out (e.g., abdominal cramping).	Reassures patient about procedure and how long it will last.
c For upper GI procedures, suction if there are excessive oral secretions or vomitus.	Prevents aspiration of oral secretions or gastric contents.
13 Place tissue specimens in proper laboratory containers or on proper slides. Seal as needed. Date, time, and initial all specimen containers before sending to laboratory.	Ensures proper specimen preservation and labeling and preparation of specimens for microscopic examination.
14 Help patient return to comfortable position.	Promotes relaxation.
15 Help to dispose of equipment and perform hand hygiene.	Reduces transmission of infection.
16 In recovery, after sedation resolves, inform patient not to eat or drink until gag reflex returns.	Reduces risk for aspiration.

EVALUATION

1 Monitor vital signs and oxygen saturation according to agency policy, which can be every 15 minutes for 2 hours.	Change in vital signs may indicate new bleeding in GI tract or oversedation.
2 Assess for levels of sedation and consciousness (see Skill 44-1).	Determines patient's response to IV sedation.
3 Ask patient to describe level of comfort using pain scale of 0 to 10. Observe for pain.	Monitors for sudden abdominal pain, which can indicate rupture of abdominal organs.
4 Evaluate emesis or aspirate for frank or occult blood (see Chapter 43).	Monitors for GI bleeding.
5 Assess for return of gag reflex, usually in 2 to 4 hours. Provide oral hygiene when gag reflex returns.	Determines when effects of anesthetic have disappeared. Gag reflex prevents aspiration.
6 Ask patient to state postprocedure dietary and activity limitations.	Evaluates patient understanding.

Unexpected Outcomes

- Vasovagal response caused by stimulation of baroreceptors during endoscope insertion as evidenced by:
 - Feeling nauseous, faint, dizzy, and/or light-headed.
 - Diaphoresis with slow, steady pulse.
 - Few seconds of unconsciousness.
- For upper GI procedures: Laryngospasm and bronchospasm as evidenced by:
 - Sudden, severe shortness of breath
- For upper GI procedures: Hypoxemia as evidenced by:
 - Gradual shortness of breath
 - Decreasing level of consciousness
- Pulmonary aspiration as evidenced by:
 - Dyspnea, tachypnea, decreasing levels of oxygen saturation.
- Abdominal pain, fever, or bleeding, indicating damage to intestinal wall.
- Oversedation with decreasing level of consciousness.

Related Interventions

- Lower head of table.
- Support airway.
- Call physician immediately.
- Support airway (positioning).
- Prepare emergency resuscitation equipment.
- Anticipate possible cricothyrotomy.
- Monitor SpO₂.
- Maintain airway and breathing.
- Notify physician immediately.
- Support airway.
- Follow specific postprocedural orders related to findings.
- Monitor oxygen saturation.
- Continue to monitor vital signs.
- Notify physician of findings.
- See Skill 44-1.

Recording and Reporting

- Record the procedure, duration, patient's tolerance, complications and interventions, and collection and disposition of specimen.
- Report onset of bleeding, abdominal pain, dyspnea, and vital sign changes to physician.

Special Considerations

Teaching

- Upper GI endoscopy:
 - Explain method for endoscope insertion. Prepare patient for a slight feeling of not being able to breathe. Assure him or her that this feeling is common but that air is delivered through the endoscope and suffocation will not occur.
 - Teach patient simple hand signals for pain or discomfort because he or she will not be able to speak after the endoscope is positioned in the esophagus.
- Lower GI procedures (colonoscopy, sigmoidoscopy, proctoscopy):
 - Explain that it is normal to experience increased flatus and abdominal cramping.
 - Small amounts of blood in the stool are common if a biopsy was taken.

Pediatric

- Introduction of the endoscope in infants and small children who have a narrow and collapsible airway may result in respiratory distress.

Gerontologic

- Older adults frequently have reduced drug clearance from decreased glomerular filtration rate (GFR) and nephron activity or decreased hepatic function. It is important to monitor the effects of medications given to older adults (Meiner, 2011).
- Because of age-related changes in older adults, the gastric mucosa is thinner, which increases the incidence of irritation and ulceration (Meiner, 2011).
- Physical exposure and room temperature contribute to hypothermia in frail older adults who are unable to communicate that they are cold. Use warmed blankets or forced-air heat to maintain core temperature at comfortable, safe levels (Lewis et al., 2011).
- Some older adults experience dehydration, electrolyte imbalance, and exhaustion from pretest preparation. If the procedure is done on an ambulatory care basis, it is helpful to have someone stay with the patient for at least 24 hours afterwards.

Home Care

- Explain that patient might have hoarseness or a sore throat after an upper GI procedure. Patient can have ice chips or anesthetic lozenges after gag reflex returns.
- Instruct patient or family to notify physician if patient has a fever, abdominal pain, rigid abdomen, and rectal bleeding or stool in blood.

SKILL 44-6 Obtaining an Electrocardiogram

A 12-lead electrocardiogram (ECG) is a graphic representation of the electrical activities, or conduction system, of the heart. The electrical impulse for each heartbeat originates within the sinoatrial (SA) node, the “pacemaker” of the heart. The rate of impulses initiated at the SA node for an adult at rest is about 60 to 100 beats/min. The electrical impulses are then transmitted through the atria to the atrioventricular (AV) node. The AV node assists with atrial emptying by delaying the impulse before transmitting it through the bundle of His and the ventricular Purkinje network. The normal sequence on the ECG records the path of these electrical impulses, called *normal sinus rhythm (NSR)*, which contains PQRST waves (Fig. 44-7). The PR interval represents atrial depolarization during which the atria empty their blood supply into the ventricles. The QRS interval represents ventricular depolarization, during which ventricular contraction occurs. The remainder of the

waveform through the end of the T wave signifies ventricular repolarization.

The electrical activity of the conduction system is recorded on a 12-lead ECG to determine baseline cardiac function (e.g., preoperative, prediagnostic testing), to evaluate response to cardiac medications, to monitor recovery after a myocardial infarction (MI), or when a patient experiences chest discomfort (Chernecky and Berger, 2008). An ECG monitors the regularity and path of the electrical impulse through the conduction system; however, it does not reflect muscular work of the heart.

Disturbances in conduction result when impulses cannot travel through the normal pathways. These rhythm disturbances are called *dysrhythmias*, meaning a deviation from the NSR (Table 44-4). Dysrhythmias occur as a response to ischemia, valvular abnormality, anxiety, drug toxicity, or acid-base or electrolyte imbalance. Some common dysrhythmias include tachycardia (greater than 100 beats/min), bradycardia (less than 60 beats/min), premature ventricular or atrial contractions (premature ventricular contractions [PVCs], premature atrial contractions [PACs]), atrial fibrillation, or heart block (delayed or absent beat).

The electrical impulses are conducted to the surface of the body and detected by electrodes placed on the limbs and torso. The electrodes carry these impulses to a continuously running graph that plots the ECG wave pattern. The appearance of the ECG pattern helps diagnose whether there are any abnormalities in the electrical conduction through the heart. A 12-lead ECG machine includes 10 leads and electrodes. One electrode is placed on each of the four extremities, and six electrodes are placed at specific sites on the chest (precordial). The 12 “leads” that are produced are 12 different graphic pictures, based on how the electricity flows between specific electrodes. They are the bipolar limb leads I, II, III; augmented limb leads aV_R, aV_L, aV_F; and precordial chest leads

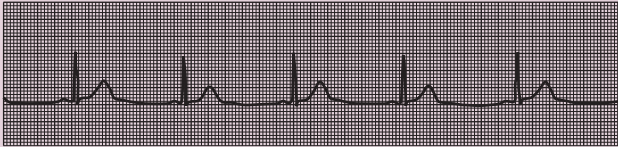

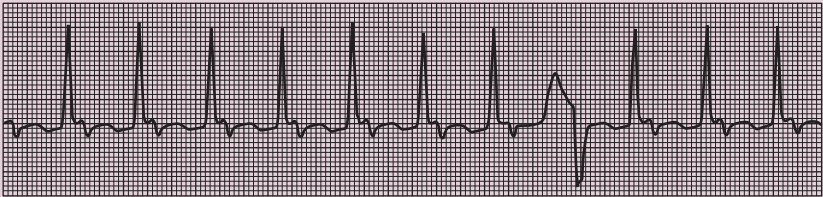

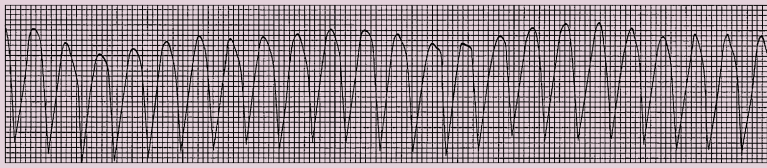

FIG 44-7 Normal ECG waveform. (From Pagana KD, Pagana TJ: Mosby's manual of diagnostic and laboratory tests, ed 4, St Louis, 2010, Mosby.)

TABLE 44-4 Common Basic Cardiac Dysrhythmias

Rhythm Characteristics	Appearance	Clinical Significance
<p>Sinus tachycardia: Regular rhythm, rate 100-180 beats/min, normal PQRS complex</p>	 <p><i>From Wellens HJJ, Conover MB: The ECG in emergency decision making, ed 2, Philadelphia, 2006, Saunders.</i></p>	Normal response to exercise, emotion, pain, fever, hyperthyroidism, and certain drugs
<p>Sinus bradycardia: Regular rhythm, rate less than 60 beats/min, normal P, PR interval, and QRS complex</p>		Associated with decreased cardiac output, dizziness, syncope, and chest pain
<p>Premature ventricular contractions (PVCs): Irregular rhythm followed by compensatory pause</p>		Caused by irritable focus; if more than 6 beats/min or in pairs, indicates increased ventricular irritability
<p>Ventricular tachycardia: Rhythm slightly irregular, rate 100-200 beats/min, P wave absent, PR interval absent, QRS complex wide and bizarre</p>		Often a forerunner of ventricular fibrillation; may cause decreased cardiac output because of decreased ventricular filling time

V₁ to V₆. Because the leads are specific to portions of the anatomy of the heart, abnormalities in conduction help determine which part of the heart has sustained damage. Although a 12-lead ECG is considered diagnostic, a 3- or 5-lead ECG is considered interpretive (see Fig. 44-7).

Three- or five-lead ECG tracings are used during emergencies and pacemaker insertion. In a three- or five-lead procedure, one electrode is substituted sequentially for the six chest electrodes. For diagnostic procedures requiring a continuous ECG recording over an extended period of time, use a Holter monitor. A Holter monitor is a small, portable device that records electrical activity of the heart for up to 24 hours. The ECG is recorded on magnetic tape or in a digital record and monitors cardiac rhythm during activity, rest, and sleep.

Delegation and Collaboration

The skill of obtaining an ECG reading can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Immediately notify the nurse if the patient states any chest pain or appears anxious.

Equipment

- 12-lead ECG machine
- ECG leads and electrodes (self-stick adhesive)
- Electrode gel (*optional*)
- Alcohol wipes
- Hair clippers (*optional*)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Verify type of ECG ordered. 2 Determine rationale for obtaining ECG (e.g., baseline assessment or diagnostic [chest pain]). 3 Assess patient's level of understanding of procedure, including any concerns. 4 Assess patient's ability to follow directions and remain still in supine position. | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>If ECG is ordered for active chest pain, test must be performed immediately.</p> <p>Determines extent of instruction and level of support required.</p> <p>Provides clear, accurate recording without electrical artifacts, which distort wave form.</p> |
|---|---|

STEP

RATIONALE

NURSING DIAGNOSES

- Acute pain
- Anxiety
- Deficient knowledge regarding procedure
- Fear

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient tolerates procedure without anxiety or discomfort.
 - Clear recording of ECG waveform is obtained.

Appropriate preparation decreases anxiety.
 Normal ECG waveform (see Fig. 44-7) consists of P, Q, R, S, and T waves plotted on graph paper. Each small block on graph paper measures 0.04 second. A “normal” ECG waveform demonstrates the following:
 PR interval = 0.12 to 0.20 second
 QRS width = less than 0.10-second QT interval = less than 0.38 second
 ST segment is isoelectric (on same horizontal level as PR interval)
 Provides privacy.

- 2 Close room door or bedside curtains.

IMPLEMENTATION

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare patient identifiers with information on patient's identification bracelet.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
- 2 Perform hand hygiene.

Reduces transmission of microorganisms.
- 3 Remove or reposition patient's clothing to expose only patient's chest and arms. Keep pelvis and thighs covered.

Facilitates correct placement of cardiac leads.
 Minimizes patient's embarrassment. Improper lead placement produces electrical artifact, which requires repeating test (Chernecky and Berger, 2008).
- 4 Place patient in supine position.

Exposes patient for lead placement.
- 5 Instruct patient to lie still without talking (12-lead ECG only) and to not cross legs.

Body movement produces artifact, which necessitates repeating test (Chernecky and Berger, 2008).
- 6 Clean and prepare skin; wipe sites with alcohol. It is often necessary to clip hair from chest if large amounts are present. In patients who are very thin and emaciated, it is difficult to secure electrodes because of bony structure and decreased amount of subcutaneous tissue.

Skin preparation helps remove oils that prevent adherence of electrodes.
- 7 Apply self-sticking electrode, being careful to use pressure on perimeter only, and attach leads. (If self-sticking leads are not available, apply electrode paste to skin before attaching leads.)

Position of leads promotes proper display of ECG on paper. Pressure on center of lead displaces electroconductive gel and results in poor tracing.

 - a **For 12-lead ECG:**
 - (1) Chest (precordial leads) (Fig. 44-8):
 - (a) V_1 —Fourth intercostal space (ICS) at right sternal border
 - (b) V_2 —Fourth ICS at left sternal border
 - (c) V_3 —Midway between V_2 and V_4
 - (d) V_4 —Fifth ICS at midclavicular line
 - (e) V_5 —Left anterior axillary line at level of V_4 horizontally
 - (f) V_6 —Left midaxillary line at level of V_4 horizontally
 - (2) Extremities: one lead on each extremity. Place on lower portion of each extremity, avoiding any bone prominences.
 - (a) aV_r —Right wrist
 - (b) aV_l —Left wrist
 - (c) aV_f —Left ankle
 - (d) aV_7 —Right ankle

Proper position of leads promotes accurate display of ECG on paper.

Positioning of leads in this manner produces fewer artifacts.

STEP

RATIONALE

- 8 Turn on ECG machine, enter required demographic information into computer, and obtain tracing.
- a Simultaneous 12-channel recording:**
Enter patient's name and medical record number into ECG machine menu. Obtain test tracing.
- Reposition leads as needed. Activate machine to obtain simultaneous tracing of all 12 leads. If patient experiences chest pain, document occurrence on ECG printout.
- b Three or five-lead recording:**
- (1) After placing limb electrodes, apply electroconductive gel over V₁ to V₆ locations (described previously).
 - (2) Turn lead selector to lead "1," turn on machine, and begin recording. If tracing is clear, run sequential 6-second tracings for leads I, II, III, aV_R, aV_L, and aV_F by turning lead selector to corresponding settings.
 - (3) Stop machine, position V electrode over V₁ position, and run a 6-second tracing. Repeat sequentially by moving V electrode over V₂, V₃, V₄, V₅, and V₆ positions.
- c For continuous interpretation/monitoring:**
- (1) Apply limb electrodes. Apply electroconductive gel over location for single chest lead where designated by agency policy or as ordered.
 - (2) Maintain either two upper limb electrodes (3-lead), or four limb electrodes (5-lead).
- 9 Disconnect leads and wipe off excess electrode paste from chest. If serial tracings are expected, some cardiologists will have you mark where leads were placed to ensure subsequent tracings from same electrode sites.
- 10 Deliver ECG tracing to appropriate laboratory or health care provider. Provide any previous ECG tracings.

Transfers electrocardiac conduction to ECG tracing paper for subsequent analysis by cardiologist.

Chest pain experienced during study is often correlated to arrhythmia on ECG (Pagana and Pagana, 2010).

Promotes comfort and hygiene.

Provides for review of ECG by cardiologist. Comparison with previous readings helps to detect abnormalities.

FIG 44-8 Anatomic placement of precordial leads. (From Monahan F et al: Phipps' medical-surgical nursing: health and illness perspectives, ed 8, St Louis, 2006, Mosby.)

STEP

RATIONALE

EVALUATION

- 1 Although procedure is painless, it is important to note and document if patient is experiencing any chest discomfort during ECG recording.

Helps correlate ECG changes to symptoms of chest pain.

Unexpected Outcomes

- 1 ECG cannot be interpreted because of absence of tracing in one or more leads; presence of electrical artifact in tracing.
- 2 Patient has chest pain or anxiety.

Related Interventions

- Inspect electrodes for secure placement.
- Reposition any leads that move as result of patient breathing or movement or vibrations in environment and repeat tracing.
- Remind patient who moves that it is necessary to lie still to obtain an accurate tracing.
- If artifact looks like 60-cycle interference (looks like very thick-lined waveform), unplug battery-operated equipment in room one item at a time to see if interference disappears. NOTE: 60-cycle interference is rare.
- Continue to monitor.
- Reassess factors contributing to anxiety.
- Follow specific postprocedure orders related to findings.
- Notify health care provider.

Recording and Reporting

- Record when ECG was obtained (date and time) and where tracing was sent, rationale for obtaining ECG (e.g., pain, discomfort, before surgery, after surgery), and baseline vital signs. Include rhythm strip in patient's chart (check agency policy).
- Report any arrhythmias or patient chest pain to health care provider immediately.

activities and occurrence of chest pain help to diagnose condition). Also inform patient that the Holter monitoring interpretation will be available in a few days.

Gerontologic

- Be aware that medications such as antiarrhythmics can affect results.

Special Considerations

Teaching

- If Holter monitoring is being used, instruct patient to maintain an accurate diary of activities (detailed documentation of

Critical Thinking Exercises

Mr. Hall, a 67-year-old African-American, is a retired executive. He is scheduled for a cardiac catheterization under moderate sedation. Currently he is taking warfarin (Coumadin). The order for the procedure faxed from the health care provider's office lists "new-onset chest pain" as the clinical indication for the procedure.

- 1 Which laboratory data would you review as part of your preparation of Mr. Hall for his procedure?
- 2 Describe the steps you would take to perform patient verification safety procedures for Mr. Hall.
- 3 Cardiac catheterization often involves the use of intravenous moderate sedation. The health care provider has not requested the presence of an anesthesiologist during the procedure. You are responsible for verifying Mr. Hall's ASA classification before the procedure. Which ASA classification would you consider appropriate for Mr. Hall?
 - 1 ASA 1
 - 2 ASA 2
 - 3 ASA 3E
 - 4 ASA 4
 - 5 ASA 5E
 - 6 ASA 6

- 4 When you review Mr. Hall's chart, you see that the consent form for the procedure is unsigned. When you ask him whether the health care provider explained the procedure and the risks and asked if he had any questions, he replies, "My doctor told me that I needed this to find out why my chest pain is happening. But I don't know how risky it is." What would you do?
- 5 Mr. Hall's cardiac catheterization procedure is finished. The right femoral site was used for catheter insertion. Which items take priority in your postprocedure assessments of Mr. Hall?
 - 1 Heart rate and rhythm, respiratory effort, oxygen saturation/end-tidal CO₂, procedure site for bleeding control, pedal pulses
 - 2 Blood pressure, pain level, neurologic checks, complete blood count, electrolytes
 - 3 Pupil checks, level of consciousness, breath sounds, bowel sounds
 - 4 Level of consciousness, pain level, neurologic checks, and oxygen saturation/end-tidal CO₂ levels

 REVIEW QUESTIONS

- 1 The registered nurse is reassessing a patient who is recovering after a cardiac catheterization via a femoral artery approach. Which set of postprocedure assessment data should be reported immediately to the physician?
 - 1 Increase in heart rate from 92 to 116 beats/min and low back pain radiating to the sides
 - 2 Occasional premature ventricular contractions (PVCs) and mild tenderness at catheter insertion site
 - 3 Urine output of 40 mL in the first hour after catheterization and decrease in oxygen saturation from 99% to 96%
 - 4 Bloody drainage visible at the edge of the dressing
- 2 On the urologic unit each of the registered nurse's patients is scheduled for an intravenous pyelogram. For which patient is this procedure contraindicated?
 - 1 The patient with renal insufficiency
 - 2 The patient with a urinary tract infection
 - 3 The patient with possible kidney stones
 - 4 The patient with only one kidney
- 3 The nurse is helping a patient who has just had a paracentesis performed. Which assessment data indicate that the desired results from the procedure have occurred?
 - 1 Increased abdominal girth, decreased respiratory effort, increased respiratory rate
 - 2 Increased abdominal girth, increased respiratory effort, decreased respiratory rate
 - 3 Decreased abdominal girth, decreased respiratory effort, decreased respiratory rate
 - 4 Decreased abdominal girth, increased respiratory effort, increased respiratory rate
- 4 The nurse is providing a 77-year-old male instructions about how to prepare for his colonoscopy next week. Which information should be included in his instructions?
 - 1 Eat only soft foods for 3 days before the day of the procedure. Administer a cleansing enema in the morning before the test. Consume no food or fluids for 4 hours before the procedure.
 - 2 Have a full-liquid diet the day before the procedure. Drink a bowel-cleansing preparation the night before the procedure. Take the prescribed antibiotic the morning of the procedure.
 - 3 No diet modifications are needed in the days before the procedure. Fast from food and fluids, except for medications, the night before the procedure. Have a bowel movement the morning before the procedure.
 - 4 Consume clear liquids the day before the procedure. Complete the bowel preparation the afternoon and evening before the procedure. Fast from food and fluids for 8 hours before the procedure. Take only medications that are ordered by the physician the morning of the procedure.
- 5 Place the steps listed here in the correct order for helping a patient who is undergoing a lumbar puncture.
 - 1 Help patient maintain lateral recumbent position with head and neck flexed.
 - 2 Properly label specimen in presence of patient.
 - 3 Assess patient's condition during procedure.
 - 4 Take "Time-Out" to verify patient's name, type of procedure scheduled, and procedure site.
 - 5 Explain to patient that pain may occur when lidocaine (local anesthetic) is injected into the site.
 - 6 Record the opening intracranial pressure; observe fluid for color.
- 6 You are caring for a patient before a colonoscopy. The patient asks if he can ask you questions during the procedure. Your best response would be which of the following?
 - 1 "You'll be receiving a sedative that will make you sleep throughout the procedure."
 - 2 "You'll actually be awake throughout the procedure and can ask questions at any time."
 - 3 "You'll be awake during the procedure but not able to talk; so let me go over some nonverbal signs you can use to communicate with us."
 - 4 "You'll be relaxed and able to talk with us, but you won't remember the discussion."
- 7 A patient underwent a bronchoscopy and is now entering the recovery area. The patient develops sudden, severe shortness of breath. You should take which of the following set of actions?
 - 1 Monitor SpO₂ and lower head of procedure table.
 - 2 Support patient's airway, call physician immediately, and prepare for possible resuscitation.
 - 3 Measure vital signs and prepare for administration of intravenous (IV) fluids.
 - 4 Observe for blood-tinged mucus, suction airway, and lower head of procedure table.
- 8 You are caring for a patient who has undergone conscious sedation for a cardiac catheterization. Which criteria below best represent what you measure to determine the patient's response to sedation?
 - 1 Complete blood count (CBC) level, hydration status, and respiratory rate
 - 2 Femoral pulse, end-tidal carbon dioxide (CO₂), and gag reflex
 - 3 Heart rate, arterial oxygen saturation (SpO₂), and level of consciousness
 - 4 Prothrombin time, SpO₂, and respiratory rate
- 9 When preparing a patient for a 12-lead electrocardiogram (ECG), it is necessary to apply six precordial chest leads. Match the lead on the left with the correct position on the right.
 - 1 V₁ ___ a Fifth intercostal space (ICS) at midclavicular line
 - 2 V₂ ___ b Left midaxillary line at level of V₄ horizontally
 - 3 V₃ ___ c Left anterior axillary line at level of V₄ horizontally
 - 4 V₄ ___ d Fourth ICS at right sternal border
 - 5 V₅ ___ e Midway between V₂ and V₄
 - 6 V₆ ___ f Fourth ICS at left sternal border
- 10 Which of the following patients would be unable to undergo an angiogram? (Select all that apply.)
 - 1 44-year-old female who is taking warfarin (Coumadin)
 - 2 52-year-old male suspected of having an abdominal aneurysm
 - 3 77-year-old female who is suspected of having an arterial occlusion of the renal artery
 - 4 65-year-old female who is 30 weeks' pregnant

Answer Key

CHAPTER 1

Answers to Critical Thinking Questions

- 1 Does a (I) low carbohydrate diet compared with a (C) high carbohydrate diet affect (O) gastrointestinal symptoms of (P) adult patients with inflammatory bowel disease (T) within 3 months?
- 2 A systematic review is a summary of all evidence that exists regarding a particular clinical problem or issue in the literature. Basically a researcher has asked a PICOT question and then examined all of the well-designed relevant randomized controlled trials (RCTs) that ask the same question. A systematic review explains if the evidence exists for a practice change.
- 3 A case control study

Answers to Review Questions

- 1 The correct order is 5, 1, 6, 4, 2, 3.
- 2 **Rationale:** In this case the knowledge that there is new information about wound care triggers a question about antiinfection solutions. The trigger was not a result of a problem or trend on the nurse's unit. Peer focused and PICOT focused are not triggers for questions.
- 3 **Rationale:** Question four has the primary components of an identified patient population (P), the intervention thought to be worthwhile (I), and a desired outcome (O). The question also has a comparison intervention. Questions 1 and 2 have no outcome. Question 3 has no population or area of interest.
- 4 **Rationale:** This is an example of a problem (i.e., lower patient satisfaction scores), triggering interest in a question for EBP.
- 5 P—female obstetric patients, I—hourly rounding, C—none, O—perception of nursing care or patient satisfaction, T—none.
- 6 **Rationale:** Qualitative studies examine individuals' experiences with health problems or life experiences and the contexts in which the experiences occur. These studies would be helpful in the nurse's review.
- 7 **Rationale:** The best outcome measure to detect a change in pain acuity is the patient's report of pain severity. Ability of patients to follow coaching or the time it takes to perform guided imagery is not an outcome that determines if guided imagery was effective. Frequency of using pain medication can be an outcome to measure a patient's pain experience, but it is not the best measure of pain acuity.
- 8 **Rationale:** A background question is broad and general. When the question is answered, it provides general knowledge. In contrast, a foreground question such as the other three examples is relevant to a specific practice issue.
- 9 **Rationale:** It is important to build staff support for the EBP process by educating all involved and keeping staff informed. It is best to involve all staff, using an interdisciplinary approach when possible. Do not involve all staff in data collection. Involve only a few who can collect data consistently in the same way.
- 10 **Rationale:** Resources for implementation of an EBP change include staff from all disciplines (as appropriate) and administrative support and costs of the implementation. Accuracy of the device is not a resource but a clinical factor that should be addressed in your literature review supporting use of the device. Patient satisfaction could be an outcome measure that you choose to include in the pilot.

CHAPTER 2

Answers to Critical Thinking Exercises

- 1 Additional information that would be helpful as you assume care for Mrs. Hampton includes:

- Level of consciousness and findings from neurologic assessment.
 - Patient's medical history, including medications; information regarding any recent changes in medication or treatment plan.
 - Blood glucose level, home insulin schedule and dosages, whether home insulin was administered before presenting to hospital.
 - Results of any testing completed such as computed tomography (CT) scan of head or magnetic resonance imaging (MRI).
 - Patient's plans or expectations for discharge (e.g., plans to return home with assistance of husband).
 - Referrals that have been made for physical therapy and speech therapy.
 - Discharge planning that has been started by the discharge planner or case manager.
- 2 You introduce yourself to Mr. and Mrs. Hampton, explain that you are the nurse who will be caring for Mrs. Hampton during the day shift, and accompany them to the assigned room. Orient them to the room and help put Mrs. Hampton's belongings away after making sure that all of her personal belongings were brought with her. Show the Hamptons the call light system and how to get help if needed. Provide Mr. Hampton with a comfortable chair and support his interactions with his wife. Allow Mr. Hampton to participate in Mrs. Hampton's care to the extent that he is comfortable. Reinforce the reasons for the transfer and answer any questions that the Hamptons have about it. Allow them the opportunity to express their anxiety about the move from the intensive care unit.
 - 3 Ask Mr. Hampton to bring a copy of the advance directive to the hospital. Notify the health care provider that Mrs. Hampton has an advance directive. Document in the medical record the presence of an advance directive and the request made for Mr. Hampton to bring the document to the hospital. Ask Mrs. Hampton to explain the substance of the advance directive to determine her understanding of it. Place a copy of the advance directive in the medical record.
 - 4 Recognize that Mr. Hampton's anxiety is normal and allow him to express his concerns related to taking his wife home. Ask Mr. Hampton about family or other help that is available. Have him describe the home and identify which problems may be related to Mrs. Hampton's mobility and risk for falls. Discuss with Mr. Hampton changes that can be made in the home to improve safety (e.g., removal of throw rugs, having grab bars installed in the bathroom at the toilet and tub (see Chapter 41). Have the discharge planner or case manager work with Mr. Hampton to get the home equipment that is needed to help Mrs. Hampton bathe and navigate through her home. Get confirmation from physical therapy that Mrs. Hampton uses her walker correctly.

Answers to Review Questions

- 1 **Rationale:** The nurse is responsible for identifying allergies and, if present, places an allergy band on the patient. It is also the nurse's role to clarify the specific details pertaining to the patient's advance directive. All the other activities may be done by the admission clerk.
- 2 **Rationale:** The discharge planning process is comprehensive and multidisciplinary, including representatives from all the services who provided care.
- 3 **Rationale:** The patient's current status must be accurate to anticipate the needs that may occur during the transfer or discharge.
- 4 **Rationale:** Toddlers do better in unfamiliar settings when they have items that they are used to having to comfort them. They also think in the present; thus having something they can hold onto is most important. The other information from the parents regarding the child's rituals and preferences is important but might not be used, depending on the child's medical needs.

- 5 3 **Rationale:** Matching the services provided at the skilled care facility provides the best referral for the individualized needs of the patient. This assists with promoting positive patient outcomes.
- 6 2 **Rationale:** Respecting and understanding the patient's health beliefs and customs leads to the development of an individualized plan of care for patients with different cultures, religions, and beliefs.
- 7 2 **Rationale:** Introducing yourself as the nurse and other staff and orienting the patient should be completed to ensure some reduction in patient anxiety with his or her new surroundings. Other components of the admission process are completed as appropriate to the patient's needs and condition.
- 8 1 **Rationale:** When a patient in any type of unit or facility leaves without a written order from his or her health care provider, it is defined as *against medical advice*.
- 9 Transitional care is defined as nursing actions implemented to ensure coordination and continuity of care for patients who are transferring between different care settings or care levels.
- 10 3 **Rationale:** The Joint Commission suggests a reading level of fifth grade or below for all written documents used for patient teaching and information.

CHAPTER 3

Answers to Critical Thinking Exercises

- 1 Ensure that the environment is quiet and free from disturbance. Show empathy and respect, speak slowly and clearly, and face the patient when speaking to her. Give the patient time to process and respond to the information. Obtain an accurate health history; use collateral sources to obtain health information. Perform a mini-mental examination or tool used by your institution to establish a baseline of the patient's cognitive status. Repeat information as needed. Encourage patient to use any form of communication that she feels comfortable using. Avoid arguing with her.
- 2 Pause and consider your feelings and thoughts that are interacting with the cognitively impaired patient. Assess orientation status of patient. Try a calm, firm approach using a comfortable voice. Use simple language. Make sure that patient has hearing aid and/or glasses.
- 3 Strategies useful to communicate effectively with a cognitively impaired patient include use of touch to aid concentration and offer encouragement, pictorial drawings, gestures, and yes-or-no questions.

Answers to Review Questions

- 1 4 **Rationale:** A therapeutic nurse-patient relationship is goal directed. It can also include the need to help a patient discuss any pertinent topics, whether comfortable or uncomfortable.
- 2 1 **Rationale:** Therapeutic communication is goal directed, which in this situation is better pain management for the patient.
- 3 3 **Rationale:** The use of "why" questions may cause defensiveness in the patient and hinder communication. The other options promote communication by encouraging the patient to communicate.
- 4 3 **Rationale:** The nurse needs to first assess the level of anxiety so appropriate communication techniques and strategies can be used. The patient may not have the insight to understand what is currently causing his or her behavior.
- 5 2 **Rationale:** Speaking louder and bringing in other team members may be perceived as threatening and may cause the patient's behavior to become out of control faster. The patient may not be aware of his or her behavior; therefore asking about comfort measures to relieve the threatening behavior may also cause him or her to escalate. The nurse may need to leave the room quickly. By positioning himself or herself near the door, he or she should not be trapped by the patient.
- 6 3 **Rationale:** Direct eye contact and excessive touch can be offensive to persons from certain cultures. The patient's right to privacy must be guarded; therefore the use of a medical interpreter provides for correct, confidential communication.
- 7 4 **Rationale:** Patients with anxiety need assistance in clarifying factors that cause the anxiety and coping more effectively. Active

listening helps to identify the source of the anxiety. Meeting basic needs and being nonjudgmental and accepting of feelings is important but not your first step. Ultimately once a cause for anxiety is known, you can help the patient by letting him or her make as many choices about care as possible.

- 8 2 **Rationale:** Distraction is often effective for this type of patient. Strategies that may have worked before may not be as effective now. There is no time to call the family when the patient is already hostile. A show of force could make the patient agitated.
- 9 4 **Rationale:** Even though being positive about the situation is a strategy, this patient is grieving for the loss of his extremity and is depressed. Antidepressant medications are not given initially. The patient needs the opportunity to express feelings, especially anger, which is normal behavior. The health care provider, not the physical therapist, would be consulted about when he would be evaluated for a prosthesis.
- 10 4 **Rationale:** The method of instruction should be based on the patient's preferred method of learning. It can incorporate a variety of methods that would be appropriate for the information being conveyed and how the patient learns best. The other options are either demeaning (option 1), too narrow in scope and closed ended (option 2) or family-centered instead of patient-centered (option 3).

CHAPTER 4

Answers to Critical Thinking Exercises

- 1 Vital signs and glucose testing can be recorded by nursing assistive personnel (NAP) on flow sheets. It is appropriate for the NAP to document repetitive care aspects. As a nurse you must give the NAP specific information as to when you want to be notified about vital sign data (e.g., temperature above 99° F [37.2 C] orally, heart rate greater than 100 beats/min, blood pressure less than 100/70 mm Hg or greater than 130/85 mm Hg, and glucose measurement less than 60 mg/dL or greater than 120 mg/dL). Pain assessment and preoperative teaching must be done and recorded by the nurse.
- 2 You specify in your report to the NAP that he or she is to notify you if there is any change in the pain; if there are any symptoms of hypoglycemia, such as dizziness, pallor, or confusion; and if the patient expresses any lack of understanding about the preoperative teaching.
- 3 Include the following elements: location of pain, description of type of pain, duration, information obtained from palpation of area, pain intensity on a scale of 0 to 10, patient comments, results of pain relief measures.
- 4 Notify the physician using SBAR.
S (Situation): Give patient's name and room number. Give vital signs of 90/50, pulse 110, and respirations 24. Patient is complaining of dizziness and feeling sweaty.
B (Background): Patient history, events leading up to the change in vital signs.
A (Actions taken): Placed patient back in bed.
R (Recommendation): Start IV fluids, apply oxygen, check intake and output.
- 5 Document fully the patient's current understanding of the preoperative teaching. Document return verbalization of understanding or demonstration of teaching to validate that learning has taken place.

Answers to Review Questions

- 1 1, 3, 4 **Rationale:** Documentation is to be entered by the nurse who provided the care or made the observation, not by anyone else.
- 2 3 **Rationale:** Military time is one 24-hour time cycle; thus for this example you would begin with 1200 (noon) and add 4 (four) hours, which adds up to 1600 hours in military time.
- 3 1 **Rationale:** Focus charting begins with the concern or problem being experienced (data), what was done about the problem (action), and the patient's outcome (response).
- 4 3 **Rationale:** The purpose is identification of trends in clinical care.
- 5 3 **Rationale:** SBAR is a standardized approach for transferring information during shift report.

- 6 1 **Rationale:** Because of the complexity of the patient's medical condition and family situation, SBAR documentation provides a framework for cross-discipline communication in an efficient, timely format.
- 7 4 **Rationale:** All nursing care is based on the patient's needs, which are identified during the assessment process. Both objective and subjective data are included but not the nurse's hunches or personal thoughts.
- 8 2 **Rationale:** The information must be focused only on the patient and would show an improvement in the patient's condition. The other options either show a negative situation or are not focused on the patient.
- 9 2 **Rationale:** Whenever unexpected adverse events resulting in injury either to caregivers or the recipients of care occur, an incident report needs to be completed.
- 10 3 **Rationale:** Data should be objective, reflecting the patient's status. Never document in the record that an incident report was completed.

CHAPTER 5

Answers to Critical Thinking Exercises

- The nurse must obtain all admission vital signs. All of the routine vital signs can be delegated. Temperature should be tympanic or temporal because patient is sedated and may not be able to hold an oral thermometer. Blood pressure can be taken on the right arm or leg.
- The NAP reported a change in BP; the priority nursing intervention is for the nurse to immediately obtain a new blood pressure reading and further assess the patient. Once the nurse determines that the patient is indeed stable, other explanations for the differences can be explored. Possible explanations for differences are technique, equipment, and patient-related findings. Technique includes site of blood pressure measurement and whether the nursing assistive personnel (NAP) used the proper method. The nurse may want to observe the NAP's technique in blood pressure measurement. Equipment differences include using a cuff that is too small or an electronic blood pressure machine. An example of a patient-related finding is that the patient was in pain in the emergency department, thus raising blood pressure. After receiving pain medication the blood pressure decreases.
- The NAP was instructed to report any respiratory rate less than 16 immediately. The nurse needs to reinforce that instruction and determine why this directive was not followed. The respiratory rate has likely been affected by the pain medication, which can depress the respiratory center of the brain.
- The NAP should be told to obtain the respiratory rate before waking the patient and taking the blood pressure. A sleepy patient is unlikely to have a respiratory rate of 20. The blood pressure was obtained in the right arm, which had a IV present. The nurse should instruct the NAP to retake the BP and should observe the NAP during this measurement. Therefore the nurse can identify and correct any problems with obtaining the BP.

Answers to Review Questions

- 1, 2 **Rationale:** It is common to find sweat in the axilla of a patient with fever. Drying the axilla helps the probe make better contact with the skin. The axillary route would be best because of the patient's confusion. As with other sites for measuring body temperature, the probe must be held in the appropriate position for maximum contact.
- 2 **Rationale:** With aging cerumen (earwax) tends to be drier and can interfere with an accurate tympanic temperature measurement. The cerumen acts as a barrier; therefore the temperature reading would not be reliable.
- 2 **Rationale:** With increased fluid in the abdomen, the patient's respiratory status can be compromised. For patient comfort and accuracy of assessment, his or her head should be elevated.
- 4 **Rationale:** Crossing the legs can falsely increase the systolic and diastolic blood pressure. The cuff should be on the bare arm, but uncrossing the legs is more important. The other two statements are true but would not necessarily promote an accurate reading.

- 3 is the correct sequencing for obtaining a two-step blood pressure measurement using the brachial artery.
- 2 **Rationale:** Electronic blood pressure measurement devices can be used for the patient with diabetes mellitus. Patients with constant body movement, irregular heart rates, peripheral vascular disease, and seizures are not candidates for use of the electronic blood pressure devices.
- 4 **Rationale:** Older adults are less like to demonstrate a high fever. Heart rate increases with fever, not infection.
- 3 **Rationale:** Abnormal radial pulse should be rechecked with apical heart rate assessment. The radial pulse may be too weak to count.
- 3, 4 **Rationale:** Pulse deficit should be determined with a 60-second count starting with zero, and any peripheral artery can be used. Both health care providers must count simultaneously.
- 2, 3 **Rationale:** These are American Heart Association definitions of prehypertension, which are systolic values greater than 120 or diastolic values greater than 80.

CHAPTER 6

Answers to Critical Thinking Exercises

- Focused systems assessments would include musculoskeletal (focused on R hip), skin (IV site and surgical wound), cardiovascular and respiratory (postoperative status), abdomen (screening for return of peristalsis), peripheral neurovascular (circulation to affected leg), perineal (catheter insertion site), and intake and output.
 - Key elements of each system:
 - Cardiovascular:* Blood pressure (BP); heart rate (HR); inspection, palpation, and auscultation of the heart
 - Musculoskeletal:* Range of motion and position of affected extremity. ROM will be limited until physician orders activity
 - Peripheral neurovascular:* Inspecting and palpating extremities; checking peripheral pulses, edema, skin color and temperature, capillary refill of nail beds; sensation, movement
 - Respiratory:* Checking rate and depth of respirations, chest excursion, lung sounds
 - Skin:* Condition of skin around IV site. Condition of skin around surgical incision. Presence of pressure areas in dependent body parts
 - Abdominal:* Checking size and shape of abdomen, palpating bladder, assessing bowel sounds
 - Intake and output:* Intake, output (Foley, Jackson-Pratt drain), intravenous site patency
- A crackling noise on inspiration indicates crackles. Crackles indicate fluid in the alveoli and small airways. Priority nursing diagnosis is ineffective airway clearance.
- This indicates a normal heart rate, which is between 60 and 100 beats/min, regular rate and rhythm.
- The nurse must listen for 5 minutes over each quadrant before deciding that bowel sounds are absent. It is common for bowel sounds to be hypoactive for 24 hours or more after surgery.
- See Skill 6-4 for specifics. Unilateral leg edema is one of the most reliable findings of deep vein thrombosis. Other symptoms include pain or tenderness, erythema, increased warmth, and firmness of affected area.

Answers to Review Questions

- 4 **Rationale:** Palpation or percussion of the abdomen can cause bowel sounds to be heard, although peristalsis can be absent. All the other responses are correct.
- 3 **Rationale:** Comparison of areas side to side is extremely important in evaluating a patient's neurologic system. This prevents omissions between the affected and unaffected areas.
- 2 **Rationale:** Diarrhea would be accompanied by hyperactive bowel sounds, and because so much fluid had already been lost, the urine would be darker, therefore concentrated.
- 3 **Rationale:** Having the patient breathe deeper enables the nurse to fully assess lung sounds in the bases of his or her lungs.

- 5 780 mL **Rationale:** 3 ounces = 90 mL (orange juice) + 120 mL (milk) + 90 mL (popsicle) + 360 mL (cola) + 120 mL ice (ice is calculated as half its volume).
- 6 1, 5 **Rationale:** The general survey includes assessment of vital signs, height and weight, general behavior, and appearance.
- 7 3 **Rationale:** A lesion colored blue/black or with variegated, nonuniform pigmentation or variations/multiple colors (tan, black) with areas of pink, white, gray, blue or red may indicate melanoma.
- 8 4 **Rationale:** The sounds are abnormal. Crackles sound like crushing cellophane; rhonchi sound like blowing air through fluid with a straw. Wheezes are musical.
- 9 4 **Rationale:** S₁ and S₂ are normal components of the cardiac cycle and an expected physical assessment finding.
- 10 2, 3, 4, 1 **Rationale:** Percussion and palpation are completed after inspection and auscultation because of the risk for causing increased bowel sounds that could be interpreted as an abnormal finding.

CHAPTER 7

Answers to Critical Thinking Exercises

- 1 Joe should wash his hands with soap and water and put on gloves to continue his assessment, explaining the rationale for this to Mr. Nesbitt. He should put Mr. Nesbitt on contact precautions because the drainage from his sacral wound may contain pathogens. His gloves should be changed if they become soiled.
- 2 After assessing the wound, if his gloved hand contacted it, it would be necessary to remove the gloves, perform hand hygiene, and reglove before checking the Foley catheter, especially if he touched the catheter. However, gloves would not be necessary to visually inspect the position and condition of the tubing. Hand hygiene should be performed when Joe leaves the patient's room.
- 3 Contact precautions do not require use of a mask. However, if the nurse has a respiratory infection, he or she might choose to wear a mask to protect the patient from exposure.

Answers to Review Questions

- 1 4 **Rationale:** Soap and water are essential for visibly dirty hands according to the Centers for Disease Control and Prevention.
- 2 2 **Rationale:** Lathering the hands with the cleaning agent using friction is the best method to remove dirt and transient bacteria.
- 3 1, 2, 3, 4, 5 **Rationale:** All of the first five factors relate to patient/family needs, the type of isolation devices needed, and organizing nursing care. Item 6 does not impact the delivery of nursing while on isolation precautions.
- 4 2 **Rationale:** A mask provides a barrier when the patient has droplet precautions.
- 5 3, 4 **Rationale:** Gowns are used once and discarded because of the chance of being contaminated. Hand hygiene should always be performed before and after going into a room.
- 6 1 **Rationale:** Microorganisms causing pneumonia exist in droplets of mucus and do not remain suspended in air; therefore they can be spread by direct contact with secretions, especially by unclean hands.
- 7 1, 2 **Rationale:** Gloves form a barrier that prevents entrance of microorganisms on the nurse's hands into the urinary device and protects the nurse from exit of microorganisms in the urine.
- 8 2 **Rationale:** Soap and water flush spores from hands more efficiently.
- 9 4 **Rationale:** Health care worker's hands are the greatest source of microorganisms.
- 10 3 **Rationale:** Explaining the reason for isolation and answering questions relieve patient's anxiety.

CHAPTER 8

Answers to Critical Thinking Exercises

- 1 Insertion of an indwelling urinary catheter requires wearing sterile gloves. Clean gloves are used for nasogastric tube and oral cavity suction. No gloves are necessary to measure blood pressure.

- 2 Ask Mrs. Lorenzo if she has an allergy to latex or if she has ever had a previous reaction to the following items within hours of exposure: adhesive tape, dental or face mask, golf club grip, ostomy bag, rubber band, balloon, bandage, elastic underwear, IV tubing, rubber gloves, condom. Use latex-free products when caring for Mrs. Lorenzo.
- 3 Nothing. Only 2.5 cm (1 inch) from the border of the drape to the edge is considered contaminated.

Answers to Review Questions

- 1 2 **Rationale:** The pair of synthetic gloves affords some protection from the latex. All other options offer no protection.
- 2 2 **Rationale:** The area below the waist is more likely out of direct vision and can become contaminated easier by contact with a nonsterile surface.
- 3 1 **Rationale:** The inside of the glove becomes unsterile when it comes in contact with the ungloved hand.
- 4 4 **Rationale:** Individuals with spina bifida are at risk for latex allergy; thus the nurse should use a nonlatex catheter and nonlatex gloves. Individuals with spina bifida who have a latex sensitivity may also be allergic to bananas, avocados, kiwi fruit, and tomatoes, but not eggs.
- 5 3 **Rationale:** The label of the bottle should be facing the student's palm so it does not become distorted or ruined if fluid runs down the bottle.
- 6 1 **Rationale:** Provides steam under pressure, the most effective means of sterilizing instruments and packaged dressings.
- 7 1 **Rationale:** When a nurse is sick and needs to get close to an open wound of a patient whose immune system is not functioning well, it is appropriate to ask someone else to change the dressing rather than put the patient at risk. This is the best answer and the only one that keeps the sick nurse away from the patient.
- 8 3 **Rationale:** Opening the first flap toward the nurse would require the nurse to reach over the sterile field to completely open the pack. The flap should open away from the nurse.
- 9 "position" **Rationale:** The NAP can be most effective by helping the patient assume and maintain the position that the nurse needs to perform the procedure.
- 10 1, 3, 4 **Rationale:** Procedures listed invade sterile body cavities.

CHAPTER 9

Answers to Critical Thinking Questions

- 1 Additional information may include the following: vital signs, transfer restrictions until CT scan performed, ability to move hands and arms, presence of paralysis, level of orientation and alertness (cognitive status), and patient's level of comfort.
- 2 1, 2, and 3 are correct answers. Mr. Clark is in pain most likely related to his lacerations and fractures. Pain management is a priority at this time. In addition to pain management, explaining to Mr. Clark the purpose of the CT scan helps elicit his cooperation. He is most likely fearful of movement because of his pain and uncertainty of his condition. Describing the method of transfer and showing him that there will be additional personnel to help transfer him to the stretcher increases his trust and cooperation. Option 4 is incorrect. You may inform Mr. Clark that it is a health care provider's order, but the patient has the right to refuse treatment. You are more likely to elicit Mr. Clark's cooperation by determining the underlying reasons for his refusal to transfer.
- 3 Mr. Clark should be logrolled until the results of the CT scan have been determined. A nurse must supervise and aid NAP and all personnel when log rolling a patient with a spinal cord injury to keep the spinal column in straight alignment to prevent further injury.
- 4 Considering his weight and injuries, a slide board with the assistance of three caregivers should be used. Appropriate transfer equipment (such as a slide board) in combination with proper body mechanics reduces the risk of injuries to health care providers.

Answers to Review Questions

- 1 3 **Rationale:** The three-person lift for horizontal transfer from the bed to the stretcher is no longer recommended. Physical stress can be decreased significantly by using a slide board.

- 2 3 **Rationale:** Keeping the knees bent allows for better balance and leverage; keeping the trunk erect helps prevent muscle fatigue because the muscles are working together.
- 3 3 **Rationale:** A transfer belt is contraindicated around the patient's waist after abdominal surgery. It is far better to have the patient sit on the side of the bed dangling for a few minutes with the nurse there to allow for a smoother transition from supine to upright position for the first time. This also allows the nurse to assess for orthostatic hypotension.
- 4 2 **Rationale:** The patient's pain may be at a level at which he does not want to move. There are no data to support any of the other options.
- 5 2 **Rationale:** The patient's skeleton must be kept in alignment, which requires the patient to be turned as a total unit, using enough staff for the turning and positioning. The patient should not participate in the activity because of the instability of the spinal cord.
- 6 2 **Rationale:** Rebound hypertension would result after prolonged bed rest. There is no indication that the patient is experiencing difficulty with proprioception. There is no indication that the patient has pathology related to the central nervous system.
- 7 4 **Rationale:** Because of the patient's weight and limited ability to bear weight, a ceiling lift provides the best and safest technique to transfer this patient. A transfer board is used when transferring a patient from a bed to stretcher. A stand-assist device requires the patient to possess full weight-bearing capacity. A three-person carry is inappropriate and no longer recommended.
- 8 2 **Rationale:** By logrolling and moving the patient as a unit, the nurse prevents twisting and damage to the unstable spinal cord. The step-by-step method causes twisting and bending of the spine, causing further damage. The patient should remain nonweight bearing to prevent further damage to the injured spine. The use of a mechanical lift poses the risk of twisting and bending the spine during transfer.
- 9 4 **Rationale:** Spacing your feet farther apart allows you to widen your base of support. Leaning back shifts your center of gravity and causes a decrease in stability. Tensing and tightening back muscles could cause back strain. Keeping your knees in a locked position is not correct body mechanics—maintain trunk erect and knees bent so multiple muscle groups work together.
- 10 4 **Rationale:** A slide board is the most appropriate method to transfer this patient. Carefully assessing the need for additional assistance and the patient's ability to help provides better protection from injury than body mechanics alone.

CHAPTER 10

Answers to Critical Thinking Questions

- Mr. Timber reports a pain level of 8 on a scale of 0 to 10. A nursing priority is to provide pain management strategies and lower his level to an agreed-on range. In addition, Mr. Timber may have concerns about his ability to safely ambulate without falling or injuring himself. Spending time with him and explaining about and demonstrating the use of crutches will help to minimize his anxiety and concerns.
- To minimize the effects of orthostatic hypotension allow Mr. Timber to sit with the head of the bed elevated for several minutes before dangling him on the side of the bed. During dangling instruct him to take several deep breaths and move his feet up and down and in a circular motion to promote venous return via intermittent contraction and relaxation of the skeletal leg muscles.
- Assess the safety of the CPM machine by inspecting the electrical cord for fraying and damage. In addition, put the CPM machine through one full cycle before applying to patient to ensure that the machine is functioning properly. Assess the setup of the machine before placing on the patient's bed: check the stability of the frame, the flexion/extension controls, the padding to exposed metal parts or hard surfaces, and the on/off switch.
- The appropriate crutch gait for Mr. Timber is the three-point alternating, or three-point gait, which requires the patient to bear all of his weight on one foot. Several teaching considerations are needed for

Mr. Timber. It is important that these considerations are individualized to meet his learning needs. Some examples of teaching considerations for Mr. Timber are the following:

- Instruct patient with axillary crutches about the dangers of pressure on the axillae, which occurs when leaning on the crutches to support body weight.
- Explain why patient must use crutches measured for him or her.
- Demonstrate how to routinely inspect crutch tips. Rubber tips should be securely attached to the crutches. When tips are worn, they should be replaced. Rubber crutch tips increase surface friction and help prevent slipping.

Answers to Review Questions

- 2 **Rationale:** Range-of-motion exercises are done only until resistance is met, not until pain is felt by the patient.
- 4 **Rationale:** Risk for activity intolerance is common for patients who have been immobile for a period of time and are beginning to exert more energy. This diagnosis places the patient initially at risk when exercise begins to increase.
- 3 **Rationale:** If a blood clot is suspected in a leg, the patient should be kept calm and quiet in bed, and the nurse should inform the physician. There should be no rubbing or movement of the leg. The elastic stockings and sequential compression devices are for prevention and, if a DVT is suspected, the health care provider should be notified immediately.
- 3 **Rationale:** NAP can make sure that the patient's environment is free from potential threats to patient safety such as spills or clutter.
- 4 **Rationale:** The nurse stands on the patient's right side or strong side for support.
- 3 **Rationale:** By changing the heel size, the patient's height will be either higher or lower than when the height of the crutches was adjusted initially. Two-to-three fingers should fit between the axilla and the crutch, and the elbow should be slightly bent for proper fit.
- 1 **Rationale:** When a patient is using a supportive device such as a cane, the nurse stands on the weak side. The patient's cane would be in the right hand since the weakness is on the left.
- 4 **Rationale:** The arms of the chair are more stable to use when standing. The walker could tip over. Rocking the patient works when another person is helping to stand a patient. Moving toward front or edge of chair helps make it easier to stand.
- 4 **Rationale:** The patient should always be checked first, before equipment or implementing any treatment.
- 1, 3, 4 **Rationale:** Pallor, nausea, and dizziness are all signs of orthostatic hypotension. Bradycardia is incorrect; tachycardia is actually a symptom. Irritability is not a classic sign of the condition.

CHAPTER 11

Answers to Critical Thinking Exercises

- The correct answer is C. A fiberglass cast sets up and is dry in 15 to 20 minutes, so it is not necessary to prevent indentation nor does the cast remain damp after that time period. A plaster of Paris cast will take much longer and is susceptible to indentation and dampness and the need to assist in the drying process.
- The correct answer is B. The patient is receiving pain medication, and the assessment data indicate muscle spasms. You do not release the traction because the traction is in place to reduce the muscle spasms.
- The correct answer is D. A heating pad would increase the swelling at this point. The key data are increased swelling and pain that is out of proportion to what is expected, given that she is being medicated and the extremity is elevated. The concern is compartment syndrome and altered neurovascular status. To bivalve the cast, cut it in two lengthwise along each side. In addition, the wadding underneath is cut to relieve the pressure. Although a window may be cut in a cast to visualize a wound underneath, it does not relieve pressure. Typically, wrist fractures are initially placed in an ace and splint configuration to accommodate initial swelling.

Answers to Review Questions

- 1 2 **Rationale:** A plaster cast needs to breathe and should not be covered. Exposure to water causes the cast to crumble. Sharp edges should be covered with tape or moleskin to prevent skin damage.
- 2 2 **Rationale:** The first step involves positioning. Then explaining before using the saw will decrease anxiety. The skin must be inspected for integrity before using an enzyme wash.
- 3 2, 4 **Rationale:** Shaving can create micro nicks that can become inflamed under traction. The boot should fit snugly to prevent slipping. The heel should sit properly in the boot without the need for padding, which can increase pressure. Weight is added slowly and gently to prevent muscle spasm and pain. Neurovascular status is assessed distal to the traction.
- 4 Every 2 hours **Rationale:** Permanent neurovascular deficits can occur in as little as 6 hours.
- 5 A, B, C, E, G **Rationale:** Symptoms indicate swelling under the cast. Elevation promotes venous return and decreases edema. Heat and lowering the cast increase edema. More frequent neurovascular checks are needed because swelling could increase. Checking for the degree of tightness will reflect any change. The health care provider must be notified. Analgesics do not relieve edema and could mask increasing symptoms.
- 6 2 **Rationale:** A cotton T-shirt should be worn under the brace to protect the skin. The brace should be examined for anything that might damage the skin. Joints are cleaned with pipe cleaners and oiled weekly. Ammonia damages any plastic parts.
- 7 4 **Rationale:** Crusting and clear drainage are expected from pin sites. Ashen color indicates possible circulatory problems but not infection. Erythema (redness), warmth, or purulent drainage from the pin sites indicates infection.
- 8 2 **Rationale:** Nursing does not determine the amount of weight to be applied or manipulate the traction pins. If a pin moved, the nurse should notify the health care provider. The pull of the traction should be in a straight line, with the rope going over the pulley in a 90-degree angle.
- 9 3 **Rationale:** Patients should use the overhead trapeze to move in bed. Weights are never removed from skeletal traction because the callus formation may be damaged and delay healing. If weights do not hang freely at the end of the bed, the pull of the traction is affected. Proper limb alignment ensures proper pull of the traction.
- 10 1 **Rationale:** Itching is expected but can be managed with medication.

CHAPTER 12

Answers to Critical Thinking Exercises

- 1 Complete assessment with emphasis on pressure ulcer risk, current mobility status, and skin integrity.
- 2 Determine patient's level of pressure ulcer risk and then determine whether pressure reduction or relief is needed. Mr. Hoji is at high risk for pressure ulcers. He has decreased mobility and sensation. He needs pressure relief. The rationale is that he has no ability to independently change position. In addition, because of impaired sensation, he cannot perceive pressure on his skin and tissues.
- 3 Anxiety and nausea are common with air-suspension beds; the patient's comfort can be improved with pharmacologic agents to reduce anxiety and nausea, but the nurse should also provide reassurance to the patient about the safety of the bed and that his needs will be addressed. In addition, when lateral rotation is also used, the patient's nausea increases. When patients are prescribed an antiemetic such as prochlorperazine (Compazine) be sure that this medication is given routinely as opposed to an "as needed" (prn) order. Explaining to the patient that these sensations are temporary and will gradually improve is important. However, the patient cannot really process this information unless he is comfortable. For these reasons pharmacologic agents to control anxiety, nausea, and any pain are beneficial to patients on support surfaces.

Answers to Review Questions

- 1 3 **Rationale:** Patients tend to perspire on this bed. The surface of the bed quickly removes fluids from contact with the patient's skin; thus the evidence of perspiration may be minimized. The perspiration and/or diaphoresis can go undetected, and the increase in insensible fluid loss may not be noticed until the patient develops dehydration or electrolyte changes.
- 2 2 **Rationale:** Stop the rotation of the bed and assess the patient further. He or she may experience orthostatic hypotension when the bed rotates. Stopping rotation while remaining with the patient and conducting further blood pressure assessments will indicate if the problem diminishes. The rotation can begin again, perhaps at a decreased angle and at a slower cycle.
- 3 4 **Rationale:** Consider changing to a pressure-relief device because this patient is not responding to pressure reduction. The patient needs to move to a pressure-relief system because of the development of pressure ulcers on more than one position area (e.g., supine and left lateral positions).
- 4 1 **Rationale:** A patient's ability to assist with transfer to the bed is the least factor to be considered. A severely overweight patient has problems with mobility and therefore needs a bed that will enable the caregiving staff to reposition and provide care while relieving pressure on the skin.
- 5 1 **Rationale:** A patient should never be placed in prone position on an air-fluidized bed because of the chance of suffocation. All of the other options are appropriate.
- 6 1 **Rationale:** A person with paraplegia does not have normal sensation below the waist. Thus he should not rely on his own "feeling" to adjust the inflation of his seat cushion. Continued redness indicates that a stage I pressure ulcer is developing and should be reported immediately to the nurse or case manager.
- 7 3 **Rationale:** The nurse should check with a hand placed under the seat cushion after proper inflation to be sure that the cushion is providing pressure relief. The nurse's hand should not feel a patient's ischia, but the nurse should also note that overinflation of the cushion can damage tissue and cause pressure areas. A general rule of thumb is about linch of support between the patient's ischia and the bottom of the chair.
- 8 3 **Rationale:** Current best practice shows a decrease in nurse injury associated with the use of mechanical lifts in the hospital and long-term care. Safe lifting protocols and practices are being integrated into nursing curricula and include the use of mechanical lifts as routine practice.
- 9 1 **Rationale:** Best practice suggests that assessing the person's risk factors provides the best basis for choosing a pressure-relieving device.
- 10 The correct order is 3, 2, 5, 4, 1 **Rationale:** Proper application of an air mattress overlay is essential to reduce the risk of pressure on a patient's skin or tissues. Ensuring that the sheet is free of wrinkles also reduces the risk for impaired skin integrity. Inflating the mattress before patient transfer verifies that the mattress inflates properly and to the manufacturer's recommended pressure. The intermittent cycling of the air mattress continually alternates pressure against the skin and soft tissue.

CHAPTER 13

Answers to Critical Thinking Exercises

- 1 Diarrhea may cause Mr. Werneck to have to get out of bed often to use toilet facilities. The diarrhea can cause electrolyte and fluid imbalances that increase risk for dizziness or orthostatic hypotension. The weakness in his leg and his sense of fatigue also add to his risk. Anti-hypertensive medications increase risk for orthostatic hypotension, which increases fall risk. Being in his room alone after visiting hours might prompt him to walk more on his own. Finally, his age is also a risk factor.
- 2 Provide a bedside commode to eliminate the need to walk to the bathroom. Inform his wife of her husband's risk for falls and involve her in reminding the patient to sit up and dangle his feet before he

attempts to get up to sit on the commode. Keep the call light close by and respond promptly if patient complains of discomfort or needs assistance to get up. Place a nonskid pad alongside the bed. Place Mr. Werneck in a room close to the nurses' station.

- 3 Call for help, assess the patient for injury, and stay with him until assistance arrives.

Answers to Review Questions

- 1 **4 Rationale:** Never leave a seizing patient alone and observe his breathing status. Loss of the airway and protection from injury are primary issues when a patient has a seizure. It is appropriate to turn a patient on his or her side, but airways are not placed by NAP. The patient needs to be watched so he doesn't bump his head, but he shouldn't be held firmly during a seizure. Side rails should be raised, not lowered, if a patient has a seizure.
- 2 **4 Rationale:** If dentures are loose, they can be removed after the postictal phase of the seizure. Never try to remove anything from the mouth when a patient is showing warning signs of a seizure or during a seizure. Immediately after a seizure the patient may still be unconscious, and there is still a risk that he or she will bite down on your hands. If the dentures are firmly in place, leave them alone.
- 3 **2 Rationale:** If a head or neck injury is suspected, a cervical collar should be placed on the patient to prevent additional injury. It is the only answer that protects the patient from further injury. Using three people would protect the caregivers from injury.
- 4 **3 Rationale:** According to The Joint Commission standards, a patient must be seen by a health care provider within 1 hour to perform an assessment after restraints are applied. The assessment will either support the use of continued restraints or their removal. The other actions are not mandated by standards.
- 5 **3 Rationale:** For safety sake, one restraint should be removed at a time with an additional staff member present because of the erratic patient behavior.
- 6 **3, 4 Rationale:** QSEN skills for safety competency include demonstrating effective use of strategies such as evidence-based assessment guidelines to reduce risk of harm to patients. In addition, communication to staff members of any observations related to errors such as a fall occurrence is essential. Reliance on memory is not a safety competency, nor is the use of a new technology without having received proper training.
- 7 **2 Rationale:** The one evidence-based intervention among the choices is a standard vision assessment. Restraints do not prevent falls. Diversional activities and the RAWS are designed to reduce the use of restraints, not prevent falls.
- 8 **3 Rationale:** The patient should not be involved in securing the fire. He or she should be evacuated as quickly and safely as possible.
- 9 **2, 3, 4, 1 Rationale:** Follow the acronym RACE—Rescue, Activate alarm, Contain fire, Evacuate patient.
- 10 **1, 3, 4 Rationale:** A patient-centered approach involves considering the patient's and family member's cultural perspectives and the meaning that restraints have for them. A restraint can be perceived as a form of punishment. In addition, when possible, always consider a patient's or family member's preference for type of restraint to use. It is important to apply evidence in an assessment, but a patient-centered approach includes the views and opinions of the patient and family.

CHAPTER 14

Answers to Critical Thinking Exercises

- 1 Rescue workers should wear respiratory and skin personal protective equipment (PPE) and locate selves upwind and uphill unless cyanide is suspected.
- 2 A 22-year-old with cyanosis, a respiratory rate of 35 breaths/min, and confusion would be color coded immediate, red. A 14-year-old with a diffuse red rash on the extremities would be color coded minimal, green. A 56-year-old with controlled bleeding of deep lacerations received from falling debris would be color coded delayed, yellow. A 41-year-old with burns on 50% of the body would be color coded immediate, red. Those coded red would receive highest priority.

- 3 The primary objective for initial care is decontamination. Decontamination is the process used to remove harmful contaminants from the surface of the skin. It is achieved by removing clothing and scrubbing the skin and by hydrolysis, a process of chemical dilution using large volumes of water.
- 4 Clothing should be cut off rather than pulled over the head to prevent contamination of the head and hair. Clothing should then be placed in a biohazard bag, labeled, and sealed to reduce the likelihood of secondary chemical contamination.
- 5 Children may be frightened by separation from their parents, the appearance of rescue workers in PPE, and decontamination procedures. To avoid secondary contamination do not immediately pick up a child. Offer verbal encouragement and praise to facilitate treatment. Observe children closely for symptoms of exposure because they are more prone to the effects of chemical toxins (being closer to the ground and having a higher respiratory rate than adults). Children are also more susceptible to hypothermia with decontamination procedures.

Answers to Review Questions

- 1 **1 Rationale:** Practice makes staff more familiar with disaster protocols in the event of a true disaster.
- 2 **4 Rationale:** A nurse who must inform a mother that her three children did not survive would have the most difficult job.
- 3 **2 Rationale:** A disaster victim who arrives at the ED with labored respirations, cool skin, a pulse of 120 beats/min, and a blood pressure of 90/60 mm Hg should receive the highest level of priority of care because of the presenting signs. This victim stands a good chance of survival with appropriate care.
- 4 **2 Rationale:** Contact isolation is needed because of the mechanism of transmission.
- 5 **1 Rationale:** The health care workers must be protected first because of the chance of spreading whatever contamination may be present. If the health care workers become infected, no one will be available to care for the victims.
- 6 **4 Rationale:** Assessment cannot be delegated to NAP at any time. The nurse may direct the NAP to gather supplies and use appropriate PPE to prevent contamination.
- 7 **2 Rationale:** Rapid decontamination of the patient is more important than determining the exact agent and decreases the risk of secondary exposure to health care providers.
- 8 **3 Rationale:** Level A protection is used in highly contaminated areas. Level B is used by first responders and includes a self-contained breathing apparatus. Level C first responders (emergency personnel first on the scene) and hospital personnel are trained and fitted to use level C protection. Level D consists of the standard work uniform and the implementation of standard precautions.
- 9 **1 Rationale:** Potassium iodide is the treatment of choice for radioactive exposure.
- 10 **4 Rationale:** Vaccination within 3 days of exposure completely prevents the disease or significantly reduces its effect. Vaccination 4 to 7 days after exposure offers some protection from disease or decreases its severity.

CHAPTER 15

Answers for Critical Thinking Questions

- 1 Every 4 hours for assessment is appropriate for someone in her condition; and, as with many elderly patients, the verbal scale is easier to use than the numeric scale. You may have to explain it each time because Mrs. Silver is legally blind. The FACES scale could not be used correctly by Mrs. S. because she is unable to see it.
- 2 Guided imagery and massage are good options. Repositioning off of her right side would likely be helpful as well.
- 3 The nurse should explain that the pain could be contributing to the constipation. The patient's immobility also adds to the problem. However, morphine also can lead to constipation. The nurse should assess the patient's diet and confer with the health care provider about an alternative pain medication and possibly a stool softener.

Answers for Review Questions

- 1 3 **Rationale:** Frequent button pushing indicates an increase in pain; thus a pain assessment is needed. Assessment alone does nothing to help the patient; action must be taken right away to make him or her comfortable again. Pain is not “normal” and should never be ignored. It may be expected after surgery but should still be treated appropriately. A patient is limited to the amount of medication ordered until the prescriber is notified and orders received, but patients are never told that they can only push so many times an hour.
- 2 3 **Rationale:** Teenagers usually are comfortable with technology; at this developmental stage the autonomy of being able to determine when to take their pain medication is very satisfying and reassuring.
- 3 2 **Rationale:** A person with sleep apnea already has periods of decreased oxygenation as a result of episodes in which they briefly stop breathing while asleep (apnea). Obesity often causes partial obstruction of the trachea, especially when the pharynx is relaxed during sleep. These patients need frequent pain and sedation assessment. When they receive prn medications, the nurse assesses pain and sedation with each injection of analgesia.
- 4 4 **Rationale:** The orders should always be checked independently by two registered nurses; the pump is programmed to the checked and double-checked dosage. If the two nurses do not agree, they need to recheck their calculations.
- 5 2 **Rationale:** Monitoring frequency should be based on patient factors (e.g., whether they are opioid naïve, type of surgery or illness, previous sleep apnea). Using a standard scale (individual institutional policy) ensures that each caregiver bases the assessment on the same patient factors. Detecting and treating oversedation helps to prevent respiratory depression, a life-threatening situation if not corrected quickly; oversedation proceeds respiratory depression. Simply awakening a patient does not mean that consistent assessment is used. Once a shift is not enough to observe for oversedation. Medications may need to be adjusted if oversedation is present.
- 6 **From top to bottom, four, one, two, three. Rationale:** Treating patient’s pain is the number one priority. Using a pain scale is important to assess and document actual pain at the time of occurrence. Positioning patients helps with pain management. Assessing and treating the patient’s pain are priorities over searching through the chart to see if patient was ever nonverbal.
- 7 2 **Rationale:** Vital signs are not a reliable indicator for persistent/chronic pain as the body adapts to the changes caused by pain. Patients are not used to determining pain intensity. With acute/transient pain, changes in the vital signs may be seen initially; but one person’s blood pressure may rise dramatically with severe pain, whereas another’s may drop significantly.
- 8 2 **Rationale:** Elderly patients do very well on opioids; but, because of age-related decline in liver and kidney function, the opioids need to be started at very low doses, and dosage increases should be slower.
- 9 1 **Rationale:** ATC dosing is the most effective by stabilizing the blood level of the drug, which helps provide reliable pain control.
- 10 3 **Rationale:** Rather than looking for hidden meanings, believe a patient’s self-report of pain. Although a patient might think that anxiety may be relieved by pain medication, teaching is needed. If the symptoms are anxiety based with no underlying pain, try some complementary methods. If a patient is unable to relax, contact the health care provider or nurse practitioner for orders for medication for relaxation. It is extremely rare that a patient will say that she is having pain to gain attention, although some patients have learned that it is one way to get someone to come to their room. Try to spend time with the patient and help her with other needs and then do a pain assessment. Requesting additional pain relief is not a symptom of addiction.

CHAPTER 16

Answers to Critical Thinking Exercises

- 1 Because you do not know what Mr. Corbin has been told about his situation, begin by exploring his perceptions of his health status and validate his feelings. “Tell me what you were told about your illness. I would like to understand better.” Discussion helps reveal misperceptions or the need for factual information to help Mr. Corbin gain a sense of control. Mr. Corbin has also opened the door for a conversation about his emotional state. Paraphrase by saying, “It sounds like you are feeling all alone and don’t know where to go for help. Is that right?” Sit down while speaking and ensure privacy by closing the door.
- 2 The correct answer is 2. The nurse should gather more assessment data before selecting an intervention (choices 1 and 4). Perform a physical assessment of the patient’s abdomen and ask about normal bowel patterns, current pain medications, and recent diet and fluid intake. Assess the type, timing, location, precipitating and relieving factors, and intensity of Mr. Corbin’s abdominal pain. Allow him to describe his own symptoms instead of asking his wife (choice 3). Ask him about other symptoms he may be experiencing.
- 3 Assess what Mr. Corbin and his wife already know about hospice care and what it means to them. People face many changes when opting to receive home hospice care. Their familiar health care patterns and relationships will change, and caregivers will come into their home. To accept hospice care admits that death is presumed likely within the next few months or sooner. Symptom management becomes the primary focus of care. Assess the Corbin family’s degree of openness and awareness concerning death. The family must provide the care for all daily activities, necessitating some temporary changes in roles and schedules. However, families do have access to professional and volunteer hospice team members throughout their experience. Hospice professionals provide teaching, support, counseling, home visits as needed, and 24-hour contact for medical emergencies or questions. Family members need a support system to meet the challenges of helping their loved one die at home.

Answers to Review Questions

- 1 3 **Rationale:** Palliative care prioritizes care based on patient needs and preferences. Nurses help patients identify their own goals of care. An open-ended question always elicits more information than a closed-ended one.
- 2 3 **Rationale:** It is normal after a significant loss to experience the presence of the lost person and have difficulty resuming life activities.
- 3 4 **Rationale:** Others do not consider the woman’s loss to be significant enough for her grief expression; thus she feels disenfranchised.
- 4 1 **Rationale:** When patient and family members are ready to discuss goals of care, it is best to include the patient, family members, and members of the care team so patient preferences can be expressed and health care team can provide needed information.
- 5 4 **Rationale:** Options 1, 2, and 3 offer solutions to fix the problem. Disease process, medications, social withdrawal, and a slowing of bodily functions cause persons nearing the end of life to lose their interest in food.
- 6 2 **Rationale:** When a loss has been long anticipated, some people experience relief that the experience has come to an end. They have been grieving for some time before the actual loss happens.
- 7 6 **Rationale:** Palliative care interventions are available to patients who wish to have good symptom management and also continue their disease-modifying treatments.
- 8 2 **Rationale:** People from some cultures do not want full disclosure (“honesty”) related to their prognosis, nor do all people value self-determination as practiced in Western medical culture.
- 9 1 **Rationale:** Persons specially educated are best for making for organ donation requests. Many times family members give consent based on their knowledge of the deceased’s values (options 2 and 3). Because the options for donating organs and tissue are numerous, request for organ or tissue donation is routinely made (option 4) of most patients.

- 10 **The correct order is 9, 6, 5, 7, 2, 3, 1, 4, 8** **Rationale:** Perform all preliminary activities, including elevating patient head (completed first in case of delays in other activities), confirming organ donation, talking to family, and requesting support persons for the family. Perform activities that could lead to soiling the body (specimens and tube removal) before bathing and positioning the patient. Tag the body before transport to the morgue but after patient family has viewed the body.

CHAPTER 17

Answers to Critical Thinking Exercises

- The correct answers are 1, 3, and 4. Patients with diabetes should wear socks made of natural fibers to aid in absorption of perspiration. Cotton socks are most commonly recommended. A professional should trim nails to minimize chance of injury and infection. It is recommended that patients with diabetes mellitus should not soak feet for two reasons: (1) decreased sensation in lower extremities caused by peripheral neuropathy makes it difficult to determine temperature; and (2) soaking the feet causes maceration of the skin around the nails and feet, which can cause infection.
- The correct answer is 2. Patients with diabetes should have a podiatrist who performs foot and nail care at least annually. Patients should be taught signs and symptoms that warrant the need to seek medical attention.

Answers to Review Questions

- 3** **Rationale:** Moving a cloth on the skin during bathing not only cleans but also removes dead skin cells.
- 4** **Rationale:** A patient with arthritis in her neck may have pain and limited movement. This could cause a problem when her head is turned and repositioned while her hair is washed.
- 4** **Rationale:** A patient who becomes aggressive or uncooperative would do best with a warm, disposable bath in bed. It provides a more thorough bath in the safest environment for both patient and caregiver.
- 3** **Rationale:** Muslims use the left hand for cleaning the genital area. The right hand is reserved for eating and praying. As long as the caregiver is a woman, it is not necessary to have another woman present. If the nurse is right-handed, she should switch and perform the perineal care using her left hand to show respect for her patient's beliefs. Gloves should be used for all patients when doing perineal care.
- 4** **Rationale:** Before administering oral care to an unconscious patient, check the gag reflex to determine risk for aspiration. A pupil check indicates if intracranial pressure is developing. The Glasgow Coma Scale measures level of consciousness. It is important to inspect the oral cavity, but this will not reveal any risk for aspiration.
- 1, 3, 4** **Rationale:** A bed bath, tub bath, and shower are all considered cleaning baths. An herbal bath is a therapeutic bath because it is ordered for a specific effect.
- 3** **Rationale:** Oral care with peroxide is not recommended with mechanically ventilated patients. Normal saline can be used to moisten the mucosa; however, it is not associated with prevention of VAP. Oral care using chlorhexidine has proved to reduce VAP in mechanically ventilated cardiac surgery patients. It has also shown benefit with patients who do not have a pneumonia diagnosis before intubation.
- 2** In the absence of a blink reflex, the eyelids should be kept closed with an eye patch or shield after gently closing the eye with the back of your fingertip. Taping the eyelids closed is not accepted practice; and leaving the eyes open causes excessive dryness of the eye, leading to corneal drying, abrasions, and eye infection.
- The correct order is 1, 4, 3, 2, 5** **Rationale:** Assessing the environment for safety should always precede care. Making sure that you have your supplies arranged nearby eliminates leaving the bedside and interrupting care. Raising the bed to working height is a necessary part of safe body mechanics to avoid injury to the caregiver. Lowering the side rail allows easy access to the patient for positioning and performing the procedure.

- 10 **Mucositis.** Mucositis is inflammation of the mucous membrane of the mouth.

CHAPTER 18

Answers to Critical Thinking Exercises

- Ms. Willett is unable to move well in bed or change position because of the immobilizer and the pain that she is experiencing. She is also on bed rest. She is a high risk under the activity subscale on the Braden Scale because of her bed rest.
- The correct answer is 2, eschar, nonstageable. Granulation tissue is red and moist and is found in wounds that are moving toward healing; this wound can be stage II or III, depending on the depth of the tissue loss. Slough tissue can be tan, yellow, brown, or gray; is moist; and is found in wounds that require interventions to clean this tissue from the wound. Staging may be difficult if the base of the wound is not clearly defined. Erythema stage I is intact red skin that is warm to the touch. Eschar, nonstageable, the correct answer, is dead devitalized tissue that may need to be removed to allow the area to heal. As long as the eschar covers the ulcer, it cannot be staged; staging is done when the base of the wound is visible. An eschar-covered wound does not allow the wound base assessment.
- The correct answer is 1. A sheet burn opens the top layer of skin, and the area is slightly moist. Blistering is caused when the two layers of skin, dermis and epidermis, separate and allow fluid to accumulate. A blistered area is intact. Bruising results in breakage of the local capillaries and discoloration of the tissues. The correct answer is erythema.
- It is likely that the erythema has occurred because of unrelieved pressure over Ms. Willett's sacrum. She is on bed rest and not moving well because of her pain and the immobilizer. This area is at risk for pressure ulcer development. The nurse should palpate the reddened area. If it does not blanch, the nurse can suspect tissue damage.

Answers to Review Questions

- 1, 2** **Rationale:** The patient with the surgical wound most likely has an infection that delays wound healing because the inflammatory phase of wound healing is prolonged. A steroid such as cortisol also delays the inflammatory phase of wound healing. Vitamin C and a moist dressing are factors that promote wound healing.
- 2** **Rationale:** This provides an early baseline assessment and periodic reassessment throughout the confinement.
- 2** **Rationale:** The patient has numerous risk factors that necessitate the consultation with the wound clinical nurse specialist about the most appropriate bed surface to reduce pressure.
- 2, 3, 4** **Rationale:** The use of an incentive spirometer does not cause prolonged pressure; thus a pressure injury to the lips is unlikely. The patient is at risk for a pressure injury from the nasogastric tube (nares), IV tubing (skin along arm or wherever patient lies on tubing), and the drainage tube (wherever patient lies over tubing).
- 2** **Rationale:** This type of dressing protects the wound base and provides a moist environment, which in this case is essential to support the growth of new tissue.
- 2** **Rationale:** The head is the most common site of pressure ulcers in neonates and very young children because the skin is thin, little hair is present to absorb pressure, and they are often unable to reposition themselves adequately to reduce pressure.
- 2** **Rationale:** A moist saline gauze dressing provides a moist environment to the wound and wicks away excessive drainage, facilitating healing.
- 2** **Rationale:** A hydrocolloid dressing interacts with the moist wound base and forms a gel over the wound to support moist wound healing.
- 3** **Rationale:** All four patients have some risk factors for developing a pressure ulcer. However, the 50-year-old patient has more factors (3) placing him at risk: poor circulation from diabetes, limited mobility from his postoperative status, and presence of diaphoresis.
- 3** **Rationale:** The correct sequence of steps is to explain the purpose of the dressing change to the patient; position the patient to provide easy access for cleaning the wound; once cleaned, assess the wound and measure to determine correct size of dressing; and

apply the dressing so it extends at least 2.5 cm (1 inch) beyond the wound edge and press gently to adhere.

CHAPTER 19

Answers to Critical Thinking Exercises

- The correct answer is 3. Apply gloves when drainage is present. It is important to turn off the aid volume to prevent feedback (whistling) during removal. Grasping the device prevents accidentally dropping the aid. Wash the ear canal to remove any drainage or wax. The brush supplied with the aid is used to dislodge any wax that is transferred from the ear canal to the aid. Storing the aid in its storing case further reduces the risk of damage to the aid.
- The correct choices are 1 and 3. The batteries are very toxic to children and pets when swallowed, and a child would need to be seen by a health care professional should this occur. The aids are small and present a choking hazard to a child. Teaching Mr. Kupec to have his grandchildren face him (option 2) increases his hearing clarity when the children are speaking, but it is not related to child safety. Offering to show the children the hearing aid (option 4) addresses some of their curiosity but is not a safety measure.
- Of key importance to teach Mr. Kupec and his wife are: (1) how to clean the aids; (2) when to see an audiologist to evaluate the efficacy of the aids; (3) safety factors; and (4) any insurance or financial data regarding care, insurance, and replacement of the aids.

Answers to Review Questions

- 2** **Rationale:** The patient will be unable to care for her contact lenses immediately after surgery. No signs or symptoms have been presented to justify any of the other choices.
- 4** **Rationale:** Some disposable contact lenses are intended to be cleaned and reused. Furthermore, there is increased risk for infection with any contact lens use.
- 4** **Rationale:** The chemical should be removed as soon as possible to minimize the risk for permanent damage to the eye. Although a basin may be positioned to catch a dislodged contact lens, taking time to remove the lens delays removing the chemical from the eye and increases the risk for permanent damage. Testing the pH of secretions may be performed after an initial period of irrigation to determine the need to continue.
- 1** **Rationale:** The artificial eye should be cleaned only as often as necessary to prevent discomfort. The other statements are correct and indicate adequate teaching.
- 2, 3** **Rationale:** Make sure that a patient can see your face to facilitate comprehension. Speaking more slowly while using the same appropriate tone causes less frustration for a patient and allows you to assess whether other approaches need to be used. Raising voice volume distorts the voice and may make understanding more difficult. If a patient appears not to understand, a different choice of words may help; but a rapid series of statements or questions deprives him or her of the longer processing time needed to compensate for a hearing impairment. Gestures may not be helpful in many circumstances.
- 4** **Rationale:** Only the natural eye can react to stimuli such as when accommodation is done. Both eyes would produce tears and lubrication. Movement is present if the eye muscles have been attached to the ocular implant beneath the artificial eye, but the artificial eye would not have more natural movement than the natural eye.
- 3** **Rationale:** Heat from the blow dryer can damage hearing aids. Other substances such as hair spray or cologne also need to be kept away from the aids. The hearing aids need to be stored away from children and dogs and cats. Dogs in particular and cats are attracted to the scent of used hearing aids. Use of a desiccant prolongs the life of batteries and the hearing aid.
- 2** **Rationale:** Before any interventions are taken, the nurse must first assess a patient's ear for signs of irritation, including any presence of infection. From there the nurse can determine what needs to be done. This follows the sequence of the nursing process to first assess before implementing. Teaching a patient how to reposition his hearing aids if they are uncomfortable would be appropriate

based on the assessment findings. Reducing the volume of the hearing aid in the ear not causing a problem is inappropriate.

- 4** **Rationale:** The patient's corneas are susceptible to dryness and injury because of his or her condition since the patient does not have voluntary control to keep the eyes closed. It is essential that the corneas be kept moist by instillation of an eye lubricant, but eye irrigations would not be performed. The eyes should not be taped closed. Checking for the papillary response has nothing to do with a patient's eyes care.
- 4** **Rationale:** The nurse needs to have more information about the pain and any signs or symptoms that a patient is having such as ear drainage, any odor, and quality and quantity of pain. This assessment must be done first. Based on the information, the nurse makes the appropriate recommendations. Although the use of soap and water is appropriate, it has nothing to do with the problem expressed. Earwax helps to protect the ears, although too much can interfere with hearing. Nothing should be put into the ear until perforation of the eardrum has been ruled out.

CHAPTER 20

Answers to Critical Thinking Exercises

- The antidepressant, hormone, cardiac drug (beta-blocker), and antihypertensive medications can all potentially create adverse effects in older adults. The weakness and dizziness are likely side effects of the metoprolol and the antihypertensive. Because he takes multiple medications, there should be concern that there is possible drug interaction, with either summation or synergism occurring.
- The health care provider has the option of lowering the dose in the older adult to determine if therapeutic effects can still be achieved.
- You would need to evaluate if the patient has the motor dexterity or visual acuity to split tablets.

Answers to Review Questions

- 1** **Rationale:** Many medications bind to albumin (protein). If a patient is malnourished, the level of protein can be lowered; and toxicity can be a problem, especially if the medication would normally bind to the protein. The patient should always be watched for the other problems.
- 1** **Rationale:** The trough is drawn when the level of the medication is the lowest, which occurs right before the next dose is due.
- 1** **Rationale:** The patient is nauseated; therefore it is important to judge which route is best for her because of the chance of vomiting the medication.
- 4** **Rationale:** $0.5\text{ g} = 500\text{ mg}$. If each tablet is 250 mg, two tablets are needed.
- 4** **Rationale:** The nurse must know how the medication is metabolized and excreted (i.e., through the liver, kidneys, or intestines). Whichever system is affected can affect the manner and amount of drug absorbed or excreted.
- 3** **Rationale:** If sediment is seen at the bottom of the container of a clear liquid medication, the medication should be discarded or sent back to the pharmacy with an explanation according to institutional policy. The medication components may have gone through a change during transport or storage, or the medication may have expired.
- 4** **Rationale:** The nurse needs to check if the mouthwash contains anything that might interact with the patient's medications for possible interactions. The pharmacist or health care provider could also be contacted. The nurse could also recommend switching to a safer mouthwash unless it is contraindicated. None of the other answers is a priority or relevant.
- 3** **Rationale:** The Joint Commission has prohibited the use of MSO4 as an abbreviation for morphine sulfate. The nurse needs to call the health care provider who prescribed the order for clarification and to read back the order to the health care provider. This would then be transcribed as a verbal order and noted per institutional policy.
- 3** **Rationale:** The patient needs to be assessed and not left alone since this response to the medication was unpredicted and the

patient outcome is not known. The health care provider needs to be notified, and orders may be given for medical intervention. This type of medication can cause difficulty in the elderly population. Naloxone is used for opioid toxicity and is not appropriate.

- 10 1 **Rationale:** These medications may be appropriate or inappropriate for this patient, but it won't be known until they are identified. The nurse is attempting to assess and obtain a medication history. Since the patient doesn't know the name of the medication, the nurse should check to see if the patient brought the medications with him. Identification of medications is done by the pharmacist, not the nurse. The older adult has alterations in the absorption, distribution, metabolism and excretion of medications and needs to be monitored. Option 2 has nothing to do with the question.

CHAPTER 21

Answers to Clinical Thinking Exercises

- 1 A spacer device would be helpful for Mrs. Martin. She would just need to breathe in and out of the spacer device to receive the medication after pressing the metered-dose inhaler (MDI) canister.
- 2 The nurse should explain to Mrs. Martin that the old medication should be removed before applying new medication. The layer of old medication reduces the antibacterial action of the ointment. The nurse should demonstrate to Mrs. Martin how to care for the wound and watch as she performs it herself.
- 3 The nurse needs to review the correct technique for transdermal patch application and removal with Mrs. Martin. The old patches should be removed, folded with sticky sides together, wrapped in paper, and discarded. The new patch should be applied to a new area of skin, and the old site washed with soap and water to remove residue. Mrs. Martin may need to check to see if her health care provider would like her to have a nitrate-free period overnight. If so, the patch would be removed at bedtime, with a new patch applied in the morning.

Answers to Review Questions

- 1 4 **Rationale:** An oral-dosing syringe has the appropriate markings for accuracy and usually has a protective colored tip to prevent it from being lost in the infant's environment.
- 2 3 **Rationale:** Explain that the tablet is formulated to release slowly over time and should not be crushed, broken, or chewed.
- 3 4, 5, 6 **Rationale:** The tube should be adequately flushed after the last dose of medication to decrease the chance of crusting inside the tube and to ensure that all the medication has left it. Gastric residual should be checked before giving the medications. If too much gastric content is still left in the stomach, there may be a problem with the patient's rate of absorption, which can affect the medication absorption as well. The head of the bed should be left elevated to prevent aspiration.
- 4 2 **Rationale:** Because the patient is immunocompromised and has a large wound, sterile gloves should be used when applying medication because of the risk for infection.
- 5 1 **Rationale:** Applying the patch to a different area each time prevents skin irritation, which would affect the absorption rate.
- 6 2 **Rationale:** Wearing gloves minimizes the likelihood of the nurse being exposed to the medication.
- 7 1 **Rationale:** Steroid use can cause oral candidiasis, and therefore the mouth should be rinsed to avoid complications.
- 8 4 **Rationale:** Warming the medication is less irritating to the nerves in the ear and will reduce vertigo.
- 9 1 **Rationale:** This is the correct position for administering medication to the maxillary sinus.
- 10 2, 1, 5, 3, 4 **Rationale:** This is the correct order of action for administering ophthalmic ointment to a patient.
- 11 2 **Rationale:** Keeping the head of the bed elevated prevents aspiration and maintains an open airway.
- 12 3 **Rationale:** NAP have a limited scope of practice; the most appropriate delegation is to have them report changes in a patient's status.

CHAPTER 22

Answers to Critical Thinking Exercises

- 1 The nurse needs to know:
The drug classification, desired effect, and nursing implications related to heparin therapy; and the safe medication dose, which must be compared to the order before administration. The nurse needs to calculate how many milliliters to draw from the vial and if a filter needle is required.
- 2 The nurse needs to know:
Current diet.
Use of over-the-counter supplements and other prescribed medications.
If anything is affecting the blood flow to subcutaneous tissues of the abdomen.
Nutritional and fluid status and skin turgor.
Partial thromboplastin time to evaluate the desired effect.
- 3 The nurse should always use the smallest syringe possible when preparing medication. Usually a 25-gauge, $\frac{3}{8}$ - to $\frac{1}{2}$ -inch needle deposits medication into the subcutaneous tissue of a normal-size patient; however, this patient is overweight and may need a different-size needle. Use the abdomen, staying 5 cm (2 inches) away from the umbilicus.
- 4 The nurse needs to assess:
If the medication needs to be diluted before administering it by IV push.
The rate per minute of administration.
The compatibility of IV medications with IV fluids.
The condition of the IV site.
The level of the patient's pain.

Answers to Review Questions

- 1 2 **Rationale:** The nurse should calculate and determine how much medication needs to be injected into the patient while considering which route is being used. This needs to be done before the diluent and powder are mixed.
- 2 1 **Rationale:** The medication from the vial is withdrawn first to prevent any contamination of the vial with medication from the ampule.
- 3 4 **Rationale:** A 22-gauge, $1\frac{1}{2}$ -inch needle will penetrate the ventrogluteal area and disperse the aqueous-based medication easily. The other needle sizes are either too small or too large.
- 4 1 **Rationale:** The patient is experiencing infiltration of the IV infusion, and the site needs to be changed.
- 5 3 **Rationale:** Assessment of the condition of the IV insertion site is the priority. If there is a problem with the site, the medication cannot be given.
- 6 2 **Rationale:** An induration of greater than 10 mm in a healthy individual indicates tuberculosis exposure and requires follow-up.
- 7 1 **Rationale:** Symptoms indicate paresthesia and should not be present after an IM injection.
- 8 **Match:** 1, b; 2, c; 3, a
- 9 4 **Rationale:** Management of hypoglycemia includes drinking 4 ounces of fruit juice or regular soda or 8 ounces of skim milk or eating 6 to 10 hard candies.
- 10 **Fill in:** Dyspnea, wheezing, and circulatory collapse are symptoms of anaphylactic reactions.

CHAPTER 23

Answers to Critical Thinking Exercises

- 1 Additional information may include the following:
 - a Pulmonary system
 - (1) Measure pulse oximetry.
 - (2) Observe breathing pattern.
 - (3) Observe for use of accessory muscles and nasal flaring.
 - (4) Auscultate lungs for adventitious sounds and note if lung sounds clear with coughing.
 - (5) Observe sputum for color, thickness, amount, and patient ability to clear airway.

- b Cardiac system
 - (1) Vital signs
 - (2) Heart rate and rhythm
- c Neurologic system
 - (1) Level of consciousness (LOC)
 - (2) Orientation
 - (3) Ability to follow instructions

Mr Landon is very fatigued and short of breath, which makes taking a history difficult. Obtaining cardiopulmonary data through a focused assessment enables the nurse to identify pertinent data about the patient's status before treatment. In addition, a brief neurologic examination obtains baseline LOC and orientation and helps to determine the patient's ability to follow instructions. These baseline data help to determine the patient's present cardiopulmonary and oxygenation status without increasing his level of fatigue. Remember, in patients without underlying cardiac disease, the body adapts to decreased oxygenation or increased oxygen demands by increasing heart rate and blood pressure. In addition, the nurse has a sense of the patient's understanding of care and ability to participate in it (e.g., coughing and deep breathing, anticipated oxygen therapy).
- 2 Administration of oxygen therapy
 - a The FiO_2 level is between 24% and 28%.
 - b Hypercarbia is a risk for patients with COPD because the oxygen therapy may override the adapted respiratory drive. As a result, CO_2 is retained, and there is an increased risk for respiratory failure in this patient.
- 3 The strap on the cannula may be too tight or placed incorrectly. Inspect the external ears where the cannula strap rests to observe for any skin irritation. Adjust the fit of the cannula and place pressure-relieving devices (e.g., ear protectors or folded 4×4) under the elastic strap of the cannula.
 - The oxygen may dry out the nasal mucosa, and the cannula itself can irritate the patient's nares. Inspect nares for skin irritation. Evaluate the humidification level of the oxygen therapy; perhaps more humidification is needed.
- 4 d Partial rebreather mask mixes exhaled carbon dioxide with oxygen and causes an increase in carbon dioxide. Because Mr. Landon has underlying COPD and pneumonia, he is at risk for carbon dioxide retention, and this risk is further increased by the partial rebreather mask.

Answers to Review Questions

- 1 1 **Rationale:** A respiratory rate of 24 breaths/min could be seen in a dyspneic patient. All of the other options would be seen when hypoxia has been present for a long period of time.
- 2 2 **Rationale:** If the reservoir is deflated, the patient can breathe large amounts of carbon dioxide.
- 3 2 **Rationale:** A patient with COPD often has difficulty holding the breath at the end of inhalation. There is no reason the patient would not be able to hold the mouthpiece. Patients do not blow into an incentive spirometer. Three readings are made with a peak flow meter.
- 4 4 **Rationale:** When the oxygen rate is 4 L/min or greater, humidification is needed to prevent drying of the nasal mucous membrane. Under 4 L the moisture can be provided by the nasal passages.
- 5 2 **Rationale:** A Venturi mask is the only method of delivering an FiO_2 of 80% with the stated liters per minute. The nasal cannula delivers 44% at most, the partial rebreather must be set at a minimum of 8 liters, and the nonrebreather must be set at a minimum of 6 liters.
- 6 3 **Rationale:** Pulse oximetry measures arterial saturation immediately. Options 1 and 2 do not address the adequacy of oxygenation. Option 4 provides information about the presence of secretions or airway narrowing but not about the adequacy of oxygen therapy.
- 7 2 **Rationale:** Petroleum jelly products should not be used around oxygen because of the possibility of friction, which can cause a fire. Options 1, 3, and 4 demonstrate that the patient needs education.
- 8 2 **Rationale:** Noninvasive positive-pressure ventilation (NIPPV) maintains positive airway pressure and improves alveolar ventilation without the need for an artificial airway.

- 9 2, 3 **Rationale:** When caring for an intubated patient, nurses are encouraged to use verbal and nonverbal communication. Alphabet charts, pen and paper, slates or chalkboards, and computers are some common communication tools. Intubated patients do not have a hearing loss; thus speaking loudly may frustrate them and does not promote communication. Families can speak to the patient, but the patient still needs a mechanism of communication.
- 10 3 **Rationale:** When a patient is on humidified oxygen via tracheostomy, water can accumulate in the tubing. It is important to empty this water from the tubing so the patient may receive adequate oxygenation. This sound may be disturbing to the patient. Options 1, 2, and 4 do not address the problem of water in the tubing.

CHAPTER 24

Answers to Critical Thinking Exercises

- 1 Place bed in Trendelenburg's and use three positions: left side-lying to drain right lower lobe bronchus, right side-lying to drain left lower lobe bronchus, and left side-lying with one-quarter turn back onto pillow to drain right middle lobe.
- 2 Chest examination would reveal decreased breath sounds at bases posteriorly and over right lateral chest wall. A decreased chest wall excursion is expected, more pronounced on the right side. It is also important to assess patient's cough and sputum production. In this case you might expect patient to complain of increased dyspnea, and the respiratory rate and oxygen saturation may change.
- 3 Improvement of lobar collapse on chest x-ray film is a common clinical finding after the successful application of CPT. In addition, you would expect oxygen saturation oxygenation to improve and dyspnea, tachypnea, and fever begin to resolve.
- 4 Documentation includes the following: (a) tolerated CPT to bilateral lower lobes and right middle lobe using Trendelenburg's position; (b) breath sounds increased at both bases and right middle lobe area after treatment with decreases in rhonchi and palpable fremitus; (c) coughed up 30 mL of thick yellow secretions and drank two 8-ounce glasses of water during therapy session; (d) instructed family in how to position patient at home and how to do percussion and vibration; they performed an excellent return demonstration; and (e) repeat chest x-ray film showed reexpansion of right middle lobe and increased aeration of bilateral lower lobes.

Answer to Review Questions

- 1 2 **Rationale:** Steroids are a classification of medications that increase the risk for pathologic rib fractures.
- 2 1 **Rationale:** To help liquefy secretions, patients need a minimum of 1500 mL daily unless contraindicated by other physiologic problems. Setting up a fluid intake schedule would best help alleviate this problem.
- 3 3 **Rationale:** The oxygen saturation levels are reasonable considering what is being done to the patient. If the patient says he feels all right, continue with the therapy while continuing to monitor him. If the patient doesn't feel well, stop the session and assess further.
- 4 2 **Rationale:** Because the residual amount from the stomach is greater than 100 mL, the treatment should be held. Positioning could lead to regurgitation of gastric contents. Normally when a patient is receiving tube feedings and has a residual volume, be sure that the head of the bed is up.
- 5 1 **Rationale:** A patient with congestive heart failure is often short of breath during any exercise. Chest physiotherapy causes exertion and can worsen shortness of breath; as a result the patient needs short rest periods between the different positions. Maintaining normal hydration and oral hygiene are important for every patient.
- 6 1 **Rationale:** Right side-lying Trendelenburg's position aids in the drainage from the left lower lobe.
- 7 1 **Rationale:** Sitting up in a chair and leaning backward onto a pillow promotes drainage from the area. The upright position especially helps with the air-filled abscesses.
- 8 2 **Rationale:** Postural drainage should be avoided for 1 to 2 hours after meals. If he finished his lunch at 1 PM, the soonest that postural drainage can be done is at 2 PM.

- 9 2 **Rationale:** Forceful cough is the best option given for this type of patient to clear his secretions. Increasing fluids helps thin the secretions but does not help him to cough. Postural drainage and vibration and shaking are contraindicated because of the chance of fracturing a rib or causing injury to this frail patient.
- 10 3 **Rationale:** A current assessment of the patient is needed before decisions regarding treatment can be made. There can be a number of causes for the dyspnea and the bleeding. The health care provider will be notified but will expect current patient information to be available.

CHAPTER 25

Answers to Critical Thinking Exercises

- 1 1 **Rationale:** Yankauer suctioning is the method of choice for the upper airways; this enables the patient to clear oral secretions as needed; and it is a clean, nonsterile procedure.
- 2 1, 2, 3 **Rationale:** Hand hygiene has a direct benefit in reducing nosocomial infections and the transfer of microorganisms to health care professionals. Sterile suction technique reduces nosocomial infection in patients with new artificial airways or new tracheostomies or patients with acute illnesses/trauma. Clean suction technique can be used in patients who have permanent airways, usually a tracheostomy, and are free of any pulmonary infections. Frequently clean technique is used in the home environment.
- 3 1, 3, 5 **Rationale:** It is important to notify the health care provider because new care orders may be necessary for this patient; these orders may include antibiotics, chest physiotherapy, or diagnostic tests such as bronchoscopy. In some patients increasing fluids may help to liquefy pulmonary secretions. Before increasing fluids, be sure to determine that it is not contraindicated for this patient. For example, patients with cardiac or renal diseases may not be able to tolerate an increase in fluids. A sputum specimen for culture and sensitivity is needed because a change in thickness and/or sputum color frequently indicates an infectious process. An order is needed for a specimen. Antibiotics may be started before results of the test are available.

Answers to Review Questions

- 1 1 **Rationale:** Oropharyngeal suction uses a Yankauer or tonsillar tip suction device to remove large amounts of thick mucus. This would be most appropriate for a patient who cannot clear her airway by herself and does not have an artificial airway.
- 2 1, 3 **Rationale:** There are usually fewer infectious microorganisms in the trachea compared with the mouth. Suction from the least contaminated to the most contaminated.
- 3 4 **Rationale:** The common symptom of hypoxia is lethargy. Patients exhibit anxiety and restlessness, not a feeling of calmness, with hypoxia. In addition, patients will have tachycardia and potential dysrhythmias secondary to hypoxia. Hypoxia can cause all patients to be confused with a diminished level of consciousness.
- 4 3 **Rationale:** Whenever there is a drop in the patient's oxygen saturation, the patency of the patient's airway should be assessed for an open airway. This follows the ABCs of cardiopulmonary assessment.
- 5 1 **Rationale:** This is one of the times that notifying the health care provider is indicated. The patient has already been repositioned and suctioned, and there are no data to support that the nurse is allowed to reposition the endotracheal tube. The health care provider may need to order an x-ray film to check the placement of the endotracheal tube.
- 6 The correct order for this situation is 2, 4, 5, 1, 3, 6.
- 7 3 **Rationale:** To prevent oxygen desaturation, quickly clean the inner cannula. It should not be cleaned with hydrogen peroxide; use normal saline. Be sure to "lock it down" when appropriate after cleaning it. Leaving it unlocked increases its risk of becoming dislodged.
- 8 The correct order is 2, 5, 1, 4, 3.

- 9 3, 4 **Rationale:** Based on research, the following statements are true: Elevate the head of the bed 30 to 45 degrees to prevent aspiration. Change patient position every 2 hours to decrease risk for atelectasis, pulmonary infections, decubiti, discomfort, and urinary stasis. Provide oral care with chlorhexidine by swab every 8 hours. If chlorhexidine is contraindicated, a toothbrush can be used to remove dental plaque organisms. Maintaining the endotracheal cuff pressures at 20 cm H₂O is necessary to decrease movement of secretions to the lower airways.
- 10 2, 3 **Rationale:** Know patient's normal range of vital signs and oxygen saturation levels. Baseline vital signs compared with current measures identifies individual abnormalities and the onset of worsening of an illness. Identify conditions that increase patient's risk for aspiration of gastric contents into the lung, resulting in airway obstruction. These include the presence of enteral feeding tubes or other nasal or oral gastric tubes, a decreased level of consciousness, and a decreased swallowing ability. Review patient's condition from the past 12 or 24 hours. These are relative baseline measurements that help to distinguish between gradual and acute changes in his or her status. Perform a systematic respiratory assessment of upper and lower airways, including identifying respiratory rate, respiratory pattern, respiratory muscles used, breath sounds, ability to cough effectively, integrity of the rib cage, and the characteristics of sputum production. Identify and become familiar with the use of equipment available at the institution. Knowing how to operate the equipment before using it will benefit both you and the patient. Test all equipment before use. Have adequate supplies on hand at the bedside. Equipment must work properly to provide safe nursing care.

CHAPTER 26

Answers to Critical Thinking Exercises

- 1 Vital signs document patient's cardiopulmonary status and identify any early changes. Prompt detection and correction of air leaks related to the chest tube decrease the risks for chest tube complications and duration of chest tube placement. The hourly monitoring of chest tube drainage is to provide timely observations on the amount and type of drainage. During the first 3 hours 100 mL/hr is expected, and patient coughing and position changes can result in a temporary increase in drainage.
- 2 Avoid dependent chest tube loops; change position of patient and drainage tubes to prevent drained blood from pooling in the chest or tube.
- 3 This drainage is dark red, not bright red; it is not a large volume; and it is probably caused by the rapid discharge of accumulated drainage from the chest. This discharge of fluid was probably stimulated by the patient's activity from bed to chair. However, because this is a fresh postoperative patient, you would take his vital signs to determine his tolerance to activity and monitor cardiopulmonary status. You would also continue to monitor chest tube drainage to be sure that the volume did not increase excessively, and you would implement measures to assist in maintaining chest tube patency (see Answer 2).

Answers to Review Questions

- 1 2 **Rationale:** Explaining that by controlling pain he will be able to be active and cough well is a true statement. However, there is no guarantee that the medication will not make him sleepy.
- 2 3 **Rationale:** The pneumothorax is getting worse, possibly leading to a tension pneumothorax. The signs and symptoms indicate respiratory distress. If these symptoms are present, notify the health care provider immediately.
- 3 1 **Rationale:** Monitoring chest tube drainage and maintaining chest tube patency are the key priorities when a patient has a chest tube.
- 4 1 **Rationale:** Apical (second or third intercostal space) and anterior chest tube placement promotes removal of air.
- 5 3 **Rationale:** Placing an occlusive dressing over the chest tube site helps prevent the air leak from getting worse and prevents bacteria from entering the site. It is essential to check vital signs to assess the status of the patient.

- 6 4 **Rationale:** As noted in the skills, none of these activities can be delegated to NAP.
- 7 4 **Rationale:** The patient has a chest tube that is smaller in diameter than what one should be to drain blood. The tube should be a 24 to 32 Fr size. The nurse's priority is to be sure the tube does not become occluded. Vital sign monitoring is important, but the patient at this time is stable. The appearance of the drainage is not unusual at this time.
- 8 1 **Rationale:** The patient must not be in a prone position to complete the chest tube removal. The skill reads to help patient sit on edge of bed or lie supine or on the side without chest tubes. The following statements are true related to chest tube removal: The nurse administers the ordered analgesia 30 minutes before the procedure. The nurse offers emotional support during tube insertion. The nurse has suction available.
- 9 3 **Rationale:** You should notify the health care provider immediately since these symptoms indicate a change in chest tube drainage appearance to bright red blood and an unexpected amount of drainage. This information, along with the vital signs and complaint of dyspnea, indicates respiratory distress.
- 10 **Intrathoracic pressure Rationale:** There continues to be controversy as to whether to "strip" or "milk" a chest tube. Stripping or milking a chest tube is a process used to clear a tube of clots. Milking or stripping is the manual compression of a chest tube in an attempt to move chest tube drainage toward the collection device. Stripping causes a dangerous increase in intrathoracic pressure, which causes damage to the lung tissue.

CHAPTER 27

Answers to Critical Thinking Exercises

- 1 2 **Rationale:** On finding an unconscious patient, you must call for help immediately to mobilize necessary equipment for defibrillation.
- 2 1 **Rationale:** You must verify that the victim is pulseless before initiating AED use and/or chest compressions.
- 3 2 **Rationale:** Cardiopulmonary resuscitation (CPR) interruptions should be minimized. Only very brief interruptions should be allowed for changing CPR personnel during pulse checks, AED analysis, or defibrillation.
- 4 2 **Rationale:** Assessment of the return of patient's spontaneous pulse and respirations and cardiac rhythm analysis need to occur every 2 minutes during a chest compression interruption.
- 5 Reassessment of the primary survey will continue even after the code team has arrived. Helping the code team perform the secondary survey may include handing off the requested supplies from the crash cart, setting up suction, establishing peripheral or central IV access, chest auscultation on intubation, connecting to a monitor/defibrillator, relaying significant patient information to the code team, or administering or handing off medications. Delegation of other actions may include having someone help the victim's roommate or visitors away from the code scene, assigning pastoral care or other nurses to communicate with family members, delegating someone to remove excess furniture or equipment from the room, having someone bring the patient's chart to the bedside, assigning a fresh person to perform chest compressions, or assigning another nurse to record/document the events of the code.

Answers to Review Questions

- 1 3 **Rationale:** Goals of resuscitation are aimed at restoring cardiopulmonary and neurologic function.
- 2 1, 2, 3 **Rationale:** Rapid-response teams are created with the intention of intervening early to avoid cardiac arrest; transfer to ICU if needed and reduce hospital mortality rate.
- 3 1 **Rationale:** Family and patient's religious and cultural practices need to be considered, especially regarding resuscitation and/or end-of-life care.
- 4 4 **Rationale:** It may stimulate vomiting or laryngospasm if inserted in the semiconscious patient.
- 5 1 **Rationale:** Follow the C (circulation) D (defibrillation) A (airway) B (breathing) sequence of steps. It is essential to continue compressions if no pulse is present until the AED prompt says not to touch the patient.
- 6 3 **Rationale:** The jaw-thrust technique prevents head extension and neck movement, which is crucial to prevention of paralysis or spinal cord injury.
- 7 2 **Rationale:** Basic life support certification provides hands-on training with an AED for laypersons, nursing assistive personnel (NAP), and licensed health care professionals.
- 8 4 **Rationale:** Chest compressions at 100/min are essential for perfusing vital organs, including the heart and brain.
- 9 4 **Rationale:** Immediately after a shock, chest compressions should be continued for 2 minutes to provide minimal interruption in organ perfusion.
- 10 4 **Rationale:** If enough air fills the lung on artificial breaths, the chest will rise, indicating effectiveness.

CHAPTER 28

Answers to Critical Thinking Exercises

- 1 The correct microdrip rate would be 100 gtt/min. The correct macrodrip rate would be 25 gtt/min.
- 2 The following steps are necessary before starting a new bag of IV solution:
- You should first check the health care provider's order to ensure that there is a written order for the solution, rate of administration, additives, and medications.
 - Check the IV solution for integrity, including but not limited to discoloration, cloudiness, leakage, and expiration date.
 - Check references for information on IV fluids composition, purpose, potential incompatibilities, and side effects.
 - Provide explanation of the procedure to the patient. Allay any anxieties and answer any questions the patient may have.
 - Check laboratory data to evaluate any abnormalities before changing the IV solution.
 - Assess patency of current venous access device (VAD) site, observing for any signs or symptoms of complications such as redness, swelling, or complaints of discomfort.
- 3 The presence of discomfort at the site warrants closer inspection for signs of phlebitis or infiltration. The nurse should also check to be sure that the slower rate is not positional or that the IV tubing is not kinked. If the patient has early signs of phlebitis or infiltration, stop the infusion and restart IV in area above the affected area or in other extremity if appropriate.
- 4 Document the following:
- All signs and symptoms of complications of the IV catheter, such as tenderness and pain at site, redness, swelling
 - Discontinuation of the IV size and length of catheter, amount of fluid infused, medication administered
 - Interventions initiated, such as warm compresses
 - Patient response to procedure

Answers to Review Questions

- 1 2 **Rationale:** The formula is
- $$\frac{1000 \text{ mL} \times 15 \text{ gtt/mL}}{12 \text{ hours} \times 60 \text{ min/hr}} = 21 \text{ gtt/min}$$
- 2 3 **Rationale:** Phlebitis is evidenced by what the patient is experiencing. Coolness and swelling would be seen with infiltration. There are no data to support the other two options.
- 3 3 **Rationale:** The smallest device possible with the smallest gauge is recommended to prevent complications to inner layers of the veins.
- 4 **The correct order is 2, 4, 1, 3 Rationale:** After the tape is removed, the old or current dressing (TSM) is removed; once the dressing is removed, the site is observed for signs and symptoms of IV-related complications; site is cleaned with antiseptic swab to remove any surface microorganisms before new dressing is applied; new dressing (TSM) is applied to protect site and prevent any microorganisms from entering the insertion site.

- 5 **False** **Rationale:** A midline catheter is considered a peripheral device because of the location of the final tip placement, which is not in the superior vena cava (SVC); it terminates below the axilla.
- 6 **2** **Rationale:** Although it is desirable to place an IV infusion in the patient's nondominant hand, this patient has a medical condition that dictates that the IV catheter be placed in her dominant hand or arm.
- 7 **1** **Rationale:** The patient is susceptible to bleeding; thus pressure should be applied whenever a device such as a catheter is removed from his body while he still has prolonged bleeding times. You or the patient (if capable) can apply the pressure for the required period of time.
- 8 **4** **Rationale:** The tip of the catheter should be in the superior vena cava above the right atrium of the heart.
- 9 **1** **Rationale:** Current evidence states that chlorhexidine skin antiseptics has been shown to reduce the risk of catheter-associated infections when used as a skin prep.
- 10 **4** **Rationale:** Solution with an osmolarity of greater than 600 mOsm/L needs to be administered by a catheter placed in the SVC. The only correct option is the implanted venous port. Although the PICC is a central device, the tip placement is not in the SVC.

CHAPTER 29

Answers to Critical Thinking Questions

- 1 You should review the potential benefits and risks associated with blood transfusions. Describe and discuss options such as autologous transfusion and blood alternatives. Ms. Cooper needs to know if bleeding and blood loss may occur during her surgery. Blood transfusion may be a therapeutic regimen in her recovery. Also explain that comprehensive testing and screening of blood products now reduces incidence of infection and disease transmission. Patient's blood sample is mixed with donor's blood sample to determine the compatibility of the two. This will ensure that she gets the correct blood type. Explain the process for verification of the patient identification and blood unit label information to prevent transfusion errors.

As with any invasive procedure, the risk for infectious transmission may occur. Because transfusions are administered directly in the vascular system, nurses perform hand hygiene to prevent infection.

If transfusions are not used when clinically indicated, recovery may be impaired. Ms. Cooper has the right to refuse blood transfusions. Because Ms. Cooper's surgery is elective, she has the option of providing autologous blood, which is her own blood donated in advance, to be used in the event that she requires postoperative blood products.

- 2 Ms. Cooper needs to schedule an appointment with the blood bank to donate her own blood for personal use. Her blood cell counts, including hemoglobin and hematocrit, must be within the normal range. No donations may be made within 72 hours of surgery.
- 3 Ms. Cooper can receive all blood types in a transfusion. Her blood cells carry A and B antigens.
- 4 You should verify the health care provider's orders for the transfusion of the blood product. A signed consent form should be in the medical record. A vascular access device that is patent without complications must be assessed before initiation. You should have a 0.9% NaCl infusion setup with Y-tubing for the blood product. Obtaining baseline vital signs is necessary.

The patient's name and identification number on an arm identification bracelet should match the transfusion form information. The unit number, component, ABO, and Rh on blood product and transfusion record should match. You must verify this information with another staff member as required by facility policy. Most facilities have a transfusion form that should be completed to record the name of the blood product; identification number and expiration date; patient's and donor's blood type; and patient identification, including name and date of birth.

The blood product should not be at room temperature for more than 30 minutes before the initiation of transfusion. When there is a delay in initiating the blood transfusion, the blood product should be

returned to the blood bank. Once the product is initiated, it should be infused within 4 hours to decrease the risk for pathogen growth.

You should remain with a patient for the first 15 minutes of transfusion and monitor him or her throughout the transfusion. You may direct the nursing assistive personnel (NAP) to take frequent vital signs and inquire about the patient's comfort. However, you maintain responsibility for assessing and monitoring him or her. If any adverse signs and symptoms are present, you should implement appropriate actions and notify the health care provider.

- 5 If patient symptoms suggest a mild allergic reaction, **stop transfusion** and administer antihistamine per health care provider's order. Restart transfusion per health care provider's order. If symptoms are unclear, slow the transfusion and assess patient for rash or hives and respiratory symptoms such as coughing, wheezing, or throat or oral mucous membrane itching. You should ask patient to describe when and where the signs and symptoms occurred. The assessment should include the back and trunk because this is a common area of occurrence. Take a set of vital signs. Notify the health care provider for orders, which usually include administration of antihistamine and continuing the transfusion. You should continue monitoring the signs and symptoms, noting whether they dissipate or get worse. If they continue to worsen, the physician should again be notified. Record the response on the medical record.

Answers to Review Questions

- 1 **3** **Rationale:** Normal saline is the only intravenous solution that should be used with blood because of its isotonic quality. Dextrose solutions cause hemolysis of the red blood cells.
- 2 **3** **Rationale:** Only negative blood types can be given to a patient with a negative blood type.
- 3 **4** **Rationale:** When blood is stored, there is continual destruction of red blood cells, which release potassium from the cells into the plasma. If blood is transfused rapidly, there may be transient hyperkalemia before the potassium is reabsorbed. The hematocrit and hemoglobin values would indicate whether a patient needs a blood transfusion. The sodium level is not relevant to this situation.
- 4 **2** **Rationale:** Comparing a patient's identification bracelet with the blood bag label number is the most important step to take.
- 5 **4** **Rationale:** It is essential to maintain an IV access, but you do not want the patient to receive any more of the current blood. Another blood administration set should be primed with a new bag of normal saline in case more blood needs to be given. Remember to keep the old blood bag and saline and the administration set and send them to the appropriate department per protocol for analysis.
- 6 **4, 2, 1, 3 is the correct order of steps.**
- 7 **3** **Rationale:** The addition of adenine adds 35 days to the shelf life of the blood.
- 8 **2** **Rationale:** HLAs are immunogenic antigens, which cause serious transfusion reactions such as TRALI. Fetal hemolysis and Rh incompatibility are not a direct result of HLAs.
- 9 **4** **Rationale:** No medications or solutions (other than 0.9% normal saline solution [NS]) are to be administered with blood. Blood should never be stopped to administer another medication or solution; therefore starting a new IV is the most appropriate action.
- 10 **2** **Rationale:** Only a registered nurse (RN) (or in some states a licensed practical nurse [LPN]) may administer blood or blood products; the task may not be delegated.

CHAPTER 30

Answers to Critical Thinking Exercise

- 1 Mr. Jasper's BMI is 18.7; he is at the lower limit of "normal weight." With his condition he is at risk for being underweight unless his nutritional status improves.
- 2 Several actions should be considered: (a) Include the daughter in the teaching plan. The patient and significant others might have misconceptions about which foods are safe and nutritional. (b) Explain that the purpose of dietary modifications is to prevent him from aspirating (i.e., having fluid/food enter his lung) and having pneumonia. Teach

the signs and symptoms of aspiration. (c) Explain that thin liquids create safety risks in swallowing because of the speed with which they move. Increasing the viscosity or thickness of the liquid slows movement through the mouth and pharynx and promotes protection of the airway. (d) Explain the reason for not giving him bites of the cookie. His dry mouth will prevent him from forming a food bolus; thus he will experience dysphagia, potentially leading to aspiration. (e) Teach the daughter to provide verbal cueing while feeding. Remind patient to chew and think about swallowing. This will result in a more normal swallow to help prevent aspiration. (f) Suggest that patient's meals be eaten in a quiet area in the dining room to minimize distractions so he will be able to more easily focus on chewing and swallowing. (g) Teach the risk of backward head tilts. Food and fluids are more likely to be misdirected into the airway in this position. An alternative is a chin-tuck maneuver, which helps in airway protection.

- 3 A soft, low-residue diet includes pastas; casseroles; moist, tender meats; and canned, cooked fruits and vegetables.

Answers to Review Questions

- 1 4 **Rationale:** The patient is classified at risk for malnutrition. Although gaining weight is important, determining knowledge base related to nutrition is the priority and serves as the baseline for teaching.
- 2 93% or below. $95 \times 0.02 = 1.9$; $95 - 1.9 = 93$ **Rationale:** Bedside assessment is not sufficient for evaluating the frequency of silent aspiration, because a silent aspiration does not have specific symptoms. Recommendations include accompanying fluid administration with measurement of pulse oximetry. A drop in oxygen greater than or equal to 2% saturation indicates silent aspiration.
- 3 1 **Rationale:** The nurse screens for actual and potential nutritional alterations. Nurses focus on the effects of an illness or a disease on a patient's nutritional status such as recent weight loss and decreased oral intake.
- 4 1 **Rationale:** In adults weight is usually stable. A loss of 10 lbs (4.5 kg) during a 6-month period whether intentional or unintentional is a critical indicator for further assessment, especially in the older adult.
- 5 4 **Rationale:** Provides comfort. If a patient has nausea or pain, offer appropriate antiemetics or analgesics at least 30 minutes before mealtime.
- 6 1 **Rationale:** The single most important measure to prevent aspiration is to place the patient on NPO until a swallowing evaluation determines that dysphagia poses no substantial risk.
- 7 1 **Rationale:** Single textures are easier to swallow than multiple textures or thin liquids (low viscosity) such as water, coffee, tea, and anything that liquefies in the mouth at room temperature. Swallowing thin liquids requires the most coordination and control and creates safety risks in swallowing for patients with impaired oral motor control because of their speed and decreased texture. Jell-O and orange sherbet are thin liquids. Shredded wheat and milk are multiple textures.
- 8 4 **Rationale:** Glossitis and smooth tongue may be indicators of malnutrition.
- 9 2 **Rationale:** Cream is not a clear liquid.
- 10 2 **Rationale:** Orthodox Jews do not eat shell fish.

CHAPTER 31

Answers to Critical Thinking Questions

- 1 Assessment of the risk for placement error during feeding tube insertion centers on the patient's mental status, ability to cooperate with the procedure, presence of cough and gag reflexes, and clinical factors such as the presence of an artificial airway. When numerous risk factors for inadvertent pulmonary intubation are present, additional safety measures such as a CO₂ sensor or an electromagnetic tracking device can enhance the safety of the procedure if these devices are available.
- 2 The patient may have difficulty understanding the explanation for the procedure. Use simple phrases and take time to explain it. Show him what the feeding tube looks like. He will have trouble communicating,

depending on his level of alertness. If he can communicate, have him use his right hand to make signals. You may need assistance to position him for the insertion. If he has a reduced gag reflex, you might not offer him water or ice chips for swallowing. Plan to have to coach him to successfully swallow during tube insertion.

- 3 Aspiration of stomach contents to test pH or measure gastric residual volume (GRV) can lead to clogging of the tube. Another common cause of feeding tube occlusion is fragments from improperly crushed medications. Irrigation of the tube with water at scheduled intervals and before and after aspiration of gastric contents and medication administration is the most effective way to prevent this complication.
- 4 Because no single method for checking position of feeding tubes is completely reliable, a variety of techniques are used in combination. They include marking and monitoring the external length of the tube, noting the color, pH, and appearance of fluid withdrawn through the tube, and observing for changes in gastric residual volume. A repeat abdominal radiograph should be obtained (requires health care provider's order) if bedside checks raise any doubt regarding the location of the tube.

Answers to Review Questions

- 1 3 **Rationale:** Continue tube feeding as ordered. A gastric residual volume of 150 mL falls below recommended limits for stopping feeding (250 to 500 mL). Slowing the rate or stopping the feeding for a residual volume of 150 mL will result in inadequate nutrition. Return to the stomach residual volumes of 250 mL or less to avoid loss of nutrients, fluid, and electrolytes.
- 2 3, 4, 5, 6 **Rationale:** Both 1 and 2 are incorrect. Room number is not a valid patient identifier, and head of bed must be elevated to a minimum of 30 degrees.
- 3 1 **Rationale:** The feeding must be stopped while patient's status is being evaluated. If the tube has become misplaced, this action prevents additional fluid from being instilled. The nurse would perform all of the actions listed and in the order they appear in the options listed.
- 4 2 **Rationale:** Sorbitol can cause diarrhea. None of the other options is correct.
- 5 2 **Rationale:** Slow weight gain is expected. A gain of more than 2 lbs (0.9 kg) in 24 hours usually indicates fluid retention. This patient has gained 4 lbs in 48 hours and is probably retaining fluid. Asking the patient how he feels would provide subjective data; objective data are needed to determine why the patient is gaining weight rapidly.
- 6 4 **Rationale:** X-ray film confirmation of a blindly inserted tube is the only reliable method for verifying correct placement and is mandatory before the tube is used for administration of fluids or medication.
- 7 3 **Rationale:** A jejunostomy tube would be the safest route because it bypasses the face and is farthest from the lungs, decreasing the chance of aspiration the most, which is essential when facial injuries are present.
- 8 3 **Rationale:** Although the gastrointestinal tract is not sterile, enteral formulas provide an ideal medium for bacterial growth. All components of the system must be handled aseptically to prevent transmission of organisms and development of diarrhea.
- 9 3 **Rationale:** The nurse needs to wait at least an hour after medications are given to allow for absorption. The syringe used should be 60 mL to allow for ample room for both aspiration and irrigation. The patient should be kept with the head of the bed at least 30 degrees (preferably 45 degrees). A small amount of gastric fluid aspirated slowly can be tested for the appropriate pH level, which would indicate proper technique and proper tube placement.
- 10 1 **Rationale:** Absent bowel sounds are not a contraindication to feeding; but a change from baseline in the abdominal examination, particularly if tenderness or distention is present, should be conveyed to the ordering health care provider to determine if tube feeding can safely proceed. Administration of enteral nutrition is often unnecessarily delayed until bowel sounds are heard.

CHAPTER 32

Answers to Critical Thinking Exercises

- 1 Vital signs, electrolyte levels, weight, and fluid status (auscultating lung sounds, checking for edema).
- 2 Provides baseline for measuring tolerance to high concentration of glucose infusion.
- 3 The fever is a likely indication of an infection, which could be the result of a catheter site or bloodstream infection. You should notify the health care provider immediately.
- 4 You would caution Mr. Giles about his enthusiasm and explain that it is unlikely that he has gained all of the weight from a restoration in nutritional status. It is likely that most of the weight gain is from fluid retention. Your assessment would include auscultating lung sounds, checking for edema in the extremities, and comparing heart rate with baseline.

Answers to Review Questions

- 1, 3 **Rationale:** The fluid for the total PN is hyperosmolar. However, you should avoid complex terms in the explanation. Explaining that the smaller veins cannot tolerate the concentration of the nutrients very well and become irritated easily is more easily understood by the patient.
- 1 **Rationale:** Elevated temperature, chills, nausea and vomiting, and chest pain indicate lipid infusion intolerance. Option 2 could indicate a problem with the catheter placement. Option 3 could indicate infection, and option 4 is nonspecific.
- 2 **Rationale:** The Infusion Nurses Society recommends changing IV administration sets for 3:1 PN every 24 hours and immediately on suspected contamination.
- 1 **Rationale:** PN is a nutritional support measure to ensure adequate intake while patient is NPO. Option 2 is not correct because enteral feedings may be given in some cases concurrently with PN. Option 3 is not correct because PN is a nutritional measure, not an effective treatment for cancer. Option 4 is not correct because the risks and costs associated with PN are too high for its use as a supplement.
- 4 **Rationale:** PN is a complete mixture of each of these components.
- 3 **Rationale:** This filter is used to prevent particulate matter and large lipid droplets from reaching a patient and risking pulmonary embolism. Option 1 is not correct, because without a filter the risk of pulmonary embolism is great. Option 2 is not correct because lipid will not flow through such a small filter. This filter is used for PN that does not contain lipid. Option 4 is not correct because such filters are not used.
- 4 **Rationale:** Bloodstream infections are a risk both in hospitalized and home PN patients. Option 1 is not correct because PN does not cause gastrointestinal distress since it is infused intravenously. However, bowel obstruction may be a reason to infuse PN. Option 2 is not correct because PN is administered intravenously and not associated with pneumonia. Option 3 is not correct, because PN may be given in a clinical setting in which albumin levels are more likely to be low.
- 3 **Rationale:** Liver disease is associated with multiple bloodstream infections, severe gastrointestinal disease, and longer PN duration. Option 1 is not correct, although it may be associated with short-term PN infusion. Option 2 is not correct because PN lipid contains no cholesterol and long-term PN patients with severe GI disease more often have low cholesterol. Option 4 is not correct.
- 5 **Rationale:** All of the above conditions are clinical situations in which PN is indicated.
- 1 **Rationale:** Patients with short-bowel syndrome or severe dysmotility have permanent and severe malabsorption and require the nutrients that PN provides, even with oral food intake. Option 2 is not correct because the risks and costs associated with long-term PN outweigh the benefits as a diet supplement. Option 3 is not correct because PN is an expensive therapy that carries the risk of catheter-related bloodstream infection (CRBSI); thus it would not be justifiable based only on preference. Option 4 is not correct

because such a patient will be unable to add vitamins to the infusion bag and control the home infusion pump safely.

CHAPTER 33

Critical Thinking Exercises

- 1 The following assessments would be pertinent for this patient:
 - Determine cultural considerations that would be appropriate as you care for this patient.
 - Assess understanding and knowledge of her condition and treatment plan.
 - Assess the intake and output (I&O) record. Identify any trends, voiding patterns (e.g., increased incontinence, frequency), and the last time the patient voided.
 - Assess the ability of the patient to participate in the plan of care, which includes language, sensory, cognitive, and mobility.
 - Assess the lower one third of the abdomen for distention and/or tenderness.
 - Assess for signs and symptoms of a UTI.
- 2 An assessment of the PVR urine is very important for this patient. An abnormal PVR urine would indicate inadequate bladder emptying. She has a history of urinary retention plus a number of other conditions that increase her risk for bladder dysfunction and urinary retention such as stroke, history of UTIs, and type 2 diabetes. Her incontinence needs to be further evaluated, and PVR will determine if this incontinence is caused by an overflow of urine as a result of urinary retention. In addition, if the patient's bladder is emptying, a PVR would help rule out the use of catheterization.
- 3 The health care provider has ordered the option to use a bladder scanner or to catheterize the patient. Whenever possible, you should avoid catheterization because of the increased risk for UTI; thus the use of the bladder scanner would be appropriate. The initial assessment with the bladder scanner will dictate if you need to insert an indwelling catheter (e.g., if the bladder scanner shows a volume greater than 400 mL).
- 4 The following teaching would be appropriate when assessing PVR:
 - Explain rationale for the procedure in simple, easy terminology.
 - Explain the procedure, including that the measurement needs to be made within 10 minutes of voiding.
 - Instruct the patient to void in a measurement container.
 - Explain that the bladder scanner looks inside the body and measures the volume of urine left in the bladder after voiding. It does not hurt.

Answers to Review Questions

- 3 **Rationale:** Hygiene minimizes skin irritation and infection from continued exposure to urine. There needs to be 2.5 to 5 cm (1 to 2 inches) of space between tip of the glans penis and the end of the catheter. Excess space may cause pooling of urine, causing excessive exposure to urine. Shaving the pubic area increases the risk for skin irritation. The condom should be secure but not tight. Application of tape is contraindicated because it could interfere with circulation, increasing risk for necrosis of the penis.
- 2 **Rationale:** This is the correct order in which to insert an indwelling urinary catheter.
- 3 **Rationale:** Advancing the catheter to the bifurcation avoids inflating the catheter balloon in the prostatic urethra, causing trauma and pain. Catheter balloons are never inflated with saline. Securing the catheter drainage tubing to the bed sheets increases the risk for accidental pulling or tension on the catheter. Advancing the catheter until urine flows and then inserting $\frac{1}{4}$ inch (0.6 cm) more is not unique to the male patient.
- 2, 3 **Rationale:** By allowing the balloon to drain by gravity, the development of creases or ridges in the balloon may be avoided, minimizing trauma to the urethra during withdrawal. All patients who have a catheter removed should have their voiding monitored with a voiding record or bladder diary. The size syringe used to deflate the balloon is dictated by the size of the balloon. Catheters should be pulled out slowly and smoothly. Pulling fluid out of the

- balloon with force can cause the formation of creases or ridges in the balloon.
- 5 3, 4 **Rationale:** An established suprapubic catheter insertion site can be cleaned with medical aseptic technique. Always inspect a site for signs of infection. Anchor the catheter to the abdomen to minimize trauma and increase comfort. Wiping the catheter toward the insertion site violates principals of asepsis. Avoid applying tension to the catheter in all circumstances to minimize discomfort and potential for damage to the bladder wall.
 - 6 2 **Rationale:** The most appropriate action would be to ensure that the catheter is not occluded. Fluids should not be encouraged if the catheter is blocked. Irrigation and catheter removal are more invasive interventions that may be appropriate, depending on the cause of the decreased urine flow.
 - 7 3 **Rationale:** Adequately assess bladder function after a catheter is removed; voiding frequency and amount should be monitored. Unless contraindicated, fluids should be encouraged. To promote normal micturition, patients should be placed in as normal a posture for voiding as possible. Suprapubic tenderness and pain are possible indicators of urinary retention and/or a urinary tract infection.
 - 8 3 **Rationale:** Evidence-based guidelines support the use of indwelling catheters in the presence of urinary retention. Another indication for catheterization is healing of open sacral or perineal wounds in incontinent patients. A stage I ulcer is not an open wound but would require close observation. All other patient conditions are not appropriate for an indwelling catheter because of the increased risk for catheter-associated urinary tract infection (CAUTI).
 - 9 3 **Rationale:** Evidenced-based guidelines for the prevention of CAUTI support the use of the smallest size catheter and balloon possible, which in an adult is a size 14 Fr, 5 mL balloon.
 - 10 2 **Rationale:** An appropriate first action would be to assess the patency of the drainage system. Urine output in the drainage bag should be more than the volume of the irrigant solution infused. If the system is not draining urine and irrigant, the irrigant should be stopped immediately. The catheter may be occluded, and the bladder distended.

CHAPTER 34

Answers to Critical Thinking Questions

- 1 A fracture bedpan is best; it is easier to place in patients with restricted mobility. Mr. Simon can help with placement by using a side rail or trapeze bar. A commode is contraindicated because Mr. Simon is only able to use touch-down weight bearing and therefore may not transfer from bed to commode easily or timely.
- 2 It is expected that the Fleet enema would stimulate a bowel movement, and the fecal material expelled may be hard or range from hard-to-soft stool. In addition, Mr. Simon may have subsequent bowel movements throughout the day. You must instruct the nursing assistive personnel (NAP) about the expected outcome of the enema. In addition, you must instruct the NAP to immediately report to you any complaints of abdominal pain or discomfort, rectal bleeding, blood in the stool, enlarged abdomen, or changes in vital signs.
- 3 **d, e, a Rationale:** First you must perform an abdominal assessment. Mr. Simon's pain could be caused by many factors ranging from benign gas to perforation. You need to collect data as baseline to monitor progression of pain and other abdominal signs and symptoms. In addition, you need data when you call his health care provider. Next obtain VSs and instruct the NAP to obtain them every 15 to 30 minutes thereafter. You need to obtain the first set of VSs as a baseline and compare with the patient's range. The NAP then monitors these VSs at your direction for frequency. This obtains valuable information while you are contacting the health care provider. Finally you should notify the health care provider. You should now have abdominal assessment and your VSs measurement data to report.

You do not do the following: Instruct the NAP to palpate Mr. Simon's abdomen. Assessment is a nursing responsibility. However, you may

instruct the NAP to notify you if it appears that Mr. Simon's abdomen is getting bigger or his level of pain changes.

Nor do you give postoperative pain medication as ordered. Although Mr. Simon indeed has pain medication, that medication is to control postoperative knee pain. It will take away or diminish his abdominal pain. Until the cause of Mr. Simon's abdominal pain is identified, the presence of pain and changes in quality and intensity are important clinical assessment findings that should not be masked by analgesia.

- 4 The patient may be experiencing a slowed heart rate as a result of vagal stimulation. Immediately stop the procedure and retake the vital signs. Notify the prescriber if the vital signs remain low.

Answers to Review Questions

- 1 4 **Rationale:** This may be the result of vagus stimulation, and you should stop the procedure.
- 2 2 **Rationale:** Swallowing closes off the upper airway and prevents the tube from entering the lungs.
- 3 2 **Rationale:** Rolling patient onto a fracture pan prevents friction or injury to underlying skin and tissue. A frail patient is likely to have fragile skin.
- 4 1 **Rationale:** Surgery just 5 weeks ago would require particular precaution not to disturb the surgical site and prevent trauma to the rectum. An enema would appear to be contraindicated; thus verifying the order would be appropriate.
- 5 2 **Rationale:** Turning a patient to the left side will release the tube from the stomach lining. It is not within a nurse's scope of practice to advance a nasogastric tube after a patient has abdominal surgery or increase the suction.
- 6 1 **Rationale:** Postoperative patients generally receive opioids, which have a common side effect of constipation, for pain. Therefore the best answer is to administer an enema. An x-ray film would not be necessary at this time. The stool is too high in the colon to remove digitally. Waiting for pain is not an appropriate action.
- 7 4 **Rationale:** The bedpan should be offered an hour after breakfast. Peristalsis is strongest after the first meal of the day.
- 8 2 **Rationale:** Elevating the head of the bed to 30 to 60 degrees prevents hyperextension of the back and supports the upper torso.
- 9 2, 4, 5 **Rationale:** Toilet paper should be within easy reach, the head of the bed should be 30 to 60 degrees, and a small pillow under the lumbar curve will reduce stress on back. You should allow the patient to be alone for privacy. A flat bed places more stress on the back.
- 10 1, 3, 5 **Rationale:** Administering an enema, placing a patient on a bedpan, and providing oral care for a patient with an NG tube may all be delegated to NAP. Removing a fecal impaction and inserting an NG tube require the training and skill of a nurse.

CHAPTER 35

Answers for Critical Thinking Questions

- 1 3 **Rationale:** Stoma site should be marked before surgery to avoid having a stoma in a location that would make pouching difficult such as in a fold or crease or a location that the patient cannot see. It is not feasible for a patient to empty a pouch until after surgery. A nutrition consultation may be needed after surgery, but often there are few dietary restrictions with an ileostomy. The diagnosis of ulcerative colitis has already been made; thus this diagnostic test for colon disease would be unnecessary before surgery.
- 2 1 **Rationale:** The stoma should be red and moist. Retraction of the stoma below skin level is usually secondary to necrosis and does not occur until about 2 weeks after surgery. Stents protruding from a stoma are seen with a urostomy, not an ileostomy. The stoma may be pink after surgery, but it would be moist and producing mucus.
- 3 2 **Rationale:** To avoid having the pouch get too heavy and loosen from the skin, it should be emptied when it is one-third to one-half full. The pouch should not be changed daily because this could cause skin breakdown. Pouch emptying cannot be done on a

prescribed schedule. The frequency varies with food and fluid intake. An expected wear time for an ileostomy pouch is 3 to 5 days.

- 4 You will explain that the effluent from an ileostomy is always liquid, although it may be thick or thin. This is a normal finding with an ileostomy. The patient should not expect a formed bowel movement.

Answers for Review Questions

- 1 2, 3, 4 **Rationale:** All of these actions may facilitate additional drainage through the catheter. You cannot use urine from the pouch because it may be contaminated.
- 2 1, 2, 3 **Rationale:** Being receptive to teaching and active participation in care shows the patient's acceptance of his bodily function changes. Assigning care to his spouse is delaying or denying the return to self-care.
- 3 4 **Rationale:** The stoma will initially be edematous. The swelling will decrease normally over 4 to 6 weeks, and the size may change during that time.
- 4 4 **Rationale:** Assessment is the first step of the nursing process; and, by using an open-ended question, you can determine a patient's specific concerns. Shifting responsibility to the health care provider is inappropriate, and waiting until after the surgery to address the issue only increases a patient's anxiety. Having a person with an ostomy visit the patient before surgery may be helpful, but assessment needs to be done first.
- 5 2 **Rationale:** The patient needs assistance immediately before the enzymes from the urinary drainage break down the skin any further. The ostomy care nurse is the best resource person to contact.
- 6 The intestinal opening surgically created in the abdomen for a colostomy, ileostomy, or urostomy is called a *stoma*.
- 7 The correct order for the steps in changing an ostomy pouch is:
 1 Observe the stoma and the skin around it.
 2 Remove the old pouch.
 3 Clean and dry the peristomal skin.
 4 Measure the stoma.
 5 Trace the correct measurement onto the back of the wafer.
 6 Cut the hole in the wafer.
 7 Press the pouch into place over the stoma.
 8 Close the end of the pouch.
- 8 The pathway created for urine to exit the body when the bladder is removed is called an *ileal conduit*.
- 9 3 **Rationale:** Air in the pouch is a normal and expected sign following ostomy surgery. It is still too early to expect significant fecal drainage.
- 10 1, 3, 4 **Rationale:** Common symptoms of a UTI include dark or bloody urine; foul-smelling urine; fever (38.3°C [101° F] or higher); confusion; and flank pain, not upper abdominal pain.

CHAPTER 36

Answers to Critical Thinking Exercises

- 1 Obesity, diabetes, and smoking place Mrs. Edmonds at increased risk for an SSI. Antibiotics should not be given beyond 24 hours unless there is a clinical indication. You will need to instruct Mrs. Edmonds that she will not be allowed to smoke in the hospital, follow up to ensure that she has an order for a substitute nicotine product if needed, and offer smoking cessation instruction/consultation. Glycemic control must be maintained during the recovery period to promote incision healing.
- 2 You will need to reinforce with Mrs. Edmonds how to turn, cough, deep breathe, and use the incentive spirometer. Instruction in pain-control measures, including how to use the patient-controlled analgesia (PCA) device and how to splint her incision with a small pillow before coughing, turning, or ambulating must also be reinforced. Early ambulation and the need to wear intermittent pneumatic compression (IPC) cuffs while in bed or up in chair must also be included. Include family in teaching and reinforce that for safety reasons Mrs. Edmonds is the only person to activate the PCA device.

- 3 Given her history of smoking, following general anesthesia she is at an increased risk for pulmonary complications. Include lung auscultation as part of routine assessment and closely monitor respiratory rate, temperature, and presence of productive cough. A history of obesity, taking birth control pills, and undergoing pelvic surgery places her at an increased risk for deep vein thrombosis (DVT)/venous thromboembolism (VTE). Mrs. Edmonds will need anticoagulant therapy and must wear an IPC while she is in bed or sitting up in the chair.
- 4 Patient should be instructed to use a PCA device before ambulating/performing exercises and to splint incision with small pillow to decrease incisional discomfort.

Answers to Review Questions

- 1 1, 2, 3, 5, 6 **Rationale:** Hair is removed using a clipper so the skin is intact, thus reducing the chance of an SSI. All of the other statements are true.
- 2 2 **Rationale:** Compression devices are applied before surgery and are generally some type of either knee-high or thigh-high compression hosiery. They prevent pooling of blood in the lower extremities. The pneumatic compression devices may or may not be used during surgery. The patient may not be able to ambulate after surgery because of the nature of the surgery, or physical therapy may be needed before ambulating.
- 3 4 **Rationale:** Institution agencies protocol needs to be followed, and a representative of the agency who is familiar with these situations such as a risk manager may be helpful.
- 4 3 **Rationale:** The surgeon should discuss and document issues with the patient and/or family to determine whether DNR orders are to be maintained or modified during surgical procedures.
- 5 2 **Rationale:** Mark the dressing with a circle around the drainage and the time noted. This gives an objective assessment of the extent of the drainage and can be continually reassessed.
- 6 2 **Rationale:** It is recommended that prophylactic antibiotics be given as close to the time of incision as possible (within 60 minutes) except vancomycin and fluoroquinolones that require a longer administration time. It is recommended that antibiotics *not* be given for longer than 24 hours after surgery.
- 7 1 **Rationale:** Exercises before coughing enhance the ability to move secretions so they may be expectorated.
- 8 4 **Rationale:** Spontaneous postoperative pneumothorax does not occur because of the general anesthesia.
- 9 4 **Rationale:** Management, assessment, and teaching skills should be performed by the RN and not delegated to others.
- 10 2, 3, 4 **Rationale:** ASPAN describes the three levels of recovery care to include the postanesthesia phase I, phase II, and extended care levels of care.

CHAPTER 37

Answers to Critical Thinking Exercises

- 1 2 **Rationale:** A short prescrub wash/rinse removes gross debris and superficial microorganisms and must be completed before performing surgical antisepsis.
- 2 3 **Rationale:** Artificial nails may not be worn because they may harbor gram-negative microorganisms and fungus, thereby increasing the risk for the patient developing a surgical wound infection.
- 3 After scratching her leg, Sarah should have stopped and immediately changed the affected glove. Once Sarah reached below her waistline, she contaminated the gloves, because the area of the gown below the waistline is considered contaminated, thereby increasing the risk for the patient developing a surgical wound infection.

Answers to Review Questions

- 1 3 **Rationale:** The circulating nurse assumes responsibility and accountability for maintaining patient safety and continuity of quality care. This includes assessing the patient, reviewing consents and the medical record, supervising the scrub technician, and delegating tasks to licensed and unlicensed nursing assistive personnel (NAP) as appropriate.

- 2 1 **Rationale:** The surgical hand scrub has been used traditionally for many years.
- 3 2 **Rationale:** All surfaces on both hands, extending from the fingertips just past the forearms, should be checked for the presence of abrasions, cuts, or open lesions. Rings should be removed totally. Artificial nails need to be removed weeks before being in a surgical environment so the nails and skin can heal after the nails are removed.
- 4 1 **Rationale:** Both hands should be covered with the cuffs of the gown to provide sterility.
- 5 4 **Rationale:** Anything sterile touched by something or someone unsterile becomes unsterile.
- 6 2 **Rationale:** The gloves are removed last; regown and reglove using closed gloving method.
- 7 2 **Rationale:** Gowns are sterile from the front chest and shoulders to table level and on the sleeves to 5 cm (2 inches) above the elbow.
- 8 1 **Rationale:** Hand scrubs include inspecting, scrubbing 3 to 5 minutes, rinsing, turning off water with foot or knee controls, and backing into the OR with hands higher than elbows.
- 9 2 **Rationale:** Do a 3- to 5-minute scrub; put on sterile gown; put on sterile gloves.
- 10 1 **Rationale:** The time out involves the immediate members of the procedure team: the individual performing the procedure, anesthesia providers, circulating nurse, operating room technician, and other active participants who will be participating in the procedure from the beginning. All relevant members of the procedure team actively communicate during the time-out.

CHAPTER 38

Answers to Critical Thinking Exercises

- 1 1, 2, 5 **Rationale:**
- Prednisone is a steroid. Steroids decrease the inflammatory response and slow collagen synthesis, impairing wound healing.
 - Diabetes mellitus impairs wound healing by decreasing tissue perfusion and hindering the release of oxygen at the tissue level.
 - Age impairs wound healing. Vascular changes, diminished pliability in collagen tissue, and scar tissue tightness contribute to impaired wound healing.
- 2 Granulation tissue is composed of new blood vessels that will bring nutrients and oxygen to the tissue. This type of tissue must be present for the wound to heal. Once a wound is filled with granulation tissue, healing will progress; thus a wound filled with granulation tissue is a good finding.
- 3 The presence of the healing ridge is important because it indicates that there has been deposition of collagen in the wound. This connective tissue provides strength to the wound and decreases the risk of dehiscence. Lack of a ridge is cause for concern, and you will need to begin prompt interventions to reduce mechanical strain on the wound.

Answers to Review Questions

- 1 4 **Rationale:** The fluid needs to drain from top to bottom, allowing gravity to help.
- 2 2 **Rationale:** If there is no order for the suture removal, none of the other steps need to be taken. Nurses cannot remove staples or sutures merely because of something the health care provider said.
- 3 3 **Rationale:** The patient should be premedicated because of the wound size. He or she should be positioned as flat as possible. You place the lower tip of the staple remover under the staple, and you do not lift up on the staple when depressing the extractor handles. The incision cleaning is started at the top of the incision and not the sides. When half the staples are removed, it means that every other staple is removed. This allows observation of how the wound is healing. In some instances small strips of tape, called *Steri-Strips*, will be used where the staples were removed to help stabilize the tissue.
- 4 3 **Rationale:** The suture should be removed in a smooth, continuous manner. The knot should have been snipped at the end distal

to the knot. The scissors should have been held in your dominant hand, and the pickups in your nondominant hand. Disinfectants are never used on living tissue because of their harsh chemical action. Antiseptics may be used on skin to remove organisms.

- 5 2, 5, 6 **Rationale:** The drainage needs to be emptied, measured, and recorded. After you have emptied the drainage, you need to depress or squeeze the drain flat before putting in the plug. This helps the suction mechanism to work. Attaching the drain to the patient's gown below the level of the wound helps to prevent the drain from pulling and also keeps it in a dependent position to allow for maximum drainage.
- 6 1 **Rationale:** A surgical incision has the wound edges approximated at the time of the operation, is secured with staples, and is healing by primary intention. There is little need for tissue regeneration. Wounds that are left open to heal by secondary intention are not approximated and are left open. These types of wounds heal slowly because of the need for connective tissue to fill the area. A wound that heals by tertiary intention is left open for several days, and the edge area is approximated while the center of the wound heals by the formation of granulation tissue.
- 7 1, 2 **Rationale:** Use sterile technique and direct flow of solution from healthy to infected tissue.
- 8 2 **Rationale:** A Jackson-Pratt drain is a closed suction setup. Once the collector is drained, push out the air by compressing the drain and closing it. When the collector is drained, all the exudate is removed, and the collector is not pumped.
- 9 2, 3 **Rationale:** When you can see air under the negative-pressure wound therapy dressing, this indicates a problem with the seal. A negative-pressure wound therapy dressing should be flat over the wound dressing since all of the air should be removed from the area by the suction. Therefore the appropriate interventions include checking the seal of the transparent dressing for signs that it is not adhering to the skin or dressing and checking that the suction is working by noting that each of the connections from the suction source to the wound is intact. Changing the dressing would not be appropriate until this is done.
- 10 3 **Rationale:** The type of drainage that is clear like plasma is called *serous*. Purulent drainage is typically beige or tan, slough is used to describe nonviable yellow tissue (not drainage), and plasma is a deep red color.

CHAPTER 39

Answers to Critical Thinking Exercises

- 1 He is likely not holding the dressing in place for 30 to 60 seconds, which helps it to conform over the heel.
- 2 The hydrocolloid dressing is a good choice for clean stage II pressure ulcers. The dressing promotes a moist environment for healing and has an added benefit of reducing pain. It also is a good barrier to bacteria.
- 3 Hydrocolloid dressings interact with wound fluids and normally form a soft whitish-yellowish gel, which is sometimes hard to remove and may have a faint odor. This is a normal occurrence; Mr. Williams should not confuse this finding with pus, purulent exudate, or wound infection.

Answers to Review Questions

- 1 2 **Rationale:** To adequately debride a wound, the packing needs to be dry on removal. The dressing was too wet when it was placed in the wound initially.
- 2 4, 3, 5, 1, 2 **Rationale:** This is the correct order for application. Select size, remove backing, mold wafer over wound, hold in place for 30 to 60 seconds, and tape.
- 3 2 **Rationale:** A moist-to-dry dressing mechanically debrides the wound when exudate adheres to the moist gauze. The transparent dressing is indicated after a wound is debrided. Hydrogel debrides a wound through autolysis, and not mechanical debridement. Telfa is a dry nonadherent dressing, which is inappropriate for this purpose.

- 4 2 **Rationale:** A hydrogel dressing is soothing and is the most appropriate one for a patient with burns.
- 5 1, 2, 3, 6 **Rationale:** The following conditions, medications, or treatments interfere with wound healing: immunosuppressive drugs, diabetes, steroids, and irradiation.
- 6 4 **Rationale:** If the binder is placed either too high or too tight, a patient can experience shortness of breath, which would require you to release the binder and reapply it.
- 7 2 **Rationale:** In NPWT, negative pressure applied through the foam dressing removes exudate and contracts the wound bed to promote healing. Exudate is pulled out, not pushed into the wound. The wound bed is not flooded, and gauze pads are not placed in the wound bed.
- 8 4 **Rationale:** An increase in pain can be an indicator of neurologic and vascular changes. Options 1 and 2 evaluate circulation. Option 3 evaluates for wound infection.
- 9 2 **Rationale:** A surgical wound often has a drain in place. Gauze dressings should be removed one layer at a time to prevent accidentally pulling and removing the drain. The removal of a sterile dressing requires only clean gloves. Saline is not needed to moisten gauze unless drainage in the dressing sticks to the wound.
- 10 3 **Rationale:** Frequent dressing changes pose a risk of skin abrasion and skin tears from tape removal. A set of Montgomery ties is the best choice to secure the ABD pad.

CHAPTER 40

Answers to Critical Thinking Exercises

- 1 1, 2, 3, 4—all the options would apply. **Rationale:** Hot and cold therapies require a health care provider's order validating location, duration, and temperature as prescribed in the order. Assessing current pain level and condition of the extremity provides a baseline assessment for care. Patient education regarding procedure, precautions, and signs and symptoms of frostbite should be explained to prepare the patient.
- 2 2, 4 **Rationale:** There is greater risk for tissue injury when there is diminished circulation, a common characteristic of diabetes mellitus. A confused patient may be unable to provide feedback about how the application is feeling and will need to be monitored more closely for signs and symptoms of adverse effects.
- 3 Although this skill can be delegated to NAP, it would be unwise to delegate it initially. The patient has two risks, confusion and diabetes, which put him at risk for complications. In addition, because of these risks it is important to increase monitoring and skin assessment to maintain patient safety.

Answers for Review Questions

- 1 3 **Rationale:** It is essential to assess the area being treated. It is important to monitor the machine, but patient response is always the priority, especially because moist heat penetrates deeper into tissue layers.
- 2 3, 4, 5, 6, 7 **Rationale:** Patients with decreased circulation and conditions that cause decreased fluid or nutrients to their systems and those who use steroids for a long time are at risk for tissue injury.
- 3 1 **Rationale:** The area being treated would be slightly pale and cool to touch because of the decrease in circulation.
- 4 1 **Rationale:** Because the area being treated has little fat or tissue around it, the amount of time that cold is applied should be decreased.
- 5 1, 3, 4 **Rationale:** Localized cold therapy reduces blood flow to the injured body part, prevents edema formation, and reduces inflammation. Local analgesia is produced by slowing or blocking peripheral nerve conduction and preventing muscle spasm by decreasing spasticity.
- 6 3 **Rationale:** Shivering increases muscle activity, which in turn increases a patient's metabolic rate and therefore heat production, which is counterproductive.
- 7 2 **Rationale:** Because the patient is older and has limited mobility and strength, there may be a problem with the moist heat wrap, and he or she may need help. One hour is far too long without

checking on the patient's response to the therapy. The patient should not move the heat wrap because of the chance of moving it to an area where it could cause harm. This further supports the need for the call light to be close to the patient. The device should not be secured to the affected area with plastic wrap.

- 8 2 **Rationale:** The use of moist heat is contraindicated in patients who use patches to stop smoking and in those who use patches containing other medications because the heat increases the speed of absorption because of vasodilation. The area where the device is to be applied, not the full body, would be assessed before application. Alignment is not a priority for this therapy.
- 9 1 **Rationale:** The most effective method of determining the effectiveness of the treatment is to assess the patient's pain level. Since heat relaxes a strained muscle, a difference should be noted when the muscle is at rest. It is counterproductive for the patient to actively force the use of the affected muscle during a strenuous activity or exercise at this time.
- 10 4 **Rationale:** Because the area injured is near the bone and has less padding, the nurse needs to prevent any injury to the area as a result of the cold therapy. Therefore the nurse should check the ankle every 5 minutes. The other two options are not evaluation measures.

CHAPTER 41

Answers to Critical Thinking Exercises

- 1 The multiple medications Mrs. James takes may contribute to dizziness and lead to falls. Her visual and hearing deficits create fall risks. In addition, her immobility, bone pain, and stairs are also risk factors for falling because of muscle weakness caused by lack of exercise and pain and the risk of attempting to perform an activity she no longer can do safely.
- 2 2 **Rationale:** Asking the patient to verbally explain her medication regimen assesses cognitive function and memory. Showing the nurse where the medication is stored does not ensure that she is taking the medication correctly. Option 3 is incorrect because you are not assessing caregiver knowledge; you are directly assessing the patient's knowledge.
- 3 Despite older adults' risks, they learn how to negotiate their environment relatively well and are usually aware of potential dangers. Thus older adults may often be more cautious than younger people. Encourage the family to discuss with their mother what might provide a greater sense of security for both of them such as installing an alarm system and a medical emergency alert system. Offer a home safety assessment.

Answers to Review Questions

- 1 1-6 **Rationale:** All of these topics would be covered to determine the physical and mental status of the patient and check that she is not a victim of abuse or neglect.
- 2 2 **Rationale:** The Timed Get Up and Go (TUG) Test looks at how a person changes position and becomes mobile. MMSE is used to screen for cognitive changes. SPLATT is a mnemonic used to assess actual falls. A fall diary is used to record the events surrounding an actual fall. Safety is a priority for individuals of any age.
- 3 4 **Rationale:** Soiled dressings should be double bagged in impervious plastic.
- 4 4 **Rationale:** These are the physical abilities that a patient must have to help prevent falls.
- 5 1, 2, 4 **Rationale:** The kitchen temperature varies, and the insulin should be refrigerated until use and discarded by the expiration date.
- 6 4 **Rationale:** The patient's list of medications always needs to be reviewed for not only the dose ordered, but also for how many the patient is taking and the timing of the dosing. The nurse needs to check if the patient is taking the medication at the correct time of day. A deviation in timing could cause great distress for this patient since this individual would not be able to get the sleep needed. A night-light would be helpful, especially in the bathroom or in the hall on the way to the bathroom, but this is not the

- primary focus. Evaluate how much fluid the patient is consuming and how late at night she takes these fluids.
- 7 3 **Rationale:** Preventing fire is the prime object when using the kitchen. Older individuals often forget that they are cooking; fires can occur, or food can burn. A timer will alert the individual that something has to be done (e.g., stirring food, turning meat, or serving food that is cooked). There is no way to know the relationship of the garage to the kitchen as stated in the question. Light is important, but preventing fire and subsequent burns is the primary focus. Locks are needed in the kitchen for small children but not for this still independent individual.
- 8 4 **Rationale:** A patient should always be assessed before anything else. The physical environment needs to be checked to ensure that it is safe and has what he or she needs, but that would be done after checking him or her. Depending on the status of the patient, 9-1-1 and the appropriate state agency could be contacted, but everything would hinge on the findings of the patient's status.
- 9 3 **Rationale:** The pill organizer is useful in weekly management because each day of the week has its own holder so the patient knows if he or she took the medication for that day/time. A color chart is not helpful since pills can be different colors/shapes, depending on the pharmaceutical supplier. The patient is capable of organizing medication; thus the daughter does not need to visit each day, nor should the nurse take over the medications. You want to ensure as much independence as possible in the home care patient.
- 10 3 **Rationale:** Placing food items in realistic-size servings in easy-to-open containers provides the most independence for this couple. They are not blind and do not require clock orientation for placing food on their plates. Taking them shopping will not provide nutrition if they can't open the containers or if food preparation is painful because of their joints.

CHAPTER 42

Answers to Critical Thinking Questions

- 1 Additional information needed:
- List of current medications
 - Cognitive status
 - Problems with sensation or mobility
 - Recent vital signs: Heart rate and rhythm—expect rate to be irregular if he is in atrial fibrillation. Temperature: Did client have a temperature in the hospital at any time?
 - Client's and wife's motivation and willingness to learn
 - Past medical history
- 2 3 **Rationale:** The pulse of a client with an arrhythmia should be taken for a full minute in case the pulse is irregular.
- 3 He may be pressing too hard over the artery or is unable to locate it. Coach him in his technique and reinstruct about artery location. You might also consider teaching him how to feel his carotid artery instead. If a cognitive deficit exists, teach a family member or friend how to check the pulse.
- 4 You can use many teaching strategies to facilitate successful medication education in older adults. Some strategies to enhance learning include the following:
- Provide typewritten information in large print.
 - Provide information that client thinks is important.
 - Develop strategies to help the client and his wife remember to take the medication.
 - Repeat information that is important in the beginning and at the end of teaching sessions.
 - Develop a trusting relationship with the client and his wife.
 - Use a memory aid such as a daily checklist to help him remember to take his medications.
- 5 You will want to know which type of oral thermometer the client is using. Have the client demonstrate taking his temperature, note if he can see the reading, and teach accordingly. You will want to know what time of day the client is checking his temperature and how long he waits after drinking a hot or cold beverage and/or smoking.

Answers to Review Questions

- 1 3 **Rationale:** The best method of verifying accuracy is to obtain two readings within 1 to 2 minutes of each other using two different monitoring devices.
- 2 1, 4, 6 **Rationale:** He needs to stay away from anything that can cause a shock such as short circuiting from an electric shaver. He also needs to avoid open flames such as in a campfire or fireplace. A client with home oxygen therapy needs an extra set of oxygen delivery devices in case one should fail. Using lint-free cloths for cleaning equipment reduces friction.
- 3 3 **Rationale:** Instilling normal saline does not decrease hypoxia and is not recommended routinely. The suction pressure stated is too high. The client should not be flat. She should be elevated at least 30 to 45 degrees. The suction catheter would be in the sterile gloved dominant hand, which would allow for less chance of contamination.
- 4 2 **Rationale:** He needs time and input to learn and participate in this important part of his care. There should not be anything or anyone that could distract his attention. There are no data to support that he needs enlarged written directions.
- 5 1, 2, 3, 4 **Rationale:** Difficulty breathing and coughing are signs of aspiration. Raise the head of the bed and stop feeding. Then have the family caregiver notify the health care provider and verify tube placement. If difficult breathing continues, call 9-1-1.
- 6 3 **Rationale:** Before the nurse can make any recommendations, he or she needs more information (i.e., which symptoms the client is experiencing) since a temperature within normal range in the elderly can still reflect the presence of a fever. Adequate fluid intake is needed and should be monitored; but, since the wife gave very vague information, more information must be obtained. Changes in behavior such as delirium or dementia may occur with a temperature elevation.
- 7 2 **Rationale:** The size of the blood pressure cuff can cause an inaccurate reading. If the cuff is too large, the reading will be low; if the cuff is too small, the reading will be high. If the cuff is too small even before inflating it, it can pop off during the procedure; or, if it remains on, it will overly compress the vessels and indicate an unusually high and inaccurate reading. Options 3 and 4 have nothing to do with the technique. The nurse should be sure the client is measuring BP the same time each day, but it is not likely a factor in the BP being high consistently.
- 8 3 **Rationale:** When performing clean, intermittent catheterization, the client uses soap and water to clean the urinary meatus. Sterile gloves are not used because of the decreased chance of introducing organisms that would cause a urinary tract infection. The client's own organisms are predominant. It is essential that good hand hygiene be done immediately before the insertion and that the catheters have been cleaned, dried, and stored appropriately.
- 9 3 **Rationale:** Saying "Oxygen levels decrease with forceful coughing more as aging occurs" is the clearest answer and doesn't use confusing technical language. Although loss of elastic recoil is correct, it is not something the nurse should expect the family to understand. Anxiety can accompany decreased ability to breathe but is not relevant to the question asked.
- 10 1 **Rationale:** Compliance with medication regimens is increased if the family or client understands the medications being given. It is essential that safety elements be considered when pets or small children live where medications are given. Meaningful written materials help to prevent medication errors regarding dosing and times that the medications are given. It is important that planning occurs to prevent running out of medication.

CHAPTER 43

Answers to Critical Thinking Exercises

- 1 1, 4 **Rationale:** Testing sputum would be important to determine if Mrs. Yamamoto has pneumonia, identify the organism and guide the health care provider in selecting the best treatment. Elevated blood glucose levels occur when a person with diabetes becomes

- ill. Mrs. Yamamoto's blood glucose level is elevated because of her pneumonia.
- 2 As a point-of-care laboratory test, fingersticks for blood glucose level would give immediate results. Sputum specimens need to be cultured and take 72 hours for results.
 - 3 There are several issues to consider when deciding to teach Mrs. Yamamoto to provide a sputum specimen. Her limited use of English is a major barrier. The daughter translated previously. You should provide a professional translator by determining if the hospital has translators or using the free telephone service available in many areas. Pictures, demonstration of what is desired, and having the patient perform a redemonstration can be helpful.
 - 4 You need to assess Mrs. Yamamoto's ability to perform a fingerstick, to read the monitor, and to understand the importance of blood sugar control. Indicate to Mrs. Yamamoto that you wish to observe and assess her as she demonstrates how she performs blood glucose monitoring at home and ask and answer questions.

Answers to Review Questions

- 1 **1, 2, 5, 6 Rationale:** Option 3 is incorrect; the head of the penis is wiped in a circular motion, not back and forth. Option 4 is incorrect; the amount of urine needed is between 30 and 60 mL.
- 2 **1 Rationale:** The first urine specimen is discarded. This signifies the beginning of the collection time, which ends 24 hours later. The patient is encouraged to void right before the collection time ends.
- 3 **2 Rationale:** Tomatoes can change the result because of their high vitamin C content and their color. Numerous other foods can alter the results.
- 4 **1, 4 Rationale:** These are the only correct steps for this procedure. Leaning the head forward increases difficulty entering the mouth and decreases visualization of the oral cavity. Rinsing the mouth before collection of a specimen would decrease flora. You swab the tonsillar area, not the uvula. Blowing the nose does not affect a throat culture.
- 5 **1 Rationale:** Redness is the only objective data. All of the other choices are subjective (i.e., what the patient says he is experiencing).
- 6 **4, 2, 3, 1, 5 Rationale:** The nurse applies clean gloves and removes the old dressing to assess the wound. Before obtaining the specimen, a patient must be identified with two identifiers to comply with The Joint Commission standards and improve patient safety. Cleaning around wound edges removes skin flora, reduces spread of infection, and prevents possible contamination of the specimen. Maintain sterile technique by providing a sterile field for sterile culture tubes.
- 7 **2, 3, 1, 5, 4 Rationale:** Before beginning the procedure, clamping the catheter above the port allows collection of a fresh sterile urine specimen. Do not use urine from the drainage bag; the urine is contaminated. Cleaning the port with a disinfectant and allowing it to dry reduce microorganisms entering the catheter and contamination of the specimen. Using a Luer-Lok needleless system eliminates potential of needlestick injury. Aspirating into a syringe allows the correct amount of urine to be collected and greater accuracy of test results. Unclamping the catheter returns draining by gravity into the drainage bag, decreasing potential for damage to kidneys, infection, and discomfort.
- 8 **1, 3, 2, 5, 4 Rationale:** A nurse teaches an adult patient the initial step of hand hygiene for testing blood glucose monitoring to reduce transmission of microorganisms and potential for infection. Matching the test strips code on the vial to the code displayed on a glucometer ensures accuracy of the results. Applying gloves reduces risk for health care providers through contamination by patient blood. Cleaning the site with an antiseptic swab or wipe reduces the transmission of microorganisms and promotes direct vasodilation at the selected site. Correct application of blood to a reagent strip ensures greater accuracy. Reading the correct result on the meter display ensures accuracy in reporting, documenting, and history and provides greater accuracy in medical interventions.
- 9 **2 Rationale:** NAP may collect a urine specimen from the port of an indwelling catheter. Current practice requires indwelling catheters with Luer-Lok ports to reduce potential for needlestick injury. Use of syringe with a needle cores the port plug and allows microorganisms to enter the closed system. Urine collected for a routine analysis uses a 20-mL syringe. A needleless Luer-Lok syringe must be used to collect a specimen from a Luer-Lok port.
- 10 **1 Rationale:** The Allen test uses the radial and ulnar arteries to test for adequate circulation when collecting arterial blood for arterial blood gases.

CHAPTER 44

Answers to Critical Thinking Exercises

- 1 Cardiac catheterization poses a risk for blood loss and complications that would require emergency coronary artery bypass graft surgery. Hematocrit and hemoglobin values are needed to obtain a baseline hematologic status for later comparison. Prothrombin time/international normalized ratio (PT/INR) is affected by warfarin, which Mr. Hall takes for chronic atrial fibrillation. If so, the health care provider needed to instruct Mr. Hall to stop his warfarin 1 to 2 nights before this procedure. A current PT/INR is needed to determine whether Mr. Hall is at risk for uncontrolled bleeding. Values for blood urea nitrogen and creatinine evaluate his renal function and, along with urine specific gravity, determine if Mr. Hall is dehydrated. Patients with baseline dehydration or impaired renal function are at risk for impaired excretion of the radiographic dye used during the cardiac catheterization procedure. Baseline electrolytes (sodium and potassium) are assessed to determine possible electromechanical problems.
- 2 In the presence of another nurse, ask Mr. Hall the following on arrival and just before starting the procedure: name, identifying number such as birth date, purpose of visit. Also compare the patient identifiers with information in Mr. Hall's MAR or medical record. Document in Mr. Hall's medical record.
- 3 The correct answer is 2. Mr. Hall falls into an American Society of Anesthesiologists (ASA) classification of 2—presence of mild systemic disease without functional limitations.
- 4 Patients who have not yet given informed consent need to wait until the health care provider provides explanation of the procedure. In addition, do not administer any medication that can reduce their level of consciousness, because it will impair their ability to give legal informed consent.
- 5 The correct answer is 1. These assessments are in order of threat to life and tailored to the procedure that was done. Heart rate and rhythm are affected because of catheter irritation or injury to the heart. Respiratory effort and oxygen saturation are frequently insufficient if the intravenous sedation suppressed Mr. Hall past the level of "moderate" sedation. The procedure site can easily bleed if mechanically disrupted when Mr. Hall is transferred from the procedure table to a cart and then to his bed. A visual check is essential to make sure that the dressing, sandbag, or closure device is secure to prevent arterial bleeding. Frequent pedal pulse checks help to promptly detect any intravascular clotting that might occur at the procedure site and cause reduced circulation to the legs.

Answers to Review Questions

- 1 **1 Rationale:** The changes and assessment data indicate that bleeding is occurring retroperitoneally.
- 2 **1 Rationale:** The patient with renal insufficiency may not be able to filter out the chemicals in the intravenous pyelogram dye. The patient with one kidney may have total function of that kidney. It would not be contraindicated for the other patients.
- 3 **3 Rationale:** With the removal of fluid from the abdomen, the abdominal girth would be smaller, it would be easier to breathe, and the number of respirations per minute would be lower because of less fluid and pressure.
- 4 **4 Rationale:** Colonoscopy requires an empty bowel. Because sedation is used, the patient needs to have nothing by mouth (NPO) for 8 hours before the procedure to decrease the need for aspiration.

- 5 The correct order is 4, 1, 5, 3, 6, 2.
- 6 4 **Rationale:** Explain to patient that the intravenous (IV) sedation will cause relaxation and amnesia but he will be awake during the procedure and able to speak. Hand signals are needed if the patient has an upper gastrointestinal (GI) procedure.
- 7 2 **Rationale:** Patient is possibly experiencing bronchospasm and requires you to support his or her airway. Call physician immediately and prepare for possible resuscitation. Suctioning would not be appropriate since it would worsen bronchospasm. IV fluids are not necessary for this condition, but patient requires patent IV access.
- 8 3 **Rationale:** A patient's response to sedation is monitored by measuring heart rate, blood pressure, SpO₂ and/or end tidal CO₂, respiratory rate and depth, and level of consciousness. Laboratory values will not detect changes resulting from sedation. The femoral pulse and gag reflex are not affected by sedation.
- 9 1 d, 2 f, 3 e, 4 a, 5 c, 6 b **Rationale:** This is the correct position of the six leads.
- 10 1, 4 **Rationale:** Contraindications for an angiography include anticoagulant therapy such as warfarin, bleeding disorders, thrombocytopenia, dehydration, uncontrolled hypertension, renal insufficiency, and pregnancy.

Appendix

TERMINOLOGY/COMBINING FORMS: PREFIXES AND SUFFIXES

Medical terminology is similar to a foreign language. Many medical terms are derived from Latin and Greek sources. They often consist of two or more simple words or word elements. A word root or *combining form* may be put together with a *prefix* and a *suffix*.

Root—the basis of a word

Example: *nephr/o/tic* (degenerative changes in the kidney)

Root: *nephr-* (kidney)

Linking vowel—a vowel that joins the combining form to the suffix or another combining form

Example: *nephr/o/sis* (disease of the kidneys)

Linking vowel: *o*

Prefix—the beginning of a word

Example: *hyper/active* (excessively active)

Prefix: *hyper-* (excessive)

Suffix—the ending of a word

Example: *nephr/itis* (inflammation of the kidney)

Suffix: *-itis* (inflammation)

Combining form—the union of a word root with a linking vowel

Example: *hepato/megaly* (enlargement of the liver)

Combining form: *hepato-* (liver)

The following table provides some of the most commonly used terminology for your reference.

COMMON PREFIXES

Prefix	Definition
a-	without
ab-	away from
abd-	abdominal
acu-	sharp
ad-	toward
adip-	fat
ad lib-	freely, as wanted
aero-	air, gas
al-	toward
ambi-	both
an-	not
ana-	up
ante-	before, in front of
anti-	against
arteri-	artery
arthro-	joint
auto-	self
bi-	two
brady-	slow
cata-	down
chole-	bile
cili-	eyelid
circum-	around
co-	with, together
cogni-	know
colo-	colon
con-	with, together
contra-	against

Prefix

crani-
cut-
cyt-
de-
demi-
dent-
derm-
dia-
diplo-
dis-
dors-
dur-
dy-
dys-
ec-
ecto-
em-
embol-
encephalo-
endo-
entero-
epi-
erythro-
eso-
et-
eu-
ex-
exo-
extra-
faci-
fiss-
fore-
gastro-
glosso-
glyco-
haplo-
heme-
hemi-
hepat-
hetero-
histo-
homo-
hydro-
hyper-
hypo-
im-
in-
infra-
inter-
intra-
isch-
iso-
lapis-
lapra-
latero-
macro-

Definition

skull
skin
cell
from, lack of
half
tooth
skin
through, across
double, twofold
to free or undo
back
hard
two
bad, painful, difficult, abnormal
out, out from
outside
in
to insert
brain
in, within
intestine
above, on
red
within, inward
and
good, normal
out, away from
outside
outside
face
split, cleft
before, in front of
stomach
relating to the tongue
sugar
simple, single
iron-based
one half
liver
different
tissue
same
wet, water
excessive, above normal
under, below
not
in, not
under, below
between
in, within
deficiency
equal, alike
stone
loin or flank, sometimes abdomen
side
large

Prefix	Definition	Suffix	Definition
mal-	bad	-ase	enzyme
meato-	opening	-bi	two, double
medi-	middle	-blast	developing cell
melano-	black	-cele	hernia, swelling, sac
meso-	middle	-centesis	puncture of a cavity
meta-	beyond, change	-clasis	break, fracture
micro-	small	-clysis	irrigation, washing
mono-	one	-coccus	berry shaped
morpho-	form, structure	-crit	to separate
multi-	many, much	-cyte	cell
neo-	new	-desis	fusion, binding, fixation
nephro-	kidney	-drome	to run
oculo-	eye	-dynia	pain
onco-	tumor	-ectasis	expansion, dilation
oro-	mouth	-ectomy	excision, removal of a body part
osteo-	bone	-emesis	vomiting
pan-	all	-emia	blood
para-	beside, beyond	-er	one who
per-	through, by	-gen	forming, producing, origin
peri-	around	-genesis	forming, producing, origin
phago-	eating	-genic	origin, formation
poly-	many, much	-grade	to go
post-	after, behind	-gram	the record made, mark
pre-	before, in front of	-graph	instrument for recording, machine
primi-	first	-graphy	the process, process of recording
pro-	before, in front of	-ia	condition
pseudo-	false	-iasis	morbid condition
quadri-	four	-iatry	treatment, medicine
re-	again, backward	-ic/-ical	pertaining to
retro-	backward, behind	-icle	small, minute
rhabdo-	rod-shaped, striated	-ism	condition
rhodo-	red	-ist	one who specializes in, specialist
scler-	hardening	-itis	inflammation
semi-	one half	-lith	stone, calculus
stetho-	chest	-logist	specialist in the study of
sub-	under, below	-logy	process of study
super-	above, excessive	-lysis	dissolution, setting free
supra-	above, excessive	-malacia	softening, soft
sym-	together	-megaly	enlargement
syn-	union, together, joined	-meter	instrument for measuring
tachy-	rapid	-metry	act of measuring
tetra-	four	-odynia	pain
therm-	heat	-oid	form, shape
trans-	through, across	-ole	small, minute
tri-	three	-ology	study or science of
ultra-	beyond, excess	-oma	tumor
uni-	one	-opsy	to view
vas-	vessel or duct	-or	one who
xantho-	yellow	-orrhoea	flow, discharge
xero-	dry	-osis	condition or state
		-ous	pertaining to
		-para	to bear (offspring)
		-paresis	partial paralysis
		-pathy	disease, suffering
		-penia	deficiency, lack of, decrease
		-pexy	fixation
		-phagia	eating, swallowing
		-phasia	speech
		-philia	attraction for
		-phobia	fear
		-physis	to grow
		-plasia	formation, growth

COMMON SUFFIXES

Suffix	Definition
-ac	pertaining to
-agra	excessive pain
-al	pertaining to
-algia	painful condition, pain
-apheresis	removal
-ar	pertaining to
-ary	pertaining to

Suffix

-plasm	growth, formation
-plasty	mold, shape, repair
-plegia	paralysis
-poiesis	formation, production
-ptosis	downward displacement, falling
-ptysis	spitting
-rrhage	bursting forth, rupture
-rrhaphy	suturing in place
-rrhea	flow, discharge
-rrhexis	rupture
-scope	instrument to visually examine
-scopy	process of examining, visual examination
-sepsis	infection
-sis	state of, condition
-spasm	involuntary spasm

Definition**Suffix**

-stalsis	constriction
-stasis	control, constant level, stop
-stenosis	narrowing, stricture
-stomy	creation of an opening
-therapy	treatment
-tic	pertaining to
-tome	instrument for cutting
-tomy	process of cutting, incision
-toxic	poison
-tresia	opening
-tripsy	surgical crushing
-trophy	nourishment
-ula	small, minute
-ule	small, minute
-y	process

Definition

Glossary

A

- abdominal girth** The measurement of the circumference of the abdomen, taken at the same place with each measurement.
- abduction** Movement of an extremity away from the midline of the body.
- accommodation reflex** Adjustment of the eyes for near vision, composed of pupillary constriction, convergence of the visual axes, and increased convexity of the lens.
- accurate empathy** Communication technique used by a nurse to show understanding of a patient's feelings and experiences.
- Acetest** A test that measures the presence of ketone (acetone) bodies in the urine. A large quantity of acetone causes rapid change in the color of the Acetest tablet.
- active listening** An interpersonal process whereby a person hears a message, decodes the meaning, and conveys an understanding about the meaning to the sender.
- active range-of-motion exercises** Exercises of the joints performed by an individual without assistance.
- active-assisted range-of-motion exercises** Exercises of the joints performed by an individual with some assistance. For example, a nurse helps support an extremity.
- activity tolerance** Type and amount of exercise or work that a person is able to perform.
- actual loss** Any loss of a person or object that can no longer be felt, heard, known, or experienced.
- acuity systems** Systems to determine the right amount of staff according to weighted patient workload.
- acute pain** Severe pain with a rapid onset and of short duration.
- addiction** A compulsive physiologic need for a habit-forming drug.
- adduction** Movement of an extremity toward the midline of the body.
- adjuvant therapy** The treatment of a disease with substances that enhance the action of drugs, especially drugs that promote the production of antibodies.
- adrenergic drug** A medication that mimics the effects of sympathetic nerve stimulation of the autonomic nervous system.
- advance directive** Document defining a patient's end-of-life care decisions.
- adverse drug events (ADEs)** Unfavorable reactions to medications that present during the normal course of treatment. The effect of an ADE may range from minimal harm to significant injury or death (National Research Council, 2007).
- adverse drug reactions (ADRs)** Nontherapeutic effects of medications.
- adverse reaction** Unintended response to a drug.
- aerobe** A microorganism that lives and grows in the presence of free oxygen.
- aerobic** Pertaining to the presence of air or oxygen.
- afebrile** Without fever.
- agglutinate** A process by which cells that display antigens (red blood cells, bacteria) adhere to one another or clump together.
- air embolus** A quantity of air that circulates in the bloodstream to eventually lodge in a blood vessel.
- air fluidization** The process of blowing warm air through a collection of microspheres to create a fluidlike environment. Used in special mattresses designed to reduce pressure against a person's skin.
- air leak** Escaping air in closed chest drainage. May be patient centered or within the chest tube system.
- air-fluidized bed** A special bed designed to distribute weight evenly over its support surface. Fluidization is created by forcing a gentle flow of temperature-controlled air upward through a mass of fine ceramic microspheres.
- air-suspension bed** A device that supports a patient's weight on air-filled cushions, minimizing tissue damage from pressure and shear.
- albumin** An acute-phase protein involved in nutrient transport and the maintenance of oncotic pressure. Used as a measure of visceral protein status. Has a half-life of 14 to 20 days.
- aldosterone** A steroid hormone produced by the adrenal cortex that causes the kidney tubules to excrete potassium and reabsorb sodium and water.
- Aldrete score** Score based on the Aldrete Scoring System for determining a patient's postanesthesia recovery status.
- allergen** A substance that can produce a hypersensitive reaction in the body but that is not necessarily intrinsically harmful.
- all-hazards event** Multiple manmade or natural events with destructive capacity to cause multiple casualties.
- all-hazards preparedness** The comprehensive preparedness necessary to manage casualties resulting from a disaster, regardless of etiology.
- allogeneic** Denoting a cell type that is from the same species but genetically distinct.
- alopecia** Partial or complete lack of hair.
- Alzheimer's disease** Dementia characterized by progressive confusion, memory failure, disorientation, restlessness, and speech disturbances. Cause is not fully understood.
- amino acid** An organic compound composed of one or more basic amino groups and one or more carboxyl groups. Amino acids are the building blocks that construct proteins and the end products of protein digestion.
- amnesic syndrome** Memory impairment in the absence of other cognitive impairments.
- ampule** Small sterile glass or plastic container that usually contains a single dose of solution to be administered parenterally.
- anaerobic** Pertaining to absence of air or oxygen.
- analgesia** A decreased or absent sensation of pain.
- anaphylactic reaction** Exaggerated hypersensitivity reaction to a previously encountered antigen. It is a severe and sometimes fatal systemic reaction characterized by itching, hyperemia, angioedema and, in severe cases, vascular collapse, bronchospasm, and shock.
- anaphylaxis** An exaggerated hypersensitivity reaction to a previously encountered antigen. The reaction may be localized or generalized.
- anastomosis** A surgical joining of two ducts or blood vessels to allow flow from one to the other.
- anemia** A disorder characterized by a decrease in hemoglobin in the blood to levels below the normal range, decreased red cell production, or increased red cell destruction or blood loss.
- anesthesia** The absence of normal sensation, especially sensitivity to pain.
- anesthetics** Drugs or agents capable of producing a complete or partial loss of feeling.
- angiogenesis** The formation of new blood vessels.
- anions** Negatively charged ions.
- anthropometry** The science of measuring the height, weight, and size of component parts of the human body, including skinfolds.
- antianginal** A medication that dilates coronary arteries, improving blood flow to the myocardium to prevent angina.
- antidysrhythmic** A class of medications that possess properties for controlling abnormal cardiac rhythms (e.g., quinidine and propranolol [Inderal]).
- antiemetic** Of or pertaining to a substance or procedure that prevents or alleviates nausea and vomiting.
- antipyretic** Pertaining to a substance, such as a medication, that reduces fever.
- apical pulse** Measurement of the heartbeat taken with the stethoscope placed over the apex of the heart.
- apnea** An absence of spontaneous respirations.
- approximate** To come together, as in the edges of a wound.
- aqueous** Watery or waterlike; referring to a medication prepared with water.
- artificial airway** Plastic or rubber device inserted into the upper or lower respiratory tract to facilitate ventilation or secretion removal.
- ASA classification** A classification system for ranking the level of a patient's physical health, established by the American Society of Anesthesiologists (ASA).
- ascites** Effusion and accumulation of serous fluid in the abdominal cavity.
- asepsis** The absence of disease-producing (pathogenic) organisms.
- aseptic technique** The methods used during patient care to prevent microbial contamination. They can be either clean (medical asepsis) or sterile (surgical asepsis) techniques.
- aspirant** Fluid or particulate that is aspirated.
- aspirate** Withdrawal of fluid or air into the barrel of a syringe or suction device.
- aspiration** The entry of gastric contents into the tracheobronchial passages. This increases a patient's risk for aspiratory pneumonia.
- astigmatism** Abnormal condition of the eye in which the light rays cannot be focused clearly in a point on the retina because the spherical curve of the cornea is not equal in all meridians. Vision is blurred, and use of the eye causes discomfort.
- astringent** A topical substance that causes constriction of tissues on application; commonly used for cleansing the skin.
- atelectasis** An abnormal condition characterized by the collapse of lung tissue, preventing the respiratory exchange of carbon dioxide and oxygen.
- atmospheric pressure** Pressure exerted by the atmosphere. (Atmospheric pressure at sea level is 760 mm Hg.)
- atrophy** Wasting or diminution of size or physiological activity of a part of the body caused by disease or other influences.
- audiologist** A health professional with at least a master's degree who studies sense of hearing defects, diagnoses hearing loss, and works to provide rehabilitation of individuals with hearing loss.
- auscultation** The act of listening for sounds within the body to evaluate the condition of the heart, lungs, pleura, intestines, or other organs or to detect fetal heart sounds. Performed directly or most commonly through use of a stethoscope.

auscultatory gap The temporary disappearance of Korotkoff sounds when blood pressure is being auscultated. Occurs in hypertensive patients and may cause an underestimation of blood pressure.

autoclave An appliance used to sterilize medical instruments or other objects with steam under pressure.

Autolet A small instrument with a lancet used to obtain a capillary blood specimen.

autologous transfusion Transfusion of a patient's own blood through predeposit, blood that is salvaged intraoperatively by a cell saver, or blood shed after surgery.

automated external defibrillator (AED) Device used by basic cardiopulmonary resuscitation (CPR) providers to treat fast, irregular dysrhythmias with electrical shock to the heart using automated rhythm analysis and simplified functions.

autopsy Examination of the deceased's body performed to confirm or determine the cause of death.

autotransfusion The collection, anticoagulation, filtration, and reinfusion of blood from an active bleeding site. Used in cases of trauma and major surgery.

axillary Pertaining to the pyramid-shaped space that forms the underside of the shoulder between the upper part of the arm and the side of the chest.

B

bacteremia Presence of bacteria in the blood.

bacteriostatic Tending to inhibit development or reproduction of bacteria.

bag-valve-mask (BVM) or Ambu-bag Bag attached to a mask that provides artificial ventilations to a patient when squeezed.

balance Position in which a person's center of gravity is correct so the risk for falling is reduced.

bariatric bed A specialized surface equipped with hand controls to allow for self-positioning, providing a stable, adaptable surface for managing the morbidly obese patient.

basal energy expenditure (BEE) The amount of energy required at rest for basic life processes such as breathing, maintaining body temperature, and cardiac function. Basal energy expenditure can be estimated or measured.

basal metabolism Energy needed to maintain the basic processes of the body such as respiration, circulation, and temperature.

base of support Surface area on which an object rests.

bed rest Placement of a patient in bed for a prescribed period for therapeutic reasons.

belt restraints Type of restraint used to secure a patient on a stretcher.

bias Influences that distort the findings of a research study.

binder Bandage made of a large piece of material to fit and support a specific body part.

bioavailability The extent to which a dose of a drug reaches its site of action to produce an effect.

biohazard container Container used for medical waste that must be made of rigid material so as to be puncture resistant and labeled with the words "Sharps Waste" or with a biohazard symbol and the word "Biohazard."

biological agent Bacteria or virus that, when released into the environment, has the potential to cause widespread and continuing infection and mass casualties.

biological disaster The unexpected release of a biological agent capable of causing widespread illness or contamination into the environment.

biopsy The removal and microscopic examination of tissue, performed to establish precise diagnosis.

bioterrorism/bioterrorist attack The release of a biological agent into a specified environment with the intent of causing mass casualties.

blood culture A laboratory test on serum to determine presence of infection in the blood.

blood group Classification of blood type based on the presence or absence of genetically determined antigens on the surface of the red cell.

blood plasma The liquid portion of the blood, free of its formed elements and particles.

blood transfusion Administration of whole blood or a blood component as cells to replace blood lost through trauma, surgery, or disease.

blood type Blood type identified by genetically determined antigens on the surface of red blood cells.

blunt-tip vial access cannula A needleless cannula designed to be inserted into a vial adapter or for needleless access to fill a syringe.

body alignment Refers to the condition of joints, tendons, ligaments, and muscles in various body positions.

body mass index (BMI) A measurement of weight in comparison to height. Used to categorize an individual's degree of adiposity.

body mechanics Coordinated efforts of the musculoskeletal and nervous systems to maintain proper balance, posture, and body alignment.

bolus A large, round preparation of medicinal material for oral ingestion; a dose of a medication or a contrast material injected all at once intravenously.

bone marrow Specialized, soft tissue filling the spaces in cancellous bone of the epiphyses; responsible for red blood cell production.

borborygmus Audible abdominal sound produced by hyperactive intestinal peristalsis.

bradycardia An abnormality in heart rate in which the heart contracts steadily at a rate less than 60 contractions/min.

bradypnea Breathing that is normal in rate but abnormally slow (less than 12 breaths/min).

brain death The irreversible absence of all brain function, including brainstem function.

bronchophony An increase in intensity and clarity of vocal resonance that may result from an increase in lung tissue density, such as in the consolidation of pneumonia.

bronchospasm Abnormal contraction of the smooth muscles of the bronchi.

bronchus One of several large air passages in the lungs through which inspired air and exhaled gases pass.

bruit Abnormal sound or murmur created by turbulent blood flow heard while auscultating an organ, gland, or artery.

buccal Of or pertaining to the inside of the cheek; surface of a tooth or gum next to the cheek.

buccal medication Medication placed between the upper or lower molar teeth and cheek area and allowed to dissolve.

C

cadence Pace or rate of verbal communication.

calorie (Kcal) A calorie is the amount of heat required to raise the temperature of 1 g of water 1°C at atmospheric pressure.

cannula A small tube for insertion into a body cavity, duct, or vessel.

capillary closing pressure The amount of external pressure required to close off the blood flow to the capillaries.

carcinoma Malignant epithelial neoplasm that tends to invade surrounding tissue and spread to distant regions of the body.

cardiac Pertaining to the heart. Pertaining to a person with heart disease.

cardiac arrest The cessation of circulating blood flow that eliminates oxygen transport or perfusion, usually precipitated by ventricular fibrillation or ventricular asystole.

cardiac output Volume of blood ejected by the ventricles of the heart in 1 minute; equal to stroke volume times heart rate.

cardiomegaly Enlargement of the heart; typical sign of heart failure.

cardiopulmonary arrest Sudden cessation of respirations, pulse, and circulation.

cardiopulmonary resuscitation (CPR) Basic emergency procedure for life support consisting of artificial respiration and manual external cardiac massage.

caries Decay of a tooth; progressive decalcification of enamel and dentin of a tooth.

case management The assignment of a health care provider to help a patient by assessing need for health care and social service systems and to ensure that required services are obtained.

cast Rigid plaster or fiberglass application molded over skin tissues to hold musculoskeletal tissues to permit healing of injuries.

cast brace Combination of a brace within a cast at a joint.

cast saw Saw used to cut through plaster to remove cast.

cast shoe Shoe worn over the foot encased in plaster.

cast syndrome A series of patient signs that indicate an untoward (claustrophobic) reaction to being in a cast.

casualty Any individual who is ill, injured, missing, or killed as a result of a mass casualty incident.

catheter A tubular device for insertion into vessels or body cavities for diagnostic or therapeutic purposes, to permit injection, or to withdraw fluids.

cathartic Drug that acts to promote bowel evacuation.

catheterization Introduction of a tube through the urethra and into the bladder.

cations Positively charged ions.

cell cycle The sequence of events that occurs during the growth and division of tissue cells.

center of gravity Midpoint or center of body weight. In the adult it is the midpelvic cavity between the symphysis pubis and the umbilicus.

centigrade Temperature scale in which 0° is the freezing point of water and 100° is the boiling point of water at sea level; also called *Celsius*.

central venous access device (CVAD) A catheter placed in a large central vein to give medication, fluids, or blood product.

central venous pressure (CVP) Pressure in the great veins (superior and inferior vena cava) as blood returns to the heart.

cephalic vein One of the four superficial veins of the upper limb.

cerebrospinal fluid (CSF) Substance contained within the four ventricles of the brain, the subarachnoid space, and the central canal of the spinal cord.

cerumen Earwax. A waxy secretion produced by apocrine sweat glands in the external ear canal.

cervical halter Support for the head, made of cotton material, used for traction.

change-of-shift report Means through which nurses report information about their assigned patients to the nurses working the next shift for the purpose of providing continuity of care for patients. May be given orally in person, by audiotape recording, or during "walking-planning" rounds at each patient's bedside.

charting by exception (CBE) A charting methodology in which data are entered only when there is an exception from what is normal or expected. Reduces time spent documenting.

cheilosis Disorder of the lips and mouth characterized by scales and fissures.

chemical decontamination The process of removing or neutralizing contaminating chemical agents.

chemical warfare agent The use of the toxic properties of chemical substances to kill, injure, or incapacitate an enemy.

chemotherapy Use of drugs to prevent cancer cells from multiplying, invading adjacent tissue, and metastasizing.

- chest physiotherapy** Physical maneuvers, including postural drainage, chest percussion, vibration, rib shaking, and cough, to improve airway mucus clearance in patients with retained tracheobronchial secretions.
- chest tube** Catheter inserted through the chest wall into the intrapleural space.
- chronic pain** Pain that persists beyond the period of healing, ceases to serve a protective function, degrades patient function, and serves no adaptive purpose.
- chronic venous insufficiency** Abnormal circulatory condition characterized by decreased return of the venous blood from the legs to the trunk of the body.
- circulating nurse** A registered nurse (RN) considered to be the charge nurse in the operating room during a surgical procedure.
- circumduction** The circular movement of a limb. The motion of the head of a bone within an articulating cavity such as the hip joint.
- clarifying** An attempt to put into words vague ideas or unclear thoughts of a patient to enhance the nurse's understanding, or asking a patient to explain what he or she means.
- clean technique (medical asepsis)** The purposeful prevention of the transmission of microorganisms by using procedures such as hand hygiene and disinfection of equipment to reduce the number of microorganisms.
- cleansing enema** An enema, usually soapsuds, administered repeatedly until the colon is free of all formed fecal material.
- clean-voided specimen** A technique used to collect a urine specimen as free from bacterial contamination as possible without catheterizing the patient.
- clinical guidelines** Systematically developed statements about a plan of care for a specific set of clinical circumstances involving a specific patient population.
- Clinitest** A test that measures the amount of glucose and acetone in a urine specimen.
- closed system suction catheter** A suction catheter that is attached to the mechanical ventilator circuit encased within a sterile sheath. The catheter system permits sterile airway suctioning without interrupting mechanical ventilation or requiring the nurse to apply sterile gloves.
- coagulopathies** A disease or condition affecting the ability of the blood to coagulate.
- code event** A declaration of or a state of medical emergency and call for medical personnel and equipment to attempt to resuscitate a patient, especially when in cardiac arrest or respiratory distress or failure.
- colon** Portion of large intestine from the cecum to the rectum.
- colonization** The reproduction of microorganisms at a specific site without the signs/symptoms of a disease or tissue invasion.
- colonized** The presence of bacteria on the surface or in the tissue of a wound without indications of infection such as purulent exudate, foul odor, or surrounding inflammation. All stage II, III, and IV pressure ulcers are colonized.
- colostomy** Surgical formation of an opening of the colon onto the surface of the abdomen through which fecal matter is emptied.
- comforting** Any nursing action taken to promote comfort of a patient, such as a back rub or change in position.
- comminuted fracture** A fracture in which the bone is broken into several fragments.
- compartment syndrome** Insufficient arterial perfusion to an extremity caused by trauma or stasis; leads to ischemia and tissue necrosis if not reversed.
- compatibility** The quality or state of existing together in harmony. The formation of a stable chemical or biochemical system, specifically in medication, so two or more drugs can be administered at the same time without producing side effects.
- compliance** Fulfillment by a patient of the caregiver's prescribed course of treatment.
- compound** A substance composed of two or more different elements, chemically combined, that cannot be separated by physical means.
- compress** Soft pad of gauze or cloth used to apply heat, cold, or medications to the surface of a body part.
- computer-based patient care record (CPCR)** Record stored in a comprehensive computerized system that is used by all health care practitioners to permanently store information pertaining to a patient's health status, clinical problems, and functional abilities. The CPCR can store numerous databases, including structured assessment data, clinical decision support systems, and diagnostic artificial intelligence. It stores information pertaining to a given patient from any health care event and thereby provides access to information across a patient's life span.
- condition of participation** A requirement that all patients be notified of their rights when entering a health care facility. Part of the Key Principles of Patient's Rights documentation.
- conduction** Mechanism of heat transfer involving flow of heat from one object to another with which it is in contact.
- conjunctiva** Mucous membrane lining the inner surfaces of the eyelids and anterior part of the sclera.
- conjunctivitis** A highly contagious eye infection. The crusty drainage that collects on eyelid margins can easily spread from one eye to the other.
- constipation** Condition characterized by difficulty in passing stool or an infrequent passage of hard stool.
- contamination** The introduction of infectious material on normally clean or sterile sites.
- continent ostomy or diversion** Results from a surgical procedure that leaves a patient with an internal pouch where either stool or urine is temporarily stored and the effluent is removed by intubation through the external stoma. It is continent because the effluent does not drain spontaneously from the stoma; instead a catheter must be inserted through the stoma to drain the effluent from the internal pouch.
- continent urinary diversion** A surgical procedure that uses a distal portion of the ileum and proximal portion of the colon to create an ileal pouch. The ureters from the patient's kidneys are embedded in the pouch. A narrow ileal segment forms a stoma on the abdominal wall.
- continuous subcutaneous infusion (CSQI or CSCSI)** A method of medication administration in which medication is administered continuously into the subcutaneous tissue using a medication infusion pump.
- continuum of care** Matching an individual's ongoing needs with the appropriate level and type of medical, psychological, health, or social care or services within an organization or across multiple organizations.
- contractures** Abnormal condition of a joint characterized by flexion and fixation and caused by atrophy and shortening of muscle fibers or loss of normal elasticity of the skin.
- core temperature** Temperature of deep body tissues and organs.
- costovertebral angle (CVA) tenderness** Palpation over this region can elicit tenderness. Tenderness is common with kidney infection or trauma to the region.
- countertraction** Use of patient's body weight or other weights, ropes, and pulleys to counter the pull of the traction weight.
- crackles** Fine bubbling sound heard on auscultation of the lung.
- crepitation** The sound and/or feeling produced when bone ends rub against one another. The patient describes the sound and feeling.
- critical/collaborative pathway** Tool used in managed care that incorporates the treatment interventions of caregivers from all disciplines who normally care for a patient. Designed for a specific case type, a pathway is used to manage the care of a patient throughout a projected length of stay.
- crutch gait** Gait assumed by a person on crutches by alternately bearing weight on one or both legs and on the crutches.
- crutch palsy** Temporary or permanent loss of sensation or movement resulting from pressure on axilla from crutch.
- cryotherapy** Therapy in which the skin is exposed to cool or cold temperatures. Used to treat localized inflammatory responses.
- cuff** A plastic air- or foam-and-air-filled balloonlike attachment on the distal end of the endotracheal tube or tracheostomy tube that prevents loss of air from the lung and inhalation of foreign bodies around the tube.
- culture** Laboratory test involving the cultivation of microorganisms or cells in a special growth medium.
- cutaneous stimulation** Stimulation of the skin.
- cuticle** A thin edge of cornified epithelium at the base of a nail.
- cyanosis** Bluish discoloration of the skin and mucous membranes caused by an excess of deoxygenated hemoglobin in the blood or a structural defect in the hemoglobin molecule.
- cycloplegic** Pertaining to a drug that paralyzes ciliary muscles of the eye, causing pupillary dilation for ophthalmological examination or surgery.
- cytology** The study of cells, including their formation, origin, structure, function, biochemical activities, and pathologic characteristics.

D

- dangling** To sit on the side of a bed with legs dependent or feet on the floor.
- DAR** An acronym for a method of documentation that includes data (subjective and objective), action (nursing interventions), and response of the patient (evaluation of effectiveness).
- dead space** A cavity remaining in a wound.
- debride** To remove dead or damaged tissue from a wound. To remove dirt, foreign objects, damaged tissue, and cellular debris from a wound or burn to prevent infection and promote healing.
- debridement** Removal of dead tissue in a wound.
- decompression** Removal of pressure as from gas and fluid in the stomach and intestinal tract.
- decontamination** The process of removing foreign material such as blood; body fluids; or chemical, biological, or radioactive contaminants. It does not eliminate microorganisms but is a necessary step preceding disinfection or sterilization.
- deep sedation** An induced state of sedation characterized by depressed consciousness so the patient is unable to continuously and independently maintain a patent airway and experiences a partial loss of protective reflexes.
- deep tissue injury** Purple or maroon localized area of discolored intact skin or blood-filled blister resulting from damage to underlying soft tissue from pressure and/or shear. The injured area may be preceded by tissue that is painful, firm, mushy, boggy, or warmer or cooler compared to adjacent tissue.
- deep vein thrombosis** A thrombus in one of the deep veins of the body, most often the iliac or femoral vein. Symptoms include tenderness, pain, swelling, warmth, and discoloration of the skin. It is potentially life-threatening.
- de-escalation** A communication strategy involving the reduction of anxious and/or agitated behaviors

- exhibited verbally or nonverbally by a patient. Using a calm yet firm approach diffuses the patient's increasing anxiety and/or agitated state, thereby minimizing potentially violent outbursts.
- defecation** Passage of feces from the digestive tract through the rectum.
- dehiscence** The separation or opening of wound layers.
- dementia** A term used to describe a group of symptoms related to a loss or impairment of mental powers. These symptoms appear in a person who is awake and are demonstrated by symptoms of mental confusion, memory loss, disorientation, intellectual impairment, or similar problems.
- dental caries** Chalky white discoloration of teeth or presence of brown or black discoloration.
- dentifrice** A pharmaceutical compound used with a toothbrush for cleaning and polishing teeth.
- Department of Homeland Security (DHS)** The federal department that administers all matters relating to homeland security.
- dermatitis** An inflammatory condition of the skin characterized by erythema and pain or pruritus.
- dermatological** Pertaining to the skin.
- detection and surveillance** Awareness of the environment, recognizing what might be unusual or different and knowing what these differences mean in terms of terrorism preparedness.
- devitalized** Tissues with reduced oxygen supply and blood flow.
- dialysis** A procedure that removes fluid and solid wastes from the blood or lymph.
- diaphoresis** Secretion of sweat typically associated with hyperthermia, physical exertion, and emotional stress.
- diastolic pressure** The lower blood pressure measurement, which reflects the pressure consistently exerted within the arterial system during the period of ventricular relaxation.
- diffusion** Movement of oxygen to the red blood cells at the alveolar level.
- diluent** Agent that makes a solution or mixture thinner or more liquid by admixture.
- disaster** A catastrophic and/or destructive event that disrupts normal functioning; it may include any anticipated or unexpected event the effects of which lead to significant destruction and/or adverse consequences.
- disaster management** The discipline of dealing with and avoiding risks. It is a discipline that involves preparing for disaster before it occurs, providing disaster response, and supporting and rebuilding after disasters have occurred.
- disaster response** A phase of the disaster management cycle. Its preceding cycles aim to reduce the need for a disaster response or to avoid it.
- disaster triage** A model for sorting individuals by the seriousness of their condition and the likelihood of their survival.
- discharge planning** The process by which a nurse plans for a patient's eventual release from a health care agency. The process begins on a patient's admission to the agency.
- distraction** A pain-reduction technique that diverts an individual's attention away from the pain sensation.
- documentation** Anything written or printed that is relied on as record or proof for authorized persons. It is a vital aspect of nursing practice and a vital link between providing and evaluating health care.
- documentation system** Detailed information, in either written or computerized form, about a computer system, including its architecture, design, data flow, and programming logic.
- dorsal** Pertaining to the back or posterior.
- dorsiflexion** Flexion toward the back, as accomplished by a muscle (e.g., in the hand or foot).
- dorsum** The back of the hand.
- double-void** A procedure of discarding the first urine specimen and testing the second urine specimen that was obtained 30 to 45 minutes later; this procedure gives a more accurate amount of glucose being spilled into the urine at that particular time.
- drawsheet** A special sheet placed over the regular sheet on a bed and used to move a person in bed.
- drop factor** Refers to the calibration of intravenous (IV) tubing (IV infusion set) in drops per milliliter (e.g., the drop factor of microdrip IV tubing is 60 gtt/mL).
- drug tolerance** A decreased physiological response after repeated administration of a drug or a chemically related substance.
- dry powder inhaler (DPI)** Handheld device that disperses powdered medication for inhalation.
- duration of action** Length of time during which a drug is present in a concentration great enough to produce a therapeutic effect.
- dysphagia** Difficulty swallowing.
- dyspnea** Difficulty breathing.
- dysrhythmia** An irregular, fast, or slow heart rhythm.
- dysuria** Pain or burning on urination. May also be accompanied by difficulty in urination. Usually indicates a urinary tract infection.
- E**
- eczchymosis** Bluish discoloration of an area of skin or mucous membrane caused by the extravasation of blood into the subcutaneous tissues as a result of trauma to the underlying blood vessels or fragility of the vessel walls.
- edema** Abnormal accumulation of fluid in interstitial spaces of tissues.
- effleurage** A type of massage stroke that glides without manipulating deep muscles, smooths and extends muscles, increases nutrient absorption, and improves lymphatic and venous circulation.
- effluent** The drainage that is expected from an ostomy.
- egophony** A change in the voice sound as heard on auscultation of a patient with pleural effusion. When patient is asked to make e-e-e sounds, the sound is heard over the peripheral chest wall as a-a-a.
- elastic bandage** Bandage of elasticized fabric that provides support and allows movement.
- electrolyte** An element or compound that, when melted or dissolved in water or another solvent, dissociates into ions and is able to carry an electric current.
- electronic infusion device (EID)** Used to infuse intravenous (IV) fluid at a prescribed rate. There are two types: an infusion pump, which is designed to deliver a measured amount of fluid over a period of time; and an IV controller, which delivers fluid with the aid of gravity.
- electronic medical record** A medical record in digital format.
- embolus (emboli)** A foreign object, a quantity of air or gas, a bit of tissue or tumor, or a piece of thrombus that circulates in the bloodstream until it becomes lodged in a vessel.
- emergency responders** Individuals whose job it is to respond to an emergency situation—typically police, fire, hazardous materials (HAZMAT), and emergency medical services (EMS) personnel.
- empathy** Ability to recognize and to some extent share the emotions and state of mind of another and to understand the meaning and significance of that person's behavior.
- endemic** The expected or normal incidence present in a geographical area or population.
- end-of-life-care** The human provision of physical, psychological, social, and spiritual support to a patient and patient's family at the end of life.
- endotracheal intubation** Placement of a plastic tube into the trachea to provide artificial ventilation on a continuous basis.
- endotracheal tube** Artificial airway inserted through the mouth into the trachea.
- enema** Procedure involving introduction of a solution into the rectum for cleansing or therapeutic purposes.
- enteral nutrition** The administration of nutrition via the gastrointestinal tract (i.e., by mouth, tube feeding, or oral supplement).
- enteral tube feeding** The introduction of food or nutritive material directly into the digestive tract by nasogastric or gastric tube.
- Enteric-coated** Tablets coated with a substance that does not dissolve until reaching the intestine. Used when drug constituents are irritating to oral and gastric mucosa.
- enucleation** Removal of the eyeball, performed in cases of malignancy, severe infection, or extensive trauma or to control pain in glaucoma.
- epidemic** A disease that spreads rapidly through a demographic segment of the human population, with an incidence beyond what is expected.
- epidemiology** Study of the occurrence, distribution, and causes of disease.
- epidural** Administration of local anesthetic by way of a catheter into the epidural space of the spinal column. Designed to produce anesthesia of the pelvic, abdominal, or genital areas.
- epidural analgesia** Delivery of an analgesic into the epidural space in pain control.
- epidural blood patch** Procedure whereby a physician injects a small amount of autologous blood into the epidural space.
- episiotomy** A surgical procedure in which an incision is made in a woman's perineum to enlarge her vaginal opening for delivery of an infant. Procedure prevents tearing of perineum.
- epithelialization** The process by which epidermal cells migrate (move) over the surface of the wound to close the top or "resurface" the wound.
- erythema** Redness or inflammation of the skin or mucous membranes. Result of dilation and congestion of superficial capillaries.
- eschar** Scab or dry crust that results from excoriation of the skin.
- evaporation** Mechanism of heat loss whereby moisture from the surface of the body changes to vapor and transfers heat to the surrounding air.
- eversion** Turning outward or inside out, such as turning the foot outward at the ankle.
- evidence-based practice (EBP)** A problem-solving approach to clinical practice that combines the conscientious use of research-based evidence in combination with a clinician's expertise and patient preferences and values in making decisions about patient care.
- evisceration** The separation of wound layers with the protrusion of abdominal organs through the layers.
- excoriation** An injury to the surface of the skin or other part of the body caused by scratching or abrasion.
- excretion** The process of eliminating, shedding, or getting rid of substances by body organs or tissues.
- exercise** Performance of any physical activity for the purpose of conditioning the body, improving health, or maintaining fitness or as a therapeutic measure.
- exit site** Point at which a catheter leaves a body site.
- exophthalmos** Abnormal protrusion of one or both eyeballs caused by trauma, intracranial lesions, intraorbital disorders, or systemic disease, most commonly hyperthyroidism.
- expectorant** An agent that facilitates removal of bronchopulmonary secretions.
- expectorate** The act of coughing and spitting out mucus from the respiratory tract. Maneuver is useful

in helping a patient clear the airways of pulmonary secretions.

extension Movement increasing the angle between two adjoining bones.

external fixation Skeletal traction applied through the use of pins attached to a frame rather than weights.

external rotation Rotation of a joint outward.

external urethral sphincter Voluntary muscle that must relax for a patient to void or completely empty the bladder.

extravasation The inadvertent infiltration of intravenous fluids or medications into the subcutaneous tissues surrounding the infusion site.

extremity restraints Restraints used to immobilize one or all extremities.

exudate Any fluid that has been extruded from a tissue or its capillaries, more specifically because of injury or inflammation. It is characteristically high in protein and white blood cells.

F

Fahrenheit Temperature scale in which 32° is the freezing point of water and 212° is the boiling point of water at sea level.

fascia Fibrous connective tissue.

febrile Pertaining to or characterized by fever or an elevation in body temperature.

fenestrated drape A drape with a round or slitlike opening in the center.

fenestrated tracheostomy tube A tracheostomy tube containing a hole (fenestration) on the posterior aspect of the outer cannula that allows airflow over the vocal cords and speech in spontaneously breathing patients.

fenestration Surgical procedure in which an opening is created to gain access to the cavity within an organ or a bone.

fever An abnormal elevation of body temperature.

fiberoptic Pertaining to fiberoptics; referring to the transmission of an image along flexible bundles of coated glass or plastic fibers having special optical properties.

field triage tag Tags constructed of a high-density, water-resistant synthetic paper and printed using a special thermal printing process, allowing them to be used in field situations.

first responders Public service providers required to be the first on the scene of a disaster, typically emergency medical system (EMS), fire, or police personnel.

flexion Movement decreasing the angle between two adjoining bones; bending of a limb.

flora Microorganisms that reside on and within the body to compete with disease-producing microorganisms to provide a natural immunity against certain infections.

flossing Mechanical cleansing of tooth surfaces with the use of stringlike waxed or unwaxed dental floss.

flotation device A foam mattress with a gellike pad located in its center, designed to protect bony prominences and distribute pressure more evenly against the surface of the skin.

flotation pad A device constructed of foam or a silicone or polyvinyl chloride gel encased in a vinyl-covered square. Protects bony prominences and distributes pressure more evenly against the surface of the skin.

flow sheet A recording form used to document the same type of repeated measurements, procedures, or observations over time. Data on flow sheets allow the user to see trends over time.

fluid volume deficit (FVD) An alteration characterized by the loss of fluids and electrolytes in an isotonic fashion.

fluid volume excess (FVE) An alteration characterized by the abnormal retention of fluids and electrolytes in an isotonic fashion.

focus charting A charting methodology for structuring progress notes according to the focus of the note (e.g., symptoms and nursing diagnosis). Each note includes data, action, and patient response.

fontanel A space covered by tough membranes between the bones of an infant's cranium.

footboard Board placed perpendicular to the mattress, parallel to and touching the plantar surface of a patient's feet. Used to maintain dorsiflexion of the feet.

footdrop A falling or dragging of the foot from paralysis of the flexors of the ankle.

foramen magnum The large opening in the anterior and inferior part of the occipital bone, interconnecting the vertebral canal and cranial cavity.

four-poster cast Cast placed over the shoulders. Contains four vertical posts or poles on the anterior and posterior lateral sides of the head to immobilize the cervical vertebrae.

Fowler's position Posture assumed by a patient when the head of the bed is raised approximately 45 to 90 degrees, as though the patient is sitting upright.

fracture pan A bedpan designed for patients with body or leg casts or patients restricted from raising their hips. It has a shallow upper end that slips easily under a patient.

friction Effect of rubbing, or the resistance that a moving body meets from the surface on which it moves. A force that occurs in a direction to oppose movement. In massage, technique in which deeper tissues are stroked or rubbed, usually through strong circular movements of the hand.

friction rub Dry grating sound heard during auscultation, caused by rubbing of tissue surfaces.

G

gag reflex A normal neural reflex elicited by touching the soft palate or posterior pharynx, the response being the elevation of the palate, retraction of the tongue, and contraction of the pharyngeal muscles. Tests for function of the vagus and glossopharyngeal nerves.

gait Manner or style of walking, including rhythm, cadence, and speed.

gait belt A leather or heavy canvas belt that encircles a patient's waist. It may or may not have handles. The purpose of the belt is for a nurse to hold when ambulating an unsteady patient to reduce risk for a fall.

gastrostomy feeding tube Long, hollow, flexible tube inserted into the stomach through a stab wound in the upper left abdominal quadrant.

gingivae The gums of the mouth.

gingivitis Inflammatory condition in which the gums are red, swollen, and bleeding.

glabellar tap A reflex elicited by repetitive tapping on the forehead. Subjects blink in response to the first several taps. If the blinking persists, this is known as Myerson's sign and is abnormal.

glucose monitoring A diagnostic test to determine the blood glucose level.

granulation The presence of red, granular, moist tissue that appears during the healing of open wounds; type of tissue containing new blood vessels that bleed readily.

granulation tissue Soft, pink, fleshy projection of tissue that forms during the healing process in a wound not healing by primary intention.

gravity The heaviness or weight of an object resulting from the effect of the attraction between any body of matter and any planetary body.

guaiac test Diagnostic test to detect blood in the stool.

guided imagery Technique in which patient focuses on an image, becoming less aware of pain.

gurgle Abnormal coarse sound heard during auscultation of the lung. Produced by air entering large mucus-containing airways.

H

halitosis Offensive breath resulting from poor oral hygiene, dental or oral infections, ingestion of certain foods, or systemic diseases.

hand-off Effective hand-off allows for face-to-face communication when available, which permits the person receiving care of the patient the opportunity to ask questions.

hand rolls Cylindrical rolls of cloth or gauze placed against the palmar surface of a patient's hand to maintain hand, thumb, and fingers in a functional position.

Harris splint Expandable splint that supports the thigh in skeletal traction.

hazard/hazard identification A condition or phenomenon that increases the probability of a loss that may result in injury or illness/recognition of conditions or agents creating risk.

healing ridge Induration of collagen deposits beneath the skin extending to about 1 cm on each side of the wound.

health care—acquired infection Infection that was not present or incubating at time of admission.

Health Insurance Portability and Accountability Act (HIPAA) A federal law designed to protect the privacy of patient health information.

heatstroke Condition characterized by core body temperature of 45°C (116°F).

heave A lift or thrust felt during palpation of the heart.

hematemesis Vomiting of blood.

hematology The study of blood cells.

hematoma Collection of extravasated blood trapped in the tissues of the skin or in an organ. Results from trauma or incomplete coagulation.

hematopoiesis The formation and development of blood cells in bone marrow.

hematuria Abnormal presence of blood in the urine.

hemiparesis Muscular weakness of one half of the body.

hemiplegia Paralysis of one side of the body.

hemoconcentration The concentration of red blood cells in one area.

hemodialysis A procedure in which impurities or wastes are removed from the blood. Used in treating renal insufficiency and various toxic conditions.

hemodynamics The study of movements of the blood and the forces concerned therein.

hemolysis The destruction of red blood cells.

hemopneumothorax An accumulation of both air and blood in the intrapleural space. This condition is characterized by the signs and symptoms listed with pneumothorax and hemothorax.

hemoptysis Coughing up of blood from the respiratory tract.

hemorrhoids A varicosity in the lower rectum or anus caused by congestion in the hemorrhoidal veins.

hemostasis Termination of bleeding by mechanical or chemical means or by the coagulation process of the body.

hemothorax An accumulation of blood in the intrapleural space caused by a pulmonary infarction, tissue damage that occurs as a result of lung cancer or other chest trauma, or a complication of anticoagulant therapy after chest surgery.

Hemovac drain A type of closed drain system.

heparin lock An intravenous needle connected to a small "well" that allows for the intermittent injection of medication without the need for repeated venipuncture.

herniation The abnormal protrusion of an organ or other body structure through a defect or natural opening in a covering, membrane, muscle, or bone.

high-Fowler's position Placement of a patient in a semi-sitting position by raising the head of the bed more than 45 to 60 degrees.

hirsutism Excessive body hair in a masculine distribution, caused by heredity, hormonal dysfunction, or medication.

- Homans' sign** In the presence of phlebitis or when phlebitis is suspected, dorsiflexion of the foot elicits pain in the calf.
- homeostasis** The state of equilibrium (balance between opposing pressures) in the internal environment of the body, naturally maintained by adaptive responses that promote healthy survival.
- hospice** A system of family-centered care designed to help the terminally ill person be comfortable and maintain a satisfactory lifestyle through the phase of dying.
- Hoyer lift (mechanical/hydraulic lift)** Mechanical device that uses a canvas sling to easily lift dependent patients for transferring.
- Huber needle** Special needle with a deflected point designed to prevent damage to the silicone septum of implanted infusion ports.
- humectant** A substance that promotes retention of moisture.
- hydrocolloid** An adhesive, moldable wafer made of a carbohydrate-based material, usually with a waterproof backing. This dressing usually is impermeable to oxygen, water, and water vapor and has some absorptive properties.
- hydrogel** A water-based, nonadherent, polymer-based dressing that has some absorptive properties.
- hygiene** The science of health. Self-care measures people use to maintain their health are called *personal hygiene*.
- hypercalcemia** Greater-than-normal amounts of calcium in the blood.
- hypercapnia** Elevated arterial PaCO₂ greater than 45 mm Hg; also called *hypercarbia*.
- hyperemia** Increased blood flow in part of the body, as in the inflammatory response, local relaxation of arterioles, or obstruction of the outflow of blood from an area.
- hyperextension** Movement of a body part beyond its normal resting extended position.
- hyperkalemia** Refers to solutions with potassium concentrations greater than 5.0 mEq/L.
- hypermagnesemia** Refers to solutions with magnesium concentrations greater than 2.5 mEq/L.
- hypermagnesemia** Refers to solutions with sodium concentrations greater than 147 mEq/L.
- hyperopia** A refractive error of the eye in which parallel rays of light focus behind the retina. Causes difficulty seeing near objects.
- hyperphosphatemia** Refers to a higher-than-normal range of serum phosphorus. Normal range for serum phosphorus is 2.5 to 4.5 mg/100 mL (1.7 to 2.6 mEq/L).
- hyperpigmentation** Unusual darkening of the skin.
- hypertension** Condition characterized by an elevated blood pressure persistently exceeding 150/90 mm Hg.
- hyperthermia** Condition characterized by body temperature over 38°C (100.4°F).
- hypertonic** Having a greater concentration of solute than another solution, thus exerting more osmotic pressure.
- hypodermoclysis** The injection of an isotonic or hypotonic solution into subcutaneous tissue to supply a continuous and large amount of fluid, electrolytes, and nutrients.
- hypokalemia** Refers to solutions with potassium concentrations less than 3.5 mEq/L.
- hypomagnesemia** Refers to solutions with magnesium concentrations less than 1.5 mEq/L.
- hyponatremia** Refers to solutions with sodium concentrations less than 137 mEq/L.
- hyposmolar** State in which there is an abnormal gain in water or loss of sodium-rich fluids with replacement by water only. As a result, there is a low concentration of solutes in the body fluids.
- hypophosphatemia** Refers to a lower-than-normal range of serum phosphorus. Normal range of serum phosphorus is 2.5 to 4.5 mg/100 mL (1.7 to 2.6 mEq/L).
- hypotension** Condition characterized by a low blood pressure that is inadequate to perfuse and oxygenate body tissue.
- hypotheses** Predictions about the relationships between or among the variables of a research study.
- hypothermia** Condition characterized by body temperature below 36°C (96.8°F).
- hypothermia therapy** Techniques used to reduce elevated body temperature.
- hypotonic** Having a smaller concentration of solute than another solution, thus exerting less osmotic pressure.
- hypovolemic shock** State of physical collapse caused by massive blood loss, circulatory dysfunction, and inadequate tissue perfusion.
- hypoxemia** Abnormal deficiency of oxygen in arterial blood.
- hypoxia** Insufficient oxygen available to meet the metabolic needs of tissues and cells.
- ## I
- idiosyncratic reaction** A response to a medication or therapy that is unique to an individual.
- ileal conduit** A method of urinary diversion through intestinal tissue. Ureters are implanted in a section of dissected ileum that is then sewed to an ostomy in the abdominal wall.
- ileostomy** Surgical formation of an opening of the ileum onto the surface of the abdomen through which fecal matter is emptied.
- immobility** Pertaining to the inability of a body part or limb to be moved.
- immunocompromised** A state of defective or failed immune response that makes a person more likely to acquire an infection.
- impaction** Presence of a large or hard fecal mass in the rectum or colon.
- implanted subcutaneous port** A central venous catheter with a reservoir surgically placed under the skin that may remain in place for a prolonged period to obtain blood samples and administer medications.
- incentive spirometer** Individual patient device used to encourage full lung expansion. Reduces the risk for atelectasis in the immobilized or postoperative patient.
- incentive spirometry** Method of deep breathing providing visual feedback to patients concerning their inspiratory volume.
- Incident Command System (ICS)** A “first-on-scene” structure in which the first responder to a scene has charge of the scene until the incident has been declared resolved. A superior-ranking responder arrives on scene and seizes command.
- incident report** Confidential document that describes any patient accident while the person is on the premises of a health care agency.
- incompatibility** Describes two medications of different chemical makeup that cannot be mixed together.
- incontinence** Inability to control urination or defecation.
- incontinent diversion** A urinary diversion that does not give a patient the ability to control when urine exits the stoma, requiring the use of an external ostomy pouch.
- incubation period** Period between exposure to a pathogenic organism and the appearance of symptoms. A patient is often contagious during this time and capable of spreading disease without realizing it.
- induration** Hardening of a tissue, particularly the skin.
- infection** The invasion and reproduction of microorganisms in a body tissue that can result in a local or systemic clinical response such as cellulitis or fever.
- infiltration** Presence of intravenous fluids within the subcutaneous space surrounding a venipuncture site.
- informed consent** Permission obtained from a patient to perform a specific test or procedure.
- infusate** Volume of parenteral fluid infused into a patient over an established period of time.
- infusion** Introduction of a fluid such as a drug, electrolyte, or nutrient directly into a vein by means of gravity flow.
- infusion pump** Device designed to deliver a measured amount of fluid over a period of time.
- injection** Act of forcing a liquid into the body by means of a syringe.
- injection cap** A rubber diaphragm covering a plastic cap. Permits needle insertion into a catheter or vial.
- inspection** A physical examination skill involving the examiner's looking at external and internal body parts for physical characteristics.
- insulator** A substance that conducts temperatures poorly used to protect skin and tissues from hot or cold therapies.
- intake** Measurement of the ingestion or infusion of liquids into the body, including all liquids and semi-liquids, liquid medications, enteral tube feedings, intravenous therapy, blood components, and parenteral nutrition.
- integument** Skin and its appendages (i.e., hair, nails, and sweat and sebaceous glands).
- intercostal space (ICS)** Space found between adjoining ribs.
- internal rotation** Rotation of a joint inward.
- International Nursing Coalition for Mass Casualty Education (INCMCE)** Now known as *Nursing Emergency Preparedness Education Coalition (NEPEC)*. Coordinated by Vanderbilt University School of Nursing. It was founded in response to recognition of the need for nurses to be more adequately prepared to respond to mass casualty events.
- interviewing** The process of conducting an organized, systematic conversation with a patient. Designed to gather information regarding a patient's level of health, response to care, or perception of symptoms or events.
- intestinal obstruction** Any obstruction that results in failure of the contents of the intestine to pass through the lumen of the bowel.
- intraabdominal pressure** Amount of tension within the abdominal cavity.
- intracavitary** Within a body cavity.
- intracellular fluid** Liquid within the cell membrane.
- intraclavicular fossa** Small pocket area or indentation just below the clavicle on both sides of the neck.
- intra dermal (ID) injection** Form of injection in which a solution is introduced into the dermal skin layer.
- intramuscular (IM) injection** Form of injection in which a solution is introduced into the body of a muscle.
- intrapleural** Pertaining to or affecting the potential space between the parietal and visceral pleurae.
- intrapulmonic** Pertaining to or affecting the spaces within the lungs.
- intraspinal** Referring to both the epidural and intrathecal routes of medication administration.
- intra thecal** Of or pertaining to a structure, process, or substance within a sheath, as within the spinal canal.
- intravenous conscious sedation (IVCS)** The intravenous administration of pharmacological agents to provide a minimally depressed level of consciousness to provide comfort during diagnostic or treatment procedures.
- intravenous (IV) injection** Form of injection in which a solution is introduced into a vein.
- introitus** An entrance or orifice into a cavity.
- intubation** Passage of a tube into a body aperture.

- invasive** Referring to procedures that involve puncture, incision, or insertion of a foreign object into the body.
- invasive procedure** A procedure in which the normal protective barrier of the skin or mucous membrane is broken or compromised (e.g., an intravenous puncture or a bladder catheterization).
- inversion** Turning something upside down.
- irrigate** To flush with a fluid, usually with a slow, steady pressure on a syringe plunger. Done to cleanse a wound or clear tubing.
- irrigation** Gentle washing of an area with a stream of solution.
- ischemia** A decreased supply of oxygenated blood to a body organ or part.
- isolation** Infection control and prevention methods such as barrier technique that are used to decrease the transmission of microorganisms.
- isometric contraction** Increased muscle tension without muscle shortening.
- isometric exercise** The tightening or tensing of muscles without moving body parts.
- isotonic** A solution with a total electrolyte content of approximately 310 mEq/L.
- isotonic solution** Having the same concentration of solute as another solution, thus exerting the same amount of osmotic pressure as the solution.
- intravenous (IV) plug** A small rubber or plastic cap that connects to the open end of a patient's IV access catheter. Also referred to as *injection cap* because a needle can be inserted into the rubber cap for the administration or aspiration of fluids.
- J**
- jacket restraints** Vestlike restraints that usually cross on the back of a patient but may also cross on the front.
- Jackson-Pratt drain** A closed drain system.
- jejunostomy feeding tube** A hollow tube inserted into the jejunum through the abdominal wall for administration of liquefied foods.
- joint** Any one of the connections between bones.
- K**
- karaya** A natural gum product that softens with body heat and conforms to the contours around the stoma.
- Kardex** Trade name for a card filing system that allows quick reference to the particular need of the patient for certain aspects of nursing care.
- keloid** An overgrowth of scar tissue at the site of skin injury such as a wound or surgical incision.
- ketone** An organic chemical compound with two compounds attached to it.
- kilogram** The metric conversion for a pound; weight (pounds) \div 2.2 = kilograms.
- kinesthetic** Related to the ability to perceive the existence or direction of weight or movement.
- L**
- laryngospasm** Spasm of the muscles surrounding the larynx causing airway narrowing and stridorous breathing.
- lateral flexion** A range of joint motion exercise during which the head is tilted as far as possible toward each shoulder. Maintains neck mobility.
- latex allergy reaction** Allergic response to products containing latex (e.g., gloves, medical devices). Can present as contact dermatitis, allergic rhinitis, or immediate life-threatening reactions leading to such conditions as urticaria, bronchospasm, and edema.
- lavage** The irrigation or washing out of an organ or cavity.
- let-down reflex** A normal reflex in a lactating woman often elicited by tactile stimulation of the nipple, resulting in release of milk from the glands of the breast.
- leukopenia** A decrease in circulating white blood cells.
- leverage** Occurs when specific bones such as the humerus, ulna, and radius and the associated joints such as the elbow joint act together as a lever.
- line of gravity** An imaginary line that goes from the center of gravity to the base of support.
- lipid emulsion** A soybean oil.
- lipodystrophy** Any abnormality in metabolism and deposition of fat.
- logrolling** Maneuver used to turn a reclining patient from one side to the other or completely over without flexing the spinal column.
- loss** Absence of a significant other, object, or state of health to which the person must adapt through the grieving process.
- lotion** Liquid preparation applied externally to protect the skin or treat a dermatological disorder.
- lumen** The hollow channel within a tube.
- lunula** A semilunar structure such as the crescent-shaped pale area at the base of the nail of a finger or toe.
- M**
- macerate** To soften, usually by soaking in water.
- maceration** Skin that becomes abnormally soft and breaks down because of prolonged exposure to moisture.
- maculopapular** Discolored elevated lesions on the skin.
- malabsorption** Impaired absorption of nutrients from the gastrointestinal tract.
- malignant hyperthermia** An autosomal-dominant trait characterized by often fatal hyperthermia with rigidity of the muscles occurring in affected people exposed to certain anesthetic agents.
- malnutrition** Any disorder of nutrition.
- manmade disaster** A catastrophic event, the principal direct cause of which is attributable to human action.
- manometer** An instrument for measuring pressure or tension of liquids or gases.
- manual defibrillator** Device used by trained personnel to treat fast, irregular dysrhythmias with electrical shock to the heart.
- mass casualty disaster/event/incident (MCI)** Any event or situation that results in multiple casualties and/or deaths; an MCI exists when health care needs exceed health care resources.
- mass casualty triage** Move, Assess, Sort, and Send (MASS) approach to triage initially sorts victims into groups, which are then evaluated for transportation to treatment.
- massage** A form of cutaneous stimulation that involves the application of touch and movement to muscles, tendons, and ligaments.
- mastication** Chewing, tearing, or grinding food with the teeth while it mixes with saliva.
- material safety data sheet (MSDS)** A form containing data about the properties of the particular chemical and information for handling the substance in a safe manner (e.g., storage, disposal, protective equipment, and spill-handling procedures).
- maturational loss** A loss expressed as any change in a person's developmental process that is normally expected during a lifetime.
- meatus** Any opening or tunnel through any part of the body (e.g., the point at which the urethra opens to the skin).
- mediastinal shift** A condition in which the mediastinal contents move toward the unaffected side in the presence of a pneumothorax, hemothorax, or hemo-pneumothorax. The mediastinal shift causes compression of the organs and is a life-threatening situation.
- medical asepsis** The techniques used to reduce and prevent the spread of microorganisms (clean technique).
- medical disaster** A catastrophic event that results in human casualties that overwhelm the available health care resources.
- medicated enema** Administration of a medication via an enema. Usually used before surgery with patients scheduled for bowel surgery.
- medication administration record (MAR)** The report that serves as a legal record of the medications administered to a patient at a facility by a nurse or other health care professional.
- medication dependence** Two types of medication dependence exist: psychological (or addiction) and physical. In psychological dependence a patient desires the medication for some benefit other than the intended effect. The individual believes that a desirable effect will result when taking the medication. Physical dependence involves a physiological adaptation to a medication that manifests itself by intense physical disturbance when the medication is withdrawn.
- medication plateau** Blood serum concentration reached and maintained after repeated, fixed doses.
- medication reconciliation** A process completed during all care transitions (e.g., patient transfer from the intensive care unit to a medical-surgical unit) whereby current medication orders are compared to all medication the patient has taken previously. Reconciliation is completed in an effort to minimize the risk of drug omissions, dosing errors, drug interactions, and duplicative orders.
- medication tolerance** Decreased physiological response after repeated administration of a medication or a chemically related substance.
- medullary** Of or pertaining to the medulla of the brain.
- melanin** Black or dark brown pigment that occurs naturally in the skin, hair, and iris.
- melanocyte** A body cell capable of producing melanin, the pigment of the skin.
- melena** Darkening of the feces by blood pigments.
- metastasis** Process by which tumor cells are spread to distant parts of the body.
- metered-dose inhaler (MDI)** A device designed to deliver a measured dose of an inhalation drug.
- microorganisms** Any microscopic entity capable of sustaining living processes such as bacteria, virus, or fungi, only some of which typically cause human disease.
- microvasculature** The portion of the circulatory system composed of the capillary network.
- micturition** Urination. Act of passing or expelling urine voluntarily through the urethra.
- midarm circumference (MAC)** A measurement of the circumference of the upper arm used to estimate muscle mass.
- midstream collection** Procedure in which a patient initiates a stream of urine, inserts a sterile collection cup into the stream, and then withdraws the cup before the stream of urine stops.
- milliequivalent per liter (mEq/L)** Number of grams of a specific electrolyte dissolved in 1 L of plasma.
- Minerva jacket** Cast encasing the head (with face and ears exposed) and continuing over the thorax and back to the iliac crests.
- minimal sedation** Lightest level of sedation; includes local and topical anesthetics and peripheral nerve blocks.
- mitten restraints** Thumbless mitten devices used to restrain a patient's hands.
- mobility** The amount and quality of physical activity.
- moderate sedation** A drug-induced depression of consciousness during which patients respond purposefully to verbal commands, either alone or accompanied by light tactile stimulation.
- Modified Ramsay Sedation Scale** A numeric rating scale used to evaluate patient's level of sedation.
- moleskin** Adhesive-backed tape used for some forms of skin traction.

morgue A unit of a hospital with facilities for the storage and autopsy of the dead.

mucociliary transport Process in which cilia lining the tracheobronchial tree sweep mucus upward toward the esophagus to keep airways clear of inhaled particulate.

mucopurulent Characteristic of a combination of mucus and pus.

mummy restraints Blanket or sheet folded in such a manner as to restrain a small child or infant.

mutual aid agreement Reciprocal agreement to provide help between two or more agencies.

mydriasis Dilation of the pupil of the eye caused by contraction of dilator muscles of the iris.

mydriatics Ophthalmic preparations that stimulate the sympathetic nerve fibers or block parasympathetic nerve fibers of the eye, temporarily paralyzing the iris sphincter muscle.

myelosuppression A decrease in the cellular components of the bone marrow.

N

nares The pairs of anterior and posterior openings in the nose that allow for passage of air to the pharynx and lungs.

nasal Of or pertaining to the nose and nasal cavity.

nasal cannula Device for delivering oxygen by way of two small tubes that are inserted into the nares.

nasogastric (NG) feeding tube A small tube that is passed via the nares into the stomach.

nasointestinal (NI) feeding tube Tungsten-weighted tube inserted through the naris to allow natural peristaltic movement of the tube through the pyloric sphincter into the duodenum or jejunum.

National Dysphagia Diet Released in October 2002, the National Dysphagia Diet provides recommendations for uniformity of dysphagia diets for all health care facilities. Solid and liquid diets are separated into four levels.

natural/environmental disaster A catastrophic event that results from an ecological event that exceeds the capacity of the community.

nebulization Vaporization or dispersion of a liquid in a fine spray.

nebulizer Device used to distribute medication throughout nasal passages and tracheobronchial airway by vaporizing the medication.

necrosis Localized tissue death.

necrotic Related to death of a portion of tissue.

negative pressure Pressure (measured in millimeters of mercury [mm Hg]) that is less than atmospheric pressure.

negative pressure ventilation Therapy used for patients with primary neuromuscular illnesses that interfere with normal respiratory muscle function. The patient is fitted with a poncho or shell that is connected to the ventilator. Air is removed from between the patient's chest wall and the interior wall of the poncho or shell, causing the patient to inhale.

negative pressure wound therapy The application of pressure less than the ambient atmospheric pressure (as in a vacuum) to a wound to draw wound edges together, remove exudates and excess moisture, and promote healing.

negligence Omission of care.

neovascular assessment Series of eight observations required to measure neurological and circulatory status of a patient's peripheral tissue.

neovascularization The process by which the vascular network in a wound is generated. This can also be called angiogenesis.

neurological Pertaining to the study and treatment of the nervous system.

neuropathy An abnormal condition characterized by inflammation and degeneration of the peripheral nerves.

neurovascular assessment Series of eight observations (assessments) required to measure neurological and circulatory status of a patient's peripheral tissues.

neutropenia An abnormal decrease in the number of neutrophils in the blood.

neutropenic Having an abnormal decrease in the number of neutrophils (white blood cells) in the blood.

nitroglycerin Medication that causes dilation of coronary arteries.

noncontinent (incontinent) ostomy/diversion Results from a surgical procedure that leaves a patient with an external stoma through which either stool or urine drains. It is noncontinent/incontinent because the effluent drains spontaneously from the stoma and the patient must continuously wear an external ostomy pouch over the stoma.

noncoring Huber needle A specially designed needle (straight or a 90-degree needle) intended for use with a vascular access device. This needle permits penetration into the chamber of the vascular access device without causing damage and thus permits repeated administration of medication directly into a patient's bloodstream.

noninvasive ventilation (NIV) Noninvasive ventilation (NIV) maintains positive airway pressure and improves alveolar ventilation without the need for an artificial airway. In addition, this mechanical ventilator alternative reduces and reverses atelectasis, improves oxygenation, reduces pulmonary edema, and improves cardiac function.

nonopioids Analgesics that do not contain opioids.

nonpharmacological aids Interventions used to prevent illness and promote health without the use of or in addition to the use of medications.

nontunneled percutaneous central venous catheters Intravenous access devices inserted into the internal jugular, subclavian, or femoral vein by direct venipuncture into the vein.

noxious Harmful, injurious, or detrimental to health.

NPO Nothing to be taken or given by mouth.

nuclear event The release of radiation by a device in an explosive manner as a result of a nuclear chain reaction.

nutritional risk The potential to become malnourished because of factors that are primary (e.g., inadequate intake) or secondary (e.g., disease).

nutritional screening The systematic process of identifying risk factors related to nutritional problems and malnutrition.

nutritional support nursing The care of individuals with potential or known nutrition alterations. The goal is to help individuals restore and maintain optimal nutritional health.

O

objective data Data obtained by an observer (nurse) through direct physical examination, including observation, palpation, and auscultation, and by laboratory analyses and radiological and other studies.

obstipation The absolute inability to pass stool.

obturator Small dull-pointed introducer inserted in outer cannula that facilitates insertion of tracheostomy tube by gradually widening or dilating stoma to width of tracheostomy tube.

occlusive dressing A dressing that prevents air from reaching a wound or lesion and retains moisture, heat, body fluids, and medication.

occult blood Blood that appears from a nonspecific source, with obscure signs and symptoms. May be detected by means of a chemical test or microscopic examination.

ocular Of or pertaining to the eye.

oil-retention enema An enema containing a small volume of an oil-based solution. Used to soften fecal mass.

ointment A semisolid, externally applied preparation, usually containing a drug.

olfaction The sense of smell.

oncology A branch of medicine regarding the study of tumors.

onset of medication action Period of time after a drug is administered for it to produce a response.

opening pressure The amount of tension measured in a manometer following insertion of a spinal needle into the subarachnoid space.

ophthalmic Of or pertaining to the eye.

opioids Pertaining to natural and synthetic chemicals that have opium-like effects although they are not derived from opium.

opposition The relation between the thumb and the other digits of the hand for the purpose of grasping objects between the thumb and fingers. This maneuver is used during range-of-joint-motion exercises to maintain grasping ability of a patient.

oral airway Minimally flexible curved piece of plastic extending from the exterior of the lips over the tongue to the pharynx.

Organ Procurement Agency (OPA) Community-based agency, the focus of which is to obtain donated organs for transplantation.

organ/tissue donation Families and significant others are offered the option of organ and/or tissue donation. This process includes but is not limited to the donation of heart, lung, kidneys, liver, corneal tissue, and bone.

orientation phase Period in the nurse-patient relationship when a nurse and patient first meet and set the tone for the rest of their relationship, assessing the patient's situation and setting goals.

orthopedics Branch of medicine devoted to the study and treatment of the skeletal system, its joints, muscles, and associated structures.

orthopnea An abnormal condition in which a person must sit or stand to breathe deeply or comfortably.

orthostatic hypotension A drop in blood pressure of 15 mm Hg or more when an individual rises from a sitting to a standing position.

orthotopic neobladder A type of continent urinary diversion that uses an ileal pouch to replace the bladder. The ileal pouch is the same anatomical position as the bladder. The patient uses pelvic muscle exercises and bladder-training exercises to achieve urinary continence.

osteoblastic Physiological activity that leads to the formation of specific bone tissue, osteoblasts.

osteoblasts Osteoblasts synthesize the collagen and glycoproteins to form the matrix for bone formation.

osteoclastic Physiological activity producing osteoclast bone cells that function in the development and periods of bone growth and repair, such as the breakdown and resorption of osseous tissue.

ostomy A surgical procedure in which the elimination of stool or urine is rerouted from the usual exiting part of the patient. Instead, the stool or urine exits the body through a surgically created opening called a stoma.

otic Of or pertaining to the ear.

otitis media Inflammation or infection of the middle ear, a common childhood affliction.

ototoxic Having a harmful effect on the eighth cranial nerve or the organs of hearing and balance.

outer cannula Main portion of tracheostomy tube through which patient breathes, which stays in place at all times. The pilot balloon and faceplate are connected to the outer cannula.

output Includes all liquids excreted, such as urine, vomitus, and diarrhea, and drainage from wounds, fistulas, and suction equipment.

overdose Oral or parenteral ingestion of an excessive quantity of a medication or drug.

over-the-counter (OTC) medication Drug available to a consumer without a prescription.

over-the-needle catheter (ONC) A type of angiocatheter. The needle used for peripheral intravenous access is encased in a catheter made of Teflon, plastic, or another flexible material. After the needle pierces the skin, the catheter is threaded into a vein, and the needle is withdrawn. The catheter remains in the vein for the instillation of fluid.

oximetry Procedure used to measure amount of oxygenated hemoglobin.

oxygen mask A flexible mask that fits snugly and securely over a patient's nose and mouth for delivery of oxygen.

oxygen saturation Amount of hemoglobin that is fully saturated with oxygen expressed as percentage of total available hemoglobin.

oxygen therapy Administration of oxygen by any route to a patient to prevent or relieve hypoxia.

oxygen toxicity Administration of oxygen level greater than 50% for greater than 24 hours that results in increased permeability of the alveolar wall, alveolar-capillary leakage, noncardiogenic pulmonary edema, decreased lung compliance, and respiratory failure.

P

pain Subjective, unpleasant sensation caused by noxious stimulation of sensory nerve endings.

pain intensity The degree or extent of pain perceived by an individual.

pain rating scales Graphic or numeric representations that allow patients to quantify their pain experience.

pain threshold The amount of pain stimulus required to produce a physical or psychological response.

pain tolerance Point at which a person is not willing to accept pain of greater severity or duration.

palliative care The prevention, relief, reduction, or soothing of symptoms of disease or disorders without effecting a cure.

pallor Unnatural paleness or absence of color in the skin.

palpation A technique used in physical examination in which the examiner feels the texture, size, consistency, and location of certain parts of the body with the hands.

palpebra Portion of the conjunctiva that lines the inner surface of the eyelids. It is thick, opaque, and highly vascular.

pandemic Occurring throughout the population of a country, a people, or the world.

paralysis An abnormal condition characterized by loss of muscle function or the loss of sensation.

paralytic ileus A decrease in or absence of intestinal peristalsis that may occur after abdominal surgery, illness, or trauma.

paraphrasing Transforming a patient's words into the nurse's words, keeping the meaning intact.

parenteral Not in or through the digestive system.

parenteral nutrition (PN) The administration of nutrition into the vascular system.

pareisis Slight or partial paralysis related in some cases to local neuritis.

parietal pleura The pleural membrane that lines the thoracic cavity.

passive range-of-motion exercises Exercises of the joints performed for an individual by someone else.

patency Absence of obstruction such as clots within an intravenous (IV) needle or kinks within IV tubing; the state of being open and unblocked.

pathogen Microorganism capable of producing disease.

pathogenic microorganisms Those capable of producing an infection or disease.

Patient Care Partnership A list of patient's rights promulgated by the American Hospital Association. It offers some guidance and protection to patients by stating the responsibilities that a hospital and its

staff have toward patients and families during hospitalization. It is not a legally binding document.

patient care profile (PCP) A report that is automatically updated each shift within a computerized medical record.

Patient Self-Determination Act Legislation that requires all Medicare and Medicaid recipient hospitals to provide patients with information on advance directives and their right to accept or reject medical treatment.

patient-controlled analgesia (PCA) Technique that allows patients to self-administer small, continuous doses of intravenous or subcutaneous opioids as they feel the need.

patient's rights The rights to which patients are entitled as recipients of medical care.

peak action Time it takes for a drug to reach its highest effective concentration.

peak airway pressure The highest amount of positive pressure needed to inflate the lung.

peak concentration The highest effective concentration of a drug in the serum.

Pearson attachment The support used under the leg in balanced-suspension skeletal traction.

pediculosis Infestation of the integument with blood-sucking lice.

peer reviewed Process by which experts in a field evaluate an article or report for the quality of its scholarship, relevance to its field, and appropriateness for publication in which it may appear. Only those articles judged to meet the highest standards will be published.

PEH Acronym for pseudoepitheliomatous hyperplasia. Maceration of skin surrounding the stoma.

pelvic belt Girdle-shaped cotton belt or support that fits around the hips, lumbosacral area, and abdomen for attaching ropes and weights in pelvic belt traction.

pelvic sling A hammocklike sling that fits under a patient's lumbosacral area and hips and is then connected to ropes and weights. It suspends the pelvis off the bed as treatment for fractures of pelvic bones.

Penrose drain An open drain system.

perceived loss Any loss that is tangible and uniquely defined by the grieving patient. It may be less obvious to others.

percussion A technique in physical examination used to assess the size, borders, and consistency of some of the internal organs and to discover the presence and evaluate the amount of fluid in a cavity of the body.

percutaneous Performed through the skin, such as a biopsy or the aspiration of fluid from a space below the skin using a needle, catheter, and syringe.

percutaneous coronary intervention (PCI) Procedures such as percutaneous transluminal coronary angioplasty (PTCA) or directional coronary atherectomy (DCA) performed during cardiac catheterization.

perfusion Effect of pulmonary circulation in moving blood to and from the blood-gas barrier so gas exchange can occur.

periodontal Referring to tissues surrounding the teeth, such as the gums and buccal mucosa.

periodontitis Receding gum lines, inflammation, and gaps between teeth.

perioperative Related to the entire surgical experience.

peripherally inserted central catheter (PICC) A peripherally inserted catheter that extends to the superior vena cava or right atrium.

peristomal Referring to the area of skin surrounding a surgically created stoma.

peritoneal fluid Substance in the abdominal cavity for lubrication of peritoneal membrane and internal organs.

peritonitis Inflammation of peritoneum produced by bacteria or irritating substances introduced into the abdominal cavity by a penetrating wound or perforation of an organ in the gastrointestinal or reproductive tract.

ration of an organ in the gastrointestinal or reproductive tract.

PERRLA Acronym for pupils equal, round, reactive to light, and accommodation. The acronym is recorded in the physical examination if pupil assessment is normal.

petaling Finishing the raw or ragged edges of a plaster cast to prevent skin irritation or pressure.

pétrissage A massage technique in which the skin is gently lifted and squeezed.

pharmacokinetics The study of how medications enter the body, reach their site of action, are metabolized, and exit the body.

pharmacological agents Oral, parenteral, or topical substances used to alleviate symptoms and treat or control illness.

pharynx The throat.

phlebitis Inflammation of a vein.

phlebitis solution A hypertonic solution capable of causing inflammation of a vein.

phlebothrombosis Blood clot formation.

phlebotomy The incision of a vein for the letting of blood, as in collecting blood from a donor.

physical dependence A physiological state in which abrupt cessation of a drug results in a withdrawal syndrome.

physical restraint Any device, garment, material, or object that restricts a person's freedom of movement or access to one's body.

PICO A format approach for organizing a clinical question into four components; patient population, intervention or area of interest, comparison of interest, and outcome.

PIE An acronym for problem, intervention, and evaluation. Used as an organizing framework for narrative nurses' notes.

piggyback infusion Method for administering intravenous (IV) medications intermittently; a piggyback IV set is a supplementary set that connects with the primary IV tubing.

piloerection Erection of hair caused by the action of the arrectores pilorum muscles, the smooth muscles attached to the hair follicles. Commonly referred to as goose bumps.

plantar flexion Flexion of the foot and toes toward the sole.

plaque (dental) A thin film on teeth made up of mucin and colloidal material found in saliva and often secondarily invaded by bacteria.

plateau Blood serum concentration reached and maintained after repeated, fixed doses of a drug.

pleura Delicate serous membrane enclosing the lung.

pleural cavity Space between visceral and parietal pleurae. Pressure within the cavity is negative when compared with atmospheric pressure.

pleural fluid Substance contained between visceral and parietal pleurae for lubrication of the membranes.

pneumonitis Inflammation of the lung. May be caused by a virus or may be a hypersensitivity reaction that occurs as a result of allergy to chemical or organic dusts.

pneumothorax An accumulation of air in the intrapleural space caused by a severe blow to the chest, extremely forceful cough, chest trauma, or open-chest surgery.

podiatrist A health care professional trained to diagnose and treat diseases and disorders of the feet.

point of maximal impulse (PMI) Point at which the heartbeat can most easily be palpated through the chest wall, usually along the left midclavicular line at the fourth or fifth intercostal space.

point-of-care test Performing laboratory tests at the primary care setting, such as the bedside (e.g., glucose monitoring or assay of whole blood, plasma, or serum).

- polypharmacy** Concurrent prescription, administration, or use of multiple medications, some of which may not be indicated clinically.
- POMR** An acronym for *problem-oriented medical record*. Used as an organizing framework for a patient's complete medical record.
- positive end expiratory pressure (PEEP)** The application of positive airway pressure at the end of exhalation through a ventilator or breathing device.
- positive pressure** Pressure measured in millimeters of mercury (mm Hg) that is greater than atmospheric pressure.
- positive-pressure ventilation** Mechanical ventilation that delivers compressed gas to the airways at greater than ambient pressure.
- postanesthesia care unit (PACU)** Postsurgical recovery area where patients are closely monitored and stabilized before discharge to a specific nursing unit or, in the case of same day surgery, to home.
- postcast care** Nursing interventions performed for and with patients in casts or after cast removal.
- postmortem care** Care provided to the body after death.
- postoperative** Period of time after completion of a surgical procedure wherein a nurse monitors a patient's recovery.
- postural** Position of the body. Usually refers to change of position from supine to sitting, sitting to standing.
- postural drainage** Gravitational clearance of airway secretions by assumption of one or more of 10 different body positions for 5 to 15 minutes each. Each posture corresponds to specific segments of bronchi in the lung.
- postural hypotension** Condition in which a normotensive person becomes light-headed or dizzy and experiences low blood pressure when rising to an upright position.
- posture** Position of the body in relation to the surrounding space.
- prealbumin** A plasma protein with a half-life of only 2 days, used as a marker of nutritional status.
- precordial** Of or pertaining to the precordium, which forms the region over the heart and the lower part of the thorax.
- preemptive analgesia** A method of preventing pain while reducing opioid use.
- premature ventricular contraction (PVC)** A cardiac dysrhythmia characterized by a ventricular contraction preceding the expected contraction; it appears on an electrocardiogram as an early, wide QRS complex without a preceding P wave.
- preoperative** The period of time preceding induction of anesthesia and the beginning of a surgical procedure.
- preoperative checklist** Agency-specific list of guidelines for ensuring completion of nursing interventions. This list includes items to be assessed or verified (e.g., verification that preoperative orders are written and completed, laboratory work is in the patient's medical record, the patient has voided, current vital signs are documented).
- presbycusis** Loss of hearing sensitivity and speech intelligibility. Associated with aging.
- presbyopia** Farsightedness resulting from a loss of elasticity of the lens of the eye. The condition commonly develops with advancing age.
- pressure dressing** A temporary treatment for the control of excessive bleeding. Pressure dressings require elastic bandages to maintain the pressure and may also require the application of sandbags adjacent to the dressing to augment pressure.
- pressure ulcer** A lesion that develops in the skin as a result of prolonged, unrelieved pressure.
- primary dressing** A dressing that comes in direct contact with the wound bed.
- primary intention** Primary union of the edges of a wound, progressing to complete scar formation with granulation.
- prn** "As needed." Administration times are determined by the patient's needs.
- problem-oriented medical record (POMR)** Method of recording data about the health status of a patient that fosters a collaborative problem-solving approach by all members of the health care team.
- procedural sedation** An anesthetic procedure in which analgesia and anesthesia are accomplished without loss of consciousness.
- pronation** Movement of a body part so the front or ventral surface faces downward.
- proprioceptive function** Sensation that is achieved through stimuli originating from within the body regarding spatial position and muscular activity.
- prosthesis** An artificial replacement for a missing part of the body.
- pruritus** The symptom of itching.
- pseudoaddiction** Exhibition of drug-seeking behaviors although the true driving factor is pain relief, not physical addiction.
- Pseudomonas*** A genus of gram-negative bacteria that includes several free-living species of soil and water and some opportunistic pathogens isolated from wounds and sputum. May produce blue and yellow pigments.
- pulleys** Mechanical round, grooved disks over which ropes can move freely for traction pull.
- pulmonary aspiration** The entry of secretions or foreign material into the trachea and lungs.
- pulmonary edema** Accumulation of extracellular fluid in a patient's lung tissue and alveoli, commonly caused by left-sided heart failure, fluid overload.
- pulse deficit** Condition characterized by difference between apical and peripheral pulse rate that results in a lack of peripheral perfusion.
- pyrexia** Fever. An elevation of the body temperature above the normal range.
- pyrogen** Any substance or agent that tends to cause a rise in body temperature, such as some bacterial toxins.
- ## Q
- quality assurance** In health care, any evaluation of services provided and results achieved compared with accepted standards.
- ## R
- radial flexion** A range-of-motion exercise during which there is a bending of the wrist medially toward the thumb; maintains wrist mobility.
- radiopaque** Not permitting the passage of x-rays or other radiant energy. Bones are relatively radiopaque and therefore show as white areas on an exposed x-ray film.
- random voided specimen** A urine specimen obtained at any point of a 24-hour period.
- reactive hyperemia** The return of blood to an area of tissue on the release of externally applied pressure.
- reagent** Chemical used to indicate the presence of a particular substance.
- reduction** The alignment of fracture fragments through manipulation. Closed reduction is accomplished through manual manipulation and casting or traction.
- reflecting** A cognitive strategy that involves reappraisal of one's actions to evaluate outcomes. A communication strategy used to clarify what a patient is feeling and affirm that the patient's feelings are acceptable.
- refractive error** Condition in which parallel rays of light are not brought to focus on the retina.
- registered dietitian (RD)** A health care professional who has successfully completed an examination and maintains continuing education requirements in nutritional care for individuals and groups.
- registered nurse first assistant (RNFA)** A nurse with advanced education who assists the surgeon with surgical procedures, performing a combination of nursing and medical functions.
- reinfusion device** An apparatus that is placed, usually intraoperatively during orthopedic or vascular procedures, into a space where significant blood loss is anticipated. This device collects the blood, filters it, and is then used to reinfuse that blood intravascularly.
- relaxation** A cognitive strategy that provides mental and physical pain relief or reduces pain.
- reminiscing** A form of therapy for older adults that provides a life review. Individual talks about remote memories, expression of related feelings, and recognition of both positive experiences and conflicts.
- remission** The partial or complete disappearance of the clinical and subjective characteristics of a chronic or malignant disease.
- renal insufficiency** Partial kidney failure characterized by less-than-normal urinary excretion and abnormal urinary laboratory results (e.g., creatinine, blood urea nitrogen level).
- residual urine** The volume of urine in the bladder after a normal voiding.
- residual volume** The amount of fluid that pools in the stomach or intestine that is able to be aspirated from a gastric or intestinal tube at any given time.
- resistive isometric exercise** Contracting of muscles while pushing against a stationary object or resisting the movement of an object.
- respiratory arrest** Cessation of respirations.
- respiratory distress** Difficulty breathing that may be associated with abnormal blood oxygen or carbon dioxide levels and may require supportive measures to preserve life.
- respite care** Provision of short-term relief or time off for people providing home care to an ill, disabled, or frail older adult.
- restarting** A communication strategy involving the reiteration of a patient's verbal statements and/or questions using similar words. This affirms that the message was acknowledged by the nurse.
- restarting** The process of verbally clarifying information provided by a patient or family.
- restraint** Device used to immobilize a patient or an extremity.
- reverse Trendelenburg's position** Position in which the lower extremities are low and the body and head are elevated on an inclined plane.
- right atrial catheter** An indwelling intravenous catheter inserted centrally or peripherally and threaded into the superior vena cava or right atrium.
- rigidity** Condition of hardness, stiffness, or inflexibility.
- rigor mortis** The rigid stiffening of skeletal and cardiac muscle shortly after death.
- risk assessment tool for pressure ulcers** Evaluation protocols for assessing the likelihood for the development of pressure ulcers. Two such protocols are the Braden Scale and the Norton Scale, which assess the following five risk factors: physical condition, mental state, activity, mobility, and incontinence.
- rooting reflex** A normal response in newborns when the cheek is touched or stroked along the side of the mouth to turn the head toward the stimulated side and begin to suck.
- rotation** A basic range of joint motion allowed by various joints. The rotation of a bone around its central axis, such as shoulder rotation.
- Rotokinetic bed** A special bed equipped with an automatic turning device that completely immobilizes patients while rotating them from 90 to 270 degrees along a horizontal axis.

- S**
- S₁** Symbol for the first heart sound in the cardiac cycle occurring with ventricular systole. It is associated with the closure of the mitral and tricuspid valves.
- S₂** Symbol for the second heart sound in the cardiac cycle. It is associated with closure of the aortic and pulmonary valves just before ventricular diastole.
- saline lock** See *heparin lock*.
- SBAR** Stands for situation-background-assessment-recommendation technique that provides a framework for communication among a patient's health care team.
- sclerosis** Condition characterized by hardening of tissue resulting from any of several causes, including inflammation, the deposit of mineral salts, and infiltration of connective tissue cells.
- scrub nurse** Surgical nurse whose primary responsibility is to provide the surgeon with instruments and supplies during surgery, which requires strict surgical asepsis. In addition, this nurse along with the circulating nurse disposes of soiled sponges and accounts for sponges, needles, and instruments on the surgical field.
- scrubbed team members** Includes the surgeon and scrub nurse or technician and assisting physicians who are scrubbed.
- sebaceous gland** One of the small glands in the dermis that secretes an oily substance (sebum) on the surface of the skin and in the hair.
- seborrheic dermatitis** A common and chronic inflammatory skin disease characterized by dry or moist greasy scales and yellow crusts.
- sebum** Oily secretion of the sebaceous glands of the skin. When combined with sweat, sebum forms a moist, oily, acidic film that is antibacterial and antifungal and protects the skin against drying.
- secondary dressing** A dressing used to cover or hold primary dressings in place.
- secondary intention** Wound closure in which the edges are separated, granulation tissue develops to fill the gap and, finally, epithelium grows in over the granulation, producing a larger scar than results with primary intention.
- secretion** A product produced by a gland of the body.
- seizure** A hyperexcitation of neurons in the brain leading to a sudden, violent, involuntary series of muscle contractions that may be paroxysmal and episodic, as in a seizure disorder, or transient and acute, as after a head injury.
- seizure precautions** Measures that protect a patient from injury during a seizure.
- self-catheterization** The ability of individuals to insert a urinary catheter into their urinary meatus.
- semi-Fowler's position** Placement of patient in an inclined position, with the upper half of the body raised by elevating the head of the bed approximately 30 to 45 degrees.
- sensitivity** Laboratory test used in conjunction with culture. It measures the response of microorganisms to antibiotics that have been placed on a culture plate.
- sentinel event** An incident that involves serious physical or psychological injury or death or the risk thereof.
- sepsis** Infection, contamination.
- serology** Branch of medicine dealing with serum and blood products.
- serum half-life** The time it takes for the excretion process to lower the serum medication concentration by half.
- shaking** Physiotherapy technique in which a concurrent, compressive force is supplied to the chest wall.
- sharps container** A puncture-proof container that is used for the disposal of any used sharp items such as needles, disposable scissors, and scalpels.
- shear** An applied force or pressure exerted against the surface and layers of the skin as tissues slide in opposite but parallel planes.
- shearing** Pressure exerted against the surface and layers of the skin as tissues slide underneath the body as it moves against a surface.
- shearing force** An applied force or pressure exerted against the surface and layers of the skin as tissues slide in opposite but parallel planes.
- sheet wadding** Stretchable sheets of cotton padding used to cover skin before a cast is applied.
- shelter-in-place** To take refuge in a small interior room with no or few windows.
- side effect** An effect caused by a drug that is different from the therapeutic (desired) action. The effect may be harmless or injurious.
- sigmoid colon** The part of the large intestine that extends from the descending colon to the rectum.
- sign** Objective finding perceived by an examiner, such as a fever, rash, abnormal reflex, or abnormal breath sound.
- silicone septum** Silicone partition that covers the port chamber housed in the metal or plastic body of the implanted infusion port.
- situational loss** Loss caused by any sudden, unpredictable external event.
- sitz bath** Special bath in which only the hips and buttocks are immersed in fluid.
- skin barrier** An artificial layer of skin made of plastic or vinyl-like material that is applied to skin before application of tape or ostomy drainage bags. Protects skin from chronic irritation.
- sling** Device used to support or limit movement, enhance circulation, and prevent edema of the arm, hand, or wrist.
- slough** Necrotic (dead) tissue in the process of separating from viable portions of the body.
- smart pump** Infusion devices, referred to as a *smart pumps* by the Institute for Safe Medication Practices (ISMP), are commercially available infusion systems that perform a "test of reasonableness" to check that programming is within preestablished institutional limits before infusion can begin.
- SOAP** Acronym for subjective, objective, assessment, and plan, the four parts of the written account of a patient's health problem in a problem-oriented record.
- SOAPIE** See SOAP—Alternative acronym includes intervention and evaluation.
- solute** A substance dissolved in a solution.
- solute solution** Solute are dissolved particles and are either electrolytes or nonelectrolytes. Solute solution refers to these particles when they are found in body fluids or plasma (i.e., solution).
- solution** A mixture of one or more substances dissolved in another substance.
- spasm** Involuntary muscle contraction.
- speculum** A retractor used to separate the walls of a cavity (e.g., the vaginal cavity).
- sphygmomanometer** Device used for noninvasive measurement of arterial blood pressure. Consists of cuff, air bladder, inflation bulb, and gauge to indicate amount of air pressure being exerted.
- spica cast** An orthopedic cast applied to immobilize part or all of the trunk of the body and part or all of one or more extremities.
- splinting** Supporting the abdominal area to reduce pain caused by coughing or sneezing after surgery.
- sponge** Gauze dressing used to absorb blood in a surgical wound.
- spore** An inactive but viable state of microorganisms.
- spreader bar** A metal bar with curved hoop areas for attaching hooks or pins for traction.
- sputum** Lung mucus. Normally thin, watery, and white or clear and watery.
- standard precautions** Techniques used to reduce the risk for the transmission of bloodborne pathogens or microorganisms present in moist body substances regardless of a patient's diagnosis or infection status.
- standardized care plan** Documentation that uses the nursing process format in specifying the plan of care for patient problems.
- staples** Stainless steel wire used to close a surgical wound.
- stent** A straw or tubelike device that is placed through the stoma into bowel to keep open the flow of effluent.
- sterile** Free from all life forms, including spores.
- sterile conscience** One's personal principles and morals that guide one to maintain strict asepsis and sterile techniques at all times.
- sterile field** A specified area, such as within a tray or a sterile drape, that is considered free from microorganisms.
- sterilization** Process by which microorganisms, including spores, are killed.
- stockinette** Stretchable cotton materials of various sizes and widths used immediately over the skin to protect tissues from the irritation of felt or plaster.
- stoma** Surgically created opening between a body cavity and the surface of the body such as a colostomy.
- stomatitis** Any inflammatory condition of the mouth.
- stopcock** A valve that controls the flow of fluid or air through a tube.
- strategic national stockpile (SNS)** A national repository of the Centers for Disease Control and Prevention for antibiotics, chemical antidotes, antitoxins, life-support medications, intravenous administration supplies, airway maintenance supplies, and medical/surgical items.
- strike through** Source of contamination by which moisture permeates a sterile field or barrier.
- stroke volume (SV)** The volume of blood ejected from the left ventricle with each ventricular contraction.
- subarachnoid space** Situated or occurring between the arachnoid and the pia mater membranes, which cover the brain and spinal cord.
- subcutaneous emphysema** The presence of free air or gas in the subcutaneous tissues.
- subcutaneous injection** Form of injection in which a solution is introduced into subcutaneous tissues.
- subcutaneous tunnel** A tunnel under the skin between the exit site of a catheter and the entrance into a body cavity (such as the epidural space) or vein.
- subjective data** Data collected from a patient.
- sublingual** Route for administering a drug beneath the tongue.
- sublingual medication** Medication placed under the tongue and allowed to dissolve.
- suction** The act of sucking up a substance by reducing air pressure over its surface.
- suction catheter** Thin plastic or rubber tubing used to remove secretions.
- summarization** Reworking a lengthy interaction or discussion into a few brief sentences.
- summarizing** A process in which an interviewer organizes and condenses information provided and verifies with the patient that the information is correctly interpreted.
- summation** Occurs when the combined effect of two drugs produces a result that equals the sum of the individual effects of each drug.
- supination** Movement of a body part so the front or ventral surface faces upward.
- suppository** A solid form of medication inserted into a body cavity (e.g., the rectum or vagina). The drug is absorbed after it dissolves in the cavity.
- surgical asepsis** Practices or techniques designed to render and maintain objects and areas free from pathogenic microorganisms. Also referred to as *sterile techniques*.

surgical scrub Process of removing as many microorganisms as possible from the hands and arms by mechanical washing and chemical antiseptics.

suspension A liquid in which small particles of a solid are dispersed, but not dissolved, and in which the dispersal is maintained by stirring or shaking the mixture.

sympathomimetic A pharmacological agent that mimics the effects of stimulation of organs and structures by the sympathetic nervous system.

synergistic reaction An undesired reaction that occurs when one drug potentiates the effect of another.

systemic Of or pertaining to the whole body rather than to a localized area.

systolic pressure The higher blood pressure measurement. Reflects pressure within the arterial system during the period of ventricular contraction (systole).

T

T tube A T-shaped device that is attached to an endotracheal or tracheostomy tube for delivery of humidified air.

tachycardia An abnormality in heart rate in which the myocardium contracts regularly but at a rate over 100 beats/min.

tachypnea Condition characterized by respiratory rate greater than 20 breaths/min.

tandem setup An infusion mini-bag and tubing inserted into an injection port farthest away from a patient. Used for administration of a prepared intravenous admixture.

tartar A hard, gritty deposit that collects on the teeth.

technological disaster A catastrophic event in which people, property, community infrastructure, and economic welfare are adversely affected by the disruption of technology (e.g., industrial accidents and unplanned release of nuclear waste).

TENS (transcutaneous electrical nerve stimulation) A mild electrical stimulation that interferes with the transmission of painful stimuli.

tension pneumothorax A life-threatening situation caused by a rupture in the pleura, resulting in an increase in the amount of air in the pleural space and an increase in pressure, leading to the collapse of the lung.

tepid Moderately warm to the touch.

termination phase The period in the nurse-patient relationship when a nurse and patient examine and evaluate their relationship and its goals and results. The time when they deal with the emotional content involved in saying good-bye.

tertiary intention Wound healing that occurs when surgical wounds are not closed immediately but left open for 3 to 5 days to allow edema or infection to diminish.

The Joint Commission A private, nongovernmental agency that establishes guidelines for the operation of health care facilities. The guidelines are the basis of accreditation generally required for Medicare reimbursement. Formerly known as *The Joint Commission on Accreditation of Healthcare Organizations*.

therapeutic Treatments or interventions implemented to prevent illness and/or promote health.

therapeutic effect The intended or desired physiological response of a medication.

therapeutic silence The use of silence that encourages verbal description and reflection. Avoidance of premature verbal communication that may be caused by a nurse's anxiety.

thermoregulation Ability to control temperature within acceptable range.

third party payer An insurance plan, health maintenance organization (HMO), or preferred provider organization (PPO) that reimburses for health care services.

Thomas splint A long splint with a half or full ring at one end. Covered with towels and lined with felt or other soft material, it is used to suspend the thigh in skeletal traction.

thrill A fine vibration felt by an examiner's hand on the body of a patient over the site of an aneurysm or on the precordium.

thrombocytopenia A decrease in circulating platelets.

thrombophlebitis Inflammation of a vein, often accompanied by formation of a clot.

thrombosis An abnormal vascular condition in which thrombus develops within a blood vessel of the body.

thrombus Accumulation of platelets, fibrin, clotting factors, and the cellular elements of the blood attached to the interior wall of a vein or artery, sometimes occluding the lumen of the vessel.

tidal volume Amount (in milliliters) of air inhaled with each breath. Spontaneous tidal volume is 5 to 10 mL/kg of body weight.

tidaling A normal gentle rocking of fluid in a chest tube water-seal system or in the diagnostic indicator of waterless units. Indicates that the system is functioning properly.

timed collection The collection of a substance such as urine or stool for a specific period of time.

tinnitus Ringing heard in one or both ears.

tissue ischemia Decreased blood supply to body tissues.

TLC 1. Abbreviation for total lung capacity. 2. Informal abbreviation for tender loving care.

tolerance A phenomenon by which the body becomes increasingly resistant to a drug or other substance through continued exposure to the substance.

tongue-thrust reflex An immature form of swallowing in which the tongue is projected forward instead of retracted during swallowing.

topical Of or pertaining to a drug or treatment applied to the surface of a body part.

topical agents Pertaining to drugs or treatments applied to the surface part of the body.

toxic effects Severe and progressive negative effects of drugs.

tracheobronchial tree Anatomical divisions of the respiratory tract, including the combination of trachea, bifurcations into the right and left mainstem bronchi, and subsequent bifurcations into smaller bronchi and bronchioles.

tracheostomy Opening through the neck into the trachea with an indwelling tube inserted. Created surgically to produce an airway.

tracheostomy collar Curved oxygen delivery device with an adjustable neck strap that fits around the tracheostomy.

traction Force or pull applied to limbs, bones, or other tissues to pull the tissues apart, often for realignment.

traction boot A foam rubber boot shaped to fit a forearm or leg, used for a type of skin traction.

transdermal Refers to a form of medication that is applied to the surface of the skin and absorbed across the dermal or outer skin layer.

transfusion reaction Systemic response by the body to the administration of blood incompatible with that of the recipient.

transfusion-related acute lung injury (TRALI) A serious blood transfusion complication characterized by the acute onset of noncardiogenic pulmonary edema after transfusion of blood product.

transitional care A group of nursing behaviors and actions designed to ensure the coordination and continuity of care as patients transfer between different locations or different levels of care within the same location.

transmission-based precautions Techniques used to prevent the transmission of microorganisms from patients documented or suspected to be infected with highly transmissible pathogens for which

additional precautions beyond standard precautions are needed. The three types are airborne, droplet, and contact precautions.

transtracheal oxygen therapy (TTOT) A method of administering oxygen to a patient by establishing a low-flow catheter route directly in the trachea.

Trendelenburg's position Position in which the head is low and the body and legs are elevated.

triage Establishing priorities of patient care for urgent treatment based on the seriousness of injuries and likelihood for survival. Used in an emergency situation to maximize effectiveness of available resources.

trocár A sharp, pointed rod that fits inside a tube. Used to pierce the skin and the wall of a cavity or canal in the body to aspirate fluids, to instill a medication or solution, or to guide the placement of a soft catheter.

trough concentration The point at which the lowest amount of drug is detected in the serum.

tuberculosis A chronic granulomatous infection caused by an acid-fast bacillus, *Mycobacterium tuberculosis*, generally transmitted by the inhalation or ingestion of infected droplets and usually affecting the lungs.

tunneled central venous catheters A catheter surgically inserted into a vein in the neck or chest and passed under the skin. Only the end of the catheter is brought through the skin. Medications can be administered through this end of the catheter.

turning sheet Bed sheet folded in half and placed under a patient between shoulders and below the hips. Used by health care providers to lift, turn, and position a patient. Also called a *lift sheet*.

tympanic Pertaining to a structure that resonates when struck. Drumlike.

U

ulnar flexion A range-of-motion exercise during which there is a lateral bending of the wrist toward the fifth finger. Maintains wrist mobility.

undermining Condition of a wound in which the loss of underlying tissues is greater than the loss of the skin.

unit-dose system System of drug distribution in which a portable cart containing a drawer for each patient's medications is prepared by the pharmacy with a 24-hour supply of medications.

unscrubbed team members In surgical setting includes the anesthesiologist or anesthetist and the circulating nurse, who wear surgical attire but are not gowned or gloved.

upper airway respiratory system All respiratory structures above the epiglottis, including nose, sinuses, mouth, and pharynx.

urethral meatus The opening to the canal for the discharge of urine.

urethral sphincter Voluntary muscle at the neck of the bladder that relaxes to allow micturition.

urgency The need to void immediately.

urinal Plastic or metal receptacle for urine.

urinary retention Inability to empty the bladder, resulting from a number of possible causes.

urinary stent A thin catheter threaded into segments of the ureter that carry urine produced by the kidney either down into the bladder internally or to an external collection system.

urinary tract infection Greater than normal level of pathogens in the urinary tract.

urine Fluid secreted by the kidneys, transported by the ureters, stored in the bladder, and voided through the urethra.

urine specific gravity Measurement of the degree of concentration of the urine.

urinometer Device used for determining specific gravity of urine.

urosepsis Systemic bacterial infection frequently resulting from a bacterial infection in the urine

(bacteriuria). Bacteriuria leads to the spread of organisms into the kidney, which can lead to bacteremia or urosepsis.

urostomy The diversion of urine away from a diseased or defective bladder through a surgically created opening, or stoma, in the skin.

V

Vacutainer tube A glass tube with a rubber stopper. Air has been removed to create a vacuum.

valgus An abnormal position in which a part of a limb is bent or twisted outward away from the midline such as the heel of the foot.

Valsalva maneuver Any forced expiratory effort against a closed airway, as when an individual holds the breath and tightens the muscles in a concerted, strenuous effort to move a heavy object or change position in a bed.

variable A concept, characteristic, or trait that changes (e.g., takes on measurably different values) within an identified population in a research study.

variance Positive or negative changes in patient progress toward expected outcomes on a critical pathway. Deviations from the critical path plan most often used in the case management model of delivering health care.

varices Tortuous, dilated veins.

varus An abnormal position in which a part of a limb is turned inward toward the midline such as the heel and foot.

vascular access device (VAD) An indwelling catheter, cannula, or other instrumentation used to obtain venous or arterial access.

vasoconstriction Narrowing of the lumen of any blood vessel, especially the arterioles and the veins in the blood reservoirs of the skin and abdominal viscera.

vasodilation An increase in the diameter of a blood vessel caused by inhibition of its vasoconstrictor nerves or stimulation of dilator nerves.

vein lumen Central opening through which blood flows in a vein.

vellus Soft, fine hair covering all parts of the body except the palms, soles, and areas where other types of hair are normally found.

venipuncture Technique in which a vein is punctured transcutaneously by a sharp rigid stylet (such as a butterfly needle), a cannula (such as an

angiocatheter that contains a flexible plastic catheter), or a needle attached to a syringe.

venous thromboembolism (VTE) Terminology used to describe a condition that involves deep vein thrombosis and pulmonary embolus.

venous thrombosis A condition characterized by the presence of a clot in a vein in which the wall of the vessel is not inflamed.

ventilation Respiratory process by which gases are moved into and out of the lungs.

ventral Of or pertaining to an anterior position, toward the abdomen.

verbal order A physician's or nurse practitioner's order for a medication or other therapy that is spoken to the nurse to be entered into a patient's medical records.

vertigo A sensation of faintness or an inability to maintain normal balance in a standing or seated position, sometimes associated with giddiness, mental confusion, nausea, and weakness.

vesicant A drug capable of causing tissue necrosis when extravasated.

vial Glass container with a metal-enclosed rubber seal.

vibration Physiotherapy technique performed by contracting all the muscles in the caregiver's upper extremities to cause vibration while applying pressure to the chest wall.

viscera The internal organs enclosed within a body cavity, primarily the abdominal organs.

visceral pleura A serous membrane lining both lungs.

visceral protein status The amount of protein that pertains to the internal organs (e.g., abdominal).

vital signs Physiological parameters that reflect key body processes. Refers to temperature, blood pressure, heart rate, respiratory rate, and oxygen saturation.

void The process of emptying the bladder of urine. Urinate. Micturate.

volume-control set (Volutrol) Used to administer hourly fluids and intermittent intravenous medications, usually to children. A fluid chamber holds 100 to 150 mL of fluid to be infused over a specific period.

W

walking heel Plastic or rubber heel placed in the sole of a leg cast to allow weight bearing.

wandering Meandering, aimless, or repetitive locomotion that exposes the individual to harm and is frequently incongruent with boundaries, limits, or obstacles.

weapons of mass destruction (WMDs) Weapons that can kill large numbers of humans and/or cause great damage to structures (e.g., buildings), natural structures (e.g., mountains), or the biosphere.

weight Force exerted on a body by the gravity of the earth.

weight holder A metal, T-shaped bar that holds weights for traction.

weights Filled bags or metal disks of varying poundage used for traction.

whispered pectoriloquy The transmission of a whisper through the pulmonary structures so it is heard as normal audible speech on auscultation.

windowing Cutting a small area of a cast to permit inspection of the tissues below.

working phase The period in the nurse-patient relationship when the focus is on communication strategies, interventions for problem resolution, and enhancement of self-concept.

wound vacuum-assisted closure (V.A.C.) A type of therapy that speeds wound healing by applying localized negative pressure to draw the edges of a wound together.

X

xerostomia Dryness of the mouth caused by the cessation of normal salivary secretions. It is a common symptom of a number of diseases such as diabetes, acute infections, and Sjögren's syndrome and is a common adverse reaction to drugs.

Y

Yankauer suction A large filter-tipped rigid plastic suction catheter used mainly in the mouth or other large body cavity.

Z

Zassi Bowel Management System An intrarectal catheter used to manage diarrhea. Catheter diverts feces while at the same time provides a means to administer medications.

Z-track method Method for injecting irritating medications into muscle without tracking residual medication through sensitive tissues.
