Blood flow	When the administration site contains a rich blood supply, medications absorb rapidly.
Body surface area	A medication in contact with a large surface area (e.g., small intestine) absorbs faster than one in contact with smaller surface area (e.g., stomach).
Lipid solubility	Medications that are highly lipid soluble absorb more readily.

to develop. Early clinical recognition of ADEs is the important first step in identification. ADEs range from mild (e.g., rashes or photosensitivity to light) to potentially fatal (anaphylaxis). Prompt recognition and reporting of ADEs prevents serious injury to patients. Always assess patients who may be at high risk for an ADE such as pregnant women and patients with chronic disorders (e.g., hypertension, epilepsy, heart disease, psychoses) (Lehne, 2010). Health care providers report adverse events to the Food and Drug Administration (FDA) using the MedWatch program (USFDA, 2010).

Toxic Effects

Toxic effects develop after prolonged intake of a medication or when a medication accumulates in the blood because of impaired metabolism or excretion. Excess amounts of a medication within the body sometimes have lethal effects, depending on the action of the medication. For example, toxic levels of morphine, an opioid, cause severe respiratory depression and death. Antidotes are available to treat specific types of medication toxicity. For example, naloxone (Narcan), an opioid antagonist, reverses the effects of opioid toxicity.

Idiosyncratic Reactions

Medications sometimes cause unpredictable effects such as an idiosyncratic reaction, in which a patient overreacts or underreacts to a medication or has a reaction different from normal. Predicting which patients will have an idiosyncratic response is impossible. For example, lorazepam (Ativan) is an anti-anxiety medication that may cause agitation and delirium when given to an older adult.

Allergic Reactions

Allergic reactions also are unpredictable responses to a medication. Exposure to an initial dose of a medication causes a patient to become sensitized immunologically. The medication acts as an antigen, which causes antibodies to be produced. With repeated administration a patient develops an allergic response to the drug, its chemical preservatives, or a metabolite. An allergic reaction ranges from mild to severe, depending on the patient and the

TABLE 20-3 Mild Allergic Reactions

Symptom	Description
Urticaria (hives)	Raised, irregularly shaped skin eruptions with varying sizes and shapes; reddened margins and pale centers
Eczema (rash)	Small, raised vesicles that are usually reddened; often distributed over the entire body
Pruritus	Itching of the skin; accompanies most rashes
Rhinitis	Inflammation of mucous membranes lining the nose, causing swelling and a clear watery discharge

**FIG 20-1** Identification bracelet and medal.

medication (Table 20-3). Among the different classes of medications, antibiotics cause a high incidence of allergic reactions. Severe or anaphylactic reactions, which are life threatening, are characterized by sudden constriction of bronchiolar muscles, edema of the pharynx and larynx, severe wheezing, and shortness of breath. Some patients become severely hypotensive, necessitating emergency resuscitation measures.

It is common practice for hospitalized patients with known drug allergies to have their allergy information recorded in a clearly identifiable place. This allows all caregivers to be aware of each patient's allergies. In many agencies this information is recorded on the front of a patient's medical record, in the medication administration record (MAR), or on a specially designed label that is applied to the front of a patient's chart. Patients also receive color-coded allergy identification bands to wear around the wrist. *Always record a patient's allergies in the MAR.* Patients who are cared for in other settings (e.g., home or community clinics) and have a known history of an allergy to a medication or substance should wear an identification bracelet or medal, which alerts all health care providers to the allergies in case a patient is found unconscious or is unable to communicate (Fig. 20-1).

Medication Tolerance and Dependence

Medication tolerance occurs over time. It is usually noted clinically when patients receive the same medication for long periods and require higher doses to produce the desired therapeutic effect.

Medications known to produce tolerance include opium alkaloids (e.g., morphine), nitrates, and ethyl alcohol. Patients hospitalized for acute episodes of illness usually do not develop tolerance. It may take a month or longer for tolerance to occur.

Medication tolerance is not the same as medication dependence. Two types of medication dependence exist: physical or psychological (or addiction). In psychological dependence the patient desires the medication for benefit other than the intended effect. Physical dependence is a physiologic adaptation to a medication that manifests itself by intense physical disturbance when the medication is withdrawn. When patients receive medications for a short term such as for postoperative pain, dependence is rare. If a patient is dependent on alcohol, a higher-than-usual medication dose is necessary for the desired effect of the medication.

Medication Interactions

When one medication modifies the action of another medication, a medication interaction occurs. Medication interactions are common in individuals taking many medications. Some medications increase or diminish the action of other medications and alter the way in which another medication is absorbed, metabolized, or eliminated from the body. When two medications have a synergistic effect, their combined effect is greater than the effect of one drug given separately. For example, alcohol is a central nervous system depressant that has a synergistic effect with antihistamines, antidepressants, and narcotic analgesics. Sometimes a medication interaction is the desired effect. Prescribers often combine medications to create an interaction that has a therapeutic effect. For example, a patient with hypertension may receive several medications such as diuretics and vasodilators, which act together to control the blood pressure when one medication alone is not effective.

Medication Dose Responses

After administration a medication undergoes absorption, distribution, metabolism, and excretion. Except when administered intravenously, medications take time to enter the bloodstream. When a medication is prescribed, the goal is a constant blood level within a safe therapeutic range. The minimum effective concentration (MEC) is the plasma level of the medication below which the effect of the medication does not occur. The toxic concentration is the level at which toxic effects occur. The safe therapeutic range is between the MEC and the toxic concentration (Fig. 20-2). When a medication is administered repeatedly, its serum level fluctuates between doses. The highest level is called the *peak concentration*, and the lowest level is called the *trough concentration*. After peaking the serum concentration falls progressively. With intravenous (IV) infusions, the peak concentration occurs quickly, but the serum level also begins to fall immediately. Some medication doses (e.g., vancomycin or gentamicin [Garamycin]) are based on peak and trough serum levels. A patient's trough level is drawn as a blood sample 30 minutes before administering the drug, and the peak level is drawn whenever the drug is expected to reach its peak concentration. The results of the blood test reveal if the drug is reaching its therapeutic blood level.

All medications have a biologic half-life, which is the time it takes for excretion processes to lower the serum medication concentration by half. To maintain a therapeutic plateau, a patient needs to receive regular fixed doses. For example, current evidence shows that pain medications are most effective when they are given around-the-clock (ATC) rather than when the patient intermittently complains of pain because the body maintains an almost constant level of pain medication. After an initial medication dose,

FIG 20-2 The therapeutic range of medication occurs between the minimum effective concentration and the toxic concentration. (From Lehne R: *Pharmacology for nursing care*, ed 7, St Louis, 2010, Saunders.)

the patient receives each successive dose when the previous dose reaches its half-life. The patient and nurse need to follow regular dosage schedules and administer prescribed doses at correct intervals. Know the following time intervals of medication action to anticipate the effect of a medication:

- 1 *Onset of medication action*: Period of time it takes after you administer a medication for it to produce a therapeutic effect
- 2 *Peak action*: Time it takes for a medication to reach its highest effective peak concentration
- 3 *Trough*: Minimum blood serum concentration of medication reached just before the next scheduled dose
- 4 *Duration of action*: Length of time during which a medication is present in a concentration great enough to produce a therapeutic effect
- 5 *Plateau*: Blood serum concentration reached and maintained after repeated, fixed doses

ROUTES OF ADMINISTRATION

The route prescribed for administering a medication (Table 20-4) depends on its properties and desired effect and on a patient's physical and mental condition. Because of what you know about your patients, you need to collaborate with a prescriber in determining the best route for a patient's medical condition. Table 20-5 summarizes the factors that influence the choice of administration routes.

MEDICATION DISTRIBUTION

Health care providers write medication orders, pharmacists dispense medications, and nurses deliver medications to patients. A number of technologies for medication distribution have the potential for reducing medication errors and ADEs. The technologies include computerized provider order entry (CPOE), automated medication dispensing system (AMDS), and bar coding (Agrawal, 2009; Poon et al., 2010). The use of the AMDS may reduce the chance of medication errors (Agrawal, 2009).

Computerized Provider Order Entry

CPOE is a system that allows prescribers to electronically enter orders for medications, eliminating the need for written orders.

TABLE 20-4 Routes of Medication Administration

Route	Description
Nonparenteral	
Oral, buccal	By mouth
Sublingual	Under the tongue
Topical	On the skin (as a cream or patch) and eyedrops/eardrops
Suppository	Into the rectum or vagina
Parenteral	
Intramuscular (IM)	Into a muscle
Subcutaneous	Into the subcutaneous tissue of the skin
Intradermal (ID)	Into the dermis of the skin
Epidural	Into the epidural space
Intravenous (IV)	Into a vein

With use of CPOE, there is increased accuracy and legibility of medication orders; integration of clinical decision support into the order-entry process; and optimization of prescriber, nurse, and pharmacist time (Agrawal, 2009). Decision support software integrated into a CPOE system allows for automatic drug allergy checks, dosage indications, baseline laboratory result checks, and identification of potential drug interactions. When a prescriber enters an order through CPOE, the information about the order immediately transmits to the pharmacy and ultimately to the nurses' MAR without the need for written transcription. Use of CPOE systems may significantly reduce medication errors as much as 55% to 83% (Agrawal, 2009).

Distribution Systems

Systems for storing and distributing medications vary. Agencies providing nursing care have special areas for stocking and dispensing medications. Special medication rooms, portable locked carts, computerized medication cabinets, and individual storage units next to patients' rooms are examples of storage areas used. Medication storage areas must be locked when unattended.

Unit Dose

The standard for medication distribution is the unit-dose system. The system uses an AMDS or carts containing a drawer with a 24-hour supply of medications for each patient. Each drawer has a label with the name of the patient in the designated room. The unit dose is the ordered dose of medication that the patient receives at one time. Each medication form is wrapped in a foil or paper container separately. Liquid doses come in prepackaged foil or plastic cups. The cart also contains limited amounts of prn and stock medication for special situations. At a designated time each day the pharmacist or a pharmacy technician refills the drawers in the cart with a fresh supply. Controlled substances are not in the individual patient drawer; they are in a larger locked drawer to keep them secure. A unit-dose system is designed to reduce the number of medication errors and saves steps in dispensing medications.

Automated Medication Dispensing System

AMDSs are variations of unit-dose and floor stock systems (Fig. 20-3). The systems within the health care agency are networked with one another and with other computer systems in the agency (e.g., computerized medical record). AMDSs control the

**FIG 20-3** Automated medication dispensing system.

dispensing of all medications, including narcotics. Each nurse has a security code, which allows access to the system. If your agency uses a system that requires bioidentification, you have to place your finger on a screen to access the computer. Once logged onto the AMDS, you select a patient's name and medication profile. Then you select the medication, dosage, and route from a list displayed on the computer screen. The system opens the medication drawer or dispenses the medication to the nurse, records the event, and charges it to the patient. If the system is connected to the patient's medical record, information about the medication (e.g., name, dose, time) and the name of the nurse who retrieved it from the AMDS is recorded in the patient's medical record. There is evidence of an increase in reported medication errors with use of the system and a reduction in dispensing errors through the use of alerts that are embedded within the clinical decision support system (Agrawal, 2009). The use of AMDS has been shown to reduce the chance of medication errors (Agrawal, 2009).

Bar Coding

Bar-code labels are required on all medications, vaccines, and over-the-counter (OTC) drugs used in health care agencies (Poon et al., 2010). Electronic health record (EHR) technology is used to improve patient care quality and coordination and increase patient access to information in a secure format. The use of electronic bar codes on medication labels and packaging has the potential to improve patient safety in a number of ways. Bar codes electronically link with a hospital computer system. A patient's MAR entered into the computer database and encoded in the patient's wristband is accessible to a nurse through a handheld device. The device scans the patient's wristband and then displays the MAR. When administering a medication, the nurse scans the bar code on the drug and the patient's medical record number on the wristband. The computer processes the scanned information, charts it, and updates the patient's MAR record appropriately (Poon et al., 2010). The use of bar codes improves accuracy of patient identification, correct medication use, and improves medical record keeping (Poon et al., 2010).

SYSTEMS OF MEDICATION MEASUREMENT

NSO Safe Medication Administration Module / Lesson 3

The proper administration of medication depends on your ability to compute medication doses accurately and measure medications

TABLE 20-5 Factors Influencing Choice of Administration Routes

Advantages	Disadvantages/Contraindications
<p>Oral, Buccal, Sublingual Routes Routes are easy and comfortable to administer, convenient, economical; may produce local or systemic effects; and rarely cause anxiety for patient.</p>	<p>Routes are avoided when patient has alterations in GI function (e.g., nausea and vomiting), with reduced GI motility (after general anesthesia or bowel inflammation), and with surgical resection of portion of GI tract. Gastric secretions destroy some medications. Oral administration is contraindicated in patients who are NPO and unable to swallow (e.g., patients with neuromuscular disorders, esophageal strictures, and mouth lesions). Do not give oral medications when patient has gastric suction or before certain diagnostic tests or surgery. An unconscious or confused patient is unable or unwilling to swallow or hold sublingual medication under tongue or buccal medication in cheek. Oral medications sometimes irritate lining of GI tract, discolor teeth, or have an unpleasant taste.</p>
<p>Subcutaneous, Intramuscular, Intravenous, Intradermal, Epidural Routes Routes provide means of administration when oral medications are contraindicated. More rapid absorption occurs than with topical or oral routes.</p>	<p>There are risks for introducing infection, and medications are expensive. Some patients experience pain from repeated needlesticks. Avoid Subcutaneous, IM, and ID routes in patients with bleeding tendencies. There is risk for tissue damage with subcutaneous injections.</p>
<p>IV infusion provides medication delivery when patient is critically ill or long-term therapy is necessary. If peripheral perfusion is poor, IV route is preferred over injections.</p>	<p>IV and IM routes have higher absorption rates, thus placing patients at higher risk for reactions.</p>
<p>Epidural provides excellent pain control.</p>	<p>It limits mobility during administration, and there is risk for infection.</p>
<p>Skin</p>	
<p>Topical Topical skin applications provide primarily local effect. Route is usually painless. Limited side effects occur.</p>	<p>Extensive applications often require dressings that are bulky for a patient when maneuvering. Do not apply to skin if abrasions are present, unless that is the reason for order. Medications can be absorbed by person applying them if gloves are not worn.</p>
<p>Transdermal Transdermal applications provide prolonged systemic effects with limited side effects.</p>	<p>Application leaves oily or pasty substance on skin and may soil clothing. Some patients have sensitivity to adhesive.</p>
<p>Mucous Membranes (Includes Eyes, Ears, Nose, Vaginal, Rectal, Buccal, and Sublingual Routes) Therapeutic effects are provided by local application to involved sites. Aqueous solutions are readily absorbed and capable of causing systemic effects. Mucous membranes provide route of administration when oral medications are contraindicated.</p>	<p>Mucous membranes are highly sensitive to some medication concentrations. Insertion of rectal and vaginal medications often causes embarrassment. Rectal suppositories are contraindicated if patients have had rectal surgery or if active rectal bleeding is present. If eardrum is ruptured, otic medications are usually contraindicated.</p>
<p>Inhalation Inhalation provides rapid relief for local respiratory problems. An inhaled form of insulin is also available. Route provides easy access for introduction of general anesthetic gases.</p>	<p>Some local agents cause serious systemic effects. If patients are unable to administer inhaler correctly, medication is ineffective. Inhalation is difficult to learn for older adults and children.</p>
<p>Intraocular Disk Route is advantageous in that it does not require frequent administration (e.g., as for eyedrops). Patient can also wear disk when sleeping or swimming. Dry eyes do not affect medication delivery.</p>	<p>Local reactions such as tearing, itching, or redness of the eyes occur. Patient needs to know how to insert disk into and remove from eye. Medication is often expensive. Medication is contraindicated in patients with eye infections.</p>

GI, Gastrointestinal; ID, intradermal; IM, intramuscular; IV, intravenous; NPO, nothing by mouth.

correctly. A careless mistake in placing a decimal point or adding a zero to a dosage can lead to fatal errors. The prescriber and patient depend on you to check doses before administering medications. Medication therapy uses metric, apothecary, and household systems of measurement. The apothecary system is used infrequently today. The most common medication measurement system is the metric system.

Metric System

As a decimal system the metric system is the most logically organized of the measurement systems. Metric units are easy to convert and compute through simple multiplication and division. Each basic unit of measure is organized into units of 10. Multiplying or dividing by 10 forms secondary units. In multiplication the decimal point moves to the right; in division the decimal moves to the left. For example:

$$10 \text{ mg} \times 10 = 100 \text{ mg}$$

$$10 \text{ mg} \div 10 = 1 \text{ mg}$$

The basic units of measure in the metric system are the meter (length), the liter (volume), and the gram (weight). For drug calculations you will primarily use volume and weight units. In the metric system lowercase or capital letters designate the basic units:

$$\text{Gram} = \text{g or Gm}$$

$$\text{Liter} = \text{l or L}$$

Use only lowercase letters for abbreviations for subdivisions of major units:

$$\text{Milligram} = \text{mg}$$

$$\text{Milliliter} = \text{mL}$$

When writing medication dosages in metric units, prescribers and nurses use either fractions or multiples of a unit. Convert fractions to decimals:

$$500 \text{ mg or } 0.5 \text{ g, not } \frac{1}{2} \text{ g}$$

$$10 \text{ mL or } 0.01 \text{ L, not } \frac{1}{100} \text{ L}$$

Many actual or potential medication errors happen with the use of fractions or decimal points. Use practice standards when medications are ordered in fractions to prevent errors. For example, never use a trailing zero (e.g., 1.0 mg) and always include a zero before a decimal point (e.g., 0.1 mL) (ISMP, 2010b; TJC, 2012a).

Household Measurement

Household measures are familiar to most people, but these are not recommended for medication administration because of the variability in the size of household utensils. Household measures include drops, teaspoons, tablespoons, and cups for volume and ounces and pounds for weight. When the accuracy of a medication dose is not critical (e.g., OTC medications), it is safe to use household measures. To calculate medications accurately, you need to know common equivalents of metric and household units (Table 20-6).

TABLE 20-6 Equivalents of Measurement

Metric	Apothecary	Household
1 mL	15-16 minims (m)*	15 drops (gtt)
5 mL	1 dram*	1 teaspoon (tsp)
15 mL	4 drams*	1 tablespoon (tbsp)
30 mL	1 fluid ounce	2 tablespoon (tbsp)
240 mL	8 fluid ounces	1 cup (c)
480 mL (approximately 500 mL)	1 pint (pt)	1 pint (pt)
960 mL (approximately 1 L)	1 quart (qt)	1 quart (qt)
3840 mL (approximately 4 L)	1 gallon (gal)	1 gallon (gal)

*Minims and drams are no longer acceptable units of measure for medication administration, although some medication cups and syringes still have them listed. Use mL for safe medication administration.

Solutions

Solutions of various concentrations are used for injections, irrigations, and infusions. A solution is a given mass of solid substance dissolved in a known volume of fluid or a given volume of liquid dissolved in a known volume of another fluid. Solutions are available in units of mass per units of volume (e.g., g/mL or g/L). You can also express the concentration of a solution as a percentage. A 10% solution is 10 g of solid dissolved in 100 mL of solution. A proportion also expresses concentrations. A 1/1000 solution represents a solution containing 1 g of solid in 1000 mL of liquid or 1 mL of liquid mixed with 1000 mL of another liquid.

SAFE MEDICATION ADMINISTRATION

Standards are actions that help ensure safe nursing practice. Standards for medication administration are set by health care agencies and the nursing profession. Most agencies have procedure manuals that contain policies about which medications nurses can and cannot deliver. The types and dosages that nurses may administer often vary from unit to unit within an agency. Professional standards such as *Nursing: Scope and Standards of Practice (ANA, 2010)* apply to the activity of safe medication administration. To prevent medication errors follow the six rights of medication administration consistently every time you administer medications. Many medication errors are linked in some way to an inconsistency in adhering to the six rights:

- 1 The right medication
- 2 The right dose
- 3 The right patient
- 4 The right route
- 5 The right time
- 6 The right documentation

Right Medication

A medication order is required for every medication that you administer to a patient. Some prescribers write orders by hand in a patient's chart. However, many agencies use CPOE, eliminating the need for handwritten orders and enhancing patient safety (Sowan et al., 2010). Regardless of how an order is received, you compare the prescriber's orders with the MAR or electronic MAR (eMAR) when the medication is ordered initially. Nurses verify

medication information whenever new MARs are written or distributed or when patients transfer from one nursing unit or health care setting to another (TJC, 2012a).

The ISMP (2010a) and TJC published a list of error-prone and prohibited abbreviations that have been found to increase the incidence of errors in medication administration (Table 20-7). You are responsible for using correct abbreviations and verifying that the order was transcribed accurately.

Medication Orders

You must have a medication order before administering medications to a patient. Verbal and telephone orders are optional forms of orders when written or electronic communication between the prescriber and nurse is not possible. When you receive a verbal or telephone order, you write or enter the order on the prescriber's order sheet. The name of the prescriber and your signature are included. The prescriber will countersign the order at a later time, usually within 24 hours after making it (see agency policy). Box 20-2 provides guidelines for safely taking verbal or telephone orders for medications.

Five common types of orders based on frequency and/or urgency of medication administration orders are: standing; prn orders; and single (one-time) orders, which include stat orders and now orders. Each order needs to include the patient's name, the drug ordered, dosage, route of administration, and time(s) of administration.

You carry out a *standing order* until the health care provider cancels it by another order or until a prescribed number of days elapse. A standing order sometimes indicates a final day or number of doses. Many agencies have a policy for automatically discontinuing standing orders.

A medication can be ordered to be given only when a patient requires or requests it. This is a prn order. You must assess a patient thoroughly to determine whether he or she needs the medication. A prn order usually has a minimum interval set for the time of administration.

Single (one-time) orders are common for preoperative medications or medications given before diagnostic procedures. The medication is ordered to be given only once at a specified time. A stat order means that you give a single dose of medication immediately and only once. Stat orders are used for emergencies when a patient's condition changes suddenly. A now order is more specific and is used when a patient needs a medication quickly but not as soon as a stat order. TJC (2012a) discourages the use of range orders for prn medications. An example of a range order is morphine sulfate 2 to 6 mg IV push every 2 to 4 hours prn for pain. Range orders are often unclear and a source of medication errors.

BOX 20-2 Guidelines for Verbal and Telephone Orders

- Clearly identify patient's name, room number, and diagnosis. "Read back" all orders from the health care provider (TJC, 2012a).
- Use clarification questions to avoid misunderstandings.
- Write "TO" (telephone order) or VO (verbal order), including date and time, name of patient, and complete order; sign the name of the health care provider and nurse.
- Follow agency policies; some agencies require documentation of the "read back" or two nurses to review and sign telephone or verbal orders.
- Physician or licensed health care provider co-sign the order within the time frame required by the agency (usually 24 hours; verify agency policy).

Once you determine that information on the patient's MAR is accurate, use the MAR to prepare and administer medications. When preparing medications from bottles or containers, *compare the label of the medication container with the MAR 3 times*: (1) before removing the container from the supply drawer or shelf, (2) as the amount of medication ordered is removed from the container, and (3) at the patient's bedside before administering the medication to the patient. Never prepare medications from unmarked containers or containers with illegible labels (TJC, 2012b). With unit-dose prepackaged medications, check the label with the MAR when taking medications out of the medication dispensing system. Finally, verify all medications at the patient's bedside with the patient's MAR and use at least two identifiers before giving the patient any medications (TJC, 2012a).

If a patient questions a medication, stop and recheck to be certain there is no mistake. An alert patient or family caregiver will know whether a medication is different from those received before. In most cases the medication order has been changed or the drug is manufactured by a different company than the patient has been using at home. However, attention to a patient's question is how errors are identified and prevented.

Right Dose

The unit-dose system is designed to minimize errors. When a medication is prepared from a larger volume or strength than needed or when the prescriber orders a system of measurement different from that which the pharmacist supplies, the chance of error increases. After calculating the doses of high-risk medications such as insulin or warfarin (Coumadin) compare the calculation with one done independently by a second nurse. This is especially important if it is an unusual calculation or involves a potentially toxic drug.

After calculating doses, prepare the medication using standard measurement devices. Use graduated cups, syringes, and scaled droppers to measure medications accurately. At home teach patients to use kitchen measuring spoons rather than teaspoons and tablespoons, which vary in volume. Key principles to observe when using measuring receptacles include:

- 1 Pour liquid medication into a medication cup with the cup on a flat surface at eye level so you can see the desired amount accurately. The amount of poured liquid must be even with the base of the meniscus (Fig. 20-4, A and B)
- 2 Pour liquid medications away from a label to ensure that liquid will not run down it, making it difficult to read
- 3 Draw liquid medication into a syringe (without a needle) slowly to prevent air bubbles from entering the syringe. Air displaces medications and leads to inaccurate measurement of doses

Medication errors occur when pills need to be split. To promote patient safety in inpatient settings, pharmacists split medications, label and package them, and return them to the nurse for administration. Because pill splitting can be problematic in the home, determine if a patient has the manual dexterity or visual acuity to split tablets. If possible, determine if his or her pharmacy can split the pill or encourage the health care provider to order medications that do not require splitting.

Tablets are sometimes crushed and mixed with food. Be sure to clean the crushing device completely before crushing the tablet. Remnants of previously crushed medications increase concentration of the medication or result in a patient receiving a portion of an unprescribed medication. Mix crushed medications with very small amounts of food or liquid. Do not use a patient's favorite foods or liquids because medications alter their taste and decrease

TABLE 20-7 Institute for Safe Medication Practice List of Error-Prone Abbreviations

These abbreviations, symbols, and dose designations were reported to the Institute for Safe Medication (ISMP) through the USP-ISMP Medication Error Reporting Program for being frequently misinterpreted and involved in harmful medication errors. They should NEVER be used when communicating medical information. This includes internal communications, telephone/verbal prescriptions, computer-generated labels, labels for drug storage bins, medication administration records, and pharmacy and prescriber computer order entry screens. The Joint Commission (TJC) has established a National Patient Safety Goal that specifies that certain abbreviations must appear on the do-not-use list of an accredited organization; these items are highlighted with a double asterisk (**).

Abbreviations	Intended Meaning	Misinterpretation	Correction
µg	Microgram	Mistaken as “mg”	Use “mcg”
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use “right ear,” “left ear,” or “each ear”
OD, OS, OU	Right eye, left eye, each eye	Mistaken as AD, AS, AU (right ear, left ear, each ear)	Use “right eye,” “left eye,” or “each eye”
BT	Bedtime	Mistaken as “BID” (twice daily)	Use “bedtime”
Cc	Cubic centimeters	Mistaken as “u” (units)	Use “mL”
D/C	Discharge or discontinue	Premature discontinuation of medication if D/C (intended to mean “discharge”) has been misinterpreted as “discontinued” when followed by a list of discharge medications	Use “discharge” and “discontinue”
IJ	Injection	Mistaken as “IV” or “intrajugular”	Use “injection”
IN	Intranasal	Mistaken as “IM” or “IV”	Use “intranasal” or “NAS”
HS	Half-strength	Mistaken as bedtime	Use “half-strength”
hs	At bedtime, hour of sleep	Mistaken as half-strength	Use “bedtime”
IU**	International unit	Mistaken as IV (intravenous) or 10 (ten)	Use “units”
o.d. or OD	Once daily	Mistaken as “right eye” (OD— <i>oculus dexter</i>), leading to oral liquid medications administered in the eye	Use “daily”
OJ	Orange juice	Mistaken as OD or OS (right or left eye); drugs meant to be diluted in orange juice may be given in the eye	Use “orange juice”
Per os	By mouth, orally	The “os” can be mistaken as “left eye” (OS— <i>oculus sinister</i>)	Use “PO,” “by mouth,” or “orally”
q.d. or QD**	Every day	Mistaken as q.i.d., especially if the period after the “q” or the tail of the “q” is misunderstood as an “i”	Use “daily”
qhs	Nightly at bedtime	Mistaken as “qhr” or every hour	Use “nightly”
qn	Nightly or at bedtime	Mistaken as “qhr” or every hour	Use “nightly” or “at bedtime”
q.o.d. or QOD**	Every other day	Mistaken as q.d. (daily) or q.i.d. (4 times daily) if the “o” is poorly written	Use “every other day”
q.d.	Daily	Mistaken as q.i.d. (4 times daily)	Use “daily”
q6PM, etc.	Every evening at 6 PM	Mistaken as every 6 hours	Use “6 PM nightly” or “6 PM daily”
SC, SQ, sub q	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as “5 every”; the “q” in “sub q” has been mistaken for “every” (e.g., a heparin dose ordered “sub q 2 hours before surgery” misunderstood as every 2 hours before surgery)	Use “subcut” or “subcutaneously”
ss	Sliding scale (insulin) or ½; (apothecary)	Mistaken as “55”	Spell out “sliding scale”; use “one-half” or “½”
SSRI	Sliding scale regular insulin	Mistaken as selective-serotonin reuptake inhibitor	Spell out “sliding scale (insulin)”
SSI	Sliding scale insulin	Mistaken as Strong Solution of Iodine (Lugol’s)	Spell out “sliding scale (insulin)”
i/d	One daily	Mistaken as “tid”	Use “1 daily”
TIW or tiw	3 times a week	Mistaken as “3 times a day” or “twice a week”	Use “3 times weekly”

TABLE 20-7 Institute for Safe Medication Practice List of Error-Prone Abbreviations—cont'd

Abbreviations	Intended Meaning	Misinterpretation	Correction
U or u**	Unit	Mistaken as the number 0 or 4, causing a 10-fold overdose or greater (e.g., 4U seen as 40 or 4u seen as 44); mistaken as “cc” so dose given in volume instead of units (e.g., 4u seen as 4cc)	Use “unit”
UD	As directed (“ut dictum”)	Mistaken as unit dose (e.g., diltiazem 125 mg IV infusion “UD” misinterpreted as meaning to give the entire infusion as a unit [bolus] dose)	Use “as directed”

Used with permission, Institute for Safe Medication Practice (ISMP), Institute for Safe Medication Practices (ISMP): *ISMP's list of error-prone abbreviations, symbols, and dose designations*, 2010, available at <http://www.ismp.org/Tools/error-proneabbreviations.pdf>, accessed January 18, 2012.

**These abbreviations are included on The Joint Commission “minimum list” of dangerous abbreviations, acronyms, and symbols that must be included on the “Do Not Use” list of an organization, effective January 1, 2011.

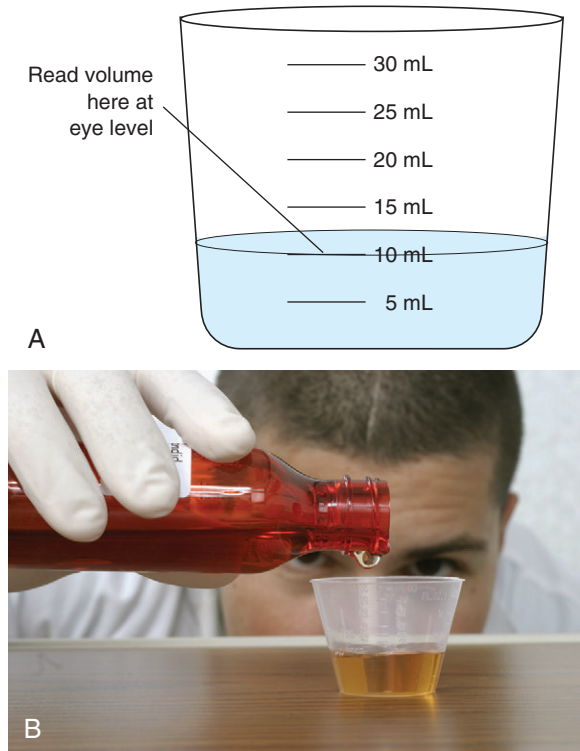

FIG 20-4 **A**, Pour desired volume of liquid so base of meniscus is level with line on scale. **B**, Place cup on flat surface and read at eye level to confirm volume poured.

the patient's desire for them. This is especially a concern for pediatric patients. Always check to determine whether a medication can be crushed (see [Chapter 21](#)). Some medications (e.g., enteric-coated or slow-release) have special coatings to prevent them from being absorbed too quickly. These medications should not be crushed. Refer to the “Do Not Crush List” ([ISMP, 2010c](#)) to ensure that a medication is safe to crush.

Right Patient

Medication errors often occur because one patient gets a drug intended for another patient. Therefore a key step in administering medications safely is being sure that you give the right medication

FIG 20-5 Before administering any medications, check patient's identification and allergy bracelets.

to the right patient. It is difficult to remember every patient's name and face. Before giving a medication to a patient, always use at least two patient identifiers ([TJC, 2012a](#)). Acceptable patient identifiers include the patient's name, an identification number assigned by a health care agency, or date of birth. Do not use the patient's room number as an identifier. [TJC \(2012b\)](#) requires use of two patient identifiers when nurses administer medications. The required identification process mandates collecting patient identifiers reliably when a patient is first admitted to a health care agency. Once identifiers are assigned to a patient (e.g., putting identifiers on an armband and placing the armband on the patient), a nurse uses them to match the patient with the patient name on the MAR.

To identify a patient correctly in an acute care setting, at the patient's bedside compare the patient identifiers on the MAR with those on his or her identification bracelet ([Fig. 20-5](#)). Asking patients to state their full names and identification information

FIG 20-6 Nurse using bar-code scanner to identify patient during medication administration.

provides a third way to verify that you are giving medications to the right patient. If an identification bracelet becomes smudged or illegible or is missing, get a new one for the patient. In health care settings that are not acute care settings, TJC (2008) does not require the use of armbands for identification. However, nurses must use a system to verify the patient's identification with at least two identifiers before administering medications.

In addition to using two identifiers, some agencies use a wireless bar-code scanner to help identify the right patient (Fig. 20-6). This system requires the nurse to scan a personal bar code that is commonly placed on the nurse's name badge first. Then a bar code is scanned from the single-dose medication package. Finally the nurse scans the patient's armband. All of this information is stored in the computer for documentation purposes. The system helps prevent medication errors because it provides another step to ensure that the right patient receives the right medication.

Right Route

The prescriber's order must designate a route of administration. If the route of administration is missing or if the specified route is not the recommended route, consult the prescriber immediately. Recent evidence shows that medication errors involving the wrong route are common. For example, enteral and parenteral medications may become confused in the pediatric setting where liquid medications are frequently given orally. When oral medications are prepared in parenteral syringes, there is an increased risk of giving an oral medication through the parenteral route (ISMP, 2010d). The injection of a liquid intended for oral use produces local complications such as sterile abscess or fatal systemic effects. Medication companies label parenteral medications "for injectable use only." Label the syringe after preparing the medication and always use different syringes for enteral and parenteral medication administration (ISMP, 2010d).

Right Time

Safe medication administration involves adherence to prescribed doses and dosage schedules. Some agencies set schedules for medication administration. However, nurses are able to alter this

schedule based on knowledge about a medication. For example, at some agencies medications that are taken once a day are given at 9:00 AM. However, if a medication works best when given at bedtime, the nurse administers it before the patient goes to sleep. In addition, acute care agencies use guidelines from the ISMP and Centers for Medicaid and Medicare Services (CMS, 2011; ISMP, 2011b) to determine safe, effective, and timely administration of scheduled medications. According to ISMP (2011b) and CMS (2011) guidelines, hospitals need to determine which medications are not eligible for scheduled dosing times and must be given at precise times (e.g., stat doses, first-time or loading doses, one-time doses). In addition, hospitals must determine which medications are time-critical scheduled and which are non-time-critical scheduled. With time-critical medications (e.g., antibiotics, anticoagulants, insulin, immunosuppressives), early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose will most likely cause harm or result in subtherapeutic responses in a patient. Non-time-critical medications include medications in which the timing of administration most likely will not affect the desired effect of the medication if the medication is given 1 to 2 hours before or after its scheduled time. Thus you administer time-critical-scheduled medications at a precise time or within 30 minutes before or after the scheduled time. You administer medications identified as non-time-critical within 1 to 2 hours of their scheduled time. Know your agency policies about the timing of medications to ensure that you administer medications at the right time (ISMP, 2011b,c).

Always know why a medication is ordered for a certain time of the day and whether you are able to alter the time schedule. For example, two medications are ordered, one q8h (every 8 hours) and the other 3 times per day. Both medications are scheduled 3 times a day over 24 hours. The prescriber intends for you to give the q8h medication around the clock to maintain its therapeutic blood levels. In contrast, you need to give the other medication during the waking hours. Each agency has a recommended time schedule for medications ordered at frequent intervals. You can alter these recommended times if necessary or appropriate.

A medication may also be ordered for special circumstances. A preoperative medication may be ordered stat (to be given immediately); now (as soon as available), usually within an hour; or on call, which means that the operating room or procedure room personnel will notify you when it is the appropriate time. Also, a medication may be given before or after meals.

Give priority to medications that must act at certain times. For example, give insulin at a precise interval before a meal. Give antibiotics on time around the clock to maintain therapeutic blood levels. Some medications require a nurse's clinical judgment in determining the proper time for administration. Administer a prn sleeping medication when the patient is ready for bed. You always document whenever there is a call to the patient's health care provider to obtain a change in a medication order.

Before discharging patients from a hospital, evaluate their medication regimen, especially if they were admitted to the hospital because of a problem with medication self-administration. A strategy to reduce medication errors at transition points is the process of medication reconciliation. Patients often leave the hospital with a basic knowledge of their medications but are unable to safely self-administer them once they return home. Help patients plan schedules based on preferred medication intervals, pharmacokinetics of the medication, and the patient's daily schedule. For patients who have difficulty remembering when to take medications, make a chart that lists the times when the patient should take each medication or prepare a special container to hold each timed dose.

Right Documentation

Accurate documentation allows nurses and other health care providers to communicate with one another and improves medication safety. Many medication errors result from inaccurate documentation. Therefore always document accurately at the time of administration and verify any inaccurate documentation before administering medications. To ensure the right documentation, first make sure that the information on your patient’s MAR corresponds exactly with the prescriber’s order and the label on the medication container. Written orders and medication forms must include the patient’s name; the name of the ordered medication; and the medication dosage, route, and frequency. If there is any question about a medication order because it is incomplete, illegible, vague, or not understood, contact the health care provider before administering the medication.

Never document that you have administered a medication until you have actually given it. Document the name of the medication, the dose, the time of administration, and the route on the patient’s MAR. Also document the site of any injections and the patient’s response to medications. Your efforts to ensure proper documentation help provide safe care (Box 20-3).

MEDICATION PREPARATION

It is legally advisable to administer only the medications that you prepare. Administering a medication prepared by another nurse

BOX 20-3 Nurse’s Six Rights for Safe Medication Administration

- 1 The right to a complete and clearly written order that clearly specifies the drug, dose, route, and frequency
- 2 The right to have the correct drug route and dose dispensed
- 3 The right to have access to drug information
- 4 The right to have policies on safe medication administration
- 5 The right to administer medications safely and identify problems in the system
- 6 The right to stop, think, and be vigilant when administering medications

From Hughes R: *Patient safety and quality: an evidence-based handbook for nurses*, Rockville, Md, 2008, Agency for Healthcare Research and Quality.

increases the opportunity for errors. You must perform several steps before actual administration of medications, including interpreting medication labels, converting measurement units within a system or between systems, and calculating medication doses. The importance of checking similar names and verifying the correct drug cannot be overemphasized.

Interpreting Medication Labels

Medication labels include several basic pieces of information: the trade name of the drug in large letters, the generic name in smaller letters, the form of the drug, the dosage, the expiration date, the lot number, and the name of the manufacturer (Fig. 20-7). The trade name given by the manufacturer suggests the action of the drug, and the generic name is the chemical name.

Clinical Calculation

To administer medications safely, use your mathematics skills to safely calculate dosages and mix solutions. This skill is important because medications are not always dispensed in the unit of measure in which they are ordered. Medication companies package and bottle medications in standard dosages. For example, a patient’s health care provider orders 20 mg of a medication that is packaged in 40-mg vials. You are responsible for converting available units of volume and weight to the desired doses. Therefore be aware of approximate equivalents in all major measurement systems and make use of conversion tables. In addition to medication administration, nurses use volume and weight conversions in a variety of other nursing activities, including converting fluid ounces to milliliters to measure intake and output (I&O) or converting volume equivalents to calculate IV flow rates.

EVIDENCE-BASED PRACTICE

Many medication errors occur when nurses become distracted or lose focus during medication administration or fail to follow best-practice protocols and procedures related to medication administration. Research reveals that 43% of medication errors are a result of workplace distraction (Trbovich et al., 2010). Areas for medication administration preparation are highly visible locations with high levels of staff traffic (ISMP, 2009). Nurses become interrupted

FIG 20-7 Interpreting medication label. (Courtesy Dr. Reddy’s Laboratories, Inc.)

while accessing dispensing systems, depositing medications into delivery containers, and confirming orders on computer screens. The majority of distractions have been identified as questions from staff or family, equipment alarms, and personal conversations (Trbovich et al., 2010). Nurses need systems in place to avoid distractions to help prevent medication errors, including:

- Raising awareness of health care team members to avoid discussion during medication preparation and administration (Relihan et al., 2010).
- Reducing the number of distractions and interruptions around the automated medication dispensing machines (Anderson et al., 2010).
- Ensuring that all medication supplies are adequately stocked before the preparation phase (Relihan et al., 2010).
- In areas where medications are being prepared, using a brightly colored sign to alert staff and family to avoid interrupting the nurse who is preparing medications.
- Avoiding initiating any conversations while preparing medications and redirecting questions to another nurse or health care provider.

Conversions Within One System

Converting measurements within one system is relatively easy; simply divide or multiply in the metric system. For example, to change milligrams to grams, divide by 1000 or move the decimal three points to the left.

$$1000 \text{ mg} = 1 \text{ g}$$

$$350 \text{ mg} = 0.35 \text{ g}$$

To convert liters to milliliters, multiply by 1000 or move the decimal three points to the right.

$$1 \text{ L} = 1000 \text{ mL}$$

$$0.25 \text{ L} = 250 \text{ mL}$$

To convert units of measurement within the household system, consult an equivalency table. For example, when converting fluid ounces to quarts, you first need to know that 32 ounces is the equivalent of 1 quart. To convert 8 ounces to a quart measurement, divide 8 by 32 to get the equivalent, $\frac{1}{4}$ or 0.25 quart.

Conversion Between Systems

You will frequently determine the correct dose of a medication by converting weights or volumes from one system of measurement to another. For example, often you will convert metric units to equivalent household measures for use at home. To convert from one measurement system to another, use equivalent measurements. Tables of equivalent measurements are available in all health care agencies. The pharmacist is also a good resource.

Before making a conversion, compare the measurement system available with that ordered. For example, a prescriber orders Robitussin 30 mL, but the patient only has tablespoons at home. To provide proper instruction to the patient, you convert milliliters to tablespoons, which requires you to know the equivalency or refer to a table such as Table 20-6.

Dosage Calculations

Dosage calculations are necessary when the dose on the medication label differs from the dose ordered. There are several dose-calculation methods, including formula (Box 20-4) and dimensional analysis (Box 20-5). The most common methods are ration-proportion or use of a formula.

Example 1: When the dose ordered has the same label as the dose available

Dose ordered: 0.5 g

Tablets available: 0.25 g per tablet

Step 1. The starting factor is 0.5 g.

The answer label is tablets (i.e., how many tablets should be given?)

Step 2. Formulate the conversion equation:

The equivalent needed is 1 tablet = 0.25 g.

$$\frac{0.5 \text{ g}}{1} \times \frac{1 \text{ tab}}{0.25 \text{ g}} = \text{tabs}$$

Cancel labels (g). **NOTE:** If properly written, all labels except the answer label will cancel.

Step 3. Solve the equation. Reduce the numerical values and multiply the numerators and denominators.

$$\frac{0.5 \cancel{\text{g}}}{1} \times \frac{1 \text{ tab}}{0.25 \cancel{\text{g}}} = 2 \text{ tabs}$$

BOX 20-4 Formula Method

$$\frac{D}{H} = V = \text{Amount to give}$$

D is the desired dose or the dose ordered by the health care provider for the patient (e.g., 250 mg of penicillin PO 4 times daily).

H is the drug dose on hand or available for use. The dose is on the drug label (e.g., penicillin tablets 250 mg each).

V is the volume (liquid) or vehicle (number of tablets, capsules) that delivers the available dose.

NOTE: The desired dose (D) and the on-hand dose (H) must be in the same unit of measurement. If they are in different units, you must convert before completing the formula.

BOX 20-5 Dimensional Analysis

Use the following steps to solve medication problems using dimensional analysis:

1. Identify the unit of measure that you need to administer. For example, if you are giving a pill, you will usually be giving a tablet or a capsule; for parenteral or oral medications, the unit is milliliters.
2. Estimate the answer in your mind.
3. Place the name or appropriate abbreviation for x on the left side of the equation (e.g., $x \text{ tab}$, $x \text{ mL}$).
4. Place available information from the problem in a fraction format on the right side of the equation. Place the abbreviation or unit that matches what you are going to administer (determined in Step 1) in the numerator.
5. Look at the medication order and add other factors into the problem. Set up the numerator so it matches the unit in the previous denominator.
6. Cancel out like units of measurement on the right side of the equation. You should end up with only one unit left in the equation, and it should match the unit on the left side of the equation.
7. Reduce to the lowest terms if possible and solve the problem or solve for x . Label your answer.
8. Compare your estimate from Step 1 with your answer in Step 2.

Example 2: When the dose ordered has a different label than the dose available

Dose ordered: 0.5 g

Tablets available: 250 mg per tablet

Step 1. The starting factor is 0.5 g.

The answer label is tablets (i.e., how many tablets should be given?)

Step 2. Formulate the conversion equation:

The equivalents needed are 1 g = 1000 mg and 1 tab = 250 mg.

$$\frac{0.5 \text{ g}}{1} \times \frac{1000 \text{ mg}}{1 \text{ g}} \times \frac{1 \text{ tab}}{250 \text{ mg}} = \text{tabs}$$

Cancel labels (g, mg).

Step 3. Solve the equation.

Reduce the values and multiply the numerators and the denominators.

$$0.5 \text{ g} \times \frac{1000 \text{ mg}}{1 \text{ g}} \times \frac{1 \text{ tab}}{250 \text{ mg}} = \frac{4}{2} = 2 \text{ tabs}$$

Example 3: When the dose ordered is available in a liquid form

Dose ordered: Keflex 250 mg PO

Available: 125 mg per 5 mL

Step 1. The starting factor is 250 mg.

The answer label is mL.

Step 2. Formulate the conversion equation:

The equivalent needed is 125 mg = 5 mL.

$$\frac{250 \text{ mg}}{1} \times \frac{5 \text{ mL}}{125 \text{ mg}} = \text{mL}$$

Cancel labels (mg).

Step 3. Solve the equation.

Reduce and multiply.

$$\frac{250 \text{ mg}}{1} \times \frac{5 \text{ mL}}{125 \text{ mg}} = 10 \text{ mL}$$

Pediatric Doses

Calculating children's medication doses requires caution (Hockenberry and Wilson, 2011). Evidence shows that children are 3 times more at risk for experiencing an ADE than adults (Potera, 2011). Factors contributing to errors include workload, distractions, lack of knowledge, and the need to dilute medications (Ozkan et al., 2011). The child's age, weight, and maturity of body systems all affect the ability to metabolize and excrete medication. Other factors that influence medication dosages in children include the difficulty in evaluating the desired effect and the hydration status of the child. In most cases the prescriber will calculate the dose for a child before ordering the medication. However, it is your responsibility to be aware of the safe dosage range for any medication administered. Different formulas and methods are used to calculate drug doses in children. The two most common methods of calculating pediatric dosages are based on the child's weight or body surface area (BSA). Refer to a pediatric pharmacology resource, a pharmacist, or the health care provider if you have to calculate a medication based on BSA. Most of the time you calculate medications based on the child's weight. An example using body weight for dosage calculation is as follows:

$$\text{Body weight} \times \text{Amount/kg} = X \text{ mg of drug}$$

For example: Prescriber orders 1 mg/kg/day of prednisone orally in two divided doses for a child weighing 55 pounds. To convert pounds to kilograms use the following formula:

$$\frac{\text{Patient's weight in pounds} \times 1 \text{ kg}/2.2 \text{ pounds}}{\text{Patient's weight in kilograms}} =$$

Step 1. Convert the child's weight to kilograms.

$$55 \text{ lbs} \times 1 \text{ kg}/2.2 \text{ lbs} = 25 \text{ kg}$$

Step 2. Solve the equation.

$$25 \text{ kg} \times 1 \text{ mg/kg} = 25 \text{ mg}$$

The patient should receive 25 mg of prednisone orally per day in two divided doses.

Older Adult Dosages

Older adults also require special consideration during medication administration (Table 20-8). The changes of aging alter pharmacokinetics. In addition to physiologic changes of aging, behavioral and economic issues influence the older adult's use of medications.

A common problem for older adults is polypharmacy. There is no consensus definition for polypharmacy, although the common definitions include six or more concurrent drugs, one or more potentially inappropriate drugs, two or more medications from the same chemical class, two or more medications to treat the same illness, or the mixing of nutritional or herbal supplements with medications (Reamer et al., 2008; Maggiore et al., 2010; Meiner, 2011). Older adults experience polypharmacy when they seek relief from a variety of symptoms (e.g., constipation, insomnia, pain) by using OTC preparations. Polypharmacy increases the risk of adverse effects and interactions with other medications.

The nurse, prescriber, and pharmacist share the responsibility of reducing or eliminating the risk factors associated with medication regimens that older adults receive by assessing the patient's health status, current medication regimen (including OTC drugs and herbal products), the reason for existing and proposed medications, and any environmental factors that influence accurate and safe medication administration by the patient and caregivers.

TABLE 20-8 Safe Medication Administration in Older Adults

- Consult with the prescriber to keep the medication plan as simple as possible (Lehne, 2010).
- Keep instructions clear and simple and provide written materials in large print (Lehne, 2010).
- Teach the complications and interactions of all over-the-counter medications (Meiner, 2011).
- Teach the older adult to set up a daily or weekly schedule for medications using memory aids such as a calendar (Meiner, 2011).
- Monitor patient's response to medications to assess for overuse or underuse of the medication and anticipate possible dosage modifications (Meiner, 2011).
- Reduce the chance of errors by color coding or labeling medication bottles (Meiner, 2011).
- Include patient's family caregiver in any type of instruction.

NURSING PROCESS

Application of the nursing process ensures that critical thinking and clinical judgment are integrated into a patient's care. As a nurse your role extends beyond simply giving drugs to a patient. You are responsible for monitoring patients' responses to medications; providing education to the patient and family; and informing the health care provider when medications are effective, ineffective, or no longer necessary.

Assessment

Before administering medications, perform a physical assessment, which will reveal physical findings for any indications or contraindications for medication therapy. Continue your assessment by determining if the patient has a history of medication allergies. When assessing for medication allergies, you must differentiate between actual allergic reactions, which can be life threatening, and drug intolerances, which are uncomfortable side effects. In an acute care setting patients with allergies wear identification bands that list each medication allergy. All allergies and types of reactions are noted on the patient's admission notes, medication records, and history and physical examination. *Never give a patient a medication when there is a known allergy.*

Your assessment also involves identifying medications that the patient takes every day at home, including prescriptions, OTC preparations, and herbal supplements. Determine how long the patient has taken each medication, current dosage schedule, and whether he or she has had any adverse effects to any of the medications. The patient should know the name, purpose, dosage, route, and side effects of medications and supplements that are being taken. Often patients take many medications and carry a list that includes this information. Patients have different levels of understanding. One patient may describe a diuretic as a "water pill," whereas another describes it as a drug to minimize swelling and lower blood pressure. By assessing the patient's level of knowledge, you determine the need for teaching. If a patient is unable to understand or remember pertinent information, it may be necessary to involve a family member.

Complete appropriate assessments, which may include vital signs, laboratory data, and the nature and severity of symptoms. If data contraindicate medication administration, hold the drug and notify the prescriber. When in doubt about medication information, check available medication references or the pharmacy.

Planning

During planning organize nursing activities to ensure the safe administration of medications. Current evidence shows that distractions or hurrying during preparation for medication administration increases the risk of medication errors (Relihan et al., 2010). The following are general goals of medication administration:

- 1 Patient achieves therapeutic effect of the prescribed medication
- 2 There are no patient complications related to the prescribed medication
- 3 Patient and/or family understand medication therapy
- 4 Patient and family self-administer medication safely (when appropriate)

Implementation

Nursing interventions focus on safe and effective drug administration. This includes careful medication preparation, accurate and timely administration, and patient education.

Pre-administration Activities

- 1 Identify the medication action, purpose, side effects, and nursing implications for administering and monitoring. Ensure that the medication order has not expired. Follow agency policy for medication order renewal.
- 2 Minimize distractions during medication preparation (e.g., discussion with staff, phone call, pager), close the door of the medication room or post "Do Not Disturb" signage, and do not perform other tasks while preparing a medication.
- 3 Make sure that the information on the medication computer sheet or MAR corresponds exactly with the prescriber's written order and with the medication container label. Do not interpret illegible handwriting; clarify with prescriber.
- 4 Read the label on the medication container and compare it with the MAR at least 3 times: before removing the container from the supply drawer, when placing the medication in an administration cup/syringe, and just before administering the medication to the patient.
- 5 Double-check all calculations and other high-risk medication administration processes (e.g., patient-controlled analgesia) and verify with another nurse.
- 6 Review any pre-administration assessments (e.g., vital signs, review of laboratory results).
- 7 Use good hand-hygiene technique. Avoid touching tablets and capsules. Use sterile technique for parenteral medications. Wear clean gloves when administering parenteral medications and certain topical medications.
- 8 Administer only those medications that you personally prepare. Do not ask another person to administer medications that you prepare. Keep medications secure.
- 9 When preparing medications, be sure that the label is clear and legible and that the drug is mixed properly; has not changed in color, clarity, or consistency; and has not expired.
- 10 Keep tablets and capsules in their wrappers and open them at the patient's bedside. This allows you to review each medication with the patient. If a patient refuses medication, there will be no question which one was withheld.

Medication Administration

- 1 Follow the *six rights* of medication administration.
- 2 Inform the patient of the name, purpose, action, and common side effects of each medication. Evaluate his or her knowledge of the medication and provide appropriate teaching.
- 3 Stay with the patient until the medication is taken. Provide assistance as necessary. Do not leave medication at the bedside without a prescriber order. For example, some patients may take their own vitamins while in the hospital.
- 4 Respect the patient's right to refuse a medication. If the medication wrapper remains intact, return the medication to the patient's unit-dose drawer. When medication is refused, determine the reason and take action accordingly.

Post-administration Activities

- 1 Record medications immediately after administration (see agency policy). Include the drug name, dose, route, time, and your signature.
- 2 Document data pertinent to patient's response. This is especially important when giving prn drugs.
- 3 If a patient refuses a medication, document that it was not given, the reason for refusal, and when you notified the health care provider.

Evaluation

After you administer a medication, consider how the medication is expected to affect the patient and evaluate his or her condition and response to it. Look for therapeutic and adverse effects. If adverse effects develop, you need to recognize the clinical signs and respond quickly.

- 1 Monitor for evidence of therapeutic effects, side effects, and adverse reactions. This includes monitoring physical response (e.g., heart rhythm, blood pressure, urine output, or laboratory results).
- 2 When a medication is given for relief of symptoms, ask the patient to report if symptoms have diminished or been relieved.
- 3 Observe injection sites for bruises, inflammation, localized pain, numbness, or bleeding.
- 4 Evaluate patient's and family caregiver's understanding of medication therapy and ability to self-administer medication.

SPECIAL HANDLING OF CONTROLLED SUBSTANCES

As a nurse, you are responsible for following legal regulations when administering controlled substances (medications with potential for abuse). Violations of the Controlled Substances Act may result in fines, imprisonment, and loss of license. Health care agencies have policies for the proper storage and distribution of controlled substances, including opioids (Box 20-6). Many agencies use computerized systems for medication access and distribution.

REPORTING MEDICATION ERRORS

Medication errors often harm patients because of inappropriate medication use. Errors include inaccurate prescribing; administering the wrong medication, by the wrong route, and in the wrong time interval; and administering extra doses or failing to administer a medication. Medication errors are related to professional practice, health care product design, or procedures and systems such as product labeling and distribution. When an error occurs, the patient's safety and well-being become the top priority. The nurse assesses and examines the patient's condition and notifies the health care provider of the incident as soon as possible. Once the patient is stable, the nurse reports the incident to the appropriate person in the agency (e.g., manager or supervisor).

The nurse is also responsible for preparing a written incident or occurrence report that must be filed usually within 24 hours of an

incident (see Chapter 4). The incident report is an internal audit tool and not a permanent part of the medical record. To legally protect the health care professional and agency, do not refer to an incident report in the nurses' notes or electronic health record (EHR). Agencies use incident reports to track incident patterns and initiate performance improvement programs as needed. Depending on the circumstances and the severity of the outcome, the nurse or agency may be responsible for reporting the incident to TJC, MedWatch (FDA Medical Products Reporting Program), or USP Medication Errors Reporting Program.

It is good risk management to report all medication errors, including mistakes that do not cause obvious or immediate harm or near misses. You should feel comfortable in reporting an error and not fear repercussions from managerial staff. Even when a patient suffers no harm from a medication error, the agency can still learn why the mistake occurred and what to do in the future to avoid similar errors. There are strategies that you can implement to prevent medication errors (Box 20-7).

PATIENT AND FAMILY TEACHING

A well-informed patient is more likely to take medications correctly. However, many patients have limited health literacy, meaning that they do not understand how to read medication labels and calculate doses. Thus any education requires a thorough assessment of a patient's learning needs and abilities. Provide an individualized approach to teaching, using visual aids, instructional booklets, or even videotapes or DVDs. When teaching patients about their medications, include people identified as being significant to the patient's recovery (e.g., family caregivers or home care providers).

Begin instruction as soon as possible so you can have several teaching sessions. It is ideal to use instructional materials written no higher than a sixth-grade reading level. When providing

BOX 20-6 Guidelines for Safe Narcotic Administration and Control

- All controlled substances are stored in a locked cabinet or container (computerized, locked cabinets are preferred).
- Authorized nurses carry a set of keys or computer entry code for the cabinet.
- An inventory record is used each time a narcotic is dispensed. Records are often kept electronically and provide an accurate ongoing account of the narcotics used, wasted, and remaining.
- Use the record to document a patient's name, date, name of medication, dose, time of medication administration, and signature of nurse dispensing the medication.
- A second nurse witnesses disposal of the unused portion, and the record is signed by both nurses. Computerized systems record the names of the nurses electronically. Follow agency policy for appropriate waste of narcotics.

BOX 20-7 Steps to Prevent Medication Errors

- Follow the six rights of medication administration.
- Only prepare medications for one patient at a time.
- Be sure to read labels at least 3 times (comparing MAR with label): When removing medication from storage, before taking to patient's room, before giving medication.
- Use at least two patient identifiers (e.g., patient name, birth date, hospital number) whenever administering a medication.
- Do not allow any other activity to interrupt your administration of medication to a patient.
- Double-check all calculations and verify with another nurse.
- Do not interpret illegible handwriting; clarify with prescriber.
- Question unusually large or small doses.
- Document all medications as soon as they are given.
- When you have made an error, reflect on what went wrong and ask how you could have prevented it.
- Evaluate the context or situation in which a medication error occurred. This helps to determine if nurses have the necessary resources for safe medication administration.
- When repeated medication errors occur within a work area, identify and analyze the factors that may have caused the errors and take corrective action.
- Attend in-service programs on the medications you commonly administer.
- Follow agency policies and protocols during medication administration; do not take short cuts.

MAR, Medication administration record.

instruction, have the patient or family caregiver repeat the name and use for each medication plus the dosing instructions. Have the patient demonstrate preparation of each medication. Provide time to discuss problem scenarios (e.g., side effects develop or a syringe becomes contaminated) to test the patient's knowledge of what to do should something go wrong. Determine if the patient requires a compliance aid or memory cue. This is especially important in older adults. Medication dose containers organized by the hours and days of the week are very useful. In the event that patients miss a dose of medication, they need to know how to adjust their medication schedule safely.

Evaluating the effectiveness of teaching ensures that the patient can administer medications in a safe manner. One method of evaluating patient understanding is to create medication cards with the generic and trade names of the medication on the front of the card and all pertinent medication information on the back of the card. You can flash the card in front of the patient and ask him or

her to read the name of the medication. Another method is to have patients read labels on prepared medications. Remember that medication bottles often have fine print and are difficult to read for the patient with impaired vision. If the patient correctly identifies the name of the medication, ask him or her the following questions:

- Why are you taking this medication?
- How often do you take this medication?
- What side effects can occur with this medication?
- If this side effect occurs, what are you going to do about it?

Be sure to also assess the patient's sensory, motor, and cognitive functions. Impairments may affect the patient's ability to safely self-administer medications, and family caregivers or home health aides may need to assist with medication administration. Many self-help devices are also available for purchase (e.g., pill boxes with times displayed and electronic dispensers).

Critical Thinking Exercises

Justin Brown is a 72-year-old patient who visits the medical clinic 1 month after a myocardial infarction (heart attack). He denies any chest pain since his angioplasty, which involved insertion of a stent into one of his coronary arteries to improve blood flow to the heart. He is currently taking an antidepressant, a thyroid supplement, a stool softener, and a cardiac drug (beta-adrenergic blocker). In addition, he takes melatonin, an herbal preparation for sleep. The physician has recently revised Mr. Brown's cardiac medication to metoprolol (Lopressor). He is now instructed to take 75 mg by mouth twice daily. The nurse notes that the drug is available in 150-mg tablets. Mr. Brown tells the clinic nurse that he has experienced some weakness and dizziness over the past week.

- 1 Which of the medications taken by Mr. Brown are likely to cause weakness and dizziness?
- 2 What might the health care provider who prescribed the medication do after receiving the nurse's report of Mr. Brown's weakness and dizziness?
- 3 As the nurse, what would be important to assess for Mr. Brown to take the 75-mg dose safely?

this morning after several bites of her soft-diet breakfast. She last received a dose of her ordered oral analgesic 4 hours ago. The medication, hydrocodone 10 mg PO, is ordered q4h prn. Which of the following rights of drug administration will most likely challenge the nurse caring for this patient?

- 1 Right route
 - 2 Right patient
 - 3 Right dose
 - 4 Right time
- 4 A medication order is for 0.5 g PO every 12 hours. The medication is available in 250-mg tablets. How many tablets should the nurse administer?
 - 1 $\frac{1}{2}$ tablet
 - 2 1 tablet
 - 3 $1\frac{1}{2}$ tablets
 - 4 2 tablets
 - 5 A patient has been having enemas until clear for an upcoming intestinal surgery. He is on several oral medications. What effect do enemas have on the absorption of medications?
 - 1 They increase the rate of excretion of the medications.
 - 2 They decrease the rate of excretion of the medications.
 - 3 They prolong the effects of the medications.
 - 4 It is unknown because the mechanism of medication excretion is not stated.

- 6 A nurse is administering multiple medications to multiple patients on a very busy unit.

Which action by the nurse requires an intervention?

- 1 The nurse performs dosage calculations and has them checked by another nurse as needed.
 - 2 The nurse keeps unit-dose medications closed in their wrappers until arriving at the patient's bedside.
 - 3 The nurse administers clear liquid medication containing sediment at the bottom of the bottle.
 - 4 The nurse checks medications at least 3 times before administering them to the patient.
- 7 The home health nurse notes that an elderly patient uses mouthwash 3 or 4 times every day and that he periodically swallows some of it. Which action is most appropriate for the nurse to take?
 - 1 Tell the patient not to use the mouthwash as often
 - 2 Ask the patient if he smokes
 - 3 Obtain a dietary history from the patient from the past 2 days
 - 4 Check the patient's medications and the mouthwash label

REVIEW QUESTIONS

- 1 An older adult is weak and malnourished. For what should the nurse be especially watching for after administering the patient's usual medications?
 - 1 Signs and symptoms of drug toxicity
 - 2 Increased dependence on the medication
 - 3 Side effects of the medication
 - 4 An allergic reaction
- 2 A nurse needs to draw a serum trough level of a medication. When should he or she obtain the blood sample?
 - 1 Right before the next dose of the drug is due
 - 2 Midpoint between the times the drug doses are given
 - 3 2 hours after the medication is given
 - 4 When the serum level is scheduled to plateau, usually early in the morning
- 3 A patient has asked for a pain medication to relieve the discomfort from her abdominal incision. She has experienced nausea since

- 8 The nurse is reviewing the medication order sheet and finds an order for MSO4 8 mg IM q 3-4h prn.
What is the appropriate initial nursing action?
- 1 Contact the pharmacist to approve the order
 - 2 Ask another nurse if she can give the medication
 - 3 Contact the prescriber for clarification, including a “read-back”
 - 4 Administer the medication as ordered by the health care provider
- 9 The nurse administered lorazepam (Ativan), an antianxiety medication, to an 84-year-old patient who now is agitated and experiencing delirium.
What are the nurse’s primary responsibilities?
- 1 Administer naloxone (Narcan) and prepare to call a “code”
 - 2 Assess the patient’s oxygen saturation and prepare to administer oxygen
 - 3 Monitor the patient and have another nurse call the prescriber
 - 4 Contact the nursing supervisor and the pharmacist
- 10 During the admission history the nurse determines that his 80-year-old patient is currently taking a salmon-colored blood pressure pill, a yellow “muscle relaxing” pill, a pink liquid to calm his stomach, and a green and yellow “joint” pill. Which action should the nurse take first?
- 1 Ask the patient if he brought the medications with him
 - 2 Check the patient’s armband before administering any medications
 - 3 Try to identify the medications by the patient’s descriptions
 - 4 Call the pharmacist to see if she can figure out what the medications are

KEY TERMS

Antianginal	Mydriatics	Ophthalmic	Suspension
Buccal medication	Nasal	Otic	Sympathomimetic
Cycloplegic	Nebulizer	Pruritus	Topical
Dermatologic	Nitroglycerin	Sublingual medication	Transdermal
Dry powder inhaler (DPI)	Ointment	Suppository	Vertigo
Metered-dose inhaler (MDI)			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Correctly administer a medication by oral, enteral, and topical routes.
- Correctly administer medications for irrigation and instillation.
- Identify guidelines for administering oral, enteral, and topical medications.
- Describe factors to assess before administering medications.
- Differentiate types of topical administrations that require sterile technique and those that require clean medical aseptic technique.
- Instruct patients in the proper use of a metered-dose inhaler (MDI), a dry powder inhaler (DPI), and small-volume nebulizer.
- Identify conditions contraindicating the administration of medications by various oral and topical routes.
- Prepare a teaching plan regarding medication use for a selected patient.

Nonparenteral medications include those that are not given by injection such as oral medications, eardrops, and eyedrops. The route chosen depends on the properties and desired effects of the medication and the physical and mental condition of a patient. The oral route (by mouth) is the easiest

and most desirable way to administer medications. There are many reasons why it may be necessary to change from one route to another. When this occurs, you are responsible for consulting with a health care provider for an order or conferring with the pharmacist to safely meet a patient's needs.

Topical administration of medications involves applying drugs directly to skin or mucous or tissue membranes. You apply medications to the skin by spraying, painting, or spreading medication over a localized area. Transdermal patches (adhesive-backed medicated disks), which are applied to the skin, provide a continuous release of medication over several hours or days. Topical administration avoids puncturing the skin and decreases the risk for infection and tissue injury that may occur with injections. When applying a disk, it is essential to rotate the site of application to decrease the incidence of a localized reaction.

Medications applied to membranes such as the cornea of the eye or the rectal mucosa are absorbed quickly because of the vascularity of the membrane. When drug concentrations are high, systemic effects can occur. For example, bradycardia and hypotension may occur after instillation of ophthalmic beta blockers such as timolol (Timoptic). Mucous and tissue membranes differ in their sensitivity to medications. For example, the cornea of the eye is very sensitive. Patients commonly experience burning sensations during administration of eyedrops and nose drops. Medications applied to vaginal or rectal mucosa are generally less irritating.

You can administer medications for topical use in the following ways:

- 1 *Direct application of liquid:* Eyedrops, gargling, swabbing the throat
- 2 *Inserting drug into a body cavity:* Rectal or vaginal suppositories, vaginal creams, or foams
- 3 *Instillation of fluid into body cavity (fluid is retained):* Ear-drops, nose drops, bladder and rectal instillation
- 4 *Irrigation of body cavity (fluid is not retained):* Flushing eye, ear, vagina, bladder, or rectum with medicated fluid
- 5 *Spraying:* Instillation into nose or throat.
- 6 *Inhalation of medicated aerosol spray:* Distributes medication throughout the nasal passages and the tracheobronchial airway; two types of devices designed for this purpose: metered-dose inhalers (MDIs) and small-volume nebulizers
- 7 *Inhalation of dry powder medication:* Distributes medication in powder form throughout the tracheobronchial airway; device designed for this purpose: dry powder inhaler (DPI)
- 8 *Direct application to skin or mucosa:* Lotion, ointment, cream, powder, foam, spray, patch, and disk
- 9 *Sublingual:* Medication placed under the tongue; is dissolvable
- 10 *Buccal:* Medication placed between the upper or lower molar teeth and cheek area; is dissolvable

EVIDENCE-BASED PRACTICE

Nurses play an essential role in all phases of the medication administration process. Medication competency is a skill that all nurses must possess to improve the quality and safety of medication administration. Increasing safety is important in improving the quality of patient care (Popescu et al., 2011). An integrative review of the literature identifies the competencies that nurses can implement to increase patient safety and promote best practices (Sulosari et al., 2011):

- Maintain current knowledge of anatomy and physiology and pharmacology.
- Maintain mathematics and calculation skills through practice and validation of correct medication doses.

- Communicate with the interdisciplinary team to ensure that the six rights of medication administration are followed.
- Assess patients before administration of medications and evaluate responses to achieve best practices.
- Accuracy of documentation is necessary to maintain patient safety.
- Best-practice guidelines for safe medication administration include clinical decision-making competency, theoretic competency, and clinical practice competency.

PATIENT-CENTERED CARE

An excellent time to provide patient education is during medication administration. Most patients discharged from hospitals continue on previously ordered medications and are placed on new medications. The goal of patient education is to improve patient adherence to medication regimens. Patients fail to adhere to medication regimens because of patient, medication, and provider issues (Berben et al., 2011; Shearer, 2009). Patient issues include cognitive impairment, depression, physical limitation, financial issues, and lack of knowledge. Medication issues include complex medication regimens and medication discrepancies. Provider issues include poor instruction, inappropriate prescriptions, and lack of provider knowledge about adherence. Patients need explanations about the purpose of medications, benefits, expected effects, and how to plan a daily schedule. Print materials should be developed to meet individual patient needs such as health literacy, visual impairment, or cognitive impairment. Be sure to involve family caregivers in the education sessions since they may be the ones administering medications.

Health beliefs vary by culture and influence how patients manage and respond to medication therapy. Differences in values, attitudes, and beliefs affect a patient's adherence to medication therapy. Herbal remedies and alternative therapies may be common practice in some cultures and interfere with prescribed medications. Some cultures discontinue their medication when symptoms are resolved, even if medications are still needed to manage the disease (Qureshi, 2010). It is also important to consider cultural influences on drug response, metabolism, and side effects if a patient is not responding to drug therapy as expected. A change in the medication may be necessary by the prescriber.

Safety Guidelines

- 1 Assess patient's sensory function, including sight, hearing, touch, and physical coordination. Sensory function and coordination deficits impair patient's ability to see medications, open prescription bottles, and read labels at home.
- 2 Patients often receive more than one oral medication at a time. Evaluate each medication for potential drug-drug or drug-food interactions. Always consult with a pharmacist to reduce the risk of an interaction.
- 3 Always assess for drug allergies. If patient reports having an allergy, ask about the type of reaction that occurred.
- 4 Evaluate if patient can take medication with food. In most cases the presence of food in the stomach delays drug absorption; however, some drugs irritate the stomach lining and need to be taken with food.
- 5 For all medications administered, review the order for patient's name, drug, dosage, route, and time of administration.
- 6 For all medications administered, gather information pertinent to the drug(s) ordered: purpose, normal dosage and route,

- common side effects, time of onset and peak, contraindications, and nursing implications.
- Determine if medications require any specific nursing actions (e.g., vital signs, drug levels, or electrolytes) before administration.

- If patients are mentally and physically able, prepare them for discharge by instructing them in self-administration techniques. Include family caregivers if possible.
- Check the expiration date for all medications.

SKILL 21-1 Administering Oral Medications

NSO Safe Medication Administration Module / Lesson 5

Patients are usually able to ingest or self-administer oral medications with few problems. If oral medications are contraindicated (e.g., inability to swallow, gastric suction) take precautions to protect patients from aspiration. Nurses usually prepare medications in areas designed for medication preparation or at unit-dose carts.

Delegation and Collaboration

The skill of administering oral medications cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and to report their occurrence.

- Informing nurse if patient condition changes or worsens (e.g., pain, itching, or rash) after medication administration.

Equipment

- Automated, computer-controlled drug dispensing system or medication cart
- Disposable medication cups
- Glass of water, juice, or preferred liquid and drinking straw
- Device for crushing or splitting tablets (*optional*)
- Paper towels
- Medication administration record (MAR) (electronic or printed)
- Clean gloves (if handling an oral medication)

STEP

RATIONALE

ASSESSMENT

- Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name and drug name, dosage, and route and time of administration. Clarify incomplete or unclear orders with health care provider before administration.
- Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
- Assess for any contraindications to patient receiving oral medication, including being on NPO status, inability to swallow, nausea/vomiting, bowel inflammation, reduced peristalsis, recent gastrointestinal (GI) surgery, gastric suction, and decreased level of consciousness (LOC). Notify health care provider if any contraindications are present.
- Assess risk for aspiration using a dysphagia screening tool if available (see Skill 30-3). Protect patient from aspiration by assessing swallowing ability (Box 21-1).

The health care provider's order is the most reliable source and only legal record of drugs that patient is to receive. Ensures that patient receives correct medication. Handwritten MARs are a source of medication errors (Poon et al., 2010; Jones and Treiber, 2010).

Allows you to anticipate effects of drug and observe patient's response.

Alterations in GI function can interfere with drug absorption, distribution, and excretion. Giving oral medications to patients with impaired swallowing or decreased LOC increases their risk for aspiration.

Aspiration occurs when food, fluid, or medication intended for GI administration is inadvertently administered into the respiratory tract. Patients with altered ability to swallow are at higher risk for aspiration (Kelly et al., 2011; Edmiaston et al., 2010).

BOX 21-1 Protecting the Patient from Aspiration

- Assess patient's ability to swallow and cough and check for presence of gag reflex.
- Prepare oral medication in form that is easiest to swallow.
- Allow patient to self-administer medications if possible.
- If patient has unilateral (one-sided) weakness, place medication in stronger side of mouth.
- Administer pills one at a time, ensuring that each medication is properly swallowed before next one is introduced.
- Thicken regular liquids or offer fruit nectars if patient cannot tolerate thin liquids.
- Avoid straws because they decrease control patient has over volume intake, which increases risk of aspiration.
- Have patient hold and drink from a cup if possible.
- Time medications to coincide with mealtimes or when patient is well rested and awake if possible.
- Administer medications using another route if risk of aspiration is severe.

STEP	RATIONALE
<p>5 Assess patient’s medical history, history of allergies, medication history, and diet history. List any drug allergies on each page of the MAR and prominently display on patient’s medical record. When allergies are present, patient should wear an allergy bracelet.</p>	<p>These factors influence how certain drugs act. Information reveals previous problems with medication administration.</p>
<p>6 Gather and review physical assessment findings and laboratory data that influence drug administration such as vital signs and results of renal and liver function studies.</p>	<p>Physical examination findings or laboratory data may contraindicate drug administration. Renal and liver function status affects metabolism and excretion of medications (Lewis et al., 2011).</p>
<p>7 Assess patient’s knowledge regarding health and medication use, medication schedule, and ability to prepare medications.</p>	<p>Determines patient’s need for medication education and guidance needed to achieve drug adherence.</p>
<p>8 Assess patient’s preference for fluids and determine if medications can be given with these fluids. Maintain fluid restrictions as prescribed.</p>	<p>Some fluids interfere with medication absorption (e.g., dairy products affect tetracycline). Offering fluids during drug administration is an excellent way to increase patient’s fluid intake. Fluids ease swallowing and facilitate absorption from the GI tract. However, fluid restrictions must be maintained.</p>

NURSING DIAGNOSES

- Deficient knowledge: medication administration
- Impaired swallowing
- Noncompliance
- Readiness for enhanced self-health management
- Nausea
- Risk for aspiration

Related factors are individualized based on patient’s condition or needs.

PLANNING

- | | |
|--|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient responds appropriately to desired medication effect. • Patient denies any GI discomfort or symptoms of alterations. • Patient explains purpose of medication and drug dosage schedule. | <p>Drug has exerted its therapeutic action.
Oral medications can irritate GI mucosa.
Demonstrates understanding of drug therapy.</p> |
| <p>2 Explain procedure to patient. Be specific if patient wishes to self-administer medications.</p> | <p>Makes patient a participant in care, which minimizes anxiety.
Begins patient teaching regarding medications. Enables patient to self-administer drug, which increases feelings of independence.</p> |

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Prepare medications.</p> | |
| <p>a Perform hand hygiene.</p> | <p>Reduces transfer of microorganisms.</p> |
| <p>b Plan medication administration to avoid interruptions, keep door to medication room closed, do not take phone calls, limit conversation with colleagues for only essential information; follow agency “No Interruption Zone” policy.</p> | <p>Interruptions contribute to medication administration errors (Hall et al., 2010; Popescu et al., 2011).</p> |
| <p>c Arrange medication tray and cups in medication preparation area or move medication cart to position outside patient’s room.</p> | <p>Organization of equipment saves time and reduces error.</p> |
| <p>d Access automated dispensing system (ADS) or unlock medicine drawer or cart.</p> | <p>Medications are safeguarded when locked in cabinet, cart, or ADS.</p> |
| <p>e Prepare medications for one patient at a time. Follow the six rights of medication administration. Keep all pages of MARs or computer printouts for one patient together or look at only one patient’s medication administration computer screen.</p> | <p>Prevents preparation errors.</p> |
| <p>f Select correct medication from ADS, unit-dose drawer, or stock supply. Compare name of medication on label with MAR or computer printout (see illustration). Exit ADS after removing drug(s).</p> | <p>Reading label and comparing it against transcribed order reduces errors. Exiting ADS ensures that no one else can remove medications using your identity. <i>This is the first check for accuracy.</i></p> |
| <p>g Check or calculate drug dose as necessary. Double-check any calculation. Check expiration date on all medications and return outdated medication to pharmacy.</p> | <p>Double-checking pharmacy calculations reduces risk for error. Agency policy may require you to check calculations of certain medications such as insulin with another nurse. Expired medications may be inactive or harmful to patient.</p> |

STEP

RATIONALE

h If preparing a controlled substance, check record for previous medication count and compare current count with supply available. Controlled drugs may be stored in computerized locked cart (see Chapter 20).

Controlled substance laws require nurses to carefully monitor and count dispensed narcotics.

i Prepare solid forms of oral medications.

Wrappers maintain cleanliness and identify drug name and dose, which can facilitate teaching.

(1) To prepare unit-dose tablets or capsules, place packaged tablet or capsule directly into medication cup without removing wrapper. Administer medications only from containers with labels that are clearly marked.

Packs provide a 1-month supply, with each “blister” usually containing a single dose.

(2) When using a blister pack, “pop” medications through foil or paper backing into a medication cup.

In health care agencies, only pharmacy should split tablets to ensure patient safety (ISMP, 2008). Reduces contamination of tablet.

(3) If it is necessary to give half the dose of medication, pharmacy should split, label, package, and send medication to unit. If you must split medication, use clean, gloved hand to cut with clean pill-cutting device (see illustration). Only cut tablets that are prescored by the manufacturer (line transverses the center of the tablet).

Keeping medications that require preadministration assessments separate from others serves as reminder and makes it easier to withhold drugs as necessary.

(4) Place all tablets or capsules that patient will receive in one medicine cup, except for those requiring preadministration assessments (e.g., pulse rate or blood pressure). Place in separate additional cup with wrapper intact.

Large tablets are often difficult to swallow. Ground tablet mixed with palatable soft food is usually easier to swallow.

(5) If patient has difficulty swallowing and liquid medications are not an option, use a pill-crushing device. Clean device before using. Place medicine in between two cups, and grind and crush (see illustration). Mix ground tablet in small amount (teaspoon) of soft food (custard or applesauce).

j Prepare liquids.

Mixing liquid suspensions just before pouring ensures that correct amount of medication, not just the solvent, is measured for the dose.

(1) Thoroughly mix by shaking gently before administration. If drug is in unit-dose container with correct volume, shaking is not needed. If drug is in multidose bottle, remove bottle cap from container and place cap upside down on work surface.

Prevents contamination of inside of cap.

(2) Hold bottle with label against palm of hand while pouring.

Prevents spilled liquid from dripping and soiling label.

(3) Place medication cup at eye level on countertop and fill to desired level on scale. Scale should be even with fluid level at its surface or base of meniscus, not edges (see illustration).

Ensures accuracy of measurement.

STEP 1f Nurse compares label of medication with transcribed medication order on computerized MAR.

STEP 1i(3) Tablet is placed in pill-cutting device and cut in half.

STEP

RATIONALE

- | | |
|---|--|
| <p>(4) Discard any excess liquid into sink or a place specially designated for wasting of medications. Wipe lip of bottle with paper towel and recap.</p> <p>(5) If giving less than 10 mL of liquid, prepare medication in oral syringe (see illustration). Do not use hypodermic syringe or syringe with needle or syringe cap.</p> | <p>Prevents contamination of contents of bottle and prevents bottle cap from sticking.</p> <p>Allows more accurate measurement of small amounts.</p> |
|---|--|

Clinical Decision Point Only use syringes specifically designed for oral use when administering liquid medications. If using hypodermic syringes, the medication may be accidentally administered parenterally; or the syringe cap or needle, if not removed from the syringe before administration, may become dislodged and accidentally aspirated during administration of oral medications (ISMP, 2010).

- | | |
|--|---|
| <p>(6) Administer liquid medication packaged in single-dose cup directly from the single-dose cup. Do not pour into a medicine cup.</p> <p>k Before going to patient's room, compare patient's name and name of medication on label of prepared drugs with MAR.</p> <p>l Return stock containers or unused unit-dose medications to shelf or drawer. Label medication cups and poured medications with patient's name before leaving medication preparation area. Do not leave drugs unattended.</p> | <p>Avoids unnecessary manipulation of dose.</p> <p>Reading labels a second time reduces errors. <i>This is the second check for accuracy.</i></p> <p>Ensures that correct medications are prepared for correct patient.</p> |
|--|---|

STEP 1i(5) Crushing tablet with pill-crushing device.

STEP 1j(3) Measuring liquid medication. Look at meniscus at eye level.

STEP 1j(5) Use special oral medication syringes to prepare small amounts of liquid medications.

STEP

RATIONALE

2 Administer medications.

- a Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Given non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.
- b Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- c At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.
- d Perform necessary preadministration assessment (e.g., blood pressure, pulse) for specific medications. Ask patient if he or she has allergies.
- e Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about drugs.

Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

Some agencies are now using a bar-code system to help with patient identification.

This is the third check for accuracy and ensures that patient receives correct medication. Confirms patient's allergy history.

Determines whether specific medications should be withheld at that time. Confirms patient's allergy history.

Patient has right to be informed, and patient's understanding of purpose of each medication improves adherence to drug therapy.

Clinical Decision Point *If patient expresses concern regarding accuracy of a medication, do not give the medication. Explore patient's concern and verify prescriber's order before administering. Listening to patient's concerns may prevent a medication error.*

- f Help patient to sitting or Fowler's position. Use side-lying position if he or she is unable to sit. Have patient stay in this position for 30 minutes after administration.
- g *For tablets:* Patient may wish to hold solid medications in hand or cup before placing in mouth. Offer water or preferred liquid to help patient swallow medications.
- h *For orally disintegrating formulations (tablets or strips):* Remove medication from packet just before use. Do not push tablet through foil. Place medication on top of patient's tongue. Caution against chewing it.
- i *For sublingually administered medications:* Have patient place medication under tongue and allow it to dissolve completely (see illustration). Caution patient against swallowing tablet or saliva.

Decreases risk for aspiration during swallowing.

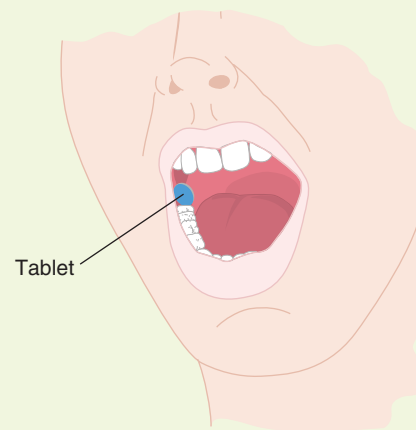

Patient can become familiar with medications by seeing each drug. Choice of fluid can improve fluid intake.

Orally disintegrating formulations begin to dissolve when placed on tongue. Water is not needed. Careful removal from packaging is necessary because tablets and strips are thin and fragile.

Drug is absorbed through blood vessels of undersurface of tongue. If swallowed, drug is destroyed by gastric juices or rapidly detoxified by liver, preventing therapeutic blood level.

STEP 2i Proper placement of sublingual tablet in sublingual pocket.

STEP 2j Buccal administration of tablet.

STEP	RATIONALE
<p>j For <i>buccal administered medications</i>: Have patient place medication in mouth against mucous membranes of cheek and gums until it dissolves (see illustration).</p>	<p>Buccal medications act locally or systemically as they are swallowed in saliva.</p>
<p>Clinical Decision Point <i>Avoid administering anything by mouth until orally disintegrating buccal or sublingual medication is completely dissolved.</i></p>	
<p>k For <i>powdered medications</i>: Mix with liquids at bedside and give to patient to drink.</p>	<p>When prepared in advance, powdered drugs thicken and some even harden, making swallowing difficult.</p>
<p>l For <i>crushed medications mixed with food</i>: Give each medication separately in teaspoon of food.</p>	<p>Ensures that patient swallows all of medicine.</p>
<p>m Caution patient against chewing or swallowing lozenges.</p>	<p>Lozenges act through slow absorption through oral mucosa, not gastric mucosa.</p>
<p>n Give effervescent powders and tablets immediately after dissolving.</p>	<p>Effervescence improves unpleasant taste and often relieves GI problems.</p>
<p>o If patient is unable to hold medications, place medication cup to lips and gently introduce each drug into mouth one at a time. A spoon can also be used to place pill in patient's mouth. Do not rush or force medications.</p>	<p>Administering a single tablet or capsule eases swallowing and decreases risk for aspiration.</p>
<p>Clinical Decision Point <i>If tablet or capsule falls to the floor, discard it and repeat preparation. Drug is contaminated.</i></p>	
<p>p Stay until patient swallows each medication completely or takes it by the prescribed route. Ask patient to open mouth if uncertain whether medication has been swallowed.</p>	<p>Ensures that patient receives ordered dose. If left unattended, patient may not take dose or may save drugs, causing health risks.</p>
<p>q For highly acidic medications (e.g., aspirin), offer patient a nonfat snack (e.g., crackers) if not contraindicated by his or her condition.</p>	<p>Reduces gastric irritation. Fat content of foods may delay drug absorption.</p>
<p>r Help patient return to position of comfort.</p>	<p>Maintains patient's comfort.</p>
<p>s Dispose of soiled supplies and perform hand hygiene. Return cart to medication room if used. Clean work area.</p>	<p>Reduces spread of microorganisms.</p>

EVALUATION

- | | |
|---|--|
| <p>1 Return within an appropriate time to evaluate patient's response to medications, including therapeutic effects, side effects or allergy, and adverse reactions.</p> | <p>Evaluates therapeutic benefit of drug and helps to detect onset of side effects or allergic reactions. Sublingual medications act in 15 minutes; most oral medications act in 30 to 60 minutes.</p> |
| <p>2 Ask patient or family caregiver to identify drug name and explain purpose, action, dose schedule, and potential side effects.</p> | <p>Determines level of knowledge gained by patient and family.</p> |

Unexpected Outcomes

- Patient exhibits adverse effects (e.g., side effect, toxic effect, allergic reaction).
- Patient is unable to explain drug information.
- Patient refuses medication.

Related Interventions

- Withhold further doses.
- Assess vital signs.
- Notify health care provider and pharmacy.
- Symptoms such as urticaria, rash, pruritus, rhinitis, and wheezing may indicate an allergic reaction and need for emergency medications.
- Add allergy information to patient's medical record.
- Further assess patient's or family caregiver's knowledge of medications and guidelines for drug safety.
- Further instruction or different approach to instruction is necessary.
- Assess why patient is refusing medication.
- Do not force patient to take medications.
- Notify health care provider.
- Record refused medication and patient's stated reason.

Recording and Reporting

- Record drug, dose, route, and time administered on patient's MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurses' notes and electronic health record (EHR).
- If drug is withheld, record reason in nurses' notes and EHR and follow agency policy for noting withheld doses.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider. Depending on medication, immediate health care provider notification may be required.

Special Considerations

Teaching

- Instruct patient and family caregiver about specific information pertaining to drug regimen (purpose, action, dose, dosage intervals, side effects, foods to avoid or take with drugs).
- All patients should learn the basic guidelines for drug safety in the home (see Skill 42-6).

Pediatric

- Liquid forms of medication are safer to swallow to avoid aspiration of small pills.
- Children refuse bitter or distasteful oral preparations. Mix the drug with a small amount (about 1 teaspoon) of a sweet-tasting substance such as jam, applesauce, sherbet, ice cream, or fruit puree. Do not use honey for infants because of the risk of botulism. Offer the child juice or a flavored ice pop after medication administration. Do not place medication in an essential food

item such as milk or formula; the child may refuse the food at a later time.

- Measure small amount of liquid medications using a plastic calibrated oral dosing syringe or a hollow-handled medicine spoon. Amounts less than a teaspoon are impossible to measure accurately with a molded medicine cup (Hockenberry and Wilson, 2011).

Gerontologic

- Physiologic changes of aging influence how oral medications are distributed, absorbed, and excreted. Common changes include loss of elasticity in oral mucosa; reduction in parotid gland secretion, causing dry mouth; delayed esophageal clearance, impaired swallowing; reduction in gastric acidity and stomach peristalsis, increased susceptibility to highly acidic drugs; reduced liver function, resulting in altered drug metabolism; and reduced renal function and colon motility, slowing drug excretion. Both altered drug metabolism and excretion may lead to drug toxicity (Lehne, 2010).
- Give medications with a full glass of water (unless restricted) to aid passage of the drug. Give patient time to swallow.
- Patients may have several health problems or chronic conditions requiring the use of multiple drugs, often prescribed by different health care providers. Polypharmacy creates a high risk for drug interactions and adverse reactions (Lehne, 2010).

Home Care

- When measuring liquid medications at home, patients should use measuring spoons, not eating utensil spoons that vary in volume.
- See Skills 41-3, Medication and Medical Device Safety, and Skill 42-6, Teaching Medication Self-Administration.

SKILL 21-2 Administering Medications Through an Enteral Feeding Tube

NSO Enteral Nutrition Module / Lesson 5

Patients who have enteral feeding tubes are unable to receive food or medications by mouth. Nasogastric feeding tubes generally are small-bore tubes that are inserted into the stomach via one of the nares (see Chapter 31). For long-term enteral feedings, a percutaneous endoscopic gastrostomy (PEG) tube or a jejunostomy tube may be inserted surgically. Do not administer medications into nasogastric tubes that are inserted for decompression.

Preferably medications administered by enteral tubes should be in liquid form. If a medication is not available in liquid, you will need to prepare an oral medication tablet or capsule by crushing or dissolving it. However, you cannot crush sublingual, sustained-release, chewable, long-acting, or enteric-coated medications. Consult with the hospital pharmacist about whether you can crush or dissolve a medication. Always verify correct placement of a nasogastric tube before administering medications (see Skill 31-2).

Delegation and Collaboration

The skill of administering medications by enteral feeding tubes cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Keep the patient's head of the bed elevated a minimum of 30 degrees (preferably 45 degrees) for 1 hour (follow agency policy) after medication administration.
- Report immediately to the nurse signs of aspiration such as coughing, choking, gagging, or drooling of liquid or dissolved pills.

Equipment

- Medication administration record (MAR) (electronic or printed)
- 60-mL syringe, catheter tip for large-bore tubes, Luer-Lok tip for small-bore tubes
- Gastric pH test strip (scale of 0 to 11.0)
- Graduated container
- Medication to be administered
- Pill crusher if medication in tablet form
- Water
- Tongue blade or straw to stir dissolved medication
- Clean gloves
- Stethoscope (for evaluation)

STEP

RATIONALE

ASSESSMENT

1 Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name, drug name and dosage, route of administration, and time for administration. Clarify incomplete or unclear orders with health care provider before administration.	The health care provider's order is the most reliable source and only legal record of drugs that patient is to receive. Ensures that patient receives correct medication. Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).
2 Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.	Allows you to anticipate effects of drug and observe patient's response.
3 Assess for any contraindications to receiving medications enterally, including presence of bowel inflammation, reduced peristalsis, recent gastrointestinal (GI) surgery, and gastric suction that cannot be turned off.	Alterations in GI function can interfere with drug absorption, distribution, and excretion. Patients with GI suction do not benefit from medication because it may be suctioned from the GI track before it is absorbed.
4 Assess patient's medical history, history of allergies, medication history, and diet history. If you identify contraindications, withhold medication and inform health care provider.	History reveals past problems with medication tolerance and response. Historical data allows you to anticipate how certain drugs act.
5 For postoperative patient, review postoperative orders for type of enteral tube care.	Manipulation and irrigation of tube or instillation of medications may be contraindicated.
6 Gather and review physical assessment data (e.g., bowel sounds, abdominal distention) and laboratory data (e.g., renal and liver function) that may influence drug administration.	Physical examination findings or laboratory data may contraindicate drug administration.
7 Assess for potential drug-food interactions.	Some drugs may require tube feeding to be stopped for an hour before and 2 hours after dose (Lehne, 2010).
8 Check with pharmacy for availability of liquid preparation for patient's medications. Prescriber may need to change dosage form.	
9 Before administration of medications verify placement of feeding tube (see Skill 31-2).	Reduces risk for aspiration.

NURSING DIAGNOSES

- Feeding self-care deficit
- Impaired swallowing
- Risk for aspiration

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient experiences desired medication effect within period of onset of medication. • Patient's feeding tube remains patent after administration of medication. • Patient does not aspirate during or after medication administration. 	Drug has exerted its therapeutic action. Patent enteral tube indicates passage of medication into stomach, ensuring proper absorption. If tube becomes blocked, administration of other medications and feedings will not be possible. Patient safety in medication administration is maintained.
2 Explain procedure to patient, including description of medication to be instilled into enteric tube.	Helps patient be a participant in care, which minimizes anxiety. Begins patient teaching regarding medications.

IMPLEMENTATION

1 Determine if medication interacts with enteral feeding. If interaction occurs, hold feeding for 30 minutes before medication administration (see agency policy or consult with pharmacist).	Facilitates absorption of medication (Phillips and Endacott, 2011).
2 Perform hand hygiene. Prepare medications for instillation into feeding tube (see Skill 21-1). Check medication label against MAR 2 times. Fill graduated container with 50 to 100 mL of tepid water. Use sterile water for immunocompromised or critically ill patients (Bankhead et al., 2009).	<i>These are the first and second checks for accuracy.</i> Preparation process ensures that right patient receives right medication. Tepid water prevents abdominal cramping, which can occur with cold water.

STEP

RATIONALE

Clinical Decision Point Whenever possible, use liquid medications instead of crushed tablets; but, if you have to crush tablets, the tubing must be flushed before and after the medication to prevent the drug from adhering to the inside of the tube. In addition, make sure that concentrated medications are thoroughly diluted. Never add crushed medications directly to a tube feeding (Phillips and Endacott, 2011).

- | | |
|--|--|
| <p>a <i>Tablets</i>: Crush each tablet into a fine powder, using pill-crushing device or two medication cups (see Skill 21-1). Dissolve each tablet in separate cup of 30 mL of warm water.</p> <p>b <i>Capsules</i>: Ensure that contents of capsule (granules or gelatin) can be expressed from covering (consult with pharmacist). Open capsule or pierce gel cap with sterile needle and empty contents into 30 mL of warm water (or solution designated by drug company). Gel caps dissolve in warm water, but this may take 15 to 20 minutes.</p> <p>c Prepare liquid medication according to Skill 21-1.</p> | <p>Fine powder dissolves more easily, reducing chance of occluding feeding tube.</p> <p>Ensures that contents of capsules are in solution to prevent occlusion of tube.</p> |
| <p>3 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.</p> | <p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).</p> |
| <p>4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). Some agencies are now using a bar-code system to help with patient identification.</p> |
| <p>5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.</p> | <p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p> |
| <p>6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the drugs.</p> | <p>Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy.</p> |
| <p>7 Elevate head of bed to minimum of 30 degrees and preferably 45 degrees (unless contraindicated) or sit patient up in a chair (Bankhead et al., 2009).</p> | <p>Reduces risk for aspiration, keeping head above stomach.</p> |
| <p>8 If continuous enteral tube feeding is infusing, adjust infusion pump to hold tube feeding.</p> | <p>Feeding solution should not infuse while residuals are checked or medications are administered.</p> |
| <p>9 Apply clean gloves. Check placement of feeding tube (see Skill 31-2) by observing gastric contents and checking pH of aspirate contents. <i>Gastric pH for a patient who has fasted for 4 hours is usually 1.0 to 4.0.</i></p> | <p>Ensures proper tube placement and reduces risk of introducing fluids into respiratory tract.</p> |
| <p>10 Check for gastric residual volume (GRV). Draw up 10 to 30 mL of air into a 60-mL syringe and connect syringe to feeding tube. Flush tube with air and pull back slowly to aspirate gastric contents (see illustration). Determine GRV using either scale on syringe or a graduate container. Return aspirated contents to stomach unless a single GRV exceeds 500 mL or if two measurements taken 1 hour apart each exceed 250 mL (Bankhead et al., 2009) (check agency policy). When GRV is excessive, hold medication and contact health care provider.</p> | <p>GRV categories have been identified in studies as significant when patients have two or more GRVs of at least 250 mL or one or more GRVs exceeding 500 mL (Bankhead et al., 2009). Large residuals indicate delayed gastric emptying and put patient at increased risk for aspiration (Metheney et al., 2010).</p> |

STEP

RATIONALE

- 11 Irrigate the tubing.
 - a Pinch or clamp enteral tube and remove syringe. Draw up 30 mL of water into syringe. Reinsert tip of syringe into tube, release clamp, and flush tubing. Clamp tube again and remove syringe.
 - b Some enteral tubes are connected to continuous-feeding tubing with stopcock apparatus such as a Lopez valve that contains a medication port (see illustration). Attach tip of syringe to medication port on stopcock; turn “off” setting of stopcock away from patient and toward infusion tubing. Flush tube and set stopcock “off” again to medication port. Remove syringe.
- 12 Remove bulb or plunger of syringe and reinsert syringe into tip of feeding tube.
- 13 Administer first dose of liquid or dissolved medication by pouring into syringe (see illustration). Allow to flow by gravity.

Pinching or clamping tubing prevents leakage or spillage of stomach contents. Flushing ensures that tube is patent.

Removal of bulb or plunger prepares syringe for delivery of medications.

Clinical Decision Point *If medication does not flow freely, raise the height of the syringe to increase the rate of flow or try having the patient change position slightly because the end of the feeding tube may be against the gastric mucosa. If these measures do not improve the flow, a gentle push with bulb of Asepto syringe or plunger of the syringe may facilitate flow of fluid.*

STEP 10 Aspirate stomach contents for residual volume.

STEP 11b Lopez valve with medication port. (Courtesy ICU Medical, Inc, San Clemente, Calif.)

STEP 13 Pour liquid medication into syringe.

STEP	RATIONALE
<p>a If giving only one dose of medication, flush with 30 mL of water after administration.</p> <p>b To administer more than one medication, give each separately and flush between medications with 15 to 30 mL of water.</p> <p>c Follow last dose of medication with 30 to 60 mL of water.</p>	<p>Maintains patency of enteral tube and ensures that medication passes through tube to stomach.</p> <p>Allows for accurate identification of medication if dose is spilled. In addition, some medications may be incompatible (Boullata, 2009).</p> <p>Maintains patency of enteral tube and ensures passage of medication into stomach (Boullata, 2009).</p>
14 Clamp proximal end of feeding tube if tube feeding is not being administered and cap end of tube.	Prevents air from entering stomach between medication doses.
15 When continuous tube feeding is being administered by infusion pump, follow medication administration Steps 1 to 13. If medications are not compatible with feeding solution, hold feeding for additional 30 to 60 minutes.	Allows for adequate absorption of medication and avoids potential drug-food interaction between medication and enteral feeding.
16 Help patient to comfortable position and keep head of bed elevated for 1 hour (see agency policy).	Reduces risk of aspiration.
17 Dispose of soiled supplies, rinse graduated container and syringe with tap water, remove and dispose of gloves, and perform hand hygiene.	Reduces spread of microorganisms.

EVALUATION

1 Return within 30 minutes to evaluate patient's response to medications.	Monitoring patient's response evaluates therapeutic benefit of drug and helps detect onset of side effects or allergic reactions.
--	---

Unexpected Outcomes

- 1 Patient exhibits signs of aspiration, including respiratory distress, changes in vital signs, or changes in oxygen saturation.
- 2 Patient does not receive medication because of blocked enteral tube.
- 3 Patient exhibits adverse effects (side effect, toxic effect, allergic reaction).

Related Interventions

- Stop all medications/fluids through feeding tube.
- Elevate head of bed and stay with patient.
- Assess vital signs and breath sounds while another staff member notifies health care provider.
- For newly inserted tube, notify health care provider and obtain x-ray film confirmation of placement.
- Requires interventions to unclog tube to ensure drug delivery (Box 21-2).
- Withhold further doses.
- Always notify health care provider and pharmacy when patient exhibits adverse effects.
- Symptoms such as urticaria, rash, pruritus, rhinitis, and wheezing indicate allergic reaction.
- Enter patient allergy in medical record.

BOX 21-2 Unclogging a Blocked Feeding Tube

- Prevent tube from becoming blocked by flushing it with at least 15 to 30 mL of tepid water before and after administering each dose of medication, 30 to 60 mL after last dose of medication, before and after checking gastric residual volumes, and every 4 to 12 hours around-the-clock (refer to agency policies) (Bankhead et al., 2009).
- Gently flush tube with large-bore syringe and warm water. Do not use small-bore syringe because this exerts too much pressure and may rupture tube.
- If irrigation with water is not effective, obtain an order for a pancrelipase tablet (e.g., Viokase) and follow manufacturer guidelines for tube irrigation. In addition, a declogging stylus may be used (see agency policy).
- The tube may have to be removed, and a new one inserted if the medication is urgent.

Modified from Williams N: Medication administration through enteral feeding tubes: obstructed feeding tubes, *Am J Health System Pharmacy* 65(23):2347, 2008.

Recording and Reporting

- Record in nurses' notes and EHR the method used to check placement of enteral tube, GRV, and pH of stomach aspirate. Record actual time that each drug was administered on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurses' notes and EHR.
- Record total amount of water used for medication administration on proper intake and output (I&O) form.
- Report adverse effects, patient response, and/or withheld drugs to nurse in charge or health care provider.

Special Considerations

Teaching

- Teach patient or family caregiver how to store medications and tube-feeding supplements (see Chapter 31).
- Teach patient or family caregiver how to verify correct placement of tube before medication or tube feeding administration.

- Demonstrate to family caregiver how to prepare medications, including crushing them if appropriate.
- Teach family caregiver the importance of consistent flushing of feeding tube following medication administration.

Pediatric

- Volumes for instillation of medications or for irrigation of enteral tubes should be small enough to clear tubing (Hockenberry and Wilson, 2011; Williams, 2008).

SKILL 21-3 Applying Topical Medications to the Skin

NSO Nonparenteral Medication Administration Module / Lesson 2

Topical administration of medication involves applying drugs locally to the skin, mucous membranes, or tissues. Topical drugs such as lotions, patches, pastes, and ointments primarily produce local effects; but they can create systemic effects if absorbed through the skin. Systemic effects are more likely to occur if the skin is thin, drug concentration is high, contact with the skin is prolonged, or the drug is applied to skin that is not intact. To protect from accidental exposure, apply topical drugs using gloves and applicators. Skin encrustations and dead tissue harbor microorganisms and block contact of medications with the affected tissue or membrane. Applying new medication over a previously applied medication does little to prevent infection or provide therapeutic benefit to a patient. Always clean the skin or wound thoroughly before applying a new dose of a topical medication. Apply each type of medication, whether an ointment, lotion, powder, or patch, in a specific way to ensure proper penetration and absorption.

Delegation and Collaboration

The skill of administering topical medications cannot be delegated to nursing assistive personnel (NAP). However, some agencies

Video Clip

(e.g., long-term care) may allow NAP to apply some forms of topical agents (e.g., skin barriers) to irritated skin or for the protection of the perineum during morning or perineal care. Check agency policies. The nurse directs the NAP about:

- The expected therapeutic effects and potential side effects to report to the nurse.

Equipment

- Clean gloves (for intact skin) or sterile gloves (for nonintact skin)
- Option: Cotton-tipped applicators or tongue blades
- Ordered medication (powder, cream, lotion, ointment, spray, patch)
- Basin of warm water, washcloth, towel, nondrying soap
- Option: Sterile dressing, tape
- Felt-tip pen
- Medication administration record (MAR) (electronic or printed)
- Option: Plastic wrap, transparent dressing

STEP

RATIONALE

ASSESSMENT

- 1 Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name, drug name and dosage, route of administration, and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
- 2 Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
- 3 Assess condition of skin or membrane where medication is to be applied (see Chapter 6). If there is an open wound, perform hand hygiene and apply clean gloves. First wash site thoroughly with mild, nondrying soap and warm water, rinse, and dry. Be sure to remove any previously applied medication or debris. Also remove any blood, body fluids, secretions, or excretions. Assess for symptoms of skin irritation such as pruritus or burning. Remove gloves when finished.
- 4 Assess patient's medical history, history of allergies (including latex and topical agent), and medication history. Ask if patient has had reaction to a cream or lotion applied to skin.
- 5 Determine amount of topical agent required for application by assessing skin site, reviewing health care provider's order, and reading application directions carefully (a thin, even layer is usually adequate).

The health care provider's order is the most reliable source and only legal record of drugs that patient is to receive. Ensures that patient receives correct medication. Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).

Allows you to anticipate effects of drug and observe patient's response.

Cleaning site thoroughly promotes proper assessment of skin surface. Assessment provides baseline to determine change in condition of skin after therapy. Application of certain topical agents can lessen or aggravate these symptoms.

Allergic contact dermatitis is relatively common and can worsen dermatologic (skin) condition. In addition, some patients may be allergic to preservatives or fragrances in topical medications. Latex allergy requires use of nonlatex gloves.

An excessive amount of topical agent can chemically irritate skin, negate effectiveness of drug, and/or cause adverse systemic effects such as decreased white blood cell (WBC) counts.

STEP	RATIONALE
6 Assess patient's knowledge of action and purpose of medication being given, application schedule, and willingness to adhere to drug regimen.	Reveals patient's level of understanding and whether instruction is necessary.
7 Determine if patient or family caregiver is physically able to apply medication by assessing grasp, hand strength, reach, and coordination.	Necessary if patient is to self-administer drug at home.

NURSING DIAGNOSES

- | | | |
|---|---|---|
| <ul style="list-style-type: none"> Deficient knowledge regarding medication application Impaired skin integrity | <ul style="list-style-type: none"> Pain (acute or chronic) Impaired physical mobility | <ul style="list-style-type: none"> Readiness for enhanced self-health management Risk for infection |
|---|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> Patient is able to identify drug and describe action, purpose, dose, side effects, and schedule of medication. Patient is able to apply medication without assistance on prescribed schedule. With repeated applications, skin becomes clear, without inflammation or drainage from lesions. 	<p>Demonstrates learning.</p> <p>Demonstrates learning and compliance.</p> <p>Existing lesions heal and/or disappear as result of therapeutic action of medication.</p>
---	---

IMPLEMENTATION

1 Prepare medications for application. Check label of medication against MAR 2 times (see Skill 22-1). Preparation usually involves taking bottle or tube of lotion, cream, ointment, or patch out of storage and to patient room. Check expiration date on container.	<i>These are the first and second checks for accuracy.</i> Process ensures that right patient receives right medication.
2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.	Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).
3 Perform hand hygiene. Help patient to comfortable position.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.	Some agencies are now using a bar-code system to help with patient identification.
5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.	<i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.
6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the drugs.	Patient has the right to be informed, and patient's understanding of each medication improves adherence to drug therapy.
7 If skin is broken, apply sterile gloves. Otherwise apply clean gloves.	Reduces spread of microorganisms.
8 Apply topical creams, ointments, and oil-based lotions.	
a Expose affected area while keeping unaffected areas covered.	Provides visualization for application and protects privacy.
b Wash, rinse, and dry affected area before applying medication (see Assessment, Step 3).	Cleaning removes microorganisms from remaining debris.

STEP

RATIONALE

- c If skin is excessively dry and flaking, apply topical agent while skin is still damp.
 - d Remove gloves, perform hand hygiene, and apply new clean or sterile gloves.
 - e Place required amount of medication in palm of gloved hand and soften by rubbing briskly between hands.
 - f Tell patient that initial application of agent may feel cold. Once medication is softened, spread it evenly over skin surface, using long, even strokes that follow direction of hair growth. Do not vigorously rub skin. Apply to thickness specified by manufacturer instructions.
 - g Explain to patient that skin may feel greasy after application.
- 9 Apply antianginal (nitroglycerin) ointment.**
- a Remove previous dose paper. Fold used paper containing any residual medication with used sides together and dispose of it in biohazard trash container. Wipe off residual medication with tissue.
 - b Write date, time, and nurse's initials on new application paper.
 - c Antianginal (nitroglycerin) ointments are usually ordered in inches and can be measured on small sheets of paper marked off in 1.25 cm (½-inch) markings. Unit-dose packages are available. Apply desired number of inches of ointment to paper-measuring guide (see illustration).

- Retains moisture within skin layers.
- Sterile gloves are used when applying agents to open, noninfectious skin lesions. Changing gloves prevents cross-contamination of infected or contagious lesions and protects you from drug effects. Softening topical agent makes it easier to spread on skin.
- Ensures even distribution and sufficient dosage of medication. Technique prevents irritation of hair follicles.
- Ointments often contain oils.
- Prevents overdose that can occur with multiple-dose papers left in place. Proper disposal protects others from accidental exposure to medication.
- Label provides reference to prevent missing doses.
- Ensures correct dose of medication.

Clinical Decision Point Unit-dose packages are available. *NOTE: One package equals 2.5 cm (1 inch); smaller amounts should not be measured from this package.*

- d Select application site: Apply nitroglycerin to chest area, back, abdomen, or anterior thigh (Lehne, 2010). Do not apply on hairy surfaces or over scar tissue.
 - e Be sure to rotate application sites.
 - f Apply ointment to skin surface by holding edge or back of paper-measuring guide and placing ointment and wrapper directly on skin (see illustration). Do not rub or massage ointment into skin.
 - g Secure ointment and paper with transparent dressing or strip of tape. Plastic wrap may be used as occlusive dressing.
- 10 Apply transdermal patches (e.g., analgesic, nicotine, nitroglycerin, estrogen).**
- a If old patch is present, remove it and clean area. Be sure to check between skinfolds for patch.

- Application on hairy surfaces or scar tissue may interfere with absorption.
- Minimizes skin irritation.
- Minimizes chance of ointment covering gloves and later touching nurse's hands. Medication is designed to absorb slowly over several hours; massaging increases absorption rate.
- Prevents staining of clothing or inadvertent removal of medication.
- Failure to remove old patch can result in overdose. Many patches are small, clear, or flesh colored and can be easily hidden between skinfolds. Cleaning removes traces of previous patch.

STEP 9c Ointment spread in inches over measuring guide.

STEP 9f Nurse applies wrapper with medication to patient's skin.

STEP	RATIONALE
<ul style="list-style-type: none"> b Dispose of old patch by folding in half with sticky sides together. Some agencies require patch to be cut before disposal (see agency policy). Dispose of it in biohazard trash bag. c Date and initial outer side of new patch before applying it and note time of administration. Use soft-tip or felt-tip pen. d Choose a new site that is clean, dry, and free of hair. Some patches have specific instructions for placement locations (e.g., Testoderm patches are placed on scrotum; a scopolamine patch is placed behind the ear; never apply an estrogen patch to breast tissue or waistline). Do not apply patch on skin that is oily, burned, cut, or irritated in any way. 	<p>Proper disposal prevents accidental exposure to medication.</p> <p>Visual reminder prevents missing or extra doses. Ballpoint pen damages patch and alters medication delivery. Ensures complete medication absorption.</p>
<p>Clinical Decision Point <i>Never apply heat such as with a heating pad over a transdermal patch because this results in an increased rate of absorption with potentially serious adverse effects.</i></p>	
<ul style="list-style-type: none"> e Carefully remove patch from its protective covering by pulling off liner. Hold patch by edge without touching adhesive edges. f Apply patch. Hold palm of one hand firmly over patch for 10 seconds. Make sure that it sticks well, especially around edges. Apply overlay if provided with patch. g Do not apply patch to previously used sites for at least 1 week. h Instruct patient that transdermal patches are never to be cut in half; a change in dose would require prescription for new strength of transdermal medication. 	<p>Touching only edges ensures that patch will adhere and that medication dose has not changed. Removing protective covering allows medication to be absorbed through skin.</p> <p>Adequate adhesion prevents loss of patch, which results in decreased dose and effectiveness.</p> <p>Rotation of site reduces skin irritation from medication and adhesive.</p> <p>Cutting transdermal patch in half would alter intended medication delivery of transdermal system, resulting in inadequate or altered drug levels.</p>
<p>Clinical Decision Point <i>It is recommended to have a daily “patch free” interval of 10 to 12 hours because tolerance develops if patches are used 24 hours a day every day (Lehne, 2010). Apply a new patch each morning, leave in place for 12 to 14 hours, and remove in the evening.</i></p>	
<ul style="list-style-type: none"> i Instruct patient to always remove old patch before applying new one. Patients should not use alternative forms of medication when using patches. For example, patients should not apply nitroglycerin ointment in addition to patch unless specifically ordered to do so by their health care provider. 	<p>Use of patch with additional or alternative drug preparation can result in toxicity or other side effects.</p>
<p>11 Administer aerosol sprays (e.g., local anesthetic sprays).</p>	
<ul style="list-style-type: none"> a Shake container vigorously. Read container label for distance recommended to hold spray away from area, usually 15 to 30 cm (6 to 12 inches). b Ask patient to turn face away from spray or briefly cover face with towel while spraying neck or chest. c Spray medication evenly over affected site (in some cases, time the spray for a period of seconds). 	<p>Mixing ensures delivery of fine, even spray. Proper distance ensures that fine spray hits skin surface. Holding container too close results in thin, watery distribution.</p> <p>Prevents inhalation of spray.</p> <p>Ensures that affected area of skin is covered with thin spray.</p>
<p>12 Apply suspension-based lotion.</p>	
<ul style="list-style-type: none"> a Shake container vigorously. b Apply small amount of lotion to small gauze dressing or pad and apply to skin by stroking evenly in direction of hair growth. c Explain to patient that area will feel cool and dry. 	<p>Mixes powder throughout liquid to form well-mixed suspension. Method of application leaves protective film of powder on skin after water base of suspension dries. Technique prevents irritation to hair follicles.</p> <p>Water evaporates to leave thin layer of powder.</p>
<p>13 Apply powder.</p>	
<ul style="list-style-type: none"> a Be sure that skin surface is thoroughly dry. With your nondominant hand, fully spread apart any skinfolds such as between toes or under axilla and dry with towel. b If area of application is near face, ask patient to turn face away from powder or briefly cover face with towel. c Dust skin site lightly with dispenser so area is covered with fine, thin layer of powder. <i>Option:</i> Cover skin area with dressing if ordered by health care provider. 	<p>Minimizes caking and crusting of powder. Fully exposes skin surface for application.</p> <p>Prevents inhalation of powder.</p> <p>Thin layer of powder has slight lubricating properties to reduce friction and promote drying (Lilley et al., 2011).</p>

STEP

RATIONALE

- | | |
|--|---|
| <p>14 Help patient to comfortable position, reapply gown, and cover with bed linen as desired.</p> <p>15 Dispose of soiled supplies in receptacle especially designated for such articles, remove and dispose of gloves, and perform hand hygiene.</p> | <p>Provides for patient's sense of well-being.</p> <p>Keeps patient's environment neat and reduces spread of infection and residual medication to others.</p> |
|--|---|

EVALUATION

- | | |
|---|--|
| <p>1 Ask patient or family caregiver to name the medication and its action, purpose, dose, schedule, and side effects.</p> <p>2 Have patient keep diary of doses taken.</p> <p>3 Observe patient or family caregiver apply topical medication.</p> <p>4 Inspect condition of skin between applications.</p> | <p>Evaluates learning.</p> <p>Confirms adherence to prescribed therapy.</p> <p>Return demonstration measures learning.</p> <p>Determines if skin condition improves.</p> |
|---|--|

Unexpected Outcomes

- 1 Skin site appears inflamed and edematous with blistering and oozing of fluid from lesions. These signs indicate subacute inflammation or eczema that can develop if skin lesions are getting worse.
- 2 Patient is unable to explain information about drug or does not administer as prescribed.

Related Interventions

- Hold medication
- Notify health care provider; alternative therapies may be needed.
- Identify possible reasons for noncompliance and explore alternative approaches or options.

Recording and Reporting

- Record actual time each drug that was administered, type of agent applied, strength, and site of application in nurses' notes/EHR and on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurses' notes. If you withhold a drug, record reason in nurses' notes and follow agency policy for noting withheld doses.
- Describe condition of skin before each application in nurses' notes and EHR.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider. Depending on medication, immediate health care provider notification may be required.

- Teach patient how to manage a transdermal patch that begins to peel off before the next dose is due. Rather than tape the patch or cover it, instruct patient to remove it, clean the skin, and apply a new patch to a different area (Ball and Smith, 2008).

Gerontologic

- Changes in the skin of an older adult patient include increased wrinkling, dryness, flaking, and increased tendency to bruise. Be aware of these changes when applying topical medications to ensure proper application. Older skin is often more fragile and must be handled gently when applying topical medications.

Home Care

- Instruct patient to wrap applicators, used patches, and similar materials and dispose of them into cardboard or plastic disposable containers. Careful disposal is necessary to ensure the safety of patient, other adults, pets, and children.

Special Considerations

Teaching

- If skin is inflamed, instruct patients to use only warm water rinse without soap for cleaning.

SKILL 21-4 Instilling Eye and Ear Medications

NSO Nonparenteral Medication Administration Module / Lesson 3

lens; but the disk is placed in the conjunctival sac, not on the cornea, and it remains in place for up to 1 week.

Common eye (ophthalmic) medications are in the form of drops and ointments, including over-the-counter preparations such as artificial tears and vasoconstrictors (e.g., Visine® and Murine®). However, many patients receive prescribed ophthalmic drugs for eye conditions such as glaucoma, infection, and following cataract extraction. In addition, there is a third type of delivery system, the intraocular disk. Medications delivered by disk resemble a contact

The eye is the most sensitive organ to which you apply medications. The cornea is richly supplied with sensitive nerve fibers. Care must be taken to prevent instilling medication directly onto the cornea. The conjunctival sac is much less sensitive and thus a more appropriate site for medication instillation.

Any patient receiving topical eye medications should learn correct self-administration of the medication, especially patients with glaucoma, who must often undergo lifelong medication administration for control of their disease. You can easily instruct patients while administering medications. Family caregivers often administer eye medications when patients are unable to manipulate applicators (e.g., arthritis or neurologic condition), immediately after eye surgery, and when a patient's vision is so impaired that it is difficult to assemble needed supplies and handle applicators correctly.

Ear (otic) medications are usually in a solution and instilled by drops. When administering ear medications, be aware of certain safety precautions. Internal ear structures are very sensitive to temperature extremes; administer eardrops at room temperature. Instilling cold drops can cause vertigo (severe dizziness) or nausea and debilitate a patient for several minutes. Although structures of the outer ear are not sterile, use sterile drops and solutions in case the eardrum is ruptured. A final safety precaution is to avoid forcing any solution into the ear. Do not occlude the ear canal with a medicine dropper because this can cause pressure within the canal during instillation and subsequent injury to the eardrum. If you follow these precautions, instillation of eardrops is a safe and effective therapy.

Delegation and Collaboration

The skill of administering eyedrop/eardrops cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and to report their occurrence.
- The potential for temporary visual impairment or hearing changes after administration of eye medications.

Equipment

- Appropriate medication (eyedrops with sterile eyedropper, ointment tube, medicated intraocular disk, or eardrops)
- Clean gloves
- Medication administration record (MAR) (electronic or printed)

Eyedrops/Ointment

- Cotton ball or tissue
- Washbasin filled with warm water and washcloth
- Eye patch and tape (*optional*)

Eardrops

- Cotton-tipped applicator, cotton balls

STEP

RATIONALE

ASSESSMENT

- 1 Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name, drug name and dosage, route (eye [s] or ear [s]), and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
- 2 Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
- 3 Assess condition of external eye or ear structures (see [Chapter 6](#)). This may be done just before drug instillation (if drainage is present, apply clean gloves).
- 4 Determine whether patient has any symptoms of eye or ear discomfort or visual or hearing impairment.
- 5 Assess patient's medical history, history of allergies (including latex), and medication history.
- 6 Assess patient's level of consciousness (LOC) and ability to follow directions.
- 7 Assess patient's knowledge regarding drug therapy and desire to self-administer medication.
- 8 Assess patient's ability to manipulate and hold dropper or ocular disk.

The health care provider's order is the most reliable source and only legal record of drugs that patient is to receive. Ensures that patient receives correct medication. Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).

Allows you to anticipate effects of drug and observe patient's response.

Provides baseline to determine if local response to medications occurs. Also indicates need to clean eye before drug application.

Certain eye medications act to either lessen or increase these symptoms. Occlusion of external ear canal by swelling, drainage, or cerumen can impair hearing acuity and cause pain.

Factors influence how certain drugs act. Reveals patient's need for medication.

If patient becomes restless or combative during procedure, greater risk for accidental eye injury exists.

Indicates need for health teaching. Motivation influences teaching approach.

Reflects patient's ability to learn to self-administer drug.

NURSING DIAGNOSES

- Deficient knowledge regarding drug and self-administration
- Readiness for enhanced self-health management
- Pain (acute or chronic)
- Impaired physical mobility
- Risk for injury

Related factors are individualized based on patient's condition or needs.

STEP

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient experiences desired effect of medication. • Patient denies discomfort. • Patient experiences no side effects, and symptoms (e.g., irritation) are relieved. • Patient is able to discuss information about medication and technique correctly. • Patient demonstrates self-instillation of eyedrops. <p>2 Explain procedure to patient.</p> | <p>Drug is administered correctly without injury to patient.
Drug is administered correctly without injury to patient.
Drug is distributed and absorbed properly.</p> <p>Demonstrates learning.</p> <p>Demonstrates learning.</p> <p>Relieves anxiety and promotes patient participation.</p> |
|---|---|

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Prepare medications for instillation. Check label of medication against MAR 2 times (see Skill 22-1). Preparation usually involves taking eyedrops/eardrops out of refrigerator and rewarming to room temperature before administering to patient. Check expiration date on container.</p> <p>2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.</p> <p>3 Perform hand hygiene and arrange supplies at bedside.</p> <p>4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> <p>5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.</p> <p>6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the drugs. Patients who self-instill medications may be allowed to give drops under nurse's supervision (check agency policy). Tell patients receiving eyedrops (mydriatics) that vision will be blurred temporarily and sensitivity to light may occur.</p> <p>7 Instill eye medications.</p> <p>a Apply clean gloves. Ask patient to lie supine or sit back in chair with head slightly hyperextended, looking up.</p> | <p><i>These are the first and second checks for accuracy.</i> Process ensures that right patient receives right medication.</p> <p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).</p> <p>Reduces spread of microorganisms; ensures smooth, orderly procedure.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Some agencies are now using a bar-code system to help with patient identification.</p> <p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p> <p>Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy.</p> <p>Position provides easy access to eye for medication instillation and minimizes drainage of medication into tear duct.</p> |
|---|--|

Clinical Decision Point Do not hyperextend the neck of a patient with cervical spine injury.

- | | |
|--|---|
| <p>b If drainage or crusting is present along eyelid margins or inner canthus, gently wash away. Soak any dried crusts with warm, damp washcloth or cotton ball over eye for several minutes. Always wipe clean from inner to outer canthus (see illustration). Remove gloves and perform hand hygiene.</p> | <p>Soaking allows easy removal of crusts without applying pressure to eye. Cleaning from inner to outer canthus avoids entrance of microorganisms into lacrimal duct (Lilley et al., 2011).</p> |
|--|---|

STEP	RATIONALE
c Explain there might be temporary burning sensation from drops.	Corneas are highly sensitive.
d Instill eyedrops.	
(1) Apply clean gloves. Hold cotton ball or clean tissue in nondominant hand on patient's cheekbone just below lower eyelid.	Cotton or tissue absorbs medication that escapes eye.
(2) With tissue or cotton resting below lower lid, gently press downward with thumb or forefinger against bony orbit, exposing conjunctival sac. Never press directly against patient's eyeball.	Prevents pressure and trauma to eyeball and prevents fingers from touching eye.
(3) Ask patient to look at ceiling. Rest dominant hand on patient's forehead; hold filled medication eyedropper approximately 1 to 2 cm ($\frac{1}{2}$ to $\frac{3}{4}$ inch) above conjunctival sac.	Action moves cornea up and away from conjunctival sac and reduces blink reflex. Prevents accidental contact of eyedropper with eye and reduces risk of injury and transfer of microorganisms to dropper (ophthalmic medications are sterile).
(4) Drop prescribed number of drops into conjunctival sac (see illustration).	Conjunctival sac normally holds 1 or 2 drops. Provides even distribution of medication across eye.
(5) If patient blinks or closes eye, causing drops to land on outer lid margins, repeat procedure.	Therapeutic effect of drug is obtained only when drops enter conjunctival sac.
(6) When administering drops that may cause systemic effects, apply gentle pressure to patient's nasolacrimal duct with clean tissue for 30 to 60 seconds over each eye, one at a time (see illustration). Avoid pressure directly against patient's eyeball.	Prevents overflow of medication into nasal and pharyngeal passages. Prevents absorption into systemic circulation.

STEP 7b Clean eye, washing from inner to outer canthus before administering drops or ointment.

STEP 7d(4) Hold eyedropper over lower conjunctival sac.

STEP 7d(6) Apply gentle pressure against nasolacrimal duct after giving eye medications.

STEP	RATIONALE
(7) After instilling drops, ask patient to close eyes gently.	Helps distribute medication. Squinting or squeezing eyelids forces medication from conjunctival sac.
e Instill eye ointment.	
(1) Holding applicator above lower lid margin, apply thin ribbon of ointment evenly along inner edge of lower eyelid on conjunctiva (see illustration) from inner to outer canthus.	Distributes medication evenly across eye and lid margin.
(2) Have patient close eye and rub lid lightly in circular motion with cotton ball if not contraindicated. Avoid placing pressure directly against patient's eyeball.	Further distributes medication without traumatizing eye.
(3) If excess medication is on eyelid, gently wipe it from inner to outer canthus.	Promotes comfort and prevents trauma to eye.
(4) If patient needs an eye patch, apply clean one by placing it over affected eye so entire eye is covered. Tape securely without applying pressure to eye.	Clean eye patch reduces risk of infection.
f Apply intraocular disk.	
(1) Open package containing disk. Gently press your fingertip against disk so it adheres to your finger. It may be necessary to moisten gloved finger with sterile saline. Position convex side of disk on your fingertip.	Allows you to inspect disk for damage or deformity.
(2) With your other hand gently pull patient's lower eyelid away from eye. Ask patient to look up.	Prepares conjunctival sac for receiving medicated disk and moves sensitive cornea away.
(3) Place disk in conjunctival sac so it floats on sclera between iris and lower eyelid (see illustration).	Ensures delivery of medication.
(4) Pull patient's lower eyelid out and over disk (see illustration). You should not be able to see disk at this time. Repeat if you can see disk.	Ensures accurate medication delivery.
8 After administering eye medications remove and dispose of gloves and soiled supplies, perform hand hygiene.	Reduces spread of microorganisms

STEP 7e(1) Nurse applies ointment along inner edge of lower eyelid from inner to outer canthus.

STEP 7f(3) Place intraocular disk in conjunctival sac between iris and lower eyelid.

STEP 7f(4) Gently pull patient's lower eyelid over disk.

STEP 9b Carefully pinch disk to remove it from patient's eye.

STEP

RATIONALE

9 Remove intraocular disk.

- a Perform hand hygiene and apply clean gloves. Gently pull downward on lower eyelid using your nondominant hand.
- b Using forefinger and thumb of your dominant hand, pinch disk and lift it out of patient's eye (see illustration).
- c Remove and dispose of gloves, perform hand hygiene.

Exposes disk.

Reduces spread of microorganisms.

10 Instill eardrops.

- a Perform hand hygiene. Apply clean gloves (only if drainage is present).
- b Warm medication to room temperature by running warm water over bottle (make sure not to damage label or allow water to enter bottle).
- c Position patient on side (if not contraindicated) with ear to be treated facing up, or patient may sit in chair or at bedside. Stabilize patient's head with his or her own hand.
- d Straighten ear canal by pulling pinna up and back to 10 o'clock position (adult or child older than age 3) or down and back to 6 to 9 o'clock position (child under age 3) (see illustrations).
- e If cerumen or drainage occludes outermost portion of ear canal, wipe out gently with cotton-tipped applicator (see illustration). Take care not to force cerumen into canal.

Reduces spread of microorganisms.

Ear structures are very sensitive to temperature extremes. Cold may cause vertigo and nausea.

Facilitates distribution of medication into ear.

Straightening ear canal provides direct access to deeper ear structures. Anatomic differences in younger children and infants necessitate different methods of positioning canal (Hockenberry and Wilson, 2011).

Cerumen and drainage harbor microorganisms and can block distribution of medication into canal. Occlusion blocks sound transmission.

STEP 10d A, Pull pinna up and back for adults and children older than 3 years. B, Pull pinna down and back for children under age 3.

STEP 10e Always clean only outer canal. Do not push cerumen or secretions into ear.

STEP 10g Nurse applies gentle pressure to tragus of ear after instilling drops.

STEP

- f** Instill prescribed drops holding dropper 1 cm ($\frac{1}{2}$ inch) above ear canal.
- g** Ask patient to remain in side-lying position for a few minutes. Apply gentle massage or pressure to tragus of ear with finger (see illustration).
- h** If ordered, gently insert portion of cotton ball into outermost part of canal. Do not press cotton into canal.
- i** Remove cotton after 15 minutes. Help patient to comfortable position after drops are absorbed.
- j** Dispose of soiled supplies in proper receptacle, remove and dispose of gloves, and perform hand hygiene.

RATIONALE

- Avoiding contact prevents contamination of dropper, which could contaminate medication in container.
- Allows complete distribution of medication. Pressure and massage move medication inward.
- Prevents escape of medication when patient sits or stands.
- Allows time for drug distribution and absorption.
- Reduces spread of microorganisms

EVALUATION

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Observe response to medication by assessing visual or hearing changes, asking if symptoms are relieved, and noting any side effects or discomfort felt. 2 Ask patient to discuss purpose of drug, action, side effects, and technique of administration. 3 Have patient or family caregiver demonstrate self-administration of next dose. | <ul style="list-style-type: none"> Evaluates effects of medication. Determines patient's level of understanding. Provides feedback regarding competency with skill. |
|--|--|

Unexpected Outcomes

- 1** Patient complains of burning or pain or experiences local side effects (e.g., headache, bloodshot eyes, local eye irritation). Drug concentration and patient's sensitivity both influence chances of side effects developing.
- 2** Patient experiences systemic effects from drops (e.g., increased heart rate and blood pressure from epinephrine, decreased heart rate and blood pressure from timolol).
- 3** Ear canal remains inflamed, swollen, tender to palpation. Drainage is present.
- 4** Patient's hearing acuity continues to be reduced.
- 5** Patient is unable to explain drug information or steps for taking eyedrops/ eardrops and/or has trouble manipulating dropper.

Related Interventions

- Eyedrops may have been instilled onto cornea, or dropper touched surface of eye.
- Notify health care provider for possible adjustment in medication type and dosage.
- Notify health care provider immediately.
- Remain with patient. Assess vital signs.
- Withhold further doses.
- Notify health care provider for possible adjustment in medication type and dosage.
- Notify health care provider.
- Cerumen may be impacted requiring ear irrigation.
- Repeat instructions and include family caregiver as appropriate. Include return demonstration.

Recording and Reporting

- Record drug, concentration, dose or strength, number of drops, site of application (left, right, or both eye/ear), and time of administration on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurse's notes and EHR.
- Record objective data related to tissues involved (e.g., redness, drainage, irritation), any subjective data (e.g., pain, itching, altered vision or hearing), and patient's response to medications. Note any side effects experienced in nurses' notes and EHR.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider. Depending on medication, immediate health care provider notification may be required.

Special Considerations

Teaching

- Warn patients that mydriatics (agent used to dilate the pupils) temporarily blur vision. Wearing sunglasses reduces photophobia. If necessary, make arrangements for someone else to drive patient home from an office or clinic visit.
- Patients who receive medications that paralyze the ciliary muscles of the eye (e.g., scopolamine [Isopto-Hyoscine], atropine [Isopto Atropine], and cycloplegics) should not drive or attempt to perform any activity that requires acute vision after receiving medication.

Pediatric

- Infants often clench the eyes tightly to avoid eyedrops. Place the drops at the nasal corner where the lids meet with the infant supine. When the infant opens the eye, the medication will flow into it.

- When both eyedrops and ointment are ordered, administer the drops first, wait 3 minutes, and then administer the ointment. This allows time for each medication to have an effect.
- If the eye ointment is to be given once a day, administer at bedtime because it will blur the child's vision (Hockenberry and Wilson, 2011).
- Insert cotton pledgets loosely into ear canal to prevent medication from flowing out. To prevent cotton from absorbing medication, premoisten it with a few drops of medication (Hockenberry and Wilson, 2011).

Gerontologic

- Before discharging an older adult, evaluate patient's ability to perform all the necessary steps for the administration of eyedrops and ointments.
- Many older adults accumulate cerumen in the ear. This should be removed by irrigation before administering medication (see Chapter 19).

Home Care

- When using over-the-counter (OTC) eyedrops, patients should not share medications with other family caregivers. Risk for infection transmission is high. In addition, instruct patients to follow manufacturer instructions carefully for dosing.

SKILL 21-5 Administering Nasal Instillations

Patients with nasal sinus problems may receive drugs by spray, drops, or tampons. The most commonly administered form of nasal instillation is a decongestant spray or drops used to relieve sinus congestion and cold symptoms. Many over-the-counter (OTC) nasal preparations contain sympathomimetic drugs (e.g., Afrin or Neo-Synephrine). These drugs are relatively safe when administered nasally because only small doses are needed. However, the drugs can enter the systemic circulation by way of the nasal mucosa or by the gastrointestinal tract if an excess amount is swallowed, causing restlessness, nervousness, tremors, or insomnia in some patients. Long-term use of decongestant nasal spray can actually worsen nasal congestion because of a rebound effect. Nasal sprays are easy for a patient to self-administer. Health care providers treat severe nosebleeds by placing nasal packing or tampons, which are treated with epinephrine to slow bleeding.

Delegation and Collaboration

The skill of administering nasal instillations cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting any bloody nasal drainage.

Equipment

- Prepared medication with clean dropper or spray container
- Facial tissue
- Small pillow (*optional*)
- Washcloth (*optional*)
- Clean gloves
- Medication administration record (MAR) (electronic or printed)

STEP

RATIONALE

ASSESSMENT

- 1 Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name, drug name and dosage, route (which sinus), and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
- 2 Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
- 3 Assess patient's history (e.g., hypertension, heart disease, diabetes, and hyperthyroidism) and for history of allergies.
- 4 Perform hand hygiene. Use penlight and inspect condition of nose and sinuses. Palpate sinuses for tenderness. Note type of drainage if present.
- 5 Assess patient's knowledge regarding use of nasal instillations, technique for instillation, and willingness to learn self-administration.

The health care provider's order is the most reliable source and only legal record of drugs that patient is to receive. Ensures that patient receives correct medication. Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).

Allows you to anticipate effects of drug and observe patient's response.

These conditions contraindicate use of decongestants that stimulate central nervous system.

Provides baseline to monitor effects of medication. Presence of discharge interferes with drug absorption. Clear nasal discharge indicates sinus problem. Yellow or greenish discharge indicates infection.

Requires health teaching regarding use of drugs. Motivation influences teaching approach.

NURSING DIAGNOSES

- Deficient knowledge regarding drug action and purpose
- Readiness for enhanced self-health management
- Ineffective breathing pattern
- Pain (acute or chronic)
- Risk for injury

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|--|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient is able to breathe without difficulty through nose. • Patient's nasal sinuses are clear, moist, pink, without drainage after repeated instillations (applies to antiinfective medications). • Patient is able to explain purpose of medication and administers nasal instillations correctly. <p>2 Explain procedure to patient and family caregiver regarding positioning and sensations to expect.</p> | <p>Nasal congestion has been relieved.
Inflammation of mucosa has been relieved.</p> <p>Feedback reflects patient's learning.</p> <p>Helps patient anticipate experience of procedure to reduce anxiety.</p> |
|--|--|

IMPLEMENTATION

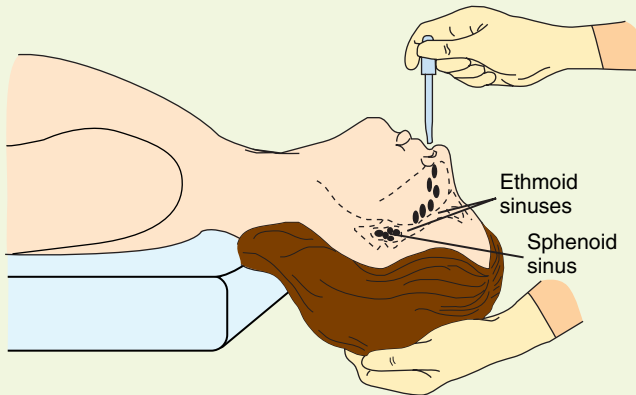

- | | |
|--|--|
| <p>1 Prepare medications for instillation. Check label of medication against MAR 2 times (see Skill 22-1). Preparation usually involves taking nasal drops or sprays out of storage and into patient room. Check expiration date on container.</p> <p>2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.</p> | <p><i>These are the first and second checks for accuracy.</i> Process ensures that right patient receives right medication.</p> <p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).</p> |
| <p>3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> <p>4 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.</p> <p>5 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about drugs. Patients who self-instill medications may be allowed to give drops under nurse's supervision (check agency policy). Tell patients receiving nasal instillation that they may experience burning or stinging of mucosa or choking sensation as medication trickles into throat.</p> <p>6 Perform hand hygiene. Arrange supplies and medications at bedside. Apply clean gloves (if drainage is present).</p> <p>7 Gently roll or shake container. Instruct patient to clear or blow nose gently unless contraindicated (e.g., risk of increased intracranial pressure or nosebleed).</p> <p>8 Administer nose drops.</p> <p>a Help patient to supine position and position head properly.</p> <ol style="list-style-type: none"> (1) For access to posterior pharynx, tilt patient's head backward. (2) For access to ethmoid or sphenoid sinus, tilt head back over edge of bed or place small pillow under patient's shoulder and tilt head back (see illustration). | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). Some agencies are now using a bar-code system to help with patient identification.</p> <p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p> <p>Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy.</p> <p>Reduces spread of microorganisms; ensures smooth, orderly procedure.</p> <p>Ensures distribution of medication. Allows medication to reach sinuses.</p> <p>Proper positioning provides access to specific nasal passages.</p> |

STEP

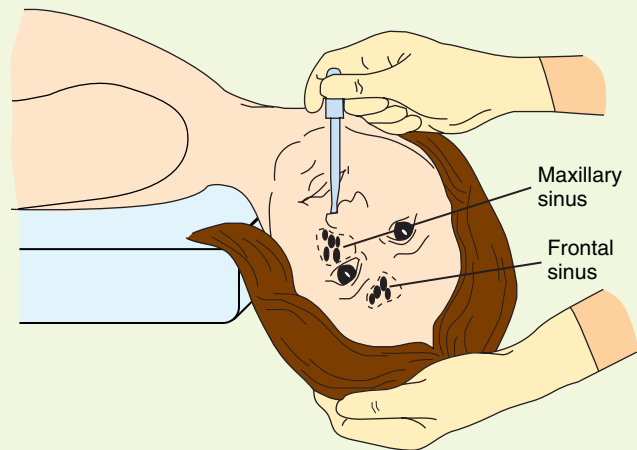

RATIONALE

- (3) For access to frontal and maxillary sinus, tilt head back over edge of bed or pillow with head turned toward side to be treated (see illustration).
- b Support patient's head with nondominant hand.
 - c Instruct patient to breathe through mouth.
 - d Hold dropper 1 cm ($\frac{1}{2}$ inch) above nares and instill prescribed number of drops toward midline of ethmoid bone.
 - e Have patient remain in supine position 5 minutes.
 - f Offer facial tissue to blot runny nose but caution patient against blowing nose for several minutes.
- 9 Administer nasal spray.**
- a Help patient into upright position with head tilted slightly forward.
 - b Help patient insert tip of nasal spray into appropriate nares and occlude other nostril with finger (see illustration). Point spray tip toward side and away from center of nose.

- Position allows medication to drain into affected sinus.
- Prevents straining neck muscles.
Mouth breathing reduces chance of aspirating nasal drops into trachea and lungs.
Avoids contamination of dropper. Instilling toward ethmoid bone facilitates distribution of medication over nasal mucosa.
- Prevents premature loss of medication through nares.
Provide comfort but allows for absorption of medication.
- Proper positioning permits medication spray to reach nasal passages.
Allows for proper administration of medication.

STEP 8a(2) Position for instilling nose drops into ethmoid or sphenoid sinus.

STEP 8a(3) Position for instilling nose drops into frontal and maxillary sinus.

STEP 9b Occlude the other nostril before self-administering nasal spray.

STEP	RATIONALE
<ul style="list-style-type: none"> c Have patient spray medication into nose while inhaling. Help him or her remove nozzle from nose and instruct to breathe out through mouth. d Offer facial tissue to blot runny nose but caution patient against blowing nose for several minutes. 	<p>Allows for proper administration and distribution of nasal medication as high into nasal passages as possible.</p> <p>Provides comfort but allows for absorption of medication.</p>
<p>Clinical Decision Point <i>Some medications are designed for one spray per dose. Examples include calcitonin (salmon), desmopressin (DDAVP, Stimate), and sumatriptan (Imitrex). It is essential to ensure that the patient understands the correct number of sprays to use per dose to prevent overdosing.</i></p>	
10 Help patient to a comfortable position after medication is absorbed.	Restores comfort.
11 Dispose of soiled supplies, remove and dispose of gloves, and perform hand hygiene.	Reduces spread of microorganisms.

EVALUATION

1 Observe patient for onset of side effects 15 to 30 minutes after administration.	Drugs absorbed through mucosa can cause systemic reaction.
2 Ask if patient is able to breathe through nose after decongestant administration. May be necessary to have patient occlude one nostril at a time and breathe deeply.	Determines effectiveness of decongestant medication.
3 Reinspect condition of nasal passages between instillations.	Condition of mucosa reveals response to medication.
4 Ask patient to describe risks of overuse of decongestants and methods for administration.	Feedback ensures that patient can self-administer drugs properly.
5 Have patient demonstrate self-medication.	Feedback demonstrates learning.

Unexpected Outcomes

- 1 Patient is unable to breathe easily through nasal passages. Mucosa appears swollen, and congestion is unrelieved, due possibly to rebound effect.
- 2 Nasal mucosa remains inflamed and tender, with discharge from nares.
- 3 Patient complains of sinus headache. Sinuses remain congested.
- 4 Patient is unable to explain technique, risks of therapy, and self-administer medication.

Related Interventions

- Stop medication use.
- Notify health care provider and consider alternative therapy.
- Consider alternative therapy.
- Consider alternative therapy.
- Reinstruction is necessary.
- Include family caregiver when possible.

Recording and Reporting

- Record drug name, concentration, number of drops, nares into which drug was instilled, and actual time of administration on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurses' notes and EHR.
- Report any unusual systemic or adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider.
- Use OTC nasal sprays or nose drops for only one illness; bottles easily become contaminated with bacteria.

Pediatric

- Positioning child with head extended over edge of bed or pillow facilitates smooth instillation of nasal drops. Child should remain in this position for at least 1 minute to ensure that drops come in contact with affected tissue.
- Infants are nose breathers, and the possible congestion caused by nasal medications may inhibit their sucking. Administer nose drops if ordered 20 to 30 minutes before feedings (Hockenberry and Wilson, 2011).

Special Considerations

Teaching

- Instruct patients that each family caregiver should have a different dropper or spray applicator. Instruct patients to wash or rinse applicators after each use.

SKILL 21-6 Using Metered-Dose Inhalers

NSO Nonparenteral Medication Administration Module / Lesson 5

Medications administered with handheld inhalers are dispersed through an aerosol spray, mist, or powder that penetrates the airways. Pressurized metered-dose inhalers (pMDIs), breath-actuated metered-dose inhalers (BAIs), and dry powder inhalers (DPIs) deliver medications that produce local effects such as bronchodilation. Some of these medications are absorbed rapidly through the pulmonary circulation and create systemic side effects (e.g., albuterol [Proventil] may cause palpitations, tremors, and tachycardia). Patients who receive drugs by inhalation frequently suffer from asthma and chronic respiratory disease. Drugs administered by inhalation provide control of airway hyperactivity or constriction. Because patients depend on these medications for disease control, they must learn about them and how to administer them safely.

An MDI is a small, handheld device that disperses medication into the airways through an aerosol spray or mist by activation of a propellant. Dosing is usually achieved with 1 or 2 puffs. DPIs deliver inhaled medication in a fine powder formulation to the respiratory tract (see Procedural Guideline 21-1). The deeper passages of the respiratory tract provide a large surface area for drug absorption, and the alveolar-capillary network absorbs medication rapidly.

An MDI delivers a measured dose of the drug with each push of a canister. Approximately 5 to 10 lbs of pressure is needed to

activate the aerosol. This is difficult for some older patients because hand strength diminishes with age. Because use of an MDI requires coordination during the breathing cycle, many patients spray only the back of their throats and fail to receive a full dose. The inhaler must be depressed to expel medication just as the patient inhales. This ensures that medication reaches the lower airways. Poor coordination can be solved by the use of spacer devices (AeroChamber, InspirEase) or a breath-activated MDI such as the Maxair Auto-inhaler. A spacer device decreases the amount of medication deposited into the oropharyngeal mucosa. Some spacers have a one-way valve that activates on inhalation, thereby removing the need for good hand-breath coordination (Lehne, 2010). Box 21-3 summarizes common problems that occur when using an inhaler.

Delegation and Collaboration

The skill of administering MDIs cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting breathing difficulty (e.g., paroxysmal coughing, audible wheezing).

Equipment

- ❑ Inhaler device with medication canister (MDI or DPI) (see Fig. 21-1, A to C)
- ❑ Spacer device such as AeroChamber or InspirEase (*optional*)
- ❑ Facial tissues (*optional*)
- ❑ Stethoscope
- ❑ Medication administration record (MAR) (electronic or printed)
- ❑ Pulse oximeter (*optional*)

BOX 21-3 Common Problems in Using An Inhaler

- **Not taking the medication as prescribed:** Taking either too much or too little.
- **Incorrect activation:** This usually occurs through pressing the canister *before* taking a breath. These actions should be done simultaneously so the drug can be carried down to the lungs with the breath.
- **Forgetting to shake the inhaler:** The drug is in a suspension; therefore particles may settle. If the inhaler is not shaken, it may not deliver the correct dose of the drug.
- **Not waiting long enough between puffs:** A delay between puffs is needed before taking a second puff; otherwise an incorrect dose may be delivered, or the drug may not penetrate into the lungs.
- **Failure to clean the valve:** Particles may jam the valve in the mouthpiece unless it is cleaned occasionally. This is a frequent cause of failure to get 200 puffs from one inhaler.
- **Failure to observe whether the inhaler is actually releasing a spray:** If it is not, this should be checked with the pharmacist.
- **Failure to recognize when the canister is empty:** This occurs when the metered-dose inhaler has no built-in dose counter or instructions in dose counting.

FIG 21-1 Types of inhalers. A, Metered-dose inhaler (MDI). B, Breath-activated inhaler (BAI). C, Dry powder inhaler (DPI).

|---|--|

STEP

RATIONALE

- 3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 4 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.
- 5 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the drugs. Explain what a metered-dose is and how to administer. Warn about overuse of inhaler and side effects.
- 6 Allow adequate time for patient to manipulate inhaler, canister, and spacer device (if provided). Explain and demonstrate how canister fits into inhaler.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). Some agencies are now using a bar-code system to help with patient identification.

This is the third check for accuracy and ensures that patient receives correct medication. Confirms patient's allergy history.

Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy.

Patient must be familiar with how to use equipment.

Clinical Decision Point *If using an MDI that is new or has not been used for several days, push a "test spray" into the air to prime the device before using. This ensures that the MDI is patent and the metal canister is positioned properly.*

- 7 Explain steps for administering MDI without spacer (demonstrate when possible).
 - a Remove mouthpiece cover from inhaler after inserting MDI canister into holder.
 - b Shake inhaler well for 2 to 5 seconds (five or six shakes).
 - c Hold inhaler in dominant hand.
 - d Instruct patient to position inhaler in one of two ways:
 - (1) Place mouthpiece in mouth with opening toward back of throat, closing lips tightly around it (see illustration).
 - (2) Position mouthpiece 2 to 4 cm (1 to 2 inches) in front of widely opened mouth (see illustration), with opening of inhaler toward back of throat. Lips should not touch inhaler.
 - e Have patient take deep breath and exhale completely.
 - f With inhaler positioned, have patient hold it with thumb at mouthpiece and index and middle fingers at top. This is a three-point or bilateral hand position.
 - g Instruct patient to tilt head back slightly and inhale slowly and deeply through mouth for 3 to 5 seconds while depressing canister fully.
 - h Have patient hold breath for about 10 seconds.

Simple step-by-step explanation allows patient to ask questions at any point during procedure.

Ensures mixing of medication in canister.

Directs aerosol spray toward airway. This is best way to deliver medication without a spacer.

Prepares airway to receive medication.

Hand position ensures proper activation of MDI (Lilley et al., 2011).

Medication is distributed to airways during inhalation.

Allows tiny drops of aerosol spray to reach deeper branches of airways.

STEP 7d(1) Patient opens lips and places inhaler mouthpiece in mouth with opening toward back of throat.

STEP 7d(2) Patient positions inhaler mouthpiece 2 to 4 cm (1 to 2 inches) from widely open mouth. This is considered the best way to deliver medication without a spacer.

STEP	RATIONALE
i Remove MDI from mouth before exhaling and exhale slowly through nose or pursed lips.	Keeps small airways open during exhalation.
8 Explain steps to administer MDI using spacer device (demonstrate when possible).	
a Remove mouthpiece cover from MDI and mouthpiece of spacer device.	Inhaler fits into end of spacer device.
b Shake inhaler well for 2 to 5 seconds (five or six shakes).	Ensures mixing of medication in canister.
c Insert MDI into end of spacer device.	Spacer device traps medication released from MDI; patient then inhales drug from device. These devices improve delivery of correct dose of inhaled medication (Barrons et al., 2011).
d Instruct patient to place spacer device mouthpiece in mouth and close lips. Do not insert beyond raised lip on mouthpiece. Avoid covering small exhalation slots with the lips.	Medication should not escape through mouth.
e Have patient breathe normally through spacer device mouthpiece (see illustration).	Allows patient to relax before delivering medication.
f Instruct patient to depress medication canister, spraying one puff into spacer device.	Device contains fine spray and allows patient to inhale more medication.
g Patient breathes in slowly and fully (for 5 seconds).	Ensures that particles of medication are distributed to deeper airways.
h Instruct patient to hold full breath for 10 seconds.	Ensures full drug distribution.
9 Instruct patient to wait 20 to 30 seconds between inhalations (if same medication) or 2 to 5 minutes between inhalations (if different medications).	Drugs must be inhaled sequentially. Always administer bronchodilators before steroids so dilators can open airway passages (Lilley et al., 2011).
10 Instruct patient to not repeat inhalations before next scheduled.	Drugs are prescribed at intervals during day to provide constant drug levels and minimize side effects. Beta-adrenergic MDIs are used either on an “as needed” basis or regularly every 4 to 6 hours.
11 Warn patients that they may feel gagging sensation in throat caused by droplets of medication on pharynx or tongue.	This occurs when medication is sprayed and inhaled incorrectly.
12 About 2 minutes after last dose, instruct patient to rinse mouth with warm water and spit water out.	Inhaled bronchodilators may cause dry mouth and taste alterations. Steroids may alter normal flora of oral mucosa and lead to development of fungal infection (Lilley et al., 2011).
13 For daily cleaning, instruct patient to remove medication canister, rinse inhaler and cap with warm running water, and be sure that inhaler is completely dry before reuse. Do not get valve mechanism of canister wet.	Removes residual medication and reduces spread of microorganisms. Water damages valve mechanism of canister.
14 Ask if patient has any questions.	Clarifies misconceptions or misunderstanding.
15 Help patient to comfortable position and perform hand hygiene.	Reduces spread of microorganisms and promotes patient comfort.

STEP 8e Using spacer device with an MDI.

STEP

RATIONALE

EVALUATION

- 1 Have patient explain and demonstrate steps in use and cleaning of inhaler.
- 2 Ask patient to explain drug schedule and dose of medication.
- 3 Ask patient to describe side effects of medication and criteria for calling health care provider.
- 4 After medication administration, assess patient's respirations, breath sounds, and peak flow measures if ordered.

Return demonstration provides feedback for measuring patient's learning.
 Improves likelihood of adherence to therapy.
 Allows patient to recognize signs of overuse and need to seek medical support when drugs are ineffective.
 Determines status of breathing pattern and adequacy of ventilation/gas exchange.

Unexpected Outcomes

- 1 Patient's respirations are rapid and shallow; breath sounds indicate wheezing.
- 2 Patient experiences paroxysms of coughing.
- 3 Patient needs bronchodilator more than every 4 hours (may indicate respiratory problem).
- 4 Patient experiences cardiac dysrhythmias (light-headedness, syncope), especially if receiving beta-adrenergics.
- 5 Patient is not able to self-administer medication properly.
- 6 Patient is unable to explain technique and risks of drug therapy.

Related Interventions

- Evaluate vital signs and respiratory status.
- Notify health care provider.
- Reassess type of medication and/or delivery method.
- Reassess patient's delivery method.
- Notify health care provider.
- Reassess type of medication and delivery methods needed.
- Notify health care provider.
- Withhold all further doses of medication.
- Evaluate cardiac and pulmonary status (see [Chapter 6](#)).
- Notify health care provider for reassessment of type of medication and delivery method.
- Explore alternative delivery routes or devices.
- Further teaching is necessary.
- Include family caregivers when possible.

Recording and Reporting

- Record drug administered, dose or strength, route, number of inhalations, and actual time administered on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurses' notes and EHR.
- Record in nurses' notes and EHR the patient's response to MDI (e.g., breath sounds), evidence of side effects (e.g., arrhythmia, feelings of anxiety), and patient's ability to use MDI.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider.

having the MDI available for use during school hours. A health care provider's order may be necessary.

Gerontologic

- Older adults may be unable to depress medication canisters because of weakened grasp or inability to coordinate actuation of the canister with inhalation. The use of a spacer device may be helpful.

Home Care

- Remind patients to carry prescribed inhalers to use as immediate treatment in case of an acute asthma attack.

Special Considerations

Teaching

- Allow for supervised practice of the procedures. Patients may have difficulty timing an inhalation with activation of the medication canister without proper instruction ([Lewis et al., 2011](#)).
- Teach patient to keep track of the number of inhalations in the MDI ([Box 21-4](#)).
- Teach patients to use small, handheld peak flowmeters to monitor response to therapy when inhalers are prescribed ([Barrons et al., 2011](#)).

Pediatric

- A spacer is of benefit to young children because they have difficulty coordinating inhaler activation and inhaling ([Hockenberry and Wilson, 2011](#)).
- Educate child and parent about the need to use the inhaler during school hours. Help family find resources within the school or day care facility. Many school systems do not permit self-administration of MDIs. Follow school policy regarding

BOX 21-4 Counting Doses in a Metered-Dose Inhaler

Most metered-dose inhalers (MDIs) currently do not have automatic dose counters. Patients need to keep careful track of the number of inhalations used in their MDIs. Failure to do so may result in patients using an empty inhaler during an acute exacerbation of a respiratory problem. To track doses:

- Note first day of use on a calendar.
- Note number of inhalations in the canister (e.g., 200 inhalations per MDI).
- Note number of inhalations used per day (e.g., 2 inhalations a day, 3 times a day, equals 6 inhalations per day).
- Divide the total number of inhalations in the canister by the number of inhalations needed per day to determine the number of days that the inhaler should last (e.g., 200 inhalations divided by 6 inhalations per day equals approximately 33 days of 3-times-a-day dosing).
- Mark on a calendar the date the inhaler will be empty and obtain a refill of the inhaler a few days before this target date.

PROCEDURAL GUIDELINE 21-1 Using Dry Powder Inhaled Medications

Dry powder inhalers (DPIs) hold dry powdered medication and create an aerosol when the patient inhales through a reservoir that contains the medication. In contrast with the MDI, a DPI has no propellant. DPIs require less manual dexterity; and, because the device is breath activated, there is no need to coordinate puffs with inhalation. Compared with MDIs, DPIs deliver more medication to the lungs (Lehne, 2010). A DPI does not require a spacer. Medication inside a DPI can clump if the patient lives in a humid climate. Some patients cannot inhale fast enough to administer the entire dose of medication.

Delegation and Collaboration

The skill of administering DPI medications cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting paroxysmal coughing, audible wheezing, and patient's report of breathlessness or difficulty breathing.

Equipment

- Dry powder inhaler (see Fig. 21-1, C, p. 520)
- Stethoscope
- Washbasin or sink with warm water
- Medication administration record (MAR) (electronic or printed)
- Facial tissues (*optional*)

Procedural Steps

- 1 Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name, drug name and dosage, route (which sinus), and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
- 2 Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
- 3 Assess patient's medical history, history of allergies, and medication and diet history.
- 4 Assess respiratory pattern and auscultate breath sounds.
- 5 Assess patient's knowledge of medication and readiness to learn (e.g., asks questions about medication, requests education in use of DPI, is mentally alert, participates in own care).
- 6 Assess patient's ability to learn: Patient should not be fatigued, in pain, or in respiratory distress; assess level of understanding of technical vocabulary terms.
- 7 Determine patient's ability to hold, manipulate, and activate DPI.
- 8 If previously instructed in self-administration of DPI, assess patient's technique in using it.
- 9 Prepare medication for inhalation and check label on inhaler against MAR 2 times (see Skill 22-1). Preparation usually involves taking inhaler device out of storage and into patient room. *These are the first and second checks for accuracy. Check expiration date on container.*
- 10 Take medication to patient at correct time (see agency policy). Give medications that require exact or precise timing when ordered, give time-critical medications at time ordered (no later than 30 minutes before or after), and give non-time-critical medications within 1 or 2 hours of scheduled dose (DHHS, 2011; ISMP, 2011). During administration apply six rights of medication administration.
- 11 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 12 At patient's bedside again compare MAR or computer print-out with names of medications on medication labels and patient name. *This is the third check for accuracy.* Ask patient if he or she has allergies.
- 13 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the drugs. Explain what a DPI is and how to administer. Warn about overuse of inhaler and side effects.
- 14 If DPI has an external counter, note number indicated to determine doses remaining. Otherwise use technique in Box 21-4 for counting doses.
- 15 Prepare DPI for administration. Perform hand hygiene. Some DPIs require loading medication before administration; some require rotation of a lever to load medication or insertion of a capsule; and some require insertion of a disk into inhaler device. Follow manufacturer specific instructions.

Clinical Decision Point *The patient's inhaled breath pulls the drug into the airway. DPIs may differ as to how fast the patient should inhale the medication; consult specific instructions of manufacturer. In addition, do not shake DPI because powdered medication may spill out of device.*

- 16 Have patient place lips over mouthpiece of DPI and inhale quickly and deeply. Remove inhaler from mouth as soon as inhalation is complete but before exhalation. Instruct patients that, unlike with other inhaled medications, they may not taste or feel the dry powder or there may be a slight sweet taste.
- 17 Have patient hold breath for 10 seconds or as long as possible and then exhale. Do not exhale into DPI.
- 18 After using DPI, have patient rinse mouth with warm water and spit it out to reduce throat irritation and prevent oral candidiasis.
- 19 Return DPI to closed position or remove loaded capsule or disk if necessary. If an external counter is present, note number, which should be one less than the number in Step 14.
- 20 Have patient demonstrate use of DPI at next scheduled dose. Ask him or her to discuss purpose, action, and side effects of medication.
- 21 Auscultate breath sounds, evaluate respiratory rate, and ask patient about his or her breathing.
- 22 Record drug, dose or strength, route, number of inhalations, and time administered on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurses' notes and EHR.

SKILL 21-7 Using Small-Volume Nebulizers

Nebulization is a process of adding medications or moisture to inspired air by mixing particles of various sizes with air. Adding moisture to the respiratory system through nebulization improves clearance of pulmonary secretions. Medications such as bronchodilators, mucolytics, and corticosteroids are often administered by nebulization.

Small-volume nebulizers convert a drug solution into a mist that is then inhaled by a patient into their tracheobronchial tree. The droplets in the mist are much finer than those created by metered-dose inhalers (MDIs) or dry powder inhalers (DPIs). A face mask or a mouthpiece held between the teeth delivers a nebulized mist. A nebulized medication is designed to create a local effect, but it can be absorbed into the bloodstream through the alveoli. As a result, systemic effects from the medication may occur.

Delegation and Collaboration

In many health care agencies a respiratory therapist performs the skill of administering medications by nebulizer. The nurse must be aware of the type and actions of the inhaled medication that the

patient is receiving. The skill of administering medications by nebulizer cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting paroxysmal coughing, ineffective breathing patterns, and other respiratory difficulties.

Equipment

- Medication ordered and diluent (if needed)
- Medicine dropper or syringe
- Nebulizer bottle and tubing assembly
- Small-volume nebulizer machine (often called *handheld nebulizer* or simply *nebulizer*)
- Pulse oximeter and peak flow device
- Stethoscope
- Medication administration record (MAR) (electronic or printed)

STEP

RATIONALE

ASSESSMENT

- 1 Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name, drug name and dosage, route, and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
- 2 Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
- 3 Assess patient's medical history, history of allergies, medication and diet history.
- 4 Assess patient's grasp and ability to assemble, hold, and manipulate nebulizer equipment.
- 5 Assess pulse, respirations, breath sounds, pulse oximetry, and peak flow measurement (if ordered) before beginning treatment.
- 6 Assess patient's knowledge of medication and readiness to learn (e.g., patient asks questions about medication, requests education in use of nebulizer, is mentally alert, participates in own care).

The health care provider's order is the most reliable source and only legal record of drugs that patient is to receive. Ensures that patient receives correct medication. Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).

Allows you to anticipate effects of drug and observe patient's response.

These factors influence how certain drugs act. Information also reflects patient's need for medications and risk for side effects. Any impairment of cognition or grasp or the presence of hand tremors affects patient's ability to use equipment.

Establishes baseline for comparison during and after treatment.

Determines level of instruction needed to assume self-administration.

NURSING DIAGNOSES

- | | | |
|---|---------------------------------|---|
| • Activity intolerance | • Anxiety | • Risk for injury |
| • Impaired gas exchange | • Ineffective breathing pattern | • Readiness for enhanced self-health management |
| • Deficient knowledge regarding use of nebulizers | | |

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient's breathing pattern is effective.
 - Patient's oxygen saturation level is adequate.
 - Patient describes side effects of medication and criteria for calling health care provider.

Demonstrates proper administration and therapeutic effect of medication.

Demonstrates proper administration and therapeutic effect of medication.

Increases likelihood of adherence to therapeutic regimen.

STEP

RATIONALE

- Patient demonstrates self-administration of nebulized dose of medication correctly.
- 2** Explain procedure to patient. Be specific if patient wishes to self-administer drug.

Demonstrates learning.

Makes patient participant in care and minimizes anxiety. Begins patient teaching regarding medications. Enables patient to self-administer drug if physically able and motivated.

IMPLEMENTATION

- 1** Prepare medications for inhalation. Check label of medication against MAR 2 times (see Skill 22-1). Preparation usually involves taking medication vial out of storage and taking to patient room. Check expiration date on container.
- 2** Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.
- 3** Perform hand hygiene and arrange equipment needed.
- 4** Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 5** At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.
- 6** Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the drugs. Explain how to assemble nebulizer and proper use.
- 7** Assemble nebulizer equipment per manufacturer directions.
- 8** Add prescribed medication by pouring medicine into nebulizer cup. (Option, you may use a medicine dropper or syringe to instill medication.)
- 9** Attach top to the nebulizer cup and be sure it is secure. Then connect cup to mouthpiece or face mask..
- 10** Connect tubing to both aerosol compressor and nebulizer cup.
- 11** Have patient hold mouthpiece between lips with gentle pressure, but be sure lips are sealed (see illustration).

These are the first and second checks for accuracy. Process ensures that right patient receives right medication.

Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).

Reduces transfer of microorganisms and saves time.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

Some agencies are now using a bar-code system to help with patient identification.

This is the third check for accuracy and ensures that patient receives correct medication. Confirms patient's allergy history.

Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy.

Assembly may vary slightly with different manufacturers. Proper assembly ensures safe delivery of medication.

Ensures proper dose and delivery of ordered medication.

Prevents loss of medication.

STEP 11 Nebulizer mouthpiece placed between patient's lips.

STEP	RATIONALE
a If patient is an infant, child, or fatigued adult or unable to follow instructions, use face mask.	Use of face mask does not require patient to remember to hold mouthpiece correctly. Correct delivery ensures sufficient deposition of medication.
b Use special adapters for patients with tracheostomy.	Promotes greater deposition of medication in airways.
12 Turn on small-volume nebulizer machine and ensure that a sufficient mist begins to flow.	Verifies that equipment is working properly during delivery of medication.
13 Have patient take deep breath, slowly, to a volume slightly greater than normal. Encourage brief, end-inspiratory pause for about 2 to 3 seconds, then have patient exhale passively.	Improves effectiveness of medication.
a If patient is dyspneic, encourage him or her to hold every fourth or fifth breath for 5 to 10 seconds.	Maximizes effectiveness of medication.
b Remind patient to repeat breathing pattern until drug is completely nebulized. This usually takes about 10 minutes. (1) Some health care providers set time limit as length of treatment rather than waiting for medication to completely nebulize.	Maximizes effectiveness of medication.
c Tap nebulizer cup occasionally during and toward end of treatment.	Releases droplets that are clinging to side of cup, thus allowing for renebulization of solution.
d Monitor patient's pulse during procedure, especially if beta-adrenergic bronchodilators are used.	Enables nurse to observe for potential side effects of medications.
14 When medication is completely nebulized, turn off machine. Rinse nebulizer cup per agency policy. Dry completely and store tubing assembly per agency policy.	Proper storage reduces transfer of microorganisms.
15 If steroids are nebulized, instruct patient to rinse mouth and gargle with warm water after nebulizer treatment.	Removes medication residue from oral cavity and helps to prevent oral candidiasis, a possible adverse effect of inhaled steroid therapy.
16 After nebulizer treatment is complete, have patient take several deep breaths and cough to expectorate mucus.	Nebulized medication is often ordered to open airways and promote expectoration of mucus.
17 Help patient to comfortable position and perform hand hygiene.	Reduces spread of microorganisms and promotes patient comfort.

EVALUATION

1 Assess patient's respirations, breath sounds, cough effort, sputum production, pulse oximetry, and peak flow measures if ordered.	Determines status of breathing pattern and adequacy of ventilation/exchange. Allows comparison with baseline data and evaluation of effectiveness of procedure.
2 Have patient explain and demonstrate steps in use of nebulizer.	Return demonstration provides feedback for measuring patient's learning.
3 Ask patient to explain drug schedule.	Improves likelihood of adherence to therapy.
4 Ask patient to describe side effects of medication and criteria for calling health care provider.	Allows patient to recognize signs of overuse and need to seek medical support when drugs are ineffective.

Unexpected Outcomes

- 1 Patient's breathing pattern is ineffective; respirations are rapid and shallow; breath sounds indicate wheezing.
- 2 Patient experiences paroxysms of coughing. Aerosolized particles can irritate posterior pharynx.
- 3 Patient experiences cardiac dysrhythmias (light-headedness, syncope), especially if receiving beta-adrenergics.
- 4 Patient is unable to self-administer medication properly.
- 5 Patient is unable to explain technique and risks of drug therapy.

Related Interventions

- Reassess type of medication and/or delivery method.
- Notify health care provider.
- Reassess type of medication and/or delivery method.
- Notify health care provider.
- Withhold all further doses of medication. Assess vital signs.
- Notify health care provider for reassessment of type of medication and delivery method.
- Explore alternative delivery routes or devices.
- Further teaching may be required.
- Include family caregivers when possible.

Recording and Reporting

- Record drug, dose and strength, route, length of treatment, and time administered on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding in nurses' notes and EHR.
- Record patient's response to treatment in nurses' notes and EHR.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider.

Special Considerations

Teaching

- Teach patient not to store medication in nebulizer for later use.
- Advise patients taking long-acting beta-agonists about possible adverse effects, including nervousness, restlessness, tremor, headache, nausea, rapid or pounding heart, and dizziness.
- Teach patients to use small, handheld peak flowmeters to monitor response to therapy when inhaled drugs are prescribed (Barrons et al., 2011).

Pediatric

- Use a mask for the nebulizer treatment if child is too young to hold mouthpiece correctly for the duration of the treatment (Hockenberry and Wilson, 2011).
- Instruct child to breathe normally with mouth open to provide a direct route to the airways for the medication.
- Educate child and parent about the need to use the nebulizer during school or day care hours. Help family find resources within the school or day care facility. Follow school policy regarding having the nebulizer and medication available for use during school hours. A health care provider's order may be necessary.

Gerontologic

- Older adults with a weak grasp, hand tremors, or coordination problems may not be able to manipulate or hold a nebulizer.

Home Care

- When at home, rinse nebulizer parts after each use with clear water and air dry. In addition, clean parts (except for tubing and nebulizer compressor) daily with warm, soapy water; rinse; and allow to dry.

SKILL 21-8 Administering Vaginal Instillations

NSO Nonparenteral Medication Administration Module / Lesson 6

Female patients who develop vaginal infections often require topical application of antiinfective agents. Vaginal medications are available in foam, jelly, cream, or suppository form. Medicated irrigations or douches can also be given. However, their excessive use can lead to vaginal irritation.

Vaginal suppositories are oval shaped and come individually packaged in foil wrappers. They are larger and more oval than rectal suppositories (Fig. 21-2). Storage in a refrigerator prevents the solid suppositories from melting. You insert a suppository into the vagina with an applicator or a gloved hand. After insertion, body temperature causes the suppository to melt, and the medication is distributed. Foam, jellies, and creams are administered with an inserter or applicator. Patients often prefer administering their own vaginal medications, and you should give them privacy to do so. After instillation of a drug, a patient may wish to wear a perineal pad to collect excess drainage. Because vaginal medications are frequently given to treat infection, any discharge is often foul smelling. Follow good aseptic technique and offer a patient frequent opportunities for perineal hygiene (see [Procedural Guideline 17-1](#)).

FIG 21-2 Vaginal suppositories (*right*) are larger and more oval than rectal suppositories (*left*).

Delegation and Collaboration

The skill of administering vaginal medications cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting any change in comfort level or new or increased vaginal discharge or bleeding to the nurse.

Equipment

- Vaginal cream, foam, jelly, tablet, suppository, or irrigating solution
- Applicators (Fig. 21-3) (if needed)
- Clean gloves
- Tissues
- Towels and/or washcloths
- Perineal pad; drape or sheet
- Water-soluble lubricants
- Bedpan
- Irrigation or douche container (if needed)
- Medication administration record (MAR) (electronic or printed)

FIG 21-3 From top: Vaginal cream with applicator, applicator, and vaginal suppository. (From Lilley LL et al: *Pharmacology and the nursing process*, ed 6, St Louis, 2011, Mosby.)

|--|--|

STEP 10a Lubricate tip of suppository.

STEP 10c Angle of vaginal suppository insertion.

STEP 11c Applicator inserted into vaginal canal. Plunger pushed to instill medication.

STEP	RATIONALE
b With nondominant gloved hand gently separate labial folds in front-to-back direction.	Exposes vaginal orifice.
c With dominant gloved hand insert rounded end of suppository along posterior wall of vaginal canal the entire length of finger (7.5 to 10 cm [3 to 4 inches]) (see illustration).	Proper placement of suppository ensures equal distribution of medication along walls of vaginal cavity.
d Withdraw finger and wipe away remaining lubricant from around orifice and labia with tissue or cloth.	Maintains comfort.
11 Apply cream or foam.	
a Fill cream or foam applicator following package directions.	Dose is based on volume in applicator.
b With nondominant gloved hand gently separate labial folds.	Exposes vaginal orifice.
c With dominant gloved hand insert applicator approximately 5 to 7.5 cm (2 to 3 inches). Push applicator plunger to deposit medication into vagina (see illustration).	Allows equal distribution of medication along vaginal walls.
d Withdraw applicator and place on paper towel. Wipe off residual cream from labia or vaginal orifice with tissue or cloth.	Maintains patient comfort.
12 Administer irrigation or douche.	
a Place patient on bedpan with absorbent pad underneath.	Allows hips to be higher than shoulders and solution to reach posterior wall of vagina. Bedpan collects solution.
b Be sure that irrigation or douche fluid is at body temperature. Run fluid through container nozzle (priming the tubing).	Body temperature promotes patient comfort. Priming tubing removes air and moistens nozzle tip.
c Gently separate labial folds and direct nozzle toward sacrum, following floor of vagina.	Correct angle allows nozzle access into vagina.
d Raise container approximately 30 to 50 cm (12 to 20 inches) above level of vagina. Insert nozzle 7 to 10 cm (3 to 4 inches). Allow solution to flow while rotating nozzle. Administer all irrigating solution.	Rotating nozzle allows irrigation of all areas in vagina.
e Withdraw nozzle and help patient to comfortable sitting position.	Remaining solution drains by gravity.
f Allow patient to remain on bedpan for a few minutes. Clean perineum with soap and water.	Ensures all solution drains from vagina. Provides comfort for patient.
g Help patient off bedpan. Dry perineal area.	Provides comfort.
13 Instruct patient who received suppository, cream, or tablet to remain on her back for at least 10 minutes.	Allows melting and spreading of medication throughout vaginal cavity and prevents loss through vaginal orifice.
14 If using an applicator, wash with soap and warm water, rinse, and store for future use.	Vaginal cavity is not sterile. Soap and water help to remove bacteria and residual cream from applicator.
15 Offer perineal pad when patient resumes ambulation.	Provides patient comfort.
16 Discard gloves by turning them inside out and dispose of them and other soiled equipment in appropriate receptacle. Perform hand hygiene.	Reduces spread of microorganisms.

EVALUATION

1 Perform hand hygiene and apply clean gloves. Thirty minutes after administration, inspect condition of vaginal canal and external genitalia between applications. Assess vaginal discharge if present. Remove gloves and perform hand hygiene.	Determines whether vaginal medication effectively reduced irritation or inflammation of tissues.
2 Question patient regarding continued pruritus, burning, discomfort, or discharge.	Determines whether symptoms are relieved.
3 Ask patient to discuss purpose, action, and side effects of medication.	Reflects patient's understanding of drug therapy.
4 Observe patient demonstrate administration of next dose.	Reflects learning of technique.

Unexpected Outcomes

- 1 Patient reports localized pruritus and burning.
- 2 Patient is unable to discuss drug therapy correctly.
- 3 Patient is unable to self-administer medications.

Related Interventions

- Results of infection or inflammation, but may be possible side effects of some medications (e.g., miconazole).
- Monitor symptoms; report to health care provider.
- Repeat instructions or assess if patient is able to learn.
- Include family caregiver when appropriate.
- Reinstruction is necessary.

Recording and Reporting

- Record drug (or solution if vaginal instillation), dose, type of instillation, and time administered on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding and ability to self-administer medication in nurses' notes and EHR.
- Report to health care provider if patient states that symptoms do not disappear or symptoms get worse.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider.

Special Considerations

Teaching

- Encourage patient to take *all* of the medication as prescribed, for the prescribed amount of time, to ensure effectiveness of the treatment.

- Women taking antifungal medications for the treatment of vaginal infections should abstain from sexual intercourse until the treatment is completed and the infection is resolved. Women should be told to continue to take the medication even if actively menstruating. Patients should notify the health care provider if symptoms persist past the treatment time period (Lilley et al., 2011).
- Many women prefer to self-administer vaginal irrigations and medications. These procedures may be self-administered while patient is sitting on the toilet. Ensure that patient is able to perform the procedure correctly.

Gerontologic

- Older adults may have difficulty manipulating suppository, applicator, or irrigating equipment. If so, a family caregiver may need instruction on how to insert the medication.

SKILL 21-9 Administering Rectal Suppositories

NSO Nonparenteral Medication Administration Module / Lesson 6

A rectal suppository is a form of medication that acts when it melts and is absorbed into the rectal mucosa. Rectal medications exert either local effects on gastrointestinal (GI) mucosa (e.g., promoting defecation) or systemic effects (e.g., relieving nausea or providing analgesia). The rectal route is not as reliable as oral or parenteral routes in terms of drug absorption and distribution. However, the medications are relatively safe because they rarely cause local irritation or side effects. Rectal medications are contraindicated in patients with recent surgery on the rectum, bowel, or prostate gland; rectal bleeding or prolapse; and very low platelet counts (Lilley et al., 2011).

Rectal suppositories are thinner and more bullet shaped than vaginal suppositories (see Fig. 21-2). The rounded end prevents anal trauma during insertion. When you administer a rectal suppository, placing it past the internal anal sphincter and against the rectal mucosa is important. Improper placement can result in expulsion of the suppository before the medication dissolves and is absorbed into the mucosa. If a patient prefers to self-administer a suppository, give specific instructions so the medication is deposited correctly. Do not cut the suppository into sections to divide

the dosage; the active drug may not be distributed evenly within the suppository, and the result may be an inaccurate dose (Lilley et al., 2011).

Delegation and Collaboration

The skill of rectal medication administration cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Reporting expected fecal discharge or bowel movement to the nurse.
- Potential side effects of medications and to report their occurrence to the nurse.
- Informing nurse of any rectal discharge, pain, or bleeding.

Equipment

- Rectal suppository
- Water-soluble lubricating jelly
- Clean gloves
- Tissue
- Drape
- Medication administration record (MAR) (electronic or printed)

STEP

RATIONALE

ASSESSMENT

- 1 Check accuracy and completeness of each medication administration record (MAR) with health care provider's medication order. Check patient's name, drug name and dosage, route, and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
- 2 Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
- 3 Review patient's medical history for history of rectal surgery or bleeding, cardiac problems, history of allergies, and medication history.
- 4 Review any presenting signs and symptoms of GI alterations (e.g., constipation or diarrhea).
- 5 Assess patient's ability to hold suppository and position self to insert medication.

The health care provider's order is the most reliable source and only legal record of drugs that patient is to receive. Ensures that patient receives correct medication. Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).

Allows you to anticipate effects of drug and observe patient's response.

Conditions may contraindicate use of suppository.

Conditions indicate use of suppository.

Mobility restriction indicates need for nurse to help with drug administration.

STEP

RATIONALE

- | | |
|---|---|
| 6 Review patient's knowledge of purpose of drug therapy and interest in self-administering suppository. | Indicates need for health teaching. Level of motivation influences teaching approach. |
|---|---|

NURSING DIAGNOSES

- | | | |
|---|--|---|
| <ul style="list-style-type: none"> • Constipation • Readiness for enhanced self-health management | <ul style="list-style-type: none"> • Deficient knowledge regarding suppository administration | <ul style="list-style-type: none"> • Impaired physical mobility • Pain (acute or chronic) |
|---|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|---|
| 1 Expected outcomes following completion of the procedure: <ul style="list-style-type: none"> • Patient reports relief or reduction in symptoms for which medication is prescribed. • Patient describes purpose of medication. • Patient demonstrates self-administration of rectal suppository. | Drug acts effectively. |
| 2 Explain procedure to patient. Be specific if patient wishes to self-administer drug. | Feedback reflects patient's learning.
Demonstrates learning.
Promotes patient's understanding and cooperation. Enables patient to self-administer drug safely if physically able and motivated. |

IMPLEMENTATION

- | | |
|---|---|
| 1 Prepare suppository for administration. Check label of medication against MAR 2 times (see Skill 22-1). Check expiration date on container. | <i>These are the first and second checks for accuracy.</i> Process ensures that right patient receives right medication. |
| 2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration. | Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011). |
| 3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
Some agencies are now using a bar-code system to help with patient identification. |
| 4 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies. | <i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history. |
| 5 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the drugs. Explain procedure if patient plans to self-administer medication. | Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy. |
| 6 Perform hand hygiene, arrange supplies at bedside, and apply clean gloves. Close room curtain or door. | Reduces transfer of microorganisms. Maintains privacy and minimizes embarrassment. |
| 7 Help patient assume left side-lying Sims' position with upper leg flexed upward. | Position exposes anus and relaxes external anal sphincter. Left side-lying Sims' position lessens likelihood of suppository or feces being expelled. |
| 8 If patient has mobility impairment, help into lateral position. Obtain assistance to turn patient and use pillows under upper arm and leg. | Provides support during procedure and patient comfort. |
| 9 Keep patient draped with only anal area exposed. | Maintains privacy and facilitates relaxation. |
| 10 Examine condition of anus externally. Option: Palpate rectal walls as needed (e.g., if impaction is suspected) (see Chapter 6). If you palpate rectal walls, dispose of gloves by turning them inside out and placing them in proper receptacle if they become soiled. Otherwise keep gloves on your hands. | Determines presence of active rectal bleeding. Palpation determines whether rectum is filled with feces, which interferes with suppository placement. Reduces spread of infection. |

STEP

RATIONALE

Clinical Decision Point Do not palpate patient's rectum if there is a recent history of rectal surgery. A suppository is contraindicated in the presence of active bleeding and diarrhea (Lilley et al., 2011).

- | | |
|---|--|
| <p>11 Apply new pair of clean gloves (if previous gloves were soiled and discarded).</p> <p>12 Remove suppository from foil wrapper and lubricate rounded end with water-soluble lubricant. Lubricate gloved index finger of dominant hand. If patient has hemorrhoids, use liberal amount of lubricant and touch area gently.</p> <p>13 Ask patient to take slow, deep breaths through mouth and relax anal sphincter.</p> <p>14 Retract patient's buttocks with nondominant hand. With gloved index finger of dominant hand, insert suppository gently through anus, past internal sphincter, and against rectal wall, 10 cm (4 inches) in adults (see illustration) or 5 cm (2 inches) in infants and children. You should feel rectal sphincter close around your finger.</p> | <p>Minimizes contact with fecal material to reduce transmission of infection.</p> <p>Lubrication reduces friction as suppository enters rectal canal.</p> <p>Forcing suppository through constricted sphincter causes pain.</p> <p>Suppository needs to be against rectal mucosa for eventual absorption and therapeutic action.</p> |
|---|--|

Clinical Decision Point Do not insert suppository into a mass of fecal material; this will reduce effectiveness of medication.

- | | |
|---|--|
| <p>15 <i>Option:</i> A suppository may be given through a colostomy (not ileostomy) if ordered. Patient should lie supine. Use small amount of water-soluble lubricant for insertion.</p> <p>16 Withdraw finger and wipe patient's anal area.</p> <p>17 Ask patient to remain flat or on side for 5 minutes.</p> <p>18 Discard gloves by turning them inside out and dispose of them and used supplies in appropriate receptacle. Perform hand hygiene.</p> <p>19 If suppository contains laxative or fecal softener, place call light within reach so patient can obtain assistance to reach bedpan or toilet.</p> <p>20 If suppository was given for constipation, remind patient <i>not</i> to flush commode after bowel movement.</p> | <p>Provides comfort.</p> <p>Prevents expulsion of suppository.</p> <p>Reduces transfer of microorganisms.</p> <p>Ability to call for assistance provides patient with sense of control over elimination.</p> <p>Allows staff to evaluate results of suppository.</p> |
|---|--|

STEP 14 Insert rectal suppository past sphincter and against rectal wall.

EVALUATION

- | | |
|--|--|
| <p>1 Return to bedside within 5 minutes to determine if suppository was expelled.</p> <p>2 Ask if patient experienced localized anal or rectal discomfort during insertion.</p> <p>3 Evaluate patient for relief of symptoms for which medication was prescribed (within time expected action of drug occurs).</p> <p>4 Ask patient to explain purpose of medication.</p> <p>5 Have patient demonstrate self-administration of next dose of medication.</p> | <p>Determines if drug is distributed properly. Reinsertion may be necessary.</p> <p>Determines whether insertion of suppository was irritating.</p> <p>Determines medication's effectiveness.</p> <p>Reflects patient's understanding of drug therapy.</p> <p>Demonstration measures learning.</p> |
|--|--|

Unexpected Outcomes

- 1 Patient's symptoms are unrelieved.
- 2 Patient experiences decreased heart rate during rectal suppository insertion.
- 3 Patient reports rectal pain during insertion.
- 4 Patient is unable to explain purpose of drug therapy.

Recording and Reporting

- Record the drug, dosage, route, and actual time and date of administration on MAR immediately after administration, not before. Include initials or signature. Record patient teaching and validation of understanding and self-administration of suppository in nurses' notes.
- Report adverse effects/patient response and/or withheld drugs to nurse in charge or health care provider.

Special Considerations

Teaching

- Be certain that patient is aware that the foil wrapper must be removed before insertion and that the suppository is to be inserted rectally and not taken orally. If patient chooses to

Related Interventions

- Explore alternative therapy.
- Unintended vagal stimulation may occur, resulting in bradycardia in some patients.
- Monitor heart rate of patient. Rectal route may not be suitable for certain cardiac conditions.
- Suppository may need more lubrication.
- Rectal route may not be suitable; assess and notify health care provider.
- Reinstruction is necessary or patient is unwilling or unable to learn.

self-administer suppositories, or if a family caregiver plans to administer, teach principles and techniques of infection control to prevent contact with and spread of fecal material.

Pediatric

- With children it is often necessary to gently hold or tape the buttocks together for 5 to 10 minutes to relieve pressure on the anal sphincter until the urge to expel the suppository is gone (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults with loss of sphincter control may have difficulty with retaining suppository.
- Older adults may have difficulty manipulating suppository, applicator, or irrigating equipment. If so, a family caregiver may need instruction on how to insert the medication

Critical Thinking Exercises

Mrs. Martin is a 75-year-old African-American homemaker hospitalized for 3 days with a diagnosis of dehydration. She has a history of hypertension, asthma, angina (heart pain), and osteoarthritis in her hands. She also has an abscess on her right calf that was caused by a bug bite that became infected. One week after her discharge, the home care nurse visits Mrs. Martin to review her medications and assess her wound. Mrs. Martin's medications include:

- Hydrochlorothiazide 25 mg every morning by mouth (PO) (diuretic)
- Diltiazem SR capsule, 60 mg twice a day PO (calcium channel blocker)
- Albuterol (Proventil) MDI 2 puffs 4 times a day (inhaled bronchodilator)
- Bacitracin topical ointment (500 units/g) applied topically to wound twice a day (antibiotic)
- Nitroglycerin transdermal patch (Nitro-Dur), 0.2 mg/hr, one each morning topically (nitrate)
- Nitrostat sublingual tablets, 400 mcg, as needed for chest pain (nitrate)

- 1 The nurse observes Mrs. Martin as she gives herself the inhaler. Mrs. Martin complains that she "just can't seem to breathe in at the same time as I press the inhaler." What action should the nurse take?
- 2 While inspecting Mrs. Martin's abscess, the nurse finds that there is a thick crust of old medication on the wound. Mrs. Martin explains, "I don't like to waste the medication that is already there, so I just put the new medicine on top of it." How should the nurse intervene?
- 3 While listening to Mrs. Martin's breath sounds, the nurse notes that she has three nitroglycerin transdermal patches on her chest. What should the nurse do?

REVIEW QUESTIONS

- 1 An infant is to receive 4 mL of an antibiotic by mouth. Which equipment would be most appropriate for preparation and administration?
 - 1 A teaspoon
 - 2 A plastic medication cup
 - 3 A syringe
 - 4 An oral-dosing syringe
- 2 A patient says that he has difficulty swallowing pills and would prefer to chew them. One of the medications is an extended-release tablet. Which is an appropriate action in response to his request?
 - 1 Break the tablet into halves or quarters so they are not as difficult to swallow
 - 2 Encourage the patient to chew the tablet instead
 - 3 Educate the patient on the purpose of extended-release tablets
 - 4 Crush the tablet and mix in applesauce
- 3 A patient is to receive medications through a gastrostomy. Which nursing actions are appropriate? (Select all that apply.)
 - 1 Verifying tube placement after medications are given
 - 2 Mixing all crushed medications together and give all at once
 - 3 Flushing tube with cold water after giving medications
 - 4 Flushing tube with 30 to 60 mL of water after the last dose of medication
 - 5 Checking for gastric residual before giving the medications
 - 6 Keeping the head of the bed elevated 30 to 60 minutes after the medications are given
- 4 An immunocompromised patient has an open wound that needs topical medication. Which nursing technique is most appropriate?
 - 1 Use clean gloves when applying the medication.
 - 2 Use sterile gloves when applying the medication.
 - 3 Previously applied medication should remain on the wound surface.
 - 4 Be sure to apply a thick layer of medication over the wound.

- 5 A patient is using transdermal patches to relieve his mild cardiac pain. Which patient statement demonstrates understanding of the use of transdermal patches?
 - 1 "I'll apply the patch to a different area each time."
 - 2 "I need to leave the old patch on to make sure I receive all the medicine."
 - 3 "If I get a headache from this medicine, I'll cut the patch in half."
 - 4 "It doesn't matter where I throw away the old patch because the medicine is gone."
- 6 The nurse is caring for a patient who is receiving nitroglycerin ointment. Which nursing intervention is most appropriate to protect the nurse against accidental exposure?
 - 1 Cleaning skin thoroughly before applying the next dose of medication
 - 2 Wearing gloves when applying the ointment
 - 3 Using the appropriate applicator to apply the medication
 - 4 Drawing blood to test for therapeutic drug values
- 7 The nurse is educating an adolescent about using a metered-dose inhaler (MDI) for exercise-induced asthma. The nurse knows that teaching was successful when the patient states:
 - 1 "I'll rinse my mouth thoroughly after I use my inhaler."
 - 2 "I'll wait 5 to 10 seconds between inhalations."
 - 3 "I'll position the inhaler between my lips and pointed toward the top of my mouth."
 - 4 "I should hold my breath 20 to 30 seconds after each inhalation."
- 8 A nurse is caring for an adult patient who is resistant to receiving his ear medication because last time it made him nauseated. Which nursing intervention will reduce the chance that this complication will happen again?
 - 1 Positioning the patient in supine position with his affected ear facing upward
 - 2 Pulling the pinna upward and outward
 - 3 Gently cleaning out any cerumen impaction before administering medication
 - 4 Running warm water over the medication bottle to warm the medication
- 9 The nurse is administering nasal drops for a maxillary sinus infection. How should the nurse position the patient to administer the drops?
 - 1 Tilt the patient's head over a pillow with the head turned to the affected side
 - 2 Tilt the patient's head backwards over the edge of the bed
 - 3 Place a small pillow under the patient's shoulder and tilt head back
 - 4 Lower the head of the bed and have the patient lie supine
- 10 A nurse is administering an ophthalmic ointment to a patient with conjunctivitis. Place the steps of the procedure in the correct order.
 - 1 Clean eye, washing from inner to outer canthus
 - 2 Assess condition of external eye structures
 - 3 Apply thin ribbon of ointment evenly along inner edge of lower eyelid on conjunctiva
 - 4 Have patient close eye and rub lid lightly in circular motion with cotton ball
 - 5 Ask patient to look at ceiling and explain steps to him or her

KEY TERMS

Adverse reaction	Compatibility	Induration	Parenteral
Air embolus	Continuous subcutaneous infusion (CSQI or CSCII)	Infiltration	Phlebitis
Allergic reaction	Diluent	Infusion	Piggyback infusion
Ampule	Extravasation	Injection	Saline lock
Anaphylactic reaction	Hematemesis	Intradermal (ID) injection	Subcutaneous injection
Aqueous	Hematuria	Intramuscular (IM) injection	Vial
Aspirate	Hypodermoclysis	Intravenous (IV) injection	Volume-control administration set (Volutrol)
Blunt-tip vial access cannula	Incompatibility	Medication administration record (MAR)	Z-track method
Bolus			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Correctly prepare injectable medications from a vial and an ampule.
- Identify advantages, disadvantages, and risks of administering medications by each injection route.
- Evaluate the effectiveness and outcomes of administering medications by each injection route.
- Explain the importance of selecting the proper-size syringe and needle for an injection.
- Discuss factors to consider when selecting injection sites.
- Discuss ways to promote patient comfort while administering an injection.
- Correctly administer intradermal, subcutaneous, and intramuscular injections.
- Compare the risks of three different intravenous routes.
- Correctly administer an intravenous infusion by intravenous piggyback, intermittent infusion, or bolus through a hanging intravenous line or saline lock.
- Initiate, maintain, and discontinue a continuous subcutaneous infusion.

The route of medication administration is the path by which a drug comes in contact with the body. *Parenteral* means administered in a manner other than through the digestive tract. Medications administered by the parenteral route enter body tissues and the circulatory system by injection. Injected medications are more quickly absorbed than oral medications; and parenteral routes are used when patients are vomiting, cannot swallow, and/or are restricted from taking oral fluids.

These medication administration procedures are invasive and thus pose greater risks than those associated with administering nonparenteral medications (see Chapter 21). Because infections originate from a variety of sources, you must use aseptic technique (Table 22-1). There are four routes for parenteral administration:

- 1 *Subcutaneous injection*: Injection into tissues just under the dermis of the skin
- 2 *Intramuscular (IM) injection*: Injection into the body of a muscle
- 3 *Intradermal (ID) injection*: Injection into the dermis just under the epidermis
- 4 *Intravenous (IV) injection or infusion*: Injection into a vein

Each type of injection requires a certain set of skills to ensure that the medication reaches the proper location. Failure to inject a medication correctly results in complications such as an inappropriate drug response (e.g., too rapid or too slow), nerve injury with associated pain, localized bleeding, tissue necrosis, and sterile abscess.

EVIDENCE-BASED PRACTICE

Currently there is increasing evidence that addresses practice guidelines for administration of injections. Over 16 billion preventive and curative injections are administered each year (Cocoman and Murray, 2010). In the past site selection was not evidence based, and needle selection was based on nursing preference. The literature has clearly identified the ventrogluteal site as best suited for intramuscular (IM) injection (Walsh and Brophy, 2010; Zimmermann, 2010). However, nurses were reluctant to use this site because of difficulty in anatomically locating it and their belief that it was not safe (Cocoman and Murray, 2010). There is now enough

consensual evidence to develop guidelines for administration of IM injections. Based on this evidence choose a muscle on the basis of its characteristics.

Ventrogluteal

- Deep and situated away from major nerves and blood vessels
- Easily identified by prominent bony landmarks
- Preferred site for medications that are larger in volume, more viscous, and irritating
- Less painful than vastus lateralis
- Recommended as pediatric IM injection site for children of all ages (Hockenberry and Wilson, 2011)

Vastus Lateralis

- Absence of major nerves and blood vessels
- Drug absorption rapid
- Site used for immunizations in children
- Recommended as pediatric IM injection site for infants up to 12 months of age (Hockenberry and Wilson, 2011)

Deltoid

- Easily accessible but not well developed in most patients
- Used for small volumes of medication
- Faster absorption rate
- May be used as a vaccination site for adults, based on development of muscle (Willcox, 2011)
- Recommended as pediatric IM injection site for children 18 months and older (Hockenberry and Wilson, 2011)

PATIENT-CENTERED CARE

Research shows that ethnicity, genetics, and culture influence drug response, pharmacokinetics, pharmacodynamics, and patient adherence and education (Giger, 2013; Groves, 2010). Knowledge about variations in therapeutic dose and adverse effects is essential in administering medications to different ethnic groups. Some patients experience a therapeutic response at a different dosage than recommended and require careful monitoring. For example, pediatric African patients do not respond well to attention deficit hyperactivity disorder (ADHD) medication (Malik et al., 2010). You need skill in communicating with and educating diverse patient populations. For example, if a patient's culture values patience and modesty, make your questions specific and take time when assessing his or her knowledge about adverse drug effects. Cultural assessment also yields information about dietary preferences, tobacco and alcohol use, and use of herbal remedies that affect drug action and response. Cultural context is essential in planning education for patients and families (Cherry and Stuart, 2011).

Safety Guidelines

Patient safety in administering medication involves following the six rights of medication administration (see Chapter 20). When managing a patient's medications, communicate clearly with the interdisciplinary team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about patient care. Follow these guidelines to ensure safe medication administration:

- 1 Be vigilant. Avoid distractions while preparing an injection. Be sure that your patients receive the appropriate medications. Know why your patient is receiving each medication; know what you need to do before, during, and after medication

TABLE 22-1 Preventing Infection During an Injection

Principle	Technique
Prevent contamination of solution	Ampules should not sit open, and medication should be removed quickly.
Prevent needle contamination	Avoid letting needle touch contaminated surface (e.g., outer edges of ampule or vial, outer surface of needle cap, your hands, countertop, or table surface). Avoid touching the length of the plunger or inner part of the barrel. Keep tip of syringe covered with cap or needle.
Prepare skin	Wash skin soiled with dirt, drainage, or feces with soap and water. Use friction and a circular motion while cleaning with an antiseptic swab. Swab from center of site and move outward in a 5-cm (2-inch) radius.
Reduce transfer of microorganisms	Perform hand hygiene for a minimum of 15 seconds.

FIG 22-1 Comparison of angles of insertion of intramuscular (90 degrees), subcutaneous (45 to 90 degrees), and intradermal (15 degrees) injections.

administration; and evaluate the effectiveness of medications and any adverse effects after administration.

- 2 Verify that the medications have not expired.
- 3 Use at least two identifiers before administering medications and check against the medication administration record (MAR). Follow agency policy for patient identification.
- 4 Clarify unclear medication orders and ask for help whenever you are uncertain about an order or calculation. Consult with your peers, pharmacists, and other health care providers and be sure that you have resolved all concerns related to medication administration before preparing and giving medications.
- 5 Use technology (e.g., bar scanning, electronic MARs) that is available in your agency when preparing and giving medications. Follow all policies related to use of the technology and do not use “workarounds.” A *workaround* bypasses a procedure, policy, or problem in a system. Nurses who use “workarounds” fail to follow agency protocols, policies, or procedures during medication administration in an attempt to administer medications to patients in a more timely manner.
- 6 Use strict aseptic technique during medication preparation and administration.
- 7 Educate patients about each medication that they take while you are administering it. Patients often are able to identify inappropriate medications. Make sure that you answer all of their questions before administering medications. Educate family caregivers if appropriate.
- 8 Most of the time you cannot delegate medication administration. Ensure that you follow standards set by the Nurse Practice Act in your state and guidelines established by your health care agency. Licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) usually can administer medications via the oral (PO), subcutaneous, IM, and ID routes. Some states allow certified medication assistants (CMAs) to administer some types of medications (e.g., oral medication) in long-term care facilities.
- 9 No-interruption zones (NIZs) have been recommended by the Institute for Safe Medicine Practices. NIZs are created by placing red tape or tile borders on the floor around medication carts. Nurses standing in these zones are not to be interrupted (Anthony et al., 2010).
- 10 Minimize a patient’s discomfort when giving an injection.

- Use sharp, beveled needles in the shortest length and smallest gauge possible.
- Change the needle if liquid medication coats its shaft.
- Position and flex a patient’s limbs to reduce muscular tension.
- Divert a patient’s attention away from the injection procedure.
- Apply a vapocoolant spray (e.g., Flouri-Methane spray or ethyl chloride) or topical anesthetic (e.g., EMLA cream) to an injection site before giving a medication when possible or place wrapped ice on the site for a minute before injection.
- Insert the needle at the proper angle, smoothly, and quickly (Fig. 22-1). Do not hesitate and slowly push the needle into tissue.
- Inject the medication slowly but smoothly.
- Hold the syringe steady once the needle is in the tissue to prevent tissue damage.
- Withdraw the needle smoothly at the same angle used for insertion.
- Gently apply an antiseptic pad (e.g., alcohol) or dry, sterile gauze pad to the site.
- Apply gentle pressure at the injection site.
- Rotate injection sites to prevent the formation of indurations and abscesses.

NEEDLESTICK PREVENTION

The most frequent route of exposure to bloodborne disease for health care workers is from needlestick injuries (American Nurses Association, 2010). Research has shown that most needlestick injuries occur in patient rooms and the operating room (American Nurses Association, 2010). These injuries occur when health care workers recap needles, mishandle intravenous (IV) lines and needles, or leave needles at a patient’s bedside. However, the implementation of safe needle devices can prevent needlestick injuries (American Nurses Association, 2010). The Needlestick Safety and Prevention Act is a federal law that mandates health care agencies to use safe needle devices to reduce the frequency of needlestick injury (see Fig. 22-2, C). Employers must update their exposure control plans and seek employee input when evaluating and selecting safer medical devices (OSHA, 2012).

FIG 22-2 A, Needleless system. B, Safety needle system. C, Detail of safety needle system. (A and B Courtesy and © Becton, Dickinson and Company.)

BOX 22-1 Recommendations for the Prevention of Needlestick Injuries

- 1 Avoid using needles when effective needleless systems or SESIP safety devices are available.
- 2 Do not recap needles after medication administration.
- 3 Plan safe handling and disposal of needles before beginning a procedure that requires the use of a needle.
- 4 Immediately dispose of used needles, needleless systems, and SESIP into puncture- and leak-proof sharps disposal containers.
- 5 Maintain a sharps injury log (see agency policy).
- 6 Attend educational offerings regarding bloodborne pathogens and follow recommendations for infection prevention, including receiving the hepatitis B vaccine.
- 7 Report all needlestick and sharps-related injuries immediately according to agency policies.
- 8 Participate in the selection and evaluation of needleless systems of SESIP devices with safety features within your place of employment whenever possible.

Data from Occupational Safety and Health Administration (OSHA): *Bloodborne pathogens and needlestick injuries*, 77 FR 19934, 2012, available at http://www.osha.gov/pls/oshaweb/owadisp.show_document?p_table=STANDARDS&p_id=10051, accessed July 2012.

SESIP, Sharps with engineered sharps injury protection.

FIG 22-3 Sharps disposal using only one hand.

A sharp with engineered sharps injury protection (SESIP) is a device that is effective in preventing needlesticks. One type of SESIP is a blunt-end cannula; another is a safety syringe equipped with a plastic guard or sheath that slips over the needle as it is withdrawn from the skin (Fig. 22-2, A to C). The guard immediately covers the needle, eliminating the chance for a needlestick injury. A variety of other SESIP devices are found in needleless IV line connection systems (see Chapter 28). Box 22-1 lists recommendations for health care workers to use to reduce their risk of needlestick injuries.

Special puncture- and leak-proof containers are available in health care agencies for the disposal of sharps. Containers are made so only one hand needs to be used when disposing of an uncapped needle. In addition, containers must stand upright, not be allowed to overfill, and be colored red or labeled with a biohazard symbol (Fig. 22-3).

EQUIPMENT

Administer parenteral medication by using a needle and a syringe, available in a variety of sizes. Determine the appropriate size of syringe, length and gauge of needle, volume of solution, and medication route. These decisions are based on the quantity and type of medication prescribed and the body size of a patient. Most syringes come with needleless systems or safety needles that help prevent needlestick injuries. A variety of electronic infusion pumps deliver IV or continuous subcutaneous infusions. Infusion pumps ensure a constant and accurate delivery of medication.

SYRINGES

Syringes are single use, disposable, and either Luer-Lok or non-Luer-Lok. The design of the syringe tip influences the name. They

are packaged separately, in a paper wrapper or rigid plastic container. Syringes come with or without a sterile needle and with a needleless SESIP device. The parts of a syringe are shown in (Fig. 22-4). Non-Luer-Lok syringes use needles or needleless devices that slip onto the tip. Luer-Lok syringes (Fig. 22-5, A) use standard needles or needleless devices that are twisted onto the tip and lock themselves in place. The Luer-Lok design prevents the accidental removal of a needle from the syringe.

Syringes come in a variety of sizes, ranging in capacity from 0.5 to 60 mL (see Fig. 22-5). When you select a syringe, choose the smallest syringe size possible to improve accuracy of medication preparation. In addition, avoid injecting a large volume of fluid into tissues. It is unusual to use a syringe larger than 5 mL for IM injections. Larger volumes create pain and discomfort for a patient. Syringes are most commonly marked in a scale of tenths of a milliliter (see Fig. 22-5, A). You use tuberculin (TB) syringes to prepare small amounts of medications, for intradermal (ID) and subcutaneous injections (see Fig. 22-5, B). Insulin syringes (see Fig. 22-5, C and D) hold 0.3 mL to 1 mL, and low-dose insulin syringes (30 units per 0.3 mL or 50 units per 0.5 mL) hold 0.3 mL to 1 mL. Both come with preattached needles and are calibrated in units. Most insulin syringes are U-100s, designed for use with U-100-strength insulin. Each milliliter of solution contains 100 units of insulin.

FIG 22-4 Parts of a syringe.

FIG 22-5 Examples of types of syringes. **A**, 3-mL Luer-Lok syringe marked in 0.1 (tenths). **B**, Tuberculin syringe marked in 0.01 (hundredths) for doses of less than 1 mL. **C**, Insulin syringe marked in units (100). **D**, Insulin syringe marked in units (50) for low dose.

Use a larger syringe to administer some IV medications, add medications to IV solutions, and irrigate drainage tubes. Some syringes are packaged with their needle attached; and some syringes require you to change the needle based on the viscosity of the medication, route of administration, and size of the patient. Before use carefully examine the syringe to determine the measurement scale and ensure that you use the correct syringe for preparing the ordered medication.

NEEDLES

Some needles come attached to syringes. Others come packaged individually to allow flexibility in selecting the right needle for a patient. Needles are disposable, and most are made of stainless steel. A needle has three parts: the hub, which fits onto the tip of a syringe; the shaft, which connects to the hub; and the bevel, or slanted tip (Fig. 22-6). The needle hub, shaft, and bevel must remain sterile at all times. To prevent contamination, use gentle force to place the needle onto the syringe with the cap intact (Fig. 22-7, A and B). Some needles come with filters for preparation of medications. Never use filters when administering a medication.

FIG 22-6 Parts of a needle.

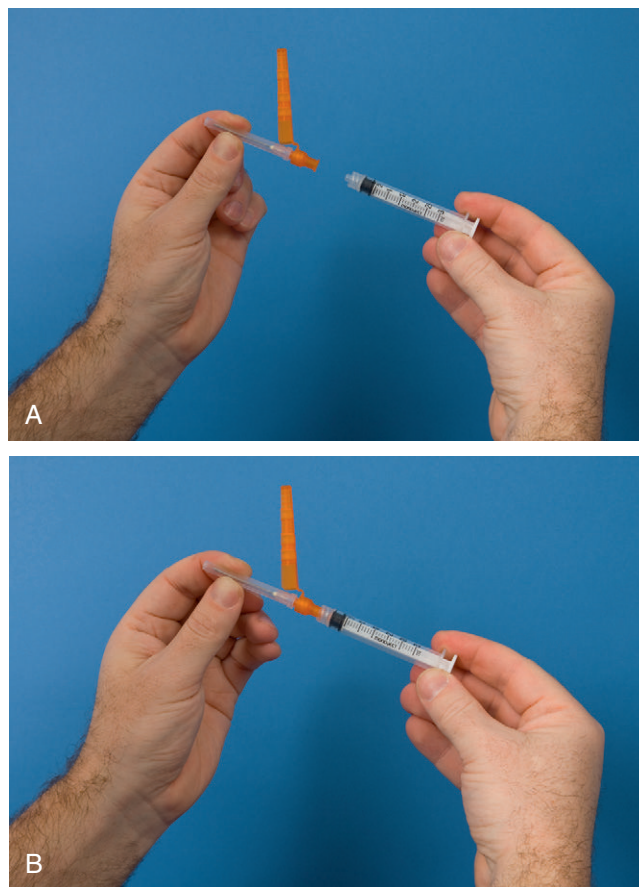

FIG 22-7 **A**, Capped needle placed on syringe tip. **B**, Needle secured.

The tip of a needle, or the bevel, is always slanted. The bevel creates a narrow slit when injected into tissue that quickly closes after the needle is removed to prevent leakage of medication, blood, or serum. Longer beveled tips are sharper and narrower, which minimizes tissue discomfort during a subcutaneous or IM injection.

Most needles vary in length from $\frac{3}{8}$ to 3 inches (Fig. 22-8). Use longer needles (1 inch to $1\frac{1}{2}$ inches) for IM injections and shorter needles ($\frac{3}{8}$ to $\frac{5}{8}$ inch) for subcutaneous injections. Choose the

FIG 22-8 Needles come in a variety of gauges and lengths. Choose correct needle, gauge and length, for the injection ordered. (Lilley LL et al: *Pharmacology for nurses*, ed 6, St Louis, 2011, Mosby.)

needle length according to a patient's size and weight, type of tissue to be injected, and route of administration. Children and small, thin adults generally require a shorter needle. The smaller the needle gauge, the larger the needle diameter. They are color coded for ease of selection. The selection of a gauge depends on the viscosity of fluid to be injected. For example, use a larger 22-gauge $1\frac{1}{2}$ -inch needle for IM injections. Use a smaller 25-gauge $\frac{5}{8}$ -inch needle for a subcutaneous injection.

DISPOSABLE INJECTION UNITS

Single-dose, prefilled, disposable syringes are available for some medications. You do not need to prepare medication doses, except perhaps to expel unneeded portions of medication or air.

However, it is important to check the medication and concentration carefully because prefilled syringes appear very similar. Prefilled unit-dose systems such as Tubex and Carpuject injection systems include reusable plastic syringe holders and disposable, prefilled, sterile, glass cartridge units. To assemble a prefilled system, place the cartridge, barrel first, into the plastic syringe holder (Fig. 22-9, A). Following manufacturer instructions, turn the plunger rod to the left (counterclockwise) (see Fig. 22-9, B) and then lock to the right (clockwise) until it "clicks" (see Fig. 22-9, C). Finally remove the needle guard and advance the plunger (see Fig. 22-9, D) to expel air and excess medication as with a regular syringe. The cartridge may be used with SESIP needles. After giving the medication dispose of the glass cartridge safely in a puncture- and leak-proof container. This design reduces the risk for needlestick injury.

FIG 22-9 A, Carpuject syringe holder and prefilled sterile cartridge with needle. B, Assembling the Carpuject. C, The cartridge slides into the syringe barrel, turns, and locks at the needle end. D, The plunger screws into the cartridge end.

SKILL 22-1 Preparing Injections: Ampules and Vials

NSO Injections Module / Lesson 2

Ampules contain single doses of injectable medication in a liquid form and are available in sizes from 1 to 10 mL or more. An ampule is made of glass with a constricted, prescored neck that is snapped off to allow access to the medication (Fig. 22-10, A). A colored ring around the neck indicates where the ampule is prescored to be broken easily. Medication is easily withdrawn from the ampule by aspirating with a filter needle and syringe. Filter needles must be used when preparing medication from a glass ampule to prevent glass particles from being drawn into the syringe (Alexander et al., 2009; Nicholl and Hesby, 2002). *Do not* use the filter needle to administer the medication. Place an appropriate-size needle on the syringe after withdrawing the medication.

FIG 22-10 A, Medication in ampules. B, Medication in vials.

A vial is a single- or multi-dose plastic or glass container with a rubber seal at the top (see Fig. 22-10, B). After you open a single-dose vial discard it, regardless of the amount of medication used (Pugliese et al., 2010). A multi-dose vial contains several doses of a medication and thus can be used several times, although only for a single patient (Pugliese et al., 2010). When using a multi-dose vial, write the date that the vial is opened on the vial label. Verify with the agency how long an opened multi-dose vial may be used. Properly discard a multi-dose vial when the allowed time for being open has expired.

A metal or plastic cap protects a rubber seal of the vial. Remove the cap when you first prepare the vial for use. Vials may contain liquid or dry forms of medications; medications that are unstable in solution are packaged dry form. The vial label specifies the solvent or diluents used to dissolve the medication and the amount needed to prepare a desired medication concentration. Normal saline and sterile distilled water are the most common solutions.

Some vials have two chambers separated by a rubber stopper. One chamber contains the diluent solution; the other contains the dry medication. Before preparing the medication, push on the upper chamber to dislodge the rubber stopper and allow the powder and the diluent to mix. Unlike an ampule, a vial is a closed system. You must inject air into the vial to permit easy withdrawal of the solution. Some medications, even when in a vial, may need to be drawn up with a filter needle because of the nature of the medication. Agency policies and package inserts from the manufacturer indicate drugs that should be prepared with a filter needle.

Occasionally the prescriber orders an injectable medication that must be reconstituted because it comes in a powdered form. This frequently occurs with a time-sensitive injectable medication, which must be administered within a specific time period to guarantee full drug effectiveness.

Delegation and Collaboration

The skill of preparing injections from ampules and vials cannot be delegated to nursing assistive personnel (NAP).

Equipment

Medication in an Ampule

- Syringe, needle, and filter needle
- Small sterile gauze pad or unopened alcohol swab

FIG 22-11 Syringe with needleless vial access adapter.

Medication in a Vial

- Syringe and two needles
- Needles:
 - Needleless blunt-tip vial access cannula (Fig. 22-11) or needle (with safety sheath) for drawing up medication (if needed)
 - Filter needle if indicated
- Small, sterile gauze pad or alcohol swab
- Diluent (e.g., 0.9% sodium chloride or sterile water if indicated)

Both

- Medication administration record (MAR) or computer printout
- Sharps with engineered sharps injury protection (SESIP) safety needle for injection
- Medication in vial or ampule
- Puncture-proof container for disposal of syringes, needles, and glass

STEP	RATIONALE
------	-----------

ASSESSMENT

- | | |
|---|---|
| <p>1 Check accuracy and completeness of each MAR or computer printout with prescriber’s written medication order. Check patient’s name, medication name and dosage, route of administration, and time of administration. Recopy or reprint any portion of MAR that is difficult to read.</p> | <p>The prescriber’s order is the most reliable source and legal record of patient’s medications. Ensures that patient receives correct medications.</p> |
| <p>2 Assess patient’s medical and medication history.</p> | <p>Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).</p> |
| <p>3 Assess patient’s history of allergies: Know type of allergies and normal allergic response.</p> | <p>Determines need for medication or possible contraindications for medication administration.</p> |
| <p>4 Review medication reference information for action, purpose, side effects, and nursing implications.</p> | <p>Do not prepare medication if there is a known patient allergy.</p> |
| <p>5 Assess patient’s body build, muscle size, and weight if giving subcutaneous or intramuscular (IM) medication.</p> | <p>Allows you to administer drug properly and monitor patient’s response.</p> |

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Proper dose is prepared. No air bubbles are in syringe barrel. | <p>Determines type and size of syringe and needle for injection.</p> |
|---|--|

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Perform hand hygiene and prepare supplies.</p> | <p>Ensures right dose. Air bubbles displace medication. Elimination of air ensures accuracy of medication dose.</p> |
| <p>2 Prepare medications.</p> <ul style="list-style-type: none"> a If using a medication cart, move it outside patient’s room. b Unlock medication drawer or cart or log onto computerized medication dispensing system. c Follow agencies “No-Interruption Zone” policy. Prepare medications for one patient at a time. Keep all pages of MARs or computer printouts for one patient together or look at only one patient’s electronic MAR at a time. d Select correct drug from stock supply or unit-dose drawer. Compare label of medication with MAR computer printout or computer screen. e Check expiration date on each medication, one at a time. f Calculate drug dose as necessary. Double-check calculation. Ask another nurse to check calculations if needed. g If preparing a controlled substance, check record for previous drug count and compare with supply available. h Do not leave drugs unattended. | <p>Reduces transmission of microorganisms.</p> <p>Organization of equipment saves time and reduces error. Medications are safeguarded when locked in cabinet, cart, or computerized medication dispensing system.</p> <p>Preventing distractions reduces medication preparation errors (LePorte et al., 2009; Nguyen et al., 2010).</p> <p>No-Interruption Zone has been shown to decrease interruptions during medication preparation (Anthony et al., 2010).</p> <p>Reading label and comparing it with transcribed order reduce errors. <i>This is the first check for accuracy.</i></p> <p>Medications used past their expiration date are sometimes inactive, less effective, or harmful to patients.</p> <p>Double-checking reduces error.</p> <p>Controlled substance laws require careful monitoring of dispensed narcotics.</p> <p>Nurse is responsible for safekeeping of drugs.</p> |
| <p>3 Prepare ampule.</p> <ul style="list-style-type: none"> a Tap top of ampule lightly and quickly with finger until fluid moves from its neck (see illustration). b Place small gauze pad around neck of ampule (see illustration). c Snap neck of ampule quickly and firmly away from hands (see illustration). | <p>Dislodges any fluid that collects above neck of ampule. All solution moves into lower chamber.</p> <p>Protects fingers from trauma as glass tip is broken off. Do not use opened alcohol swab to wrap around top of ampule because alcohol may leak into ampule.</p> <p>Protects your fingers and face from shattering glass.</p> |

STEP

- d** Draw up medication quickly, using filter needle long enough to reach bottom of ampule to access medication.
- e** Hold ampule upside down or set it on flat surface. Insert filter needle into center of ampule opening. Do not allow needle tip or shaft to touch rim of ampule.
- f** Aspirate medication into syringe by gently pulling back on plunger (see illustration).
- g** Keep needle tip under surface of liquid. Tip ampule to bring all fluid within reach of needle.
- h** If you aspirate air bubbles, do not expel air into ampule.
- i** To expel excess air bubbles, remove needle from ampule. Hold syringe vertically with needle pointing up. Tap side of syringe to cause bubbles to rise toward needle. Draw back slightly on plunger and push plunger upward to eject air. Do not eject fluid.

RATIONALE

System is open to airborne contaminants. Filter needles filter out any fragments of glass (Alexander et al., 2009).
 Broken rim of ampule is considered contaminated. When ampule is inverted, solution dribbles out if needle tip or shaft touches rim of ampule.
 Withdrawal of plunger creates negative pressure within syringe barrel, which pulls fluid into syringe.
 Prevents aspiration of air bubbles.
 Air pressure forces fluid out of ampule, and medication will be lost. Withdrawing plunger too far removes it from barrel. Holding syringe vertically allows fluid to settle in bottom of barrel. Pulling back on plunger allows fluid within needle to enter barrel so fluid is not expelled. You then expel air at top of barrel and within needle.

STEP 3a Tapping ampule moves fluid down neck.

STEP 3b Gauze pad placed around neck of ampule.

STEP 3c Neck snapped away from hands.

STEP	RATIONALE
<p>j If syringe contains excess fluid, use sink for disposal. Hold syringe vertically with needle tip up and slanted slightly toward sink. Slowly eject excess fluid into sink. Recheck fluid level in syringe by holding it vertically.</p> <p>k Cover needle with its safety sheath or cap. Replace filter needle with regular sharps with engineered sharps injury protection (SESIP) needle.</p>	<p>Safely disperses excess medication into sink. Position of needle allows you to expel medication without having it flow down needle shaft. Rechecking fluid level ensures proper dose.</p> <p>Minimizes needlesticks. Filter needles cannot be used for injection.</p>
4 Prepare vial containing a solution.	
<p>a Remove cap covering top of unused vial to expose sterile rubber seal. If a multi-dose vial has been used before, cap is already removed. Firmly and briskly wipe surface of rubber seal with alcohol swab and allow it to dry.</p> <p>b Pick up syringe and remove needle cap or cap covering needleless access device. Pull back on plunger to draw amount of air into syringe equivalent to volume of medication to be aspirated from vial.</p>	<p>Vial comes packaged with cap that cannot be replaced after seal removal. Not all drug manufacturers guarantee that rubber seals of unused vials are sterile. Swabbing with alcohol reduces transmission of microorganisms. Allowing alcohol to dry prevents alcohol from coating needle and mixing with medication.</p> <p>Injecting air into vial prevents buildup of negative pressure in vial when aspirating medication.</p>
<p>Clinical Decision Point Some medications and agencies require use of a filter needle when preparing medications from vials. Check agency policy or medication reference. If you use a filter needle to aspirate medication, you need to change it to a regular SESIP needle of the appropriate size to administer medication (Alexander et al., 2009).</p>	
<p>c With vial on flat surface, insert tip of needle or needleless device through center of rubber seal (see illustration). Apply pressure to tip of needle during insertion.</p> <p>d Inject air into air space of vial, holding on to plunger. Hold plunger firmly; plunger is sometimes forced backward by air pressure within vial.</p> <p>e Invert vial while keeping firm hold on syringe and plunger. Hold vial between thumb and middle fingers of nondominant hand (see illustration). Grasp end of syringe barrel and plunger with thumb and forefinger of dominant hand to counteract pressure in vial.</p>	<p>Center of seal is thinner and easier to penetrate. Using firm pressure prevents dislodging rubber particles that could enter vial or needle.</p> <p>Injection of air creates vacuum needed to get medication to flow into syringe. Injecting into air space of vial prevents formation of bubbles and an inaccurate dose.</p> <p>Inverting vial allows fluid to settle in lower half of container. Position of hands prevents forceful movement of plunger and permits easy manipulation of syringe.</p>

STEP 3f Medication aspirated with ampule inverted.

STEP

RATIONALE

- f Keep tip of needle or needleless device below fluid level.
- g Allow air pressure from vial to fill syringe gradually with medication. If necessary, pull back slightly on plunger to obtain correct amount of medication.
- h When you obtain desired volume, position needle in needleless device into air space of vial; tap side of syringe barrel gently to dislodge any air bubbles. Eject any air remaining at top of syringe into vial.
- i Remove needle or needleless access device from vial by pulling back on barrel of syringe.
- j Hold syringe at eye level at 90-degree angle to ensure correct volume and absence of air bubbles. Remove any remaining air by tapping barrel to dislodge any air bubbles (see illustration). Draw back slightly on plunger; then push it upward to eject air. Do not eject fluid. Recheck volume of medication.

- Prevents aspiration of air.
- Positive pressure within vial forces fluid into syringe.
- Forcefully striking barrel while needle is inserted in vial may bend needle. Accumulation of air displaces medication and causes dose errors.
- Pulling plunger rather than barrel causes plunger to separate from barrel, resulting in loss of medication.
- Holding syringe vertically allows fluid to settle in bottom of barrel. Tapping dislodges air to top of barrel. Pulling back on plunger allows fluid within needle to enter barrel so you do not expel fluid. You then expel air at top of barrel and within needle.

Clinical Decision Point When preparing medication from single-dose vial, do not assume that volume listed on label is total volume in vial. Some manufacturers provide small amount of extra liquid, expecting loss during preparation. Be sure to draw up only desired volume.

- k If you need to inject medication into patient's tissue, change needle to appropriate gauge and length according to route of medication administration.
 - l For multi-dose vial, make label that includes date of opening, concentration of drug per milliliter, and your initials.
- 5 Prepare vial containing powder (reconstituting medications).**
- a Remove cap covering vial of powdered medication and cap covering vial of proper diluent. Firmly swab both rubber seals with alcohol swab and allow alcohol to dry.
 - b Draw up manufacturer suggestion for volume of diluent into syringe following Steps 4b through 4j.
 - c Insert tip of needle or needleless device through center of rubber seal of vial of powdered medication. Inject diluent into vial. Remove needle.
 - d Mix medication thoroughly. Roll in palms. Do not shake.

- Inserting needle through rubber stopper dulls beveled tip. New needle is sharper, and because no fluid is along shaft, does not track medication through tissues.
- Ensures that nurses will prepare future doses correctly. You discard some drugs within a certain time frame after mixing.
- Allowing alcohol to dry prevents it from coating needle and mixing with medication.
- Prepares diluent for injection into vial containing powdered medication.
- Diluent begins to dissolve and reconstitute medication.
- Ensures proper dispersal of medication throughout solution and prevents formation of air bubbles.

STEP 4c Insert safety needle through center of vial diaphragm (with vial flat on table).

STEP 4e Withdraw fluid with vial inverted.

STEP 4j Hold syringe upright; tap barrel to dislodge air bubbles.

STEP	RATIONALE
<p>e Reconstituted medication in vial is ready to be drawn into new syringe. Read label carefully to determine dose after reconstitution.</p> <p>f Draw up reconstituted medication into syringe. Insert needleless device/needle into vial. Do not add air. Then follow Steps 4e through 4j.</p>	<p>Once you add diluent, concentration of medication (mg/mL) determines dose you give. Reading medication label carefully decreases medication errors.</p> <p>Prepares medication for administration.</p>
<p>Clinical Decision Point Some agencies require that you verify dose of certain medications (e.g., insulin and heparin) for accuracy with another nurse. Check guidelines before administering medication.</p>	
<p>6 Compare label of medication with MAR, computer screen, or computer printout.</p> <p>7 Dispose of soiled supplies. Place broken ampule and/or used vials and used needle or needleless device in puncture- and leak-proof container. Clean work area and perform hand hygiene.</p>	<p>This is the second check for accuracy.</p> <p>Proper disposal of glass and needle prevents accidental injury to staff.</p> <p>Controls transmission of infection.</p>

EVALUATION

<p>1 Just before administering drug to patient, compare MAR with label of prepared drug and compare dose in syringe with desired dose.</p>	<p>Ensures that dose is accurate. This is the third check for accuracy.</p>
---	---

Unexpected Outcomes

- Air bubbles remain in syringe.
- Incorrect dose of medication is prepared.

Related Interventions

- Expel air from syringe and add medication to it until you prepare correct dose.
- Discard prepared dose.
- Prepare correct new dose.

PROCEDURAL GUIDELINE 22-1 Mixing Parenteral Medications in One Syringe

Some medications need to be mixed from two vials or from a vial and an ampule. Mixing compatible medications avoids the need to give a patient more than one injection. Most nursing units have medication compatibility charts. Compatibility charts are in drug reference guides, posted within patient care areas, or available electronically. If you are uncertain about medication compatibilities, consult a pharmacist. When mixing medications, you must correctly aspirate fluid from each type of container. When using multi-dose vials, do not contaminate the contents of the vial with medication from another vial or ampule.

When you mix medications from a vial and an ampule, you prepare medications from the vial first. Then you withdraw medication from the ampule using the same syringe and a filter needle. When mixing medications from two vials, do not contaminate one medication with another, ensure that the final dose is accurate, and maintain aseptic technique.

Give special consideration to the proper preparation of insulin, which comes in vials. Insulin is the hormone used to treat diabetes mellitus. Insulin is classified by rate of action, including short duration, intermediate duration, and long duration. Often patients with diabetes mellitus receive a combination of different types of insulin to control their blood glucose levels. Before preparing insulin, gently roll all cloudy insulin preparations (Humulin-N) between the palms of your hands to resuspend the insulin (Lehne, 2010).

If more than one type of insulin is required to manage the patient's diabetes, you can mix them into one syringe if they are

compatible. Always prepare the short- or rapid-acting insulin first to prevent it from being contaminated with the longer-acting insulin (Lehne, 2010). In some settings insulin is not mixed. Box 22-2 lists recommendations for mixing insulins.

Delegation and Collaboration

The skill of mixing medications in one syringe cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential side effects of medications and the need to report their occurrence to the nurse.

BOX 22-2 Recommendations for Mixing Insulins

- Patients whose blood glucose is well controlled on a mixed-insulin dose should maintain their individual routine when preparing and administering their insulin doses.
- No other medication or diluent should be mixed with any insulin product unless approved by the prescriber.
- Do not mix insulin glargine (Lantus) or insulin detemir (Levemir) with any other types of insulin and do not administer them intravenously.
- Inject rapid-acting insulins mixed with NPH insulin within 15 minutes before a meal.
- Verify insulin dosages during preparation with another nurse (if required by agency policy).

Data from American Diabetes Association (ADA): Standards of medical care in diabetes—2010: position statement, *Diabetes Care* 33(1):S11, 2010.

PROCEDURAL GUIDELINE 22-1 Mixing Parenteral Medications in One Syringe—cont'd

Equipment

- ❑ Single- or multi-dose vials and ampules containing medication
- ❑ Syringe and two needles
- ❑ Needles:
 - Needleless blunt-tip vial access cannula or needle for drawing up medication
 - Filter needle if indicated
 - Sharps with engineered sharps injury protection (SESIP) needle for injection
- ❑ Alcohol swab
- ❑ Puncture-proof container for disposing of syringes, needles, and glass
- ❑ Medication administration record (MAR) or computer printout
- ❑ Medication in vial or ampule

Procedural Steps

- 1 Check accuracy and completeness of MAR or computer printout with prescriber's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Recopy or reprint any portion of MAR that is difficult to read.
- 2 Review pertinent information related to medication, including action, purpose, side effects, and nursing implications.
- 3 Assess patient body build, muscle size, and weight if giving subcutaneous or (intramuscular) IM medication.
- 4 Consider compatibility of medications to be mixed and type of injection.
- 5 Check expiration date of medication printed on vial or ampule.
- 6 Perform hand hygiene.
- 7 Prepare medication for one patient at a time following the six rights of medication administration (see Chapter 20). Select an ampule or vial from the unit-dose drawer or automated dispensing system. Compare the label of each medication with the MAR or computer printout. In the case of insulin, ensure that correct type(s) of insulin are prepared. *This is the first check for accuracy.*

8 Mixing medications from two vials (see illustration):

- a Take syringe with needleless device or filter needle and aspirate volume of air equivalent to first medication dose (vial A).

- b Inject air into vial A, making sure that needle or needleless device does not touch solution (see illustration A).
- c Holding on to plunger, withdraw needle or needleless device and syringe from vial A. Aspirate air equivalent to second medication dose (vial B) into syringe.
- d Insert needle or needleless device into vial B, inject volume of air into vial B, and withdraw medication from vial B into syringe (see illustration B).
- e Withdraw needle or needleless device and syringe from vial B. Ensure that proper volume has been obtained.
- f Determine on syringe scale what the combined volume of medications should measure.
- g Insert needle or needleless device into vial A, being careful not to push plunger and expel medication within syringe into vial. Invert vial and carefully withdraw the desired amount of medication from vial A into syringe (see illustration C).
- h Withdraw needle or needleless device and expel any excess air from syringe. Check fluid level in syringe for proper dose. Medications are now mixed.

Clinical Decision Point *If too much medication is withdrawn from second vial, discard syringe and start over. Do not push medication back into either vial.*

- i Change needle or needleless device for appropriate-size needle if medication is being injected. Keep needle or needleless device capped until administration time.

9 Mixing insulin:

- a If patient takes insulin that is cloudy, roll bottle of insulin between hands to resuspend insulin preparation.
- b Wipe off tops of both insulin vials with alcohol swab.
- c Verify insulin dose against MAR.
- d If mixing rapid- or short-acting insulin with intermediate- or long-acting insulin, take insulin syringe and aspirate volume of air equivalent to dose to be withdrawn from intermediate- or long-acting insulin first (see illustration). If two intermediate- or long-acting insulins are mixed, it makes no difference which vial is prepared first.

Clinical Decision Point *If long-acting insulin glargine (Lantus) is ordered, note that this is a clear insulin, and it should not be mixed with other insulin preparations.*

STEP 8 A, Injecting air into vial A. B, Injecting air into vial B and withdrawing dose. C, Withdrawing medication from vial A; medications are now mixed.

PROCEDURAL GUIDELINE 22-1 Mixing Parenteral Medications in One Syringe—cont'd

STEP 9d Aspirate air equivalent to dose to be withdrawn from intermediate insulin.

STEP 9k Withdrawal of intermediate insulin.

STEP 9g Withdrawal of short-acting insulin.

- e Insert needle and inject air into vial of intermediate- or long-acting insulin. Do not let tip of needle touch solution.
- f Remove syringe from vial of insulin without aspirating medication.
- g With the same syringe, inject air equal to the dose of rapid- or short-acting insulin into vial and withdraw correct dose into syringe (see illustration).
- h Remove syringe from rapid- or short-acting insulin and remove any air bubbles to ensure accurate dose.
- i Verify short-acting insulin dosage with MAR and show insulin prepared in syringe to another nurse to verify that correct dosage of insulin was prepared. Determine which point on syringe scale the combined units of insulin should measure by adding the number of units of both insulins together (e.g., 4 units Regular +10 units NPH = 14 units total). Verify combined dosage.
- j Place needle of syringe back into vial of intermediate- or long-acting insulin. Be careful not to push plunger and inject insulin in syringe into vial.

- k Invert vial and carefully withdraw desired amount of insulin into syringe (see illustration).
- l Withdraw needle and check fluid level in syringe. Keep needle of prepared syringe sheathed or capped until ready to administer medication.

10 Mixing medications from a vial and an ampule:

- a Prepare medication from vial first, following Skill 22-1, Step 4.
- b Determine on syringe scale what combined volume of medications should measure.

Clinical Decision Point *If needleless access device was used in preparing medication from vial, change needleless system to filter needle from ampule.*

- c Next, using the same syringe, prepare second medication from ampule, following Step 3 in Skill 22-1.
- d Withdraw filter needle from ampule and verify fluid level in syringe. Change filter needle to appropriate SESIP needle. Keep device or needle sheathed or capped until administering medication.
- e Check syringe carefully for total combined dose of medications.
- 11 Compare MAR, computer screen, or computer printout with prepared medication and labels on vials/ampules. *This is the second check for accuracy.*
- 12 Dispose of soiled supplies. Place used ampules and/or vials and needle or needleless device in puncture- and leak-proof container.
- 13 Clean work area and perform hand hygiene.
- 14 Check syringe again carefully for total combined dose of medications.
- 15 *The third check for accuracy occurs at patient's bedside.*

SKILL 22-2 Administering Intradermal Injections

NSO Injections Module / Lesson 4

Video Clip

You typically give intradermal (ID) injections for skin testing (e.g., tuberculosis screening and allergy tests). Because such medications are potent, you inject them into the dermis, where blood supply is reduced and drug absorption occurs slowly. A patient may have an anaphylactic reaction if the medications enter the circulation too rapidly. For patients with a history of multiple allergies, the physician may perform skin testing. Skin testing often requires you to visually inspect the test site; therefore make sure that the ID sites are free of lesions and injuries and relatively hairless. The inner forearm and upper back are ideal locations.

To administer an ID injection, use a tuberculin (TB) or small syringe with a short ($\frac{3}{8}$ - to $\frac{5}{8}$ -inch), fine-gauge (25 to 27) needle. The angle of insertion for an ID injection is 5 to 15 degrees (see Fig. 22-1). Inject only small amounts of medication (0.01 to 0.1 mL) intradermally. Only administer amounts up to 0.1 mL to children (Hockenberry and Wilson, 2011). If a bleb does not appear or if the site bleeds after needle withdrawal, the medication may have entered subcutaneous tissues. In this situation skin test results will not be valid.

Delegation and Collaboration

The skill of administering ID injections cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential medication side effects and to report their occurrence to the nurse.
- Reporting any change in the patient's condition to the nurse.

Equipment

- Syringe: 1-mL TB syringe with preattached 25- or 27-gauge needle, $\frac{3}{8}$ - to $\frac{5}{8}$ -inch
- Small gauze pad
- Alcohol swab
- Vial or ampule of medication
- Clean gloves
- Medication administration record (MAR) or computer printout
- Puncture-proof container

STEP

RATIONALE

ASSESSMENT

- 1 Check accuracy and completeness of MAR or computer printout with prescriber's original medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Recopy or reprint any portion of MAR that is difficult to read.
- 2 Review medication reference information about expected reaction when testing skin with specific allergen or medication and appropriate time to read site.
- 3 Assess patient's history of allergies: known type of allergens and normal allergic reaction.
- 4 Assess for contraindication to ID injections, such as reduced local tissue perfusion. Assess for history of severe adverse reactions or necrosis that happened after previous ID injection.
- 5 Assess patient's knowledge of purpose and response to skin testing.
- 6 Check date of expiration for medication.

The prescriber's order is the most reliable source and legal record of patient's medications. Ensures that patient receives correct medications.

Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).

Type of reaction depends on patient's ability to mount a cell-mediated immune response. Knowledge of expected and adverse reactions to skin testing helps you determine for which symptoms to monitor, how frequently, and when to reassess patient.

You do not administer any medication if there is known patient allergy.

Medications are potent and can cause severe anaphylaxis.

Patients need to know when to return for follow-up reading of skin test and when and how to report any reaction.

Dose potency increases or decreases when outdated.

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding skin testing
- Health-seeking behaviors regarding disease screening practices
- Fear

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient experiences very mild burning sensation during injection but no discomfort after injection.
 - Small, light-colored bleb approximately 6 mm ($\frac{1}{4}$ inch) in diameter forms at site and gradually disappears. Minimal bruising may be present.
 - Patient is able to identify signs of skin reaction and their significance.

Normal reaction to medication deposited in dermis.

Medication is in dermis and eventually absorbed. Bruising is result of minor bleeding from capillaries.

Demonstrates learning.

STEP

RATIONALE

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Prepare medications for one patient at a time using aseptic technique and avoiding distractions (see Skill 22-1). Check label of medication carefully with MAR or computer printout 2 times (see Skill 22-1 or Procedural Guideline 22-1) when preparing medication.</p> <p>2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.</p> <p>3 Close room curtain or door.</p> <p>4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> <p>5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.</p> <p>6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions. Tell him or her that injection will cause a slight burning or sting.</p> <p>7 Perform hand hygiene and apply clean gloves. Keep sheet or gown draped over body parts not requiring exposure.</p> <p>8 Select appropriate site. Note lesions or discolorations of skin. If possible, select site three to four finger widths below antecubital space and one hand width above wrist. If you cannot use forearm, inspect upper back. If necessary, use sites appropriate for subcutaneous injections.</p> <p>9 Help patient to comfortable position. Have him or her extend elbow and support it and forearm on flat surface.</p> <p>10 Clean site with antiseptic swab. Apply swab at center of site and rotate outward in circular direction for about 5 cm (2 inches). <i>Option:</i> Use vapocoolant spray (e.g., ethyl chloride) before injection.</p> <p>11 Hold swab or gauze between third and fourth fingers of nondominant hand.</p> <p>12 Remove needle cap from needle by pulling it straight off.</p> <p>13 Hold syringe between thumb and forefinger of dominant hand with bevel of needle pointing up.</p> <p>14 Administer injection.</p> <p style="padding-left: 20px;">a With nondominant hand stretch skin over site with forefinger or thumb.</p> <p style="padding-left: 20px;">b With needle almost against patient's skin, insert it slowly at 5- to 15-degree angle until resistance is felt. Advance needle through epidermis to approximately 3 mm ($\frac{1}{8}$ inch) below skin surface. You will see bulge of needle tip through skin (see illustration).</p> | <p>Ensures that medication is sterile. Preventing distractions reduces medication preparation errors (LePorte et al., 2009; Nguyen et al., 2010). <i>These are the first and second checks for accuracy</i> and ensure that correct medication is administered.</p> <p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).</p> <p>Provides privacy.</p> <p>Ensures correct patient. Complies with <i>The Joint Commission standards and improves patient safety</i> (TJC, 2012).</p> <p>Some agencies are now using a bar-code system to help with patient identification.</p> <p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p> <p>Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy. Helps minimize patient's anxiety.</p> <p>Reduces transmission of infection.</p> <p>An ID injection site is free of discoloration or hair so you can see results of skin test and interpret them correctly (CDC, 2011b).</p> <p>Stabilizes injection site for easy accessibility.</p> <p>Mechanical action of swab removes secretions containing microorganisms.</p> <p>Decreases pain at injection site.</p> <p>Gauze or swab remains readily accessible when withdrawing needle.</p> <p>Preventing needle from touching sides of cap prevents contamination.</p> <p>Smooth injection requires proper manipulation of syringe parts. With bevel up, you are less likely to deposit medication into tissues below dermis.</p> <p>Needle pierces tight skin more easily.</p> <p>Ensures that needle tip is in dermis. You will obtain inaccurate results if you do not inject needle at correct angle and depth (CDC, 2011b).</p> |
|--|---|

STEP

- c Inject medication slowly. Normally you feel resistance. If not, needle is too deep; remove and begin again.

Slow injection minimizes discomfort at site. Dermal layer is tight and does not expand easily when you inject solution.

Clinical Decision Point *It is not necessary to aspirate because dermis is relatively avascular.*

- d While injecting medication, note that small bleb (approximately 6 mm [$\frac{1}{4}$ inch]) resembling mosquito bite appears on skin surface (see illustration).
- e After withdrawing needle, apply alcohol swab or gauze gently over site.
- 15 Help patient to comfortable position.
- 16 Discard uncapped needle or needle enclosed in safety shield and attached syringe in puncture- and leak-proof receptacle.
- 17 Remove gloves and perform hand hygiene.
- 18 Stay with patient for several minutes and observe for any allergic reactions.

Bleb indicates that you deposited medication in dermis.

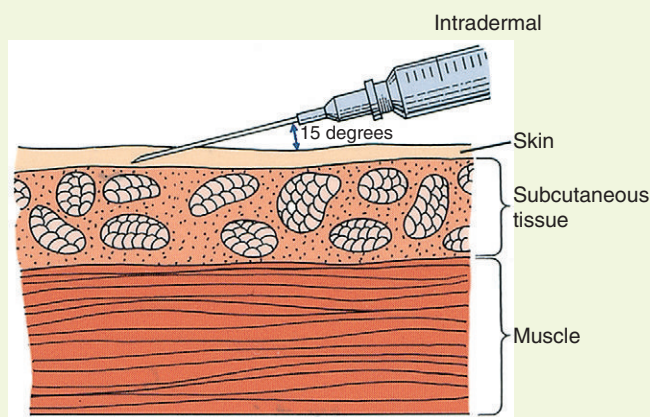

Do not massage site. Apply bandage if needed.

Gives patient sense of well-being.

Prevents injury to patients and health care personnel. Recapping needles increases risk for a needlestick injury (OSHA, 2012).

Reduces transmission of microorganisms.

Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.

STEP 14b Intradermal needle tip inserted into dermis.

STEP 14d Injection creates small bleb.

EVALUATION

- Return to room in 15 to 30 minutes and ask if patient feels any acute pain, burning, numbness, or tingling at injection site.
- Ask patient to discuss implications of skin testing and signs of hypersensitivity.
- Inspect bleb. *Optional:* Use skin pencil and draw circle around perimeter of injection site. Read TB test site at 48 to 72 hours; look for induration (hard, dense, raised area) of skin around injection site of:
 - 15 mm or more in patients with no known risk factors for tuberculosis.
 - 10 mm or more in patients who are recent immigrants; injection drug users; residents and employees of high-risk settings; patients with certain chronic illnesses; children less than 4 years of age; and infants, children, and adolescents exposed to high-risk adults.

Continued discomfort could indicate injury to underlying tissues.

Patient's ability to recognize signs of skin testing helps to ensure timely reporting of results.

Determines if reaction to antigen occurs; indication positive for TB or tested allergens.

Degree of reaction varies based on patient condition.

Site must be read at various intervals to determine test results.

Pencil marks make site easy to find. You determine results of skin testing at various times, based on type of medication used or type of skin testing completed. Manufacturer directions determine when to read test results.

STEP

- 5 mm or more in patients who are human immunodeficiency virus (HIV) positive, have fibrotic changes on chest x-ray film consistent with previous tuberculosis infection, have had organ transplants, or are immunosuppressed (CDC, 2011b).

Unexpected Outcomes

- 1 Patient complains of localized pain or continued burning at injection site, indicating potential injury to nerve or vessels.
- 2 Raised, reddened, or hard zone (induration) forms around ID test site.
- 3 Patient has adverse reaction with signs of urticaria, pruritus, wheezing, and dyspnea.
- 4 Patient is unable to explain purpose or signs of skin testing.

Recording and Reporting

- Record drug, dose, route, site, time, and date on MAR immediately after administration, not before. Correctly sign MAR according to agency policy.
- Record area of ID injection and appearance of skin in your notes.
- Report any undesirable effects from medication to patient's health care provider and document adverse effects according to agency policy.
- Record patient teaching, validation of understanding, and patient's response to medication.

Special Considerations

Teaching

- Instruct patient not to squeeze medication out of injection site.
- Teach patients that negative skin tests may not rule out allergies, especially when low concentrations of medication are used.

RATIONALE

Related Interventions

- Assess injection site.
- Notify patient's health care provider.
- Notify patient's health care provider.
- Document sensitivity to injected allergen or positive test if tuberculin skin testing was completed.
- Notify patient's health care provider.
- Follow agency policy for appropriate response to drug reactions (e.g., administration of antihistamine such as diphenhydramine [Benadryl] or epinephrine).
- Add allergy information to patient's record.
- Provide further teaching to patient or family caregiver.
- Recognize that patient is unable to learn at this time.

- Patient should wear medical identification band listing all allergies.
- Caution patient not to wash off pencil markings around injection site.
- Explain to patient how to observe for skin reactions.

Pediatric

- Children who are exposed to people with confirmed or suspected infectious tuberculosis should be tested for it immediately following exposure (Hockenberry and Wilson, 2011).
- Children with ongoing exposure to high-risk individuals (e.g., HIV-infected, homeless, incarcerated) should be tested for tuberculosis every 2-to-3 years (Hockenberry and Wilson, 2011).

Gerontologic

- The skin of the older adult is less elastic and must be held taut to ensure that ID injection is administered correctly.

SKILL 22-3 Administering Subcutaneous Injections

NSO Injections Module / Lesson 3

Subcutaneous injections involve depositing medication into the loose connective tissue underlying the dermis. Because subcutaneous tissue does not contain as many blood vessels as muscles, medications are absorbed more slowly than with intramuscular (IM) injections. Physical exercise or application of hot or cold compresses influences the rate of drug absorption by altering local blood flow to tissues. Any condition that impairs blood flow is a contraindication for subcutaneous injections.

You give subcutaneous medications in small doses of less than 2 mL that are isotonic, nonirritating, nonviscous, and water soluble. Limited research indicates that volumes up to 2 mL may be given without tissue damage (Cocoman and Murray, 2008, 2010; Walker et al., 2010). In infants and children the recommendation is to administer amounts up to 0.5 mL in one site (Hockenberry and Wilson, 2011). Examples of subcutaneous medications

 Video Clip

include epinephrine, insulin, allergy medications, opioids, and heparin. Because subcutaneous tissue contains pain receptors, the patient often experiences some discomfort.

The best subcutaneous injection sites include the outer aspect of the upper arms, the abdomen from below the costal margins to the iliac crests, and the anterior aspects of the thighs (Fig. 22-12). These areas are easily accessible and are large enough to allow rotating multiple injections within each anatomic location.

Choose an injection site that is free of skin lesions, bony prominences, and large underlying muscles or nerves. Site rotation prevents the formation of lipohypertrophy or lipoatrophy in the skin. The patient's body weight and amount of adipose tissue indicate the depth of the subcutaneous layer. Therefore base the needle length and angle of needle insertion on the patient's weight and estimate of subcutaneous tissue. Generally a 25-gauge $\frac{5}{8}$ -inch

FIG 22-12 Common sites for subcutaneous injections.

FIG 22-13 Insulin injection pen. (From Lewis SL et al: *Medical-surgical nursing: assessment and management of clinical problems*, ed 8, St Louis, 2011, Mosby.)

needle inserted at a 45-degree angle or a $\frac{1}{2}$ -inch needle inserted at a 90-degree angle deposits medications into the subcutaneous tissue of a normal-size patient. A child usually requires a 26- to 30-gauge $\frac{1}{2}$ -inch needle inserted at a 90-degree angle (Hockenberry and Wilson, 2011). If the patient is obese, pinch the tissue and use a needle long enough to insert through the fatty tissue at the base of the skinfold. Thin patients sometimes have insufficient tissue for injections. Therefore the upper abdomen is the best injection site for patients with little peripheral subcutaneous tissue. Aspiration after an injection, including heparin and insulin, is not necessary. Piercing a blood vessel and causing a hematoma formation are rare (Hunter, 2008b).

Several new technologies are available for administration of subcutaneous injections. *Injection pens* are a technology that patients can use to self-administer medications (e.g., epinephrine, insulin, or interferon) subcutaneously (Fig. 22-13). They offer a convenient delivery method using prefilled, disposable cartridges. The patient pinches the skin, inserts the needle, and injects a predetermined medication dose. Teaching is essential to ensure that patients use the correct injection technique and deliver the correct dose of medication. Patients need to be taught the importance of purging the pen before a dose is given. The disadvantages to this technology include increased risk for needlestick injury and

FIG 22-14 Jet injection system is held perpendicular to skin. (Image courtesy Pharmajet. All rights reserved.)

FIG 22-15 Subcutaneous device. (Image courtesy IntraPump Infusion Systems. All rights reserved.)

user's lack of knowledge and skill in administration technique and how to store the device (Aschenbrenner and Venable, 2009). One new technology is a *needleless injection system* that administers subcutaneous medications without the use of needles. Needle-free injections use high pressure to penetrate the skin with the medication into the subcutaneous tissue (Fig. 22-14). Another new advance in subcutaneous injection is the *subcutaneous injection device* (e.g., insuflon) (Fig. 22-15), which is inserted into the subcutaneous tissue; the needle is then removed, leaving the cannula in the tissue to provide an avenue for administering medications for up to 3 days without having to puncture the skin with each injection (Riley and Raup, 2010).

Special Considerations for Administration of Insulin

Most patients manage type 1 diabetes mellitus with injections. Anatomic injection site rotation is no longer necessary because newer human insulins carry a lower risk for hypertrophy. Patients choose one anatomic area (e.g., the abdomen) and systematically rotate sites within that region, which maintains consistent insulin absorption from day to day. Absorption rates of insulin vary based on the injection site. Insulin is most quickly absorbed in the abdomen and most slowly in the thighs (Lehne, 2010).

TABLE 22-2 Comparison of Insulin Preparations

Insulin Type*	Onset	Peak Effect (Hours)	Duration of Action (Hours)
Rapid-Acting			
Insulin lispro (Humalog)	15-30 min	½-2 ½	3-6 ½
Insulin aspart (NovoLog)	10-20 min	1-3	3-5
Insulin glulisine (Apidra)	10-15 min	1-1 ½	3-5
Short-Acting			
Regular insulin† (e.g., Humulin R, Novolin R)	30-60 min	1-5	6-10
Intermediate-Acting			
Isophane insulin suspension (NPH)	1-2 hr	6-14	16-24
Long-Acting			
Insulin glargine (Lantus)‡	1 hr	Plateau	24
Insulin detemir (Levemir)‡	0.8-2 hr	Peakless	Up to 24

Data from Hodgson BB, Kizior RJ: *Saunders Nursing Drug Handbook 2013*, St Louis, 2013, Saunders.

*All above insulins are available in 100-unit strengths.

†This is the only insulin approved for intravenous or intramuscular use.

‡Cannot be mixed with other insulins.

The timing of injections is critical to correct insulin administration. Health care providers plan insulin injection times based on blood glucose levels and when a patient will eat. Knowing the peak action and duration of the insulin is essential when developing an effective diabetes management plan. [Table 22-2](#) compares a variety of insulin preparations. [Box 22-3](#) provides general guidelines for insulin administration.

Special Considerations for Administration of Heparin

Heparin therapy provides therapeutic anticoagulation to reduce the risk for thrombus formation by suppressing clot formation. Therefore patients receiving heparin are at risk for bleeding, including bleeding gums, hematemesis, hematuria, or melena. Results from coagulation blood tests (e.g., activated partial thromboplastin time [aPTT] and partial thromboplastin time [PTT]) allow you to monitor the desired therapeutic range for intravenous (IV) heparin therapy.

Before administering heparin, assess for preexisting conditions that contraindicate its use, including cerebral or aortic aneurysm, cerebrovascular hemorrhage, severe hypertension, and blood dyscrasias. In addition, assess for conditions in which increased risk for hemorrhage is present: recent childbirth; severe diabetes and renal disease; liver disease; severe trauma; and active ulcers or lesions of the gastrointestinal (GI), genitourinary (GU), or respiratory tract. Assess the patient's current medication regimen, including use of over-the-counter (OTC) and herbal medications (e.g.,

BOX 22-3 General Guidelines for Insulin Administration

- Store vials of insulin in the refrigerator, not the freezer. Keep vials currently being used at room temperature. Do not inject cold insulin.
- Inspect vials before each use for changes in appearance (e.g., clumping, frosting, precipitation, change in clarity or color) indicating lack of potency.
- Do not interchange insulin types unless approved by the patient's prescriber.
- Preferred injection site includes the abdomen, avoiding a 5 cm (2-inch) radius around the umbilicus and the outer aspect of the thighs.
- Have patient self-administer insulin whenever possible. Generally children begin self-administration by adolescence.
- Patients who take insulin need to self-monitor their blood glucose.
- All patients who take insulin should carry at least 15 g carbohydrate (e.g., 4 ounces of fruit juice, 4 ounces of regular soft drink, 8 ounces of skim milk, 6 to 10 hard candies) in the event of a hypoglycemic reaction.

Adapted from American Diabetes Association: Standards in medical care of diabetes, 2011, *Am Diabetes Care* 34(S1):S11, 2011; Sheeja VS et al: Insulin therapy in diabetes management, *Int J Pharm Sci Rev Res* 2(2):98, 2010.

garlic, ginger, ginkgo, horse chestnut, or feverfew), for possible interaction with heparin. Other medications that interact with heparin include aspirin, nonsteroidal antiinflammatory drugs (NSAIDs), cephalosporins, antithyroid agents, probenecid, and thrombolytics.

You administer heparin subcutaneously or intravenously. Low-molecular-weight heparins (LMWHs) (e.g., enoxaparin [Lovenox]) are more effective than heparin in some patients. The anticoagulant effects are more predictable ([Lehne, 2010](#)). LMWHs have a longer half-life and require less laboratory monitoring but are expensive. To minimize the pain and bruising associated with LMWH, it is given subcutaneously on the right or left side of the abdomen, at least 5 cm (2 inches) away from the umbilicus (the patient's "love handles"). Administer LMWH in its prefilled syringe with the attached needle and do not expel the air bubble in the syringe before giving the medication ([Sanofi-Aventis, 2010](#)).

Delegation and Collaboration

The skill of administering subcutaneous injections cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential medication side effects and to report their occurrence to the nurse.

Equipment

- Proper size syringe with engineered sharps injury protection (SESIP) needle:
 - Subcutaneous: syringe (1- to 3-mL) and needle (25- to 27-gauge, ⅜- to ⅝-inch)
 - Subcutaneous U-100 insulin: insulin syringe (1 mL) with preattached needle (28- to 31-gauge, ⅙- to ½-inch)
 - Subcutaneous U-500 insulin: 1 mL tuberculin (TB) syringe with needle (25- to 27-gauge, ½- to ⅝-inch)

- Small gauze pad (*optional*)
- Alcohol swab
- Medication vial or ampule
- Clean gloves
- Medication administration record (MAR) or computer printout
- Puncture-proof container

STEP

IMPLEMENTATION

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Perform hand hygiene and prepare medication using aseptic technique. Check label of medication carefully with MAR or computer printout 2 times (see Skill 22-1 or Procedural Guideline 22-1) when preparing medication. 2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration. | <p>Ensures that medication is sterile. <i>These are the first and second checks for accuracy</i> and ensure that correct medication is administered.</p> <p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).</p> |
|--|---|

STEP	RATIONALE
<p>3 Close room curtain or door.</p> <p>4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> <p>5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.</p> <p>6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions. Tell patient that injection will cause slight burning or sting.</p> <p>7 Perform hand hygiene and apply clean gloves. Keep sheet or gown draped over body parts not requiring exposure.</p> <p>8 Select appropriate injection site. Inspect skin surface over sites for bruises, inflammation, or edema. Do not use an area that is bruised or has signs associated with infection.</p>	<p>Provides privacy.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Some agencies are now using a bar-code system to help with patient identification.</p> <p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p> <p>Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy. Helps minimize patient's anxiety.</p> <p>Reduces transmission of infection. Respects dignity of patient while exposing injection area.</p> <p>Injection sites are free of abnormalities that interfere with drug absorption. Sites used repeatedly become hardened from lipohypertrophy (increased growth in fatty tissue).</p>

Clinical Decision Point *Applying ice to the injection site for 1 minute before the injection may decrease the patient's perception of pain (Hockenberry and Wilson, 2011).*

<p>9 Palpate sites and avoid those with masses or tenderness. Be sure that needle is correct size by grasping skinfold at site with thumb and forefinger. Measure fold from top to bottom. Make sure that needle is one-half length of fold.</p> <p>a When administering insulin or heparin, use abdominal injection sites first, followed by thigh injection site.</p> <p>b When administering LMWH subcutaneously, choose site on right or left side of abdomen, at least 5 cm (2 inches) away from umbilicus.</p> <p>c Rotate insulin site within an anatomic area (e.g., abdomen) and systematically rotate sites within that area.</p> <p>10 Help patient into comfortable position. Have him or her relax arm, leg, or abdomen, depending on site selection.</p> <p>11 Relocate site using anatomic landmarks.</p> <p>12 Clean site with antiseptic swab. Apply swab at center of site and rotate outward in circular direction for about 5 cm (2 inches) (see illustration).</p>	<p>You can mistakenly give subcutaneous injections in muscle, especially in abdomen and thigh sites. Appropriate size of needle ensures that you inject medication into subcutaneous tissue (Gibney et al., 2010; Hunter, 2008b).</p> <p>Risk for bruising is not affected by site (Aschenbrenner and Venable, 2009).</p> <p>Injecting LMWH on side of abdomen helps decrease pain and bruising at injection site (Sanofi-Aventis, 2010).</p> <p>Rotating injection sites within same anatomic site maintains consistency in day-to-day insulin absorption (Sheeja et al., 2010).</p> <p>Relaxation of site minimizes discomfort.</p> <p>Injection into correct anatomic site prevents injury to nerves, bone, and blood vessels.</p> <p>Mechanical action of swab removes secretions containing microorganisms.</p>
--	--

STEP 12 Cleaning site with circular motion.

STEP	RATIONALE
13 Hold swab or gauze between third and fourth fingers of nondominant hand.	Swab or gauze remains readily accessible for use when withdrawing needle after the injection.
14 Remove needle cap or protective sheath by pulling it straight off.	Preventing needle from touching sides of cap prevents contamination.
15 Hold syringe between thumb and forefinger of dominant hand; hold as dart (see illustration).	Quick, smooth injection requires proper manipulation of syringe parts.
16 Administer injection: <ul style="list-style-type: none"> <li data-bbox="136 413 776 466">a For average-size patient, hold skin across injection site or pinch skin with nondominant hand. <li data-bbox="136 472 776 588">b Inject needle quickly and firmly at 45- to 90-degree angle (see illustration). Release skin if pinched. <i>Option:</i> When using injection pen or giving heparin, continue to pinch skin while injecting medicine. <li data-bbox="136 594 776 646">c For obese patient pinch skin at site and inject needle at 90-degree angle below tissue fold. <li data-bbox="136 653 776 793">d After needle enters site, grasp lower end of syringe barrel with nondominant hand to stabilize it. Move dominant hand to end of plunger and slowly inject medication over several seconds (Hunter, 2008b) (see illustration). Avoid moving syringe. 	<p data-bbox="818 413 1500 466">Needle penetrates tight skin more easily than loose skin. Pinching elevates subcutaneous tissue and desensitizes area.</p> <p data-bbox="818 472 1500 558">Quick, firm insertion minimizes discomfort. (Injecting medication into compressed tissue irritates nerve fibers.) Correct angle prevents accidental injection into muscle.</p> <p data-bbox="818 594 1500 619">Obese patients have fatty layer of tissue above subcutaneous layer.</p> <p data-bbox="818 653 1500 705">Movement of syringe may displace needle and cause discomfort. Slow injection of medication minimizes discomfort.</p>
<p>Clinical Decision Point <i>Aspiration after injecting a subcutaneous medication is not necessary. Piercing a blood vessel in a subcutaneous injection is very rare (Hunter, 2008b). Aspiration after injecting heparin and insulin is not recommended (Aschenbrenner and Venable, 2009).</i></p>	
e Withdraw needle quickly while placing antiseptic swab or gauze gently over site.	Supporting tissues around injection site minimizes discomfort during needle withdrawal. Dry gauze may minimize patient discomfort associated with alcohol on nonintact skin.
17 Apply gentle pressure to site. Do not massage site. (If heparin is given, hold alcohol swab or gauze to site for 30 to 60 seconds.)	Aids absorption. Massage can damage underlying tissue. Time interval prevents bleeding at site.
18 Help patient to comfortable position.	Gives patient sense of well-being.
19 Discard uncapped needle or needle enclosed in safety shield (see illustrations) and attached syringe into puncture- and leak-proof receptacle.	Prevents injury to patients and health care personnel. Recapping needles increases risk for needlestick injury (OSHA, 2012).

STEP 15 Holding syringe as if grasping a dart.

STEP 16b Subcutaneous injection. Angle and needle length depend on thickness of skinfold.

STEP 16d Inject medication slowly.

STEP

- 20 Remove gloves and perform hand hygiene.
- 21 Stay with patient for several minutes and observe for any allergic reactions.

RATIONALE

Reduces transmission of microorganisms.
Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.

STEP 19 Needle with plastic guard to prevent needlesticks. **A**, Position of guard before injection. **B**, After injection guard locks in place, covering needle.

EVALUATION

- | | |
|---|--|
| <ol style="list-style-type: none"> 1 Return to room in 15 to 30 minutes and ask if patient feels any acute pain, burning, numbness, or tingling at injection site. 2 Inspect site, noting bruising or induration. Provide warm compress to site. 3 Observe patient's response to medication at times that correlate with onset, peak, and duration of medication. Review laboratory results as appropriate (e.g., blood glucose, partial thromboplastin). 4 Ask patient to explain purpose and effects of medication. | <p>Continued discomfort may indicate injury to underlying bones or nerves.</p> <p>Bruising or induration indicates complication associated with injection.</p> <p>Adverse effects of parenteral medications develop rapidly. Evaluate effect of medication based on onset, peak, and duration of action.</p> <p>Evaluates patient's understanding of information taught.</p> |
|---|--|

Unexpected Outcomes

- 1 Patient complains of localized pain, numbness, tingling, or burning at injection site.
- 2 Patient displays adverse reaction with signs of urticaria, eczema, pruritus, wheezing, and dyspnea.
- 3 Hypertrophy of skin develops from repeated subcutaneous injection.

Related Interventions

- Assess injection site; may indicate potential injury to nerve or tissues.
- Notify patient's health care provider and do not reuse site.
- Monitor patient's heart rate, respirations, blood pressure, and temperature.
- Follow agency policy or guidelines for appropriate response to allergic reactions (e.g., administration of antihistamine such as diphenhydramine [Benadryl] or epinephrine) and notify patient's health care provider immediately.
- Add allergy information to patient's record.
- Do not use site for future injections.
- Instruct patient not to use site for 6 months.

Recording and Reporting

- Immediately after administration, record medication, dose, route, site, time, and date given on MAR. Correctly sign MAR according to agency policy.
- Record patient teaching, validation of understanding, and patient's response to medication in nurses' notes and electronic health record (EHR).
- Report any undesirable effects from medication to patient's health care provider and document adverse effects in record.

Special Considerations

Teaching

- Instruct patient to wear medical identification bracelet indicating important medical information, including bleeding tendencies, illnesses (e.g., diabetes) and allergies.
- Patients who require daily injections need to learn techniques of self-administration (see Skill 42-6). Teach injection techniques to a family caregiver.

Pediatric

- Administer only amounts up to 0.5 mL subcutaneously to small children (Hockenberry and Wilson, 2011).

Gerontologic

- Aging patients have less elastic skin and reduced subcutaneous skinfold thickness. The upper abdominal site is the best site to use when the patient has little subcutaneous tissue.

Home Care

- Improper disposal of used needles and sharps in the home setting poses a health risk to the public and waste workers. Several options for safe sharps disposal at home exist, including allowing patients to transport their own sharps containers from home to collection sites (e.g., doctor's office, a hospital, or a pharmacy); mailing their used syringes to a collection site (mail-back programs); syringe exchange programs; or special devices that destroy the needle on the syringe, rendering it safe for disposal. If the patient cannot implement any of these options, have him or her dispose of needles and other sharps in a hard

plastic or metal container with a tightly sealed lid (e.g., empty detergent bottle or coffee can). Pamphlets for safe home disposal of sharps are on the [Environmental Protection Agency \(EPA\) website \(2004\)](#).

- Most insulin preparations have bacteriostatic properties that inhibit bacterial growth on the skin. Therefore patients with diabetes may reuse their syringes at home if they can safely recap the needles. Syringes should be discarded when the needles become dull or bent or contact any surface other than the skin. Wiping the needle off with alcohol is not recommended because the silicon coating on the needle is removed, making injections more painful. Immunocompromised patients and patients with poor personal hygiene, acute illness, or open hand wounds should not reuse syringes ([American Diabetes Association, 2011](#)).
- Teach injection techniques that minimize patient discomfort to patient and family caregiver.

SKILL 22-4 Administering Intramuscular Injections

NSO Injections Module / Lesson 5

The intramuscular (IM) injection route deposits medication into deep muscle tissue, which has a rich blood supply, allowing medication to absorb faster than by the subcutaneous route. However, there is an increased risk for injecting drugs directly into blood vessels. Any factor that interferes with local tissue blood flow affects the rate and extent of drug absorption.

An IM injection requires a longer and larger-gauge needle to penetrate deep muscle tissue (see [Fig. 22-1](#)). The viscosity of the medication, injection site, patient's weight, and amount of adipose tissue influence needle size selection. Determine needle gauge by the medication to be administered. For example, administer immunizations and parenteral medications in aqueous solutions with a 20- to 25-gauge needle. Give viscous or oil-based solution with an 18- to 21-gauge needle. Use a small-gauge (22- to 25-gauge) needle for children. The [CDC \(2011a\)](#) current recommendations for needle length are based on patient weight and body mass index (BMI). An adult patient who is thin requires a needle length of $\frac{5}{8}$ to 1 inch; whereas an average patient requires a 1-inch needle; patients over 70 kg require a 1- to $1\frac{1}{2}$ -inch needle, and those over 90 kg require a $1\frac{1}{2}$ -inch needle ([CDC, 2011a](#)). Evidence-based practice recommends needle lengths for adults based on site selection: vastus lateralis, 16- to 25-mm ($\frac{5}{8}$ - to 1-inch); ventrogluteal, 38 mm ($1\frac{1}{2}$ -inch); and deltoid, 25- to 38-mm (1- to $1\frac{1}{2}$ -inch) ([Nicholl and Hesby, 2002](#)). Recommendations for needle length include 25 mm (1 inch) for infants; 25- to 32- mm (1- to $1\frac{1}{4}$ -inch) in toddlers; and 38- to 51-mm ($1\frac{1}{2}$ - to 2-inch) needle in older children ([Hockenberry and Wilson, 2011](#)). Preterm and small, emaciated infants may require a shorter needle based on weight and muscle mass. Obese children may require a longer needle up to 38 mm ($1\frac{1}{2}$ inch) ([Middleman et al., 2010](#)). Based on the evidence, the recommendation for pediatric IM injection sites includes use of the anterolateral thigh for infants up to 12 months of age, deltoid in children 18 months and older, and ventrogluteal for children of all ages ([Hockenberry and Wilson, 2011](#)).

Muscle is less sensitive to irritating and viscous medication. A normal, well-developed adult can safely tolerate 2 to 5 mL of medication in larger muscles such as the ventrogluteal ([Hunt, 2008](#); [Nicholl and Hesby, 2002](#)). However, clinically it is unusual to administer over 3 mL of medication in a single injection because the

body does not absorb it well. Older adults and thin patients often tolerate only 2 mL in a single injection. The muscles of older infants and small children can tolerate 1 mL of medication in a single site. Children with larger muscles are able to tolerate a maximum volume of 2 mL of medication ([Hockenberry and Wilson, 2011](#)).

Administer IM injections so the needle is perpendicular to the patient's body and as close to a 90-degree angle as possible ([Zimmerman, 2010](#)). Rotate IM injection sites to decrease the risk for hypertrophy. Emaciated or atrophied muscles absorb medication poorly; thus avoid their use when possible. The Z-track method, a technique for pulling the skin during an injection, is recommended for IM injections ([Nicholl and Hesby, 2002](#)). It prevents leakage of medication into subcutaneous tissues, seals medication in the muscle, and minimizes irritation. To use the Z-track method, apply the appropriate-size needle to the syringe and select an IM site, preferably in a large, deep muscle such as the ventrogluteal. Pull the overlying skin and subcutaneous tissues approximately 2.5 to 3.5 cm (1 to $1\frac{1}{2}$ inches) laterally to the side with the ulnar side of the nondominant hand. Hold the skin in this position until you have administered the injection ([Fig. 22-16, A](#)). After cleaning a site, inject the needle deeply into the muscle. To reduce injection site discomfort, there is no longer any need to aspirate after the needle is injected when *administering vaccines* ([CDC, 2011a](#)). It is the nurses' responsibility to follow agency policy for aspirating after injecting the needle. Keep the needle inserted for 10 seconds to allow the medication to disperse evenly. Release the skin after withdrawing the needle. This leaves a zigzag path that seals the needle track wherever tissue planes slide across one another see ([Fig. 22-16, B](#)). The medication is sealed in the muscle tissue.

Injection Sites

When selecting an IM site, determine that the site is free of pain, infection, necrosis, bruising, and abrasions. Also consider the location of underlying bones, nerves, and blood vessels and the volume of medication that you will administer. Because of the sciatic nerve location, the dorsogluteal muscle is not recommended as an injection site. If a needle hits the sciatic nerve, the patient may experience partial or permanent paralysis of the leg ([Hunter, 2008a](#); [Zimmerman, 2010](#)).

FIG 22-16 **A**, Pulling on overlying skin with dorsum of hand during IM injection moves tissue to prevent later tracking. **B**, Z-track left after injection prevents deposit of medication through sensitive tissue.

Ventrogluteal Site

The ventrogluteal muscle involves the gluteus medius and minimus and is a safe injection site for adults and children (Hockenberry and Wilson, 2011; Zimmerman, 2010). Research has shown that pain and nerve and tissue injury are associated with inappropriate site selection (Hunt, 2008; Hunter, 2008a; Zimmerman, 2010).

To locate the ventrogluteal muscle, have a patient lie in either the supine or lateral position; place the heel of your hand over the greater trochanter of the patient's hip with the wrist almost perpendicular to the femur. Use your right hand for the left hip and the left hand for the right hip. Point the thumb toward the patient's groin; point the index finger to the anterior superior iliac spine; and extend the middle finger back along the iliac crest toward the buttock. The index finger, the middle finger, and the iliac crest form a V-shaped triangle. The injection site is the center of the triangle (Fig. 22-17, A) (Nicholl and Hesby, 2002). To relax this muscle, patients lie on their side or back, flexing the knee and hip (see Fig. 22-17, B).

Vastus Lateralis Muscle

The vastus lateralis muscle is another injection site used in adults and is the preferred site for administration of biologics (e.g., immunizations) to infants, toddlers, and children (Hockenberry and Wilson, 2011). The muscle is thick and well developed; it is located on the anterior lateral aspect of the thigh. It extends in an adult from a hand breadth above the knee to a hand breadth below the greater trochanter of the femur (Fig. 22-18, A) (Nicholl and Hesby, 2002). Use the middle third of the muscle for injection. The width of the muscle usually extends from the midline of the thigh to the midline of the outer side of the thigh. With young children or

FIG 22-17 **A**, Anatomic view of ventrogluteal injection site. **B**, Injection at ventrogluteal site avoids major nerves and blood vessels.

cachectic patients, it helps to grasp the body of the muscle during injection to be sure that the medication is deposited in muscle tissue. To help relax the muscle, ask the patient to lie flat with the knee slightly flexed and foot externally rotated or assume a sitting position (Fig. 22-18, B).

Deltoid Muscle

Although the deltoid site is easily accessible, the muscle is not well developed in many adults. There is potential for injury because the axillary, radial, brachial, and ulnar nerves and the brachial artery lie within the upper arm under the triceps and along the humerus. Use this site for small medication volumes (2 mL or less) (Nicholl and Hesby, 2002). Carefully assess the condition of the deltoid muscle; consult medication references for suitability of medication; and carefully locate the injection site using anatomic landmarks. Use this site for small medication volumes; for administration of routine immunizations in toddlers, older children, and adults; or when other sites are inaccessible because of dressings or casts.

Locate the deltoid muscle by fully exposing the patient's upper arm and shoulder and asking him or her to relax the arm at the side or by supporting the patient's arm and flexing the elbow. Do not roll up any tight-fitting sleeve. Allow the patient to sit, stand, or lie down. Palpate the lower edge of the acromion process, which forms the base of a triangle in line with the midpoint of the lateral aspect of the upper arm. The injection site is in the center of the triangle, about 3 to 5 cm (1 to 2 inches) below the acromion process (Fig. 22-19, A) (Nicholl and Hesby, 2002). You

A

B

FIG 22-18 A, Landmarks for vastus lateralis site. B, Giving IM injection in vastus lateralis site.

A

B

FIG 22-19 A, Landmarks for deltoid site. B, Giving IM injection in deltoid site.

locate the apex of the triangle by placing four fingers across the deltoid muscle with the top finger along the acromion process. The injection site is three finger widths below the acromion process (see Fig. 22-19, B).

Delegation and Collaboration

The skill of administering intramuscular injections cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential medication side effects and to report their occurrence to the nurse.
- Reporting any change in the patient's condition to the nurse.

Equipment

- ❑ Proper-size syringe and SESIP needle:
 - 2- to 3-mL for adult
 - 0.5- to 1-mL for infants and small children

- ❑ Needle length corresponds to site of injection and age and size of patient
- ❑ Needle gauge often depends on length of needle; administer biologic and medication in aqueous solution with a 20- to 25-gauge needle
- ❑ Alcohol swab
- ❑ Small gauze pad
- ❑ Vial or ampule of medication
- ❑ Clean gloves
- ❑ Medication administration record (MAR) or computer printout
- ❑ Puncture-proof container

STEP

RATIONALE

ASSESSMENT

1	Check accuracy and completeness of each MAR or computer printout with prescriber's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Recopy or reprint any portion of MAR that is difficult to read.	The prescriber's order is the most reliable source and legal record of patient's medications. Ensures that patient receives the correct medications. Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).
2	Assess patient's medical and medication history.	Determines need for medication or possible contraindications for medication administration. Do not prepare medication if there is a known patient allergy.
3	Assess patient's history of allergies: known type of allergies and normal allergic reaction.	
4	Review medication reference information for medication action, purpose, normal dose, side effects, time of peak onset, and nursing implications.	Allows you to administer medication safely and monitor patient's response to therapy.
5	Observe patient's previous verbal and nonverbal responses toward injection.	Anticipating patient's anxiety allows you to use distraction to reduce pain awareness.
6	Assess for contraindication to IM injections such as muscle atrophy, reduced blood flow, or circulatory shock.	Atrophied muscle absorbs medication poorly. Factors interfering with blood flow to muscles impair drug absorption.
7	Assess patient's symptoms before initiating medication therapy.	Provides information for nurse to evaluate desired effects of medication.

Clinical Decision Point Because of the documented adverse effects of IM injections, other routes of medication injection are preferred. Consider contacting health care provider for alternative route of medication administration.

8	Assess patient's knowledge regarding medication to be received.	Poses implications for patient education.
---	---	---

NURSING DIAGNOSES

- Acute pain
- Anxiety
- Deficient knowledge regarding medication administration or drug therapy
- Fear

Related factors are individualized based on patient's condition or needs.

PLANNING

1	Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient experiences no pain or mild burning at injection site. • Patient achieves desired effect of medication with no signs of allergies or undesired effects. • Patient explains purpose, dosage, and effects of medication. 	Medications may cause minor tissue irritation. Medication administered without patient injury. Demonstrates learning.
---	---	---

IMPLEMENTATION

1	Prepare medications for one patient at a time using aseptic technique. Keep all pages of MARs or computer printouts for one patient together or look at only one patient's electronic MAR at a time. Check label of medication carefully with MAR or computer printout 2 times (see Skill 22-1 and Procedural Guideline 22-1) when preparing medication.	Ensures that medication is sterile. Preventing distractions reduces medication preparation errors (LePorte et al., 2009; Nguyen et al., 2010). <i>These are the first and second checks for accuracy and ensure that correct medication is administered.</i>
2	Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.	Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).

STEP	RATIONALE
3 Close room curtain or door.	Provides privacy.
4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012) . Some agencies are now using a bar-code system to help with patient identification.
5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.	<i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.
6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions. Tell patient that injection will cause a slight burning or sting.	Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy. Helps minimize patient's anxiety.
7 Perform hand hygiene and apply clean gloves. Keep sheet or gown draped over body parts not requiring exposure.	Reduces transmission of infection. Respects patient's dignity while exposing injection site.
8 Select appropriate site. Note integrity and size of muscle. Palpate for tenderness or hardness. Avoid these areas. If patient receives frequent injections, rotate sites. Use ventrogluteal if possible.	Ventrogluteal is preferred injection site for adults. It is also preferred site for children of all ages (Hockenberry and Wilson, 2011 ; Hunt, 2008 ; Zimmerman, 2010).
9 Help patient to comfortable position. Position patient depending on chosen site (e.g., sit, lie flat, on side, or prone).	Reduces strain on muscle and minimizes injection discomfort.

Clinical Decision Point Ensure that medical condition (e.g., circulatory shock) does not contraindicate patient's position for injection.

10 Relocate site using anatomic landmarks.	Injection into correct anatomic site prevents injury to nerves, bone, and blood vessels.
11 Clean site with antiseptic swab. Apply swab at center of site and rotate outward in circular direction for about 5 cm (2 inches).	Mechanical action of swab removes secretions containing microorganisms.
a <i>Option:</i> Apply EMLA cream on injection site at least 1 hour before IM injection or use vapocoolant spray (e.g., ethyl chloride) just before injection.	Decreases pain at injection site.
12 Hold swab or gauze between third and fourth fingers of nondominant hand.	Swab or gauze remains readily accessible for use when withdrawing needle after injection.
13 Remove needle cap or sheath by pulling it straight off.	Preventing needle from touching sides of cap prevents contamination.
14 Hold syringe between thumb and forefinger of dominant hand; hold as dart, palm down.	Quick, smooth injection requires proper manipulation of syringe parts.
15 Administer injection.	Z-track creates zigzag path through tissues that seals needle track to avoid tracking medication. A quick dartlike injection reduces discomfort. Z-track injections can be used for all IM injections (Hunter, 2008a ; Nicholl and Hesby, 2002).
a Position ulnar side of nondominant hand just below site and pull skin laterally approximately 2.5 to 3.5 cm (1 to 1½ inches). Hold position until medication is injected. With dominant hand inject needle quickly at 90-degree angle into muscle (see Fig. 22-16, A).	Ensures that the medication reaches muscle mass (CDC, 2011a ; Hockenberry and Wilson, 2011).
b <i>Option:</i> If patient's muscle mass is small, grasp body of muscle between thumb and forefingers.	Smooth manipulation of syringe reduces discomfort from needle movement. Skin remains pulled until after medication is injected to ensure Z-track administration.
c After needle pierces skin, still pulling on skin with nondominant hand, grasp lower end of syringe barrel with fingers of nondominant hand to stabilize it. Move dominant hand to end of plunger. Avoid moving syringe.	Aspiration of blood into syringe indicates possible placement into a vein. Slow injection reduces pain and tissue trauma. The CDC no longer recommends aspiration for blood after administering vaccine (CDC, 2011a).
d Pull back on plunger 5 to 10 seconds. If no blood appears, inject medication slowly at rate of 10 sec/mL (Nicholl and Hesby, 2002).	

Clinical Decision Point If blood appears in syringe, remove needle, dispose of medication and syringe properly, and prepare another dose of medication for injection.

- | | |
|--|---|
| e Wait 10 seconds, smoothly and steadily withdraw needle, release skin, and apply gauze gently over site (Nicholl and Hesby, 2002) (see Fig. 22-16, B). | Allows time for medication to absorb into muscle before removing syringe. Dry gauze minimizes discomfort associated with alcohol on nonintact skin. |
|--|---|

STEP	RATIONALE
16 Apply gentle pressure to site. Do not massage site. Apply bandage if needed.	Massage damages underlying tissue.
17 Help patient to comfortable position.	Gives patient sense of well-being.
18 Discard uncapped needle or needle enclosed in safety shield and attached syringe into puncture- and leak-proof receptacle.	Prevents injury to patients and health care personnel. Recapping needles increases risk for needlestick injury (OSHA, 2012).
19 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
20 Stay with patient for several minutes and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.

EVALUATION

1 Return to room in 15 to 30 minutes and ask if patient feels any acute pain, burning, numbness, or tingling at injection site.	Continued discomfort may indicate injury to underlying bones or nerves.
2 Inspect site; note any bruising or induration. Apply warm compress to site.	Bruising or induration indicates complication associated with injection. Document findings and notify health care provider.
3 Observe patient's response to medication at times that correlate with onset, peak, and duration of medication.	Intramuscular medications are absorbed rapidly. Adverse effects of parenteral medications develop rapidly. Evaluate effect of medication based on onset, peak, and duration of actions of medication.
4 Ask patient to explain purpose and effects of medication.	Evaluates patient's understanding of information taught.

Unexpected Outcomes

- 1 Patient complains of localized pain or continued burning at injection site, indicating potential injury to nerve or vessels.
- 2 During injection blood is aspirated.
- 3 Patient displays adverse reaction with signs of urticaria, eczema, pruritus, wheezing, and dyspnea.

Related Interventions

- Assess injection site.
- Notify patient's health care provider.
- Immediately stop injection and remove needle.
- Prepare new syringe of medication for administration.
- Follow agency policy or guidelines for appropriate response to allergic reactions (e.g., administration of antihistamine such as diphenhydramine [Benadryl] or epinephrine).
- Notify patient's health care provider immediately.
- Add allergy information to patient's record.

Recording and Reporting

- Immediately after administration, record medication, dose, route, site, time, and date given on MAR. Correctly sign MAR according to agency policy.
- Record patient teaching, validation of understanding, and patient's response to medication in nurse's notes and electronic health record (EHR).
- Report any undesirable effects from medication to patient's health care provider and document adverse effects in record.

Special Considerations

Teaching

- Patients who require regular injections (e.g., vitamin B₁₂) need to learn techniques of self-administration. Teach a family member or significant other injection techniques and the importance of rotating sites to decrease the risk for hypertrophy.
- Instruct patient and family member or significant other to observe injection sites for complications and immediately report complications to the health care provider.
- Instruct patient and family member or significant other to observe for effectiveness of medication and adverse reactions

and report ineffectiveness of medication and adverse reactions to the health care provider.

- Have patient perform several return demonstrations of medication preparation to validate that learning has taken place.

Pediatric

- Children can be very anxious or fearful of needles. Help with proper positioning and holding the child is sometimes necessary. Distraction such as blowing bubbles and pressure at the injection site before giving the injection can help alleviate anxiety (Hockenberry and Wilson, 2011).
- If possible apply EMLA cream on injection site at least 1 hour before IM injection or use a vapocoolant spray (e.g., ethyl chloride) just before injection to decrease pain (Hockenberry and Wilson, 2011).

Gerontologic

- Older patients may have decreased muscle mass, which reduces drug absorption from IM injections. In addition, older adults may have loss of muscle tone and strength that impairs mobility, placing them at high risk for falls from guarding an injection site.

Home Care

- Self-administration of an IM injection is difficult, especially in the vastus lateralis. Teach a significant other to identify and administer injections in this site.
- Instruct adult patients who require frequent injections to apply EMLA cream to the injection site before administration.
- Patients need instruction in safe disposal of syringes and needles (see Skill 22-3, Home Care Considerations).
- See Skill 41-1 for information about modifying safety risks in the home.

SKILL 22-5 Administering Medications by Intravenous Bolus

NSO IV Medication Administration Module I Lesson 4

In the past nurses often mixed medications into large volumes of intravenous (IV) fluids (500 to 1000 mL). However, today's safety standards and evidence-based practice no longer support this practice on a routine basis (Infusion Nurses Society [INS], 2011; ISMP, 2011; TJC, 2012). Many patient safety risks such as incorrect calculation, poor aseptic technique, incorrect labeling, pump programming errors, lack of medication knowledge, and mix-up with another medication occur when nurses have to prepare medications in IV containers on patient care units. There are a number of current best practices for preparation and administration of IV medication (Box 22-4).

An IV bolus is one method of medication administration currently practiced on patient care units. It introduces a concentrated dose of a medication directly into a vein by way of an existing IV access. An IV bolus or “push” usually requires small volumes of fluid, which is an advantage for patients who are at risk for fluid

overload. Administering medications by IV bolus is common in emergencies when you need to deliver a fast-acting medication quickly. Because these medications act quickly, it is essential that you monitor patients closely for adverse reactions. Agencies have policies and procedures that identify the medications that nurses are allowed to administer by IV push and other IV routes. These policies are based on the medication, compatibility and availability of staff, and type of monitoring equipment available. There are advantages and disadvantages to administering IV push medications (Box 22-5).

The IV bolus is a dangerous method to administer medications because it allows no time to correct errors. Administering an IV push medication too quickly can cause death. Therefore be very careful in calculating the correct amount of the medication to give. In addition, a bolus may cause direct irritation to the lining of blood vessels; thus always confirm placement of the IV catheter or needle. Never give an IV bolus if the insertion site appears edematous or reddened or if the IV fluids do not flow at the ordered rate. Accidental injection of some medications into tissues surrounding a vein can cause pain, sloughing of tissues, and abscesses.

Verify the rate of administration of IV push medication using agency guidelines or a medication reference manual. The Institute for Safe Medication Practices (ISMP, 2011) has identified the

BOX 22-4 Best Practices for Administration of Intravenous Solutions and Medications

- Use standardized concentrations and dosages of medication.
- Use standardized procedures for ordering, preparing, and administering intravenous (IV) medications.
- Administer solutions and medications prepared and dispensed from the pharmacy or as commercially prepared when possible.
- Never prepare high-alert medications (e.g., heparin, dopamine, dobutamine, nitroglycerin, potassium, antibiotics, or magnesium) on a patient care unit.
- Use standardized infusion concentrations of “high-alert” medications.
- Standardize the storage of IV medications.
- Use the mnemonic CATS PRRR to help remember safety checks for administering IV medications: C, compatibilities; A, allergies; T, tubing correct; S, site checked; P, pump safety checked; R, right rate; R, release clamps; R, return and reassess the patient (Billings & Kowalski, 2005).
- Use standardized label practices. Bold patient name, generic drug name, and patient-specific dose.
- Correctly use technology such as intelligent-infusion devices, bar code–assisted medication administration, and electronic medication administration record.

Adapted from American Society of Health-System Pharmacists [ASHP]: Preventing patient harm and death, *Am J Health-Syst Pharm*; 65:2367, 2008; Infusion Nurses Society: Infusion nursing standards of practice, *J Intraven Nurs* 34(1S), 2011; Institute for Safe Medication Practices (ISMP): *Guidelines for standard order sets*, 2010, available at <http://www.ismp.org/tools/guidelines/StandardOrderSets.pdf>, accessed July 2011; Institute for Safe Medication Practices (ISMP): *Principles of designing a medication label for intravenous piggyback medication for patient specific, inpatient use*, 2011, available at <http://www.ismp.org/tools/guidelines/labelFormats/IVPB.asp>, accessed July 5, 2012; and The Joint Commission: 2011 *National Patient Safety Goals hospital program*, 2012, available at <http://www.jointcommission.org>, accessed July 2012.

BOX 22-5 Advantages and Disadvantages of the Intravenous Push Method

Advantages

- There is rapid onset of medication effects, which is useful in patients experiencing critical or emergent health problems.
- Medications can be prepared quickly and given over a shorter time than by intravenous (IV) piggyback.
- Doses of short-acting medications can be titrated based on a patient's needs and responses to the drug therapy. This is important for infants, children, and older patients.
- Method provides a more accurate dose of medication delivered because no medication is left in intravenously.

Disadvantages

- *Not all medications can be delivered by IV push.*
- There is higher risk for infusion reactions; some are mild to severe because the medication action peaks quickly.
- When giving medication quickly (e.g., less than 1 minute), there is very little opportunity to stop the injection if an adverse reaction occurs.
- Risk for infiltration and phlebitis is increased, especially if a highly concentrated medication, a small peripheral vein, or a short venous access device is used.
- Hypersensitivity reaction can cause an immediate or delayed systemic reaction to a medication, requiring supportive measures.

following four strategies to reduce harm from rapid IV push medications:

- 1 Make sure that information regarding rate of administration of IV push medication is readily available.
- 2 Use less concentrated solutions whenever possible.
- 3 Avoid using terms in orders such as *IV push*, *IVP*, or *IV bolus* with medications that should be administered over 1 minute or longer. Use more descriptive terms such as *IV over 5 minutes*.
- 4 Consider alternatives such as a syringe pump to administer medication that has a high risk for adverse effects. If this is not an alternative to IV push, have pharmacy dilute the medication and administer in a piggyback.

Verify the rate of administration of IV push medication using agency guidelines or a medication reference manual. Review the amount of medication that a patient will receive each minute, the recommended concentration, and rate of administration. For example, if a patient is to receive 6 mL of a medication over 3 minutes, give 2 mL of the IV bolus medication every minute. Understand the purpose of the medication and any potential adverse reactions related to the rate and route of administration. Some IV medications can only be given IV push safely when a patient is being continuously monitored for dysrhythmias, blood pressure changes, or other adverse effects. Therefore you can push some medications only in specific areas within a health care agency (e.g., critical care unit). Confirm agency guidelines regarding requirements for special monitoring.

IV push medications are given through either an existing continuous IV infusion or an intermittent venous access (commonly called a *saline lock*). A saline lock is an IV catheter with a small “well” or chamber covered by a rubber cap. An IV catheter can be converted into a lock by inserting a special rubber-seal injection

cap into the end of the catheter (see [Chapter 28](#)). Use of a lock saves time by eliminating constant monitoring of an IV line. It also offers better mobility, safety, and comfort for patients by eliminating the need for a continuous IV line. After you administer an IV bolus through an intermittent venous access, flush with a normal saline solution to keep it patent.

Delegation and Collaboration

The skill of administering medications by IV bolus cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential actions and side effects of the medications and to report their occurrence to the nurse.
- Reporting any patient complaints of moisture or discomfort around insertion site.
- Obtaining any required vital signs and reporting them to the nurse.

Equipment

- Watch with second hand
- Clean gloves
- Antiseptic swab
- Medication in vial or ampule
- Proper-size syringes for medication and saline flush with needleless device or SESIP needle (21- to 25-gauge)
- Intravenous lock: Vial of normal saline flush solution (saline recommended [INS, 2011]); if agency continues to use heparin flush, the most common concentration is 10 units/mL; check agency policy.
- Medication administration record (MAR) or computer printout
- Puncture-proof container

STEP

RATIONALE

ASSESSMENT

- 1 Check accuracy and completeness of each MAR or computer printout with prescriber’s written medication order. Check patient’s name, medication name and dosage, route of administration, and time of administration. Recopy or reprint any portion of MAR that is difficult to read.
- 2 Assess patient’s medical and medication history.
- 3 Review medication reference information for medication action, purpose, side effects, normal dose, time of peak onset, how slowly to give medication, and nursing implications such as need to dilute medication or administer it through a filter.
- 4 If you give medication through an existing IV line, determine compatibility of medication with IV fluids and any additives within IV solution.
- 5 Perform hand hygiene. Assess condition of IV needle insertion site for signs of infiltration or phlebitis.
- 6 Assess patency of patient’s existing IV infusion line or saline lock (see [Chapter 28](#)).
- 7 Check patient’s history of medication allergies: known allergens and normal allergic response.
- 8 Assess patient’s symptoms before initiating medication therapy.
- 9 Assess patient’s understanding of purpose of drug therapy.

The prescriber’s order is the most reliable source and legal record of patient’s medications. Ensures that patient receives correct medications.

Handwritten MARs are a source of medication errors ([ISMP, 2010; Jones and Treiber, 2010](#)).

Identifies need for medication.

Knowledge of medication allows you to give it safely and monitor patient’s response to therapy.

IV medication is not always compatible with IV solution and/or additives, and a new site may need to be initiated.

Do not administer medication if site is edematous or inflamed.

For medication to reach venous circulation effectively, IV line must be patent, and fluids must infuse easily.

IV bolus delivers medication rapidly. Allergic response is immediate.

Provides information to evaluate the desired effects of medication.

Poses implication for education.

STEP

RATIONALE

NURSING DIAGNOSES

- Acute pain
- Deficient knowledge regarding medication therapy

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Patient experiences no medication side effects or adverse reactions.
- IV site remains intact, without signs of swelling or inflammation or symptoms of tenderness at site.
- Patient explains purpose and side effects of medication.

Medication administered safely with desired therapeutic effect achieved.

Medication infuses without complications to IV site and surrounding tissues.

Demonstrates learning.

IMPLEMENTATION

- 1 Prepare medications for one patient at a time using aseptic technique. Keep all pages of MARs or computer printouts for one patient together or look at only one patient's electronic MAR at a time. Check label of medication carefully with MAR or computer printout 2 times (see Skill 22-1 and Procedural Guideline 22-1) when preparing medication.

Ensures that medication is sterile. Preventing distractions reduces medication preparation errors (LePorte et al., 2009; Nguyen et al., 2010). *These are the first and second checks for accuracy and ensure that correct medication is administered.*

Clinical Decision Point *Some IV medications require dilution before administration. Verify with agency policy or pharmacy. If a small amount of medication is given (e.g., less than 1 mL), dilute medication in small amount (e.g., 5 mL) of normal saline or sterile water so the medication does not collect in the "dead spaces" (e.g., Y-site injection port, IV cap) of the IV delivery system.*

- 2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.

Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).

- 3 Close room curtain or door.

Provides privacy.

- 4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.

Ensures correct patient. Complies with *The Joint Commission standards and improves patient safety* (TJC, 2012).

Some agencies are now using a bar-code system to help with patient identification.

- 5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.

This is the third check for accuracy and ensures that patient receives correct medication. Confirms patient's allergy history.

- 6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions. Explain that you will give medication through existing IV line. Encourage patient to report symptoms of discomfort at IV site.

Keep patient informed of planned therapies, minimizing anxiety. Patients who verbalize pain at IV site help detect IV infiltrations early, lessening damage to surrounding tissues.

- 7 Perform hand hygiene and apply clean gloves.

Reduces transmission of infection.

8 IV push (existing IV line):

- a Select injection port of IV tubing closest to patient. Use needleless injection port.

Follows provisions of Needle Safety and Prevention Act of 2001 (OSHA, 2012).

Clinical Decision Point *Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.*

STEP

RATIONALE

- b Clean injection port with antiseptic swab. Allow to dry.
- c Connect syringe to IV line: Insert needleless tip of syringe containing drug through center of port (see illustration).
- d Occlude IV line by pinching tubing just above injection port (see illustration). Pull back gently on plunger of syringe to aspirate for blood return.

Prevents transfer of microorganisms during blunt cannula insertion. Prevents introduction of microorganisms. Prevents damage to port diaphragm and possible leakage from site. Final check ensures that medication is being delivered into bloodstream.

Clinical Decision Point In the case of smaller-gauge IV needles, blood return sometimes is not aspirated even if IV line is patent. If IV site does not show signs of infiltration and IV fluid is infusing without difficulty, give IV push.

- e Release tubing and inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administrations (see illustration). You can pinch IV line while pushing medication and release it when not pushing medication. Allow IV fluids to infuse when not pushing medication.

Ensures safe medication infusion. Rapid injection of IV drug can be fatal. Allowing IV fluids to infuse while pushing IV drug enables medication to be delivered to patient at prescribed rate.

STEP 8c Connecting syringe to IV line with needleless blunt cannula tip.

STEP 8d Occluding IV tubing above injection port.

STEP 8e Using watch to time IV push medication.

STEP	RATIONALE
f After injecting medication, withdraw syringe and recheck IV fluid infusion rate.	Injection of bolus may alter rate of fluid infusion. Rapid fluid infusion can cause circulatory fluid overload.
g If IV medication is incompatible with IV fluids, stop IV fluids, clamp IV line, and flush with 10 mL of normal saline or sterile water (see agency policy). Then give IV bolus over appropriate amount of time and flush with another 10 mL of normal saline or sterile water at <i>same rate</i> as medication was administered.	Allows IV bolus to be administered without risks associated with IV incompatibilities. Ensure that agency guidelines permit flushing lines with incompatible medications. A new site may need to be initiated.
h If IV line that is currently hanging is a medication, disconnect it and administer IV push medication as outlined in Step 9. Verify agency policy for stopping IV fluids or continuous IV medications. If unable to stop IV infusion, start new IV site (see Chapter 28) and administer medication using IV push (IV lock) method.	Avoids giving patient sudden bolus of medication in existing IV line.
9 IV push (IV lock):	
a Prepare flush solutions according to agency policy.	Normal saline is effective in keeping IV locks patent and is compatible with wide range of medications.
(1) <i>Saline flush method (preferred method)</i> : Prepare two syringes filled with 2 to 3 mL of normal saline (0.9%). Many agencies do not provide prefilled normal saline syringes for flushing IV lines.	
(2) <i>Heparin flush method (not recommended; refer to agency policy)</i> .	
b Administer medication:	
(1) Clean injection port with antiseptic swab.	Prevents transfer of microorganisms during needle insertion.
(2) Insert needleless tip of syringe with normal saline 0.9% through center of injection port of IV lock (see illustrations).	
(3) Pull back gently on syringe plunger and check for blood return.	Indicates if needle or catheter is in vein.
(4) Flush IV site with normal saline by pushing slowly on plunger.	Clears needle and reservoir of blood. Flushing without difficulty indicates patent IV line.
Clinical Decision Point Carefully observe the area of skin above the IV catheter. Note any puffiness or swelling as the IV site is flushed, which could indicate infiltration into the vein, requiring removal of catheter.	
(5) Remove saline-filled syringe.	
(6) Clean injection port with antiseptic swab.	Prevents transmission of microorganisms.
(7) Insert needleless tip of syringe containing prepared medication through injection port of IV lock.	Allows administration of medication.
(8) Inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administration.	Many medication errors are associated with IV pushes being administered too quickly. Following guidelines for IV push rates promotes patient safety.
(9) After administering bolus, withdraw syringe.	
(10) Clean injection port with antiseptic swab.	Prevents transmission of microorganisms.

STEP 9b(2) A, Intravenous catheter with saline lock adapter. B, Syringe inserted into injection port.

STEP	RATIONALE
(11) Flush injection port. (a) Attach syringe with normal saline and inject flush at same rate that medication was delivered.	Flushing IV line with saline prevents occlusion of IV access device and ensures that all medication is delivered. Flushing IV site at same rate as medication ensures that any medication remaining within IV needle is delivered at the correct rate.
10 Dispose of SESIP covered needles and syringes in puncture- and leak-proof container.	Prevents accidental needlestick injuries and follows CDC guidelines for disposal of sharps (OSHA, 2012).
11 Stay with patient for several minutes and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of anaphylactic reaction.
12 Remove clean gloves and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

- | | |
|--|---|
| 1 Observe patient closely for adverse reactions during administration and for several minutes thereafter. | IV medications act rapidly. |
| 2 Observe IV site during injection for sudden swelling and for 48 hours after IV push. | Swelling indicates infiltration into tissues surrounding vein. Signs of infiltration may not occur for 48 hours. |
| 3 Assess patient's status after giving medication to evaluate effectiveness of the medication. | Some IV bolus medications can cause rapid changes in patient's physiologic status. Some medications require careful monitoring and assessment and possibly future laboratory testing (e.g., vasopressors and antiarrhythmics require blood pressure and heart rate monitoring, and heparin requires laboratory studies after administration to determine therapeutic levels). |
| 4 Ask patient to explain purpose and side effects of medication. | Evaluates learning. |

Unexpected Outcomes

- Patient develops adverse reaction to medication.
- IV medication is incompatible with IV fluids (e.g., IV fluid becomes cloudy in tubing) (see agency policy).
- IV site shows symptoms of infiltration or phlebitis (see Chapter 28).
- Patient is unable to explain medication information.

Related Interventions

- Stop delivering medication immediately and follow agency policy or guidelines for appropriate response to allergic reaction (e.g., administration of antihistamine such as diphenhydramine [Benadryl] or epinephrine) and reporting of adverse drug reactions.
- Notify patient's health care provider of adverse effects immediately.
- Add allergy information to patient's record.
- Stop IV fluids and clamp IV line.
- Flush IV line with 10 mL of 0.9% sodium chloride or sterile water.
- Give IV bolus over appropriate amount of time.
- Flush with another 10 mL of 0.9% sodium chloride or sterile water at same rate as medication was administered.
- Restart IV fluids with new tubing at prescribed rate.
- If unable to stop IV infusion, start a new IV site (see Chapter 28) and administer medication using IV push (IV lock) method.
- Stop IV infusion immediately or discontinue access device and restart in another site.
- Determine how much damage IV medication can produce in subcutaneous tissue.
- Provide IV extravasation care (e.g., injecting phentolamine [Regitine] around IV infiltration site) as indicated by agency policy, use a medication reference, and consult pharmacist to determine appropriate follow-up care.
- Provide patient with additional information, or patient is unable to learn at this time.

Recording and Reporting

- Immediately record medication administration, including drug, dose, route, time instilled, and date and time administered on MAR. Include initials or signature.
- Report any adverse reactions to patient's health care provider. Patient's response sometimes indicates need for additional medical therapy.
- Record patient's medication response in nurses' notes and electronic health record (EHR).

Special Considerations

Teaching

- Teach patient and/or significant other that effects of IV push medications occur rapidly. Explain reasons for giving medication slowly and teach signs of adverse effects.

Pediatric

- The therapeutic dosage of IV push medications for infants and children is often small and difficult to prepare accurately, even with a tuberculin syringe. You need to infuse these medications

slowly and in small volumes because of the risk for fluid volume overload (Hockenberry and Wilson, 2011). To maintain pediatric patient safety, carefully follow agency policies when administering medications via IV bolus.

Gerontologic

- The renal and metabolic systems do not function as efficiently because of the aging process. To reduce the risk for adverse effects of IV push medications, have good drug knowledge about adverse effects and drug interactions (Aschenbrenner and Venable, 2009). Older patients may tolerate IV push medications if they are given over longer periods of time.

SKILL 22-6 Administering Intravenous Medications by Piggyback, Intermittent Infusion Sets, and Mini-Infusion Pumps

NSO IV Medication Administration Module / Lesson 2

One method of administering intravenous (IV) medications uses small volumes (25 to 250 mL) of compatible IV fluids infused over a desired period of time. This method reduces the risk for rapid dose infusion and provides independence for patients. Patients must have an established IV line that is kept patent by either a continuous infusion or intermittent flushes of normal saline. You can administer intermittent infusion of medication with any of the following methods.

Piggyback. A piggyback is a small (25- to 250-mL) IV bag or bottle connected to a short tubing line that connects to the upper Y-port of a primary infusion line or to an intermittent venous access such as a saline lock. The IV container that holds the medication is labeled following the IV piggyback medication format of the Institute for Safe Medication Practices (ISMP, 2011). The piggyback tubing is a microdrip or macrodrip system (see Chapter 28). The set is called a *piggyback* because the small bag or bottle is set *higher* than the primary infusion bag or bottle. In the piggyback setup the main line does not infuse when a compatible piggybacked medication is infusing. The port of the primary IV line contains a back-check valve that automatically stops the flow of the primary infusion once the piggyback infusion flows. After the piggyback solution infuses and the solution within the tubing falls below the level of the primary infusion drip chamber, the back-check valve opens, and the primary infusion starts to flow again.

Volume-Control Administration. Volume-control administration sets (e.g., Volutrol, Buretrol, Pediatrol) are small (50- to 150-mL) containers that attach just below the primary infusion bag or bottle. The set is attached and filled in a manner similar to that used with a regular IV infusion. However, the priming filling of the set is different, depending on the type of filter (floating valve or membrane) within the set. Follow package directions for priming sets.

Mini-Infusion Pump. The mini-infusion pump is battery operated and delivers medication in very small amounts of fluid (5 to 60 mL) within controlled infusion times using standard syringes (Fig. 22-20).

Needle Safety

The Needle Safety and Prevention Act of 2001 mandates that health care agencies use safe needle devices and manufactured needleless systems to reduce needlestick injury. Systems with catheter ports or Y-connector sites are designed to contain a needle housed in a protective covering. Needleless infusion lines allow a

Home Care

- IV push medications are frequently given in the home. Nurses, pharmacists, and health care providers need to collaborate closely in the care of these patients. Patients and families who are independently responsible for managing IV medications need to understand all aspects of administration safety. Adequate eyesight and manual dexterity are necessary to manipulate the syringe. Patients need to understand their venous access device, rate to give medications, and how to flush their access device. Patients need to safely store their medications and dispose of their IV supplies, and they should know whom to contact in case of an emergency.

direct connection with the IV line via a recessed connection port, a blunt-ended cannula, or shielded-needle device, eliminating the risk for exposure to an IV needle (OSHA, 2012).

Delegation and Collaboration

The skill of administering IV medications by piggyback, intermittent infusion sets, and mini-infusion pumps cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Potential medication actions and side effects and to report their occurrence to the nurse.
- Reporting any patient complaints of moisture or discomfort around IV insertion site.
- Reporting any change in patient's condition or vital signs to the nurse.

Equipment

- Adhesive tape (*optional*)
- Antiseptic swab
- Clean gloves

FIG 22-20 Mini-infusion pump.

- IV pole
 - Medication administration record (MAR) or computer printout
 - Puncture-proof container
- Piggyback or Mini-infusion Pump**
- Medication prepared in 50- to 250-mL labeled infusion bag or syringe
 - Prefilled syringe of normal saline flush solution (for saline lock only)

- Short microdrip, macrodrip, or mini-infusion IV tubing set with blunt-ended (needleless) cannula attachment
 - Needleless device
 - Mini-infusion pump if indicated
- Volume-Control Administration Set**
- Volutrol or Buretrol
 - Infusion tubing with needleless system attachment
 - Syringe (1 to 20 mL)
 - Vial or ampule of ordered medication

STEP	RATIONALE
------	-----------

ASSESSMENT

- | | |
|---|---|
| <p>1 Check accuracy and completeness of each MAR or computer printout with prescriber's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Recopy or reprint any portion of MAR that is difficult to read.</p> | <p>The prescriber's order is the most reliable source and legal record of patient's medications. Ensures that patient receives correct medications.</p> |
| <p>2 Assess patient's medical and medication history.</p> | <p>Handwritten MARs are a source of medication errors (ISMP, 2010; Jones and Treiber, 2010).</p> |
| <p>3 Assess patient's history of allergies: known type of allergens and normal allergic reaction.</p> | <p>Determines need for medication or possible contraindications for medication administration.</p> |
| <p>4 Review medication reference information for medication action, purpose, normal dose, side effects, time and peak of onset, how slowly to give medication, and nursing implications (e.g., need to dilute medication, administer through filter).</p> | <p>IV administration of medication may cause rapid response. Allergic response is immediate.</p> |
| <p>5 If you give medication through existing IV line, determine compatibility of medication with IV fluids and any additional additives within IV solution.</p> | <p>Allows you to administer medication safely and monitor patient's response to therapy.</p> |
| | <p>IV medication is sometimes not compatible with IV solution and/or additives.</p> |

Clinical Decision Point *Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.*

- | | |
|--|---|
| <p>6 Assess patency and placement of patient's existing IV infusion line or saline lock (see Chapter 28).</p> | <p>Do not administer medication if site is edematous or inflamed.</p> |
|--|---|

Clinical Decision Point *If patient's IV site is saline locked, clean the port with alcohol and assess the patency of the IV line by flushing it with 2 to 3 mL of sterile sodium chloride.*

- | | |
|---|--|
| <p>7 Assess patient's symptoms before initiating medication therapy.</p> | <p>Provides information to evaluate desired effects of medication.</p> |
| <p>8 Assess patient's knowledge of medication.</p> | <p>Poses implications for education.</p> |

NURSING DIAGNOSES

- | | | |
|--|--|---|
| <ul style="list-style-type: none"> • Deficient knowledge regarding medication therapy | <ul style="list-style-type: none"> • Risk for imbalanced fluid volume | <ul style="list-style-type: none"> • Risk for ineffective health maintenance |
|--|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient experiences no adverse reactions. • Medication infuses within desired time frame. • IV site remains intact without signs of swelling, inflammation, or symptoms of tenderness at site. • Patient explains medication purposes, action, side effects, and dosage. | <p>Medication was administered safely with desired therapeutic effect.</p> <p>IV line remains patent.</p> <p>Fluid infuses into vein, not tissues.</p> <p>Demonstrates learning.</p> |
|--|--|

STEP

RATIONALE

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Prepare medications for one patient at a time using aseptic technique. Check label of medication carefully with MAR or computer printout 2 times (see Skill 22-1 and Procedural Guideline 22-1) when preparing medication. Pharmacy prepares piggyback and prefilled syringes. You will prepare medication for Volutrol.</p> <p>2 Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include stat, first-time or loading doses, and one time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, immunosuppressive agents) at exact time ordered (no later than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011). During administration, apply six rights of medication administration.</p> <p>3 Close room curtain or door. Perform hand hygiene and apply clean gloves.</p> <p>4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> <p>5 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies.</p> <p>6 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions. Explain that you will give medication through existing IV line. Encourage patient to report symptoms of discomfort at site.</p> <p>7 Administer infusion.</p> <p>a Piggyback infusion:</p> <ol style="list-style-type: none"> (1) Connect infusion tubing to medication bag (see Chapter 28). Fill tubing by opening regulator flow clamp. Once tubing is full, close clamp and cap end of tubing. (2) Hang piggyback (see illustration) medication bag above level of primary fluid bag. (Use hook to lower main bag.) (3) Connect tubing of piggyback infusion to appropriate connector on upper Y-port of primary infusion line: | <p>Ensures that medication is sterile. Preventing distractions reduces medication preparation errors (LePorte et al., 2009; Nguyen et al., 2010). <i>These are the first and second checks for accuracy</i> and ensure that correct medication is administered.</p> <p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacologic effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacologic effect (ISMP, 2011; DHHS, 2011).</p> <p>Provides privacy. Reduces infection transmission.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). Some agencies are now using a bar-code system to help with patient identification.</p> <p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p> <p>Keep patient informed of planned therapies, minimizing anxiety. Patients who verbalize pain at IV site help detect IV infiltrations early, lessening damage to surrounding tissues.</p> <p>Filling infusion tubing with solution and freeing air bubbles prevent air embolus.</p> <p>Height of fluid bag affects rate of flow to patient.</p> <p>Connection allows IV medication to enter main IV line.</p> |
|---|--|

STEP 7a(2) Small-volume minibag for piggyback infusion.

STEP	RATIONALE
(a) <i>Needleless system</i> : Wipe off needleless port of main IV line with alcohol swab, allow to dry, and insert cannula tip of piggyback infusion tubing (see illustration).	Use needleless connections to prevent accidental needlestick injuries (INS, 2011; OSHA, 2012).
(4) <i>Option</i> : Normal saline lock: Follow Steps 9a(1) through 9b(6) in Skill 22-5 to flush and prepare lock. Wipe off port with alcohol swab, let dry, and insert tip of piggyback infusion tubing via needleless access.	Flushing of lock ensures patency.
(5) Regulate flow rate of medication solution by adjusting regulator clamp or IV pump infusion rate. Infusion times vary. Refer to medication reference or agency policy for safe flow rate.	Provides slow, safe, intermittent infusion of medication and maintains therapeutic blood levels.
(6) Once medication has infused: (a) Continuous infusion: Check flow rate of primary infusion. Primary infusion automatically begins after piggyback solution is empty.	Back-check valve on piggyback prevents flow of primary infusion until medication infuses. Checking flow rate ensures proper administration of IV fluids.
(b) Normal saline lock: Disconnect tubing, clean port with alcohol, and flush IV line with 2 to 3 mL of sterile 0.9% sodium chloride. Maintain sterility of IV tubing between intermittent infusions.	
(7) Regulate continuous main infusion line to ordered rate	Infusion of piggyback sometimes interferes with main line infusion rate.
(8) Leave IV piggyback and tubing in place for future drug administration (see agency policy) or discard in puncture- and leak-proof container.	Establishment of secondary line produces route for microorganisms to enter main line. Repeated changes in tubing increase risk for infection transmission.
b Volume-control administration set (e.g., Volutrol):	
(1) Fill Volutrol with desired amount of IV fluid (50 to 100 mL) by opening clamp between Volutrol and main IV bag (see illustration).	Small volume of fluid dilutes IV medication and reduces risk of fluid infusing too rapidly.
(2) Close clamp and check to be sure that clamp on air vent Volutrol chamber is open.	Prevents additional leakage of fluid into Volutrol. Air vent allows fluid in Volutrol to exit at regulated rate.
(3) Clean injection port on top of Volutrol with antiseptic swab.	Prevents introduction of microorganisms during needle insertion.
(4) Remove needle cap or sheath and insert needleless syringe or syringe needle through port and inject medication (see illustration). Gently rotate Volutrol between hands.	Rotating mixes medication with solution to ensure equal distribution in Volutrol.
(5) Regulate IV infusion rate to allow medication to infuse in time recommended by agency policy, pharmacist, or medication reference manual.	For optimal therapeutic effect, medication should infuse in prescribed time interval.
(6) Label Volutrol with name of medication; dosage, total volume, including diluent; and time of administration following ISMP (2011) safe medication label format.	Alerts nurses to medication being infused. Prevents other medications from being added to Volutrol.

STEP 7a(3)(a) A, Needleless lock cannula system. B, Blunt-ended cannula inserts into port and locks.

STEP

RATIONALE

- (7) If patient is receiving continuous IV infusion, check infusion rate after Volutrol infusion is complete.
- (8) Dispose of uncapped needle or needle enclosed in safety shield and syringe in puncture- and leak-proof container. Discard supplies in appropriate container. Perform hand hygiene.

c Mini-infusion administration:

- (1) Connect prefilled syringe to mini-infusion tubing; remove end cap of tubing.
- (2) Carefully apply pressure to syringe plunger, allowing tubing to fill with medication.
- (3) Place syringe into mini-infusion pump (follow product directions) and hang on IV pole. Be sure that syringe is secured (see illustration).
- (4) Connect end of mini-infusion tubing to main IV line or saline lock:
 - (a) *Existing IV line:* Wipe off needleless port on main IV line with alcohol swab, allow to dry, and insert tip of mini-infusion tubing through center of port.
 - (b) *Normal saline lock:* Follow Steps 9a(1) through 9b(6) in Skill 22-5 to flush and prepare lock. Wipe off port with alcohol swab, allow to dry, and insert tip of mini-infusion tubing.
- (5) Set pump to deliver medication within time recommended by agency policy, pharmacist, or medication reference manual. Press button on pump to begin infusion.
- (6) Once medication has infused:
 - (a) *Main IV infusion:* Check flow rate. Infusion automatically begins to flow once pump stops. Regulate infusion to desired rate as needed.
 - (b) *Normal saline lock:* Disconnect tubing, clean port with alcohol, and flush IV line with 2 to 3 mL of sterile 0.9% sodium chloride. Maintain sterility of IV tubing between intermittent infusions.

Ensures appropriate rate of administration.

Prevents accidental needlesticks (OSHA, 2012). Reduces transmission of microorganisms.

Special tubing designed to fit syringe delivers medication to main IV line.

Ensures that tubing is free of air bubbles to prevent air embolus.

Secure placement is needed for proper infusion.

Establishes route for IV medication to enter main IV line.

Needleless connections reduce risk for accidental needlestick injuries (OSHA, 2012).

Pump automatically delivers medication at safe, constant rate based on volume in syringe.

Maintains patent primary IV fluids.

STEP 7b(1) Filling volume-control administration device.

STEP 7b(4) Medication injected into device.

STEP 7c(3) Ensure that syringe is secure after placing it into mini-infusion pump.

STEP

- 8 Dispose of supplies in puncture- and leak-proof container.
- 9 Remove gloves and perform hand hygiene.
- 10 Stay with patient for several minutes and observe for any allergic reactions.

RATIONALE

Prevents accidental needlesticks (OSHA, 2012).
Reduces transmission of microorganisms.
Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.

EVALUATION

- 1 Observe patient for signs or symptoms of adverse reaction.
- 2 During infusion periodically check infusion rate and condition of IV site.
- 3 Ask patient to explain purpose and side effects of medication.

IV medications act rapidly.
IV must remain patent for proper drug administration. Infiltration of IV site requires discontinuing infusion.
Evaluates patient's understanding of instruction.

Unexpected Outcomes

- 1 Patient develops adverse or allergic reaction to medication.
- 2 Medication does not infuse over established time frame.
- 3 IV site shows signs of infiltration or phlebitis (see Chapter 28).

Related Interventions

- Stop medication infusion immediately.
- Follow agency policy or guidelines for appropriate response to allergic reaction (e.g., administration of antihistamine such as diphenhydramine [Benadryl] or epinephrine) and reporting of adverse medication reactions.
- Notify patient's health care provider of adverse effects immediately.
- Add allergy information to patient record per agency policy.
- Determine reason (e.g., improper calculation of flow rate, poor positioning of IV needle at insertion site, infiltration).
- Take corrective action as indicated.
- Stop IV infusion and discontinue access device.
- Treat IV site as indicated by agency policy.
- Insert new IV catheter if therapy continues.
- For infiltration determine how harmful IV medication is to subcutaneous tissue. Provide IV extravasation care (e.g., injecting phentolamine [Regitine] around IV infiltration site) as indicated by agency policy or consult pharmacist to determine appropriate follow-up care.

Recording and Reporting

- Immediately record medication, dose, route, infusion rate, and date and time administered on MAR or computer printout. Include initials or signature.
- Record volume of fluid in medication bag or Volutrol on intake and output (I&O) form.
- Report any adverse reactions to patient's health care provider.

Special Considerations

Teaching

- Review all IV medications with patient and significant others, including why patient is receiving the medication and potential adverse effects, including allergic responses.
- Teach patient and/or significant others not to alter the ordered rate of infusion without consulting the prescriber. IV medications need to be infused at a specified rate to achieve their desired effect and avoid adverse effects.
- Teach patient and/or significant others to report any adverse effects immediately.

Pediatric

- Infants and young children are more vulnerable to alterations in fluid balance and do not adjust quickly to changes in fluid

balance. Therefore, to assess fluid balance, monitor I&O carefully when infusing IV medications (Hockenberry and Wilson, 2011).

Gerontologic

- Altered pharmacokinetics of medications and the effects of polypharmacy place older adults at risk for medication toxicity. Carefully monitor the response of older adults to IV medications (Touhy and Jett, 2010).
- Older adults are at risk for developing fluid volume overload and require careful assessment for signs of overload and heart failure.

Home Care

- Patients or significant others who administer IV medications at home require education about the steps of medication administration. The patient or significant other needs to perform several return demonstrations of IV medication administration before performing this skill independently. In addition, patients and significant others need to know signs of IV medication administration complications such as phlebitis and infiltration and what to do for any problems.

SKILL 22-7 Administering Continuous Subcutaneous Medications

The continuous subcutaneous infusion (CSQI or CSCI) route of medication administration is used for selected medications (e.g., opioids, insulin). The route is also effective with medications to stop preterm labor (e.g., terbutaline [Brethine]) and to treat pulmonary hypertension (e.g., treprostinil sodium [Remodulin]). One factor that determines the infusion rate of CSQI is the rate of medication absorption. Most patients can absorb 3 to 5 mL/hr of medication (INS, 2011; Justad, 2009).

With CSQI, patients are able to manage their illness and/or pain without the risks and expenses involved with intravenous (IV) medication administration. The route is relatively easy for patients and families to learn and understand in the home setting. CSQI improves oncologic and postoperative pain control in infants, children, and adults (Cope et al., 2008; Justad, 2009). Box 22-6 summarizes benefits associated with the use of CSQI for pain management.

Patients with diabetes mellitus using CSQI for management of blood glucose levels receive intense diabetes self-management education from qualified diabetes educators and insulin pump trainers. The newest system integrates an insulin pump with real-time continuous glucose monitoring (Fig. 22-21) (Medtronic MiniMed, 2011). Patients with diabetes mellitus using insulin pumps generally require less insulin because it is absorbed and used more efficiently (Cummins et al., 2010; Jakisch et al., 2008). Box 22-7 lists criteria for selecting insulin pumps for patient use.

The procedure to initiate and discontinue CSQI therapy is similar, regardless of the type of medication being delivered.

BOX 22-6 Pain Management Benefits with Use of Continuous Subcutaneous Infusion

- Benefits patients with poor venous access
- Provides pain relief to patients who are unable to tolerate oral pain medications
- Allows patients greater mobility
- Onset of action about 20 minutes
- Better pain control than intramuscular injections
- Costs almost half of those associated with intravenous infusions

Modified from Ellershaw and Wilkinson: *Care of the dying*, ed 2, Oxford, 2010, Oxford University Press.

FIG 22-21 Mini-Med Paradigm REAL-Time Insulin CSQI Pump and Continuous Glucose Monitoring System. (Courtesy Medtronic, Inc., North-ridge, Calif.)

However, nursing assessment and interventions vary, depending on the type of medication administered. For example, if the medication is for diabetes glucose management, you evaluate the patient's blood glucose levels and monitor episodes of hypoglycemia or hyperglycemia (Carchidi et al., 2011).

Use a small-gauge (25 to 27) winged butterfly IV needle or special commercially prepared Teflon cannula to deliver medications. Although Teflon cannulas are generally more expensive, they are more comfortable for the patient and have lower rates of complications than winged IV needles. The cannulas are associated with fewer needlestick injuries. Base the choice of needle type on agency guidelines or patient preference. Use the needle with the shortest length and the smallest gauge necessary to establish and maintain the infusion.

Use the same anatomic sites for subcutaneous injections and the upper chest. Site selection depends on a patient's activity level and the type of medication delivered. For example, pain medications given to ambulatory patients are best delivered in the upper chest, which allows a patient to move freely. Insulin is absorbed most consistently in the abdomen; thus choose a site in the abdomen away from the waistline. Always avoid sites where the tubing of the pump could be disturbed. Rotate sites used for medication administration at least every 2 to 7 days or whenever complications such as leaking occur (INS, 2011).

The CSQI route requires a computerized pump with safety features, including lockout intervals and warning alarms. Ideally medication pumps are individualized based on the medication being delivered and a patient's needs. You also need to consider the availability and cost of the pump and its supplies. When possible, have patients select the pump that fits their individual and home needs and is easiest to use.

Delegation and Collaboration

The skill of administering CSQI medications cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

BOX 22-7 Patient Selection Criteria for Use of Insulin Pumps

- Possesses strong motivation and commitment to use diabetes management skills
- Requires or desires improved control of blood glucose levels
- Requires greater flexibility than allowed by traditional insulin injection schedules
- Is willing to participate in a formal diabetes education program
- Possesses strong critical thinking and problem-solving skills
- Accepts responsibilities associated with the self-management of diabetes
- Is able to perform self-blood glucose monitoring and operate the insulin pump
- Displays evidence of effective coping patterns
- Has support systems available
- Secures financial resources to cover costs associated with CSQI

Data from American Diabetes Association: Standards of medical care in diabetes, 2011, *Diabetes Care* 34(S1):S11, 2011; Cummins E et al: Clinical effectiveness and cost-effectiveness of continuous subcutaneous insulin infusion for diabetes: systematic review and economic evaluation, *Health Technol Assess* 14(11):iii, 2010.

CSQI, Continuous subcutaneous infusion.

- Potential medication side effects or reactions and to report their occurrence to the nurse.
- Reporting complications (e.g., leaking, redness, discomfort) at the CSQI needle insertion site to the nurse.
- Obtaining any required vital signs and reporting them to the nurse.

- Infusion pump
- Occlusive, transparent dressing
- Tape
- Medication in appropriate syringe or container
- Medication administration record (MAR) or computer printout

Equipment

Initiation of CSQI

- Clean gloves
- Alcohol swab
- Antibacterial skin preparation such as chlorhexidine
- Small (25- to 27-)–gauge winged IV catheter with attached tubing or CSQI designed catheter (e.g., Sof-Set)

Discontinuing CSQI

- Clean gloves
- Small, sterile gauze dressing
- Tape or adhesive bandage
- Alcohol swab and chlorhexidine (*optional*)
- Puncture-proof container

STEP

RATIONALE

ASSESSMENT

<p>1 Check accuracy and completeness of each MAR or computer printout with prescriber’s written medication order. Check patient’s name, medication name and dosage, route of administration, and time of administration. Recopy or reprint any portion of MAR that is difficult to read.</p> <p>2 Assess patient’s medical and medication history.</p> <p>3 Assess patient’s history of allergies: known type of allergens and normal allergic reaction.</p> <p>4 Collect drug reference information necessary to administer drug safely, including action, purpose, side effects, normal dose, time of peak onset, how slowly to give medication, and nursing implications.</p> <p>5 Assess patient’s previous verbal and nonverbal response to needle insertion.</p> <p>6 Assess for contraindications to CSQI (e.g., thrombocytopenia or reduced local tissue perfusion).</p> <p>7 Assess adequacy of patient’s adipose tissue to determine appropriate site.</p> <p>8 Assess patient’s knowledge regarding medication to be received and use of medication pump.</p> <p>9 Assess patient’s symptoms before initiating medication therapy. Determine severity of pain (if using analgesia) or measure blood glucose level (if using insulin).</p>	<p>The prescriber’s order is the most reliable source and legal record of patient’s medications. Ensures that patient receives correct medications.</p> <p>Handwritten MARs are a source of medication errors (<i>ISMP, 2010; Jones and Treiber, 2010</i>).</p> <p>Determines need for medication or possible contraindications for medication administration.</p> <p>CSQI administration of medications may cause rapid response. Allergic response is immediate.</p> <p>Knowledge of medication allows you to give medication safely and monitor patient’s response to therapy.</p> <p>Injections are sometimes painful. Anticipating patient’s anxiety allows you to use distraction to reduce pain awareness.</p> <p>Reduced tissue perfusion interferes with medication absorption and distribution.</p> <p>Physiologic changes of aging or patient illness influence amount of subcutaneous tissue, which affects choice of catheter insertion site.</p> <p>Information poses implications for patient education.</p> <p>Provides information to evaluate desired effects of CSQI medication.</p>
---	---

NURSING DIAGNOSES

- | | | |
|--|----------------------------------|----------------------|
| • Anxiety | • Fear | • Risk for infection |
| • Deficient knowledge regarding CSQI therapy | • Ineffective health maintenance | • Risk for injury |
| | • Pain (acute, chronic) | |

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Needle insertion site remains free from infection. • Patient achieves desired effect of medication with no signs of adverse reactions. • Patient explains purpose, dosage, and effects of medication and verbalizes understanding of CSQI therapy. 	<p>Risk for infection at needle insertion site is potential complication of CSQI therapy.</p> <p>Medication is delivered safely with desired therapeutic effect achieved.</p> <p>Demonstrates learning.</p>
---	---

STEP

RATIONALE

IMPLEMENTATION

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Review manufacturer directions for pump. 2 Perform hand hygiene. Prepare medication using aseptic technique or check dose on prefilled syringe. Connect syringe and prime tubing with medication, being careful not to lose any medication. Compare label of medication with MAR or computer printout 2 times. 3 Obtain and program medication administration pump. Place syringe in pump. 4 Read label on prefilled syringe and compare with MAR or computer printout. 5 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name. 6 At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient if he or she has allergies. 7 Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions. Tell patient that needle insertion will cause slight burning or stinging. 8 Position patient supine, drape, and provide for privacy. 9 Initiate CSQI. <ol style="list-style-type: none"> a Be sure patient is comfortable, sitting or lying down. b Select appropriate injection site free of irritation and away from bony prominences and waistline. Most common sites used are subclavicular and abdomen. c Perform hand hygiene and apply clean gloves. Clean injection site with alcohol using circular motion, followed by antiseptic, using straight cleaning strokes. Allow both agents to dry. d Hold needle in dominant hand and remove needle guard. e Gently pinch or lift up skin with nondominant hand. f Gently and firmly insert needle at 45- to 90-degree angle (see illustration). Some shorter prepackaged needles (e.g., Sof-Set, Subcutaneous-Set) are inserted at a 90-degree angle. Refer to manufacturer directions. g Release skinfold and apply tape over "wings" of needle. | <p>Ensures proper use of equipment.</p> <p>Ensures that medication is sterile. Checking label of medication with transcribed order reduces error. <i>This is the first check for accuracy</i> and ensures that correct medication is administered.</p> <p>Ensures that medication dose administered is accurate.</p> <p><i>This is the second check for accuracy.</i></p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). Some agencies are now using a bar-code system to help with patient identification.</p> <p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p> <p>Patient has right to be informed, and patient's understanding of each medication improves adherence to drug therapy.</p> <p>Respects patient's dignity.</p> <p>Eases pain associated with insertion of needle.</p> <p>Ensures proper medication absorption.</p> <p>Reduces risk for infection at insertion site.</p> <p>Prepares needle for insertion.</p> <p>Ensures that needle will enter subcutaneous tissue.</p> <p>Decreases pain related to insertion of needle.</p> <p>Secures needle.</p> |
|--|---|

Clinical Decision Point Some cannulas have a sharp needle covered with a plastic catheter. In this case remove the needle and leave the plastic catheter in the skin.

STEP 9f Insertion of butterfly needle into subcutaneous tissue of abdomen.

STEP 9h Placement of transparent dressing over insertion site.

STEP	RATIONALE
h Place occlusive, transparent dressing over insertion site (see illustration).	Protects site from infection and allows you to assess site during medication infusion.
i Attach tubing from needle to tubing from infusion pump and turn pump on.	Allows you to administer medication.
j Dispose of any sharps in appropriate leak- and puncture-proof container. Discard used supplies, remove gloves, and perform hand hygiene.	Prevents accidental needlestick injuries and follows CDC guidelines for disposal of sharps (OSHA, 2012).
k Inspect site before leaving patient and instruct patient to inform you if site becomes red or begins to leak.	Initiate new site with new needle whenever erythema or leaking occurs. If site is free from complications, rotate needle every 2 to 7 days (INS, 2011).
l Stay with patient for several minutes and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.
10 Discontinue CSQI.	If medication will be required after discontinuing CSQI, a different medication and/or route is often necessary to continue to manage patient's illness or pain.
a Verify order and establish alternative method for medication administration if applicable.	Prevents medication from spilling.
b Stop infusion pump.	Follows CDC recommendations to prevent accidental exposure to blood and body fluids (OSHA, 2012).
c Perform hand hygiene and apply clean gloves.	Exposes needle.
d Remove dressing without dislodging or removing needle. Discard properly.	
Clinical Decision Point <i>If site is infected, clean it with alcohol and antiseptic. Apply triple antibiotic cream to site if it is excoriated (abraded).</i>	
e Remove tape from wings of needle and pull needle out at same angle at which it was inserted.	Minimizes patient discomfort.
f Apply gentle pressure at site until no fluid leaks out of skin.	Dressing adheres to site if skin remains dry.
g Apply small sterile gauze dressing or adhesive bandage to site.	Prevents bacterial entry into puncture site.
11 Dispose of uncapped needles and syringes in puncture- and leak-proof container.	Prevents accidental needlestick injuries and follows CDC guidelines for disposal of sharps (OSHA, 2012).
12 Remove and dispose of gloves and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Evaluate patient's response to medication.	Determines effect of therapy. Decreased or absent response to medication may indicate that patient is not receiving medication into subcutaneous tissue (e.g., pump malfunction, medication leaking at site).
2 Assess site at least every 4 hours for redness, pain, drainage, or swelling.	Indicates infection at insertion site.
3 Ask patient to verbalize understanding of medication and CSQI therapy.	Demonstrates learning.

Unexpected Outcomes

- 1 Patient complains of localized pain or burning at insertion site; or site appears red or swollen or is leaking, indicating potential infection or needle dislodgement.
- 2 Patient displays signs of allergic reaction to medication.
- 3 CSQI becomes dislodged.

Related Interventions

- Remove needle and place new needle in different site.
- Continue to monitor original site for signs of infection and notify health care provider if you suspect infection.
- Stop delivering medication immediately and follow agency policy or guidelines for appropriate response to allergic reaction (e.g., administration of antihistamine such as diphenhydramine [Benadryl] or epinephrine) and reporting of adverse drug reactions.
- Notify patient's health care provider of adverse effects immediately.
- Add allergy information to medical record.
- Stop infusion, apply pressure at site until no fluid leaks out of skin, cover site with gauze dressing or adhesive bandage, and initiate new site.
- Assess patient to determine effects of not receiving medication (e.g., assess patient's pain level using age-appropriate pain scale, obtain blood glucose level).

Recording and Reporting

- After initiating CSQI, immediately chart medication, dose, route, site, time, date, and type of medication pump in patient's medical record. Use initials or signature.
- If medication is an opioid, follow agency policy to document waste.
- Record patient's response to medication and appearance of site every 4 hours or according to agency policy in nurses' notes and electronic health record (EHR).
- Report any adverse effects from medication or infection at insertion site to patient's health care provider and document according to agency policy. Patient's condition often indicates need for additional medical therapy.

Special Considerations

Teaching

- Instruct patient to wear medical alert bracelet along with medical information, including disease (e.g., diabetes), allergies, and a contact phone number for the pump manufacturer for technical support.
- Instruct patients to carry back-up batteries and extra medication if they are going to be away from home.
- Patients receiving insulin require intensive diabetes management education (Box 22-8).
- Never immerse pumps in water or expose them to x-ray films or magnetic resonance imaging.

Pediatric

- CSQI improves glycemic control in children and adolescents. There is a decreased rate of severe hypoglycemia, catheter-site infection, and weight gain (Cope et al., 2008; Hockenberry and Wilson, 2011).
- Insulin pumps offer more flexibility for adolescents, placing the responsibility of diabetes management on the child. Extensive child and family education is needed in using CSQI (Hockenberry and Wilson, 2011).
- Clean and change CSQI sites in children every 48 to 72 hours or at the first signs of inflammation (Hockenberry and Wilson, 2011).

Gerontologic

- CSQI delivers isotonic IV solutions to dehydrated older adults, known as *hypodermoclysis therapy*. This method of providing

BOX 22-8 Education Topics for Patients Receiving Insulin with Continuous Subcutaneous Infusion

- Blood glucose monitoring
- Meal planning and food choices
- Incorporating exercise into daily routine
- How to program and use the insulin pump
- Illness guidelines and management
- Management of hypoglycemia
- Prevention and management of hyperglycemia
- Prevention of infection, especially at CSQI infusion site
- Problem-solving and decision-making skills
- Special considerations and precautions (e.g., what to do with pump when showering and sleeping)

Modified from Dalton M et al.: Safety issues: use of continuous subcutaneous insulin infusion pumps (CSII) in hospitalized patients, *Hosp Pharm* 41(10):956, 2006.

CSQI, Continuous subcutaneous infusion.

hydration avoids the need to transfer a patient from home or long-term care facility to an acute care hospital. Infuse fluids slowly (e.g., 30 mL/hr) during the first hour of therapy. If the patient remains comfortable, you can increase the rate of infusion. Usually infusion rates do not exceed 60 mL/hr. Hypodermoclysis is an easy-to-use, safe, and cost-effective alternative to IV hydration for older adults (Gorski, 2009; Scales, 2011).

Home Care

- Patients in the home using CSQI need a responsible family caregiver if available. Educate the patient, family, and/or significant others about the desired effect of the medication, side effects and adverse effects of the medication, operation of the pump, how to evaluate the effectiveness of the medication, when and how to assess and rotate injection sites, and when to call a health care provider for problems. Patients need to know where and how to obtain and dispose of all required supplies.
- Patients managing CSQI at home may use an antibacterial soap (e.g., Hibiclens, pHisoHex) instead of alcohol and chlorhexidine to clean insertion site.

Critical Thinking Exercises

The nurse is preparing to care for a patient newly diagnosed with thrombophlebitis who is scheduled to receive heparin 5000 units subcutaneously now and every 8 hours. The heparin comes from the pharmacy as a multi-dose vial.

- 1 Which information does the nurse need to know about the medication and vial before administering?
- 2 Which information does the nurse need to know about the patient before administering the heparin?
- 3 The patient weighs 100 kg (220 pounds). The drug calculation has determined that 1 mL of heparin needs to be administered. What size syringe and needle will be used to administer the injection? Which site is most appropriate to administer the medication?
- 4 In addition to the subcutaneous heparin, the patient is also receiving morphine sulfate 1 mg intravenous (IV) push every 6 hours as needed for pain. The patient has no allergies, and the nurse has reviewed the medication references and the health care provider's order. Which additional factors does the nurse need to assess before administering the morphine?

REVIEW QUESTIONS

- 1 The nurse needs to reconstitute a medication for an intramuscular injection. Which action would indicate that the procedure was completed correctly?
 - 1 The nurse shakes the vial after the fluid is injected into it to mix it completely.
 - 2 The nurse determines the amount of prepared medication and concentration needed before adding the appropriate diluent.
 - 3 The powder is injected slowly into the vial of diluent.
 - 4 The nurse evaluates the concentration after the diluent and powder are mixed.
- 2 The nurse is mixing two medications in one syringe. One medication is in a vial, and the other is in an ampule. Which sequence of preparation is correct?
 - 1 The nurse withdraws the medication from the vial first.
 - 2 The nurse prepares the medication from the ampule first.
 - 3 The nurse draws all the medication out of both the ampule and the vial.
 - 4 The nurse inserts air into the ampule first.

- 3 An average-size 30-year-old woman is to have an intramuscular injection in the ventrogluteal site. Which needle is appropriate for administering the aqueous-based medication?
 - 1 26 gauge, $\frac{5}{8}$ inch
 - 2 20 gauge, $1\frac{1}{2}$ inch
 - 3 25 gauge, 1 inch
 - 4 22 gauge, $1\frac{1}{2}$ inch
- 4 Before administration of an intravenous (IV) push medication, the nurse notes that the patient's IV site is cool, pale, and swollen. The nurse should take which action?
 - 1 Stop the current IV infusion and change it to another site
 - 2 Slow the rate of the IV infusion
 - 3 Flush the IV line with a normal saline flush
 - 4 Take off the IV dressing and place a new one on that is not as tight
- 5 Which action is the most important for the nurse to implement before giving an intravenous (IV) push medication?
 - 1 Diluting the medication to minimize vein irritation
 - 2 Stopping the primary (maintenance) fluid infusion
 - 3 Assessing the IV insertion site
 - 4 Ensuring that the correct filter needle is used to withdraw the medication from the vial
- 6 Which of the following assessment findings indicates a positive tuberculin reaction in a patient with no known risk factors for tuberculosis?
 - 1 A large area of redness and swelling at the injection site
 - 2 An induration of 18 mm
 - 3 Frequent, productive cough accompanied by a fever
 - 4 Sudden onset of shortness of breath and wheezing
- 7 Which of the following symptoms may indicate that a patient has sustained an injury to a nerve after an intramuscular (IM) injection?
 - 1 Pain, numbness, and tingling at the injection site 2 hours after the injection
 - 2 Pain experienced during the injection
 - 3 Urticaria, eczema, wheezing, and dyspnea
 - 4 Nausea, vomiting, and diarrhea
- 8 Match the needle size to use when administering an injection in each situation listed.
 - 1 25-gauge, $\frac{5}{8}$ - to 1-inch
 - 2 22-gauge, $1\frac{1}{2}$ -inch
 - 3 27-gauge, $\frac{5}{8}$ -inch
 - a Intradermal Mantoux test
 - b Children older than 1 year
 - c Average-size female receiving intramuscular injection
- 9 A patient with diabetes is experiencing low blood glucose levels. The nurse teaches the patient to use which of the following when he or she experiences low blood glucose.
 - 1 Drink 4 ounces of sugar-free juice
 - 2 Eat several saltine crackers with peanut butter
 - 3 Eat one or two hard candies
 - 4 Drink at least 4 ounces of fruit juice
- 10 _____, _____, and _____ are symptoms of an anaphylactic reaction.

KEY TERMS

Circumoral cyanosis	Incentive spirometry	Oxygen mask	Positive-pressure ventilation
Hypercapnia	Nasal cannula	Oxygen therapy	T tube
Hypoxemia	Noninvasive positive-pressure ventilation	Peak expiratory flow rate (PEFR)	Tidal volume
Hypoxia			Tracheostomy collar

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss indications for oxygen therapy.
- Describe methods for administering oxygen therapy.
- Demonstrate applying a nasal cannula and an oxygen mask.
- Demonstrate administering oxygen therapy to a patient with an artificial airway.
- Demonstrate proper peak expiratory flow rate (PEFR) measurements.
- Demonstrate proper use of incentive spirometry.
- Demonstrate use of noninvasive positive-pressure ventilation using continuous positive airway pressure (CPAP) or bi-level positive airway pressure (BiPAP).
- Demonstrate care of a patient receiving mechanical ventilation.

Airway Management Module / Step 1

Oxygen therapy is the administration of supplemental oxygen (O₂) to a patient to prevent or treat hypoxia. Hypoxia is a condition in which there is insufficient oxygen to meet the metabolic demands of the tissues and cells. Hypoxia results from hypoxemia, a deficiency of arterial blood oxygen. Hemoglobin is the carrier of respiratory gases, oxygen, and carbon dioxide (CO₂). It combines with a gas to carry it to and from the cells. Decreased hemoglobin levels reduce the amount of oxygen transported to the cells and carbon dioxide transported away from the cells. Hemoglobin levels and acid-base status directly affect oxygenation. Acidemia increases the ability of hemoglobin to release oxygen to the tissues.

Alkalemia decreases the ability of hemoglobin to release oxygen to the tissues.

Various diseases (e.g., pneumonia, chronic bronchitis) require the use of oxygen therapy. Pneumonia results in impaired gas exchange because of fluid and secretions in the lung, which decrease the diffusion of oxygen from the lungs to the arterial blood supply. Some patients with chronic bronchitis, a form of chronic obstructive pulmonary disease (COPD), have normal arterial oxygen levels during the day but oxygen desaturation, a reduction in the arterial oxygen level, during sleep. Frequently these patients require daytime and nocturnal oxygen therapy to prevent hypoxemia (Tiep et al., 2010).

BOX 23-1 Signs and Symptoms Associated with Hypoxia

- Apprehension, anxiety, behavioral changes
- Decreased level of consciousness, confusion, drowsiness, altered concentration
- Increased pulse rate
- Increased rate and depth of respiration or irregular respiratory patterns
- Decreased lung sounds, adventitious lung sounds (e.g., crackles, wheezes)
- Elevated blood pressure evolving to decreased blood pressure
- Pulse oximetry (SpO₂) less than 90%
- Dyspnea
- Use of accessory muscles of respiration, rib retractions
- Cardiac dysrhythmias
- Pallor, cyanosis
- Increased fatigue
- Dizziness
- Clubbing of nails resulting from prolonged, chronic hypoxia

Oxygen by mask or nasal prongs is used in a wide variety of acute care settings. Usually no harm occurs with short-term use of oxygen. However, acute respiratory failure from COPD is a special case because uncontrolled administration of oxygen in this condition may cause acute hypoventilation and carbon dioxide retention with dire consequences. The recommendation is to limit oxygen administration to the minimum needed to raise arterial oxygen saturation to a level that provides adequate oxygen delivery to tissues (88% to 92%) and no higher (Austin et al., 2010).

Patients with cardiovascular disease such as left ventricular failure are not always able to supply oxygen to the tissues because of decreased cardiac output. Supplemental oxygen helps decrease the work of the left ventricle and increase oxygen delivery to the tissues.

The nursing assessment of a patient requiring supplemental oxygen therapy may reveal findings associated with hypoxia (Box 23-1). Presenting symptoms of hypoxia depend on the patient's age, level of health, present disease process, and presence of chronic illnesses. Anxiety, confusion, and restlessness are early signs (Carbery, 2008). In early stages of hypoxia, blood pressure is elevated; and, if the hypoxia remains uncorrected, hypotension develops. As hypoxia worsens, the patient's activity tolerance decreases, vital signs worsen, and the patient's level of consciousness decreases.

Cyanosis, a bluish discoloration of the skin and mucous membranes, is a late sign of hypoxia. Vasoconstriction of the peripheral blood vessels or decreased oxyhemoglobin causes cyanosis. Cyanosis is present in patients who have decreased level of oxyhemoglobin, are very cold, or have decreased peripheral circulation because of vascular disease. Never assume that a lack of cyanosis means adequate oxygenation. Cyanosis caused by hypoxia is observed in the oral mucosa; the conjunctiva of the eye; and around the lips, known as *circumoral cyanosis*.

OXYGEN DELIVERY SYSTEMS

Oxygen therapy is inexpensive, widely available, and used in a variety of settings. Patients with decreased tissue oxygenation benefit from controlled oxygen administration. Long-term oxygen treatment is one of the few interventions that improve survival in COPD (Stoller et al., 2010). Treat oxygen as a medication. As with any drug, continuously monitor the dosage or concentration of oxygen and routinely check the health care provider's orders to verify that the patient is receiving the prescribed oxygen

FIG 23-1 Flowmeter attached to oxygen source.

concentration. Follow the six rights of medication administration when administering oxygen (see Chapter 20).

Selection of the type of oxygen delivery system is based on the level of oxygen support that the patient needs, the severity of the hypoxia, and the disease process. Consider other factors such as the patient's age, level of health and orientation, presence of an artificial airway, whether the setting is in the hospital or the home, type of home environment, and type of support and care given after discharge.

Oxygen delivery devices fall into one of two categories, high flow or low flow, depending on their ability to provide enough flow to match the patient's spontaneous minute volume. Matching a patient's spontaneous minute volume is imperative for patient comfort and adequate oxygen delivery. High-flow devices discourage entraining room air, which dilutes the inspired oxygen percentage (FiO₂). High-flow devices include venturi-mask, large-volume nebulizer, and blender masks. Low-flow devices include nasal cannula and simple, nonrebreather, and partial rebreather masks. Common oxygen delivery devices include nasal cannula, various types of face masks, and tracheostomy mask.

Oxygen is available in a number of systems. In a hospital or institutional setting it is available in a bulk liquid oxygen system designed to store it at a precise and safe temperature and deliver it as a gas through wall outlets in a patient's room. An oxygen flowmeter regulates the flow rate in liters per minute (Fig. 23-1).

Oxygen is also available as compressed gas in various-size cylinders and exists as a nonliquid gas stored at a precise temperature under high pressure and measured as pounds per square inch (psi). Oxygen cylinders used in hospital and institutional care settings include large cylinders and smaller E cylinders (Fig. 23-2). In addition, still smaller, easily transported cylinders are available for use in the home. Patients using home oxygen commonly use concentrators, some of which are portable.

EVIDENCE-BASED PRACTICE

Oxygen remains one of the most effective therapeutic agents available (Tiep et al., 2010). Although this therapy benefits hypoxemic patients with pulmonary problems and those with acute exacerbations of COPD, it also relieves pulmonary vasoconstriction and right-sided heart workload and decreases myocardial ischemia. As a result, cardiac output improves. In addition, there is evidence that improved oxygen delivery to the lungs through oxygen administration decrease the work of breathing. These effects on oxygen ventilation and work of breathing may help prevent respiratory muscle fatigue (Jardins and Burton, 2011; Kim et al., 2008).

FIG 23-2 Smaller E tank for portability.

Oxygen is like any other “drug” and should be administered cautiously and observed closely for side effects:

- Initiate oxygen protocols when patients with respiratory conditions are hypoxic.
- Ensure that there are no contraindications to oxygen therapies (e.g., some patients with elevated PaCO₂ [hypercarbia] are at risk for increased respiratory failure).
- Assess physiologic gas exchange parameters when therapy is initiated and as indicated by patient’s condition. This should be done within 2 hours for any patient diagnosed with COPD.
- Check all oxygen equipment for safety and function at least once per shift.
- Check oxygen systems more frequently when oxygen concentration can vary (e.g., hood, high-flow device).
- Avoid interruption of oxygen therapy during patient transport.
- When patient has a tracheostomy and is being transported off the floor, notify respiratory therapy.

PATIENT-CENTERED CARE

Orient patients and family members to the oxygen setup and necessary precautions needed when oxygen is in use. Patients and visitors with limited English proficiency may not be able to understand signs posted in the room. Safely accommodate valued practices of cultural groups when using oxygen. For example, some cultures burn incense, which does not have a flame, to promote healing of ill members (Galanti, 2008). When oxygen is used in the home, designate areas where patients can safely burn incense and encourage family members to bring the ashes to the bedside. Some cultures light candles to celebrate or honor holidays and may accept the use of battery-operated candles while in the hospital (Spector, 2008). Collaborate with family members and religious leaders on how to accommodate these practices during illness and recovery.

BOX 23-2 Oxygen Safety Guidelines

- Remind patients that oxygen is a medication and is not adjusted without a health care provider’s order.
- In the home setting place an “Oxygen in Use” sign on the door of the residence.
- Keep oxygen delivery systems at least 5 feet from any heat source (American Lung Association, 2012).
- Oxygen supports combustion; however, it will not explode.
- No smoking is allowed on the premises.
- When using oxygen cylinders, secure them so they will not fall over. Store oxygen cylinders upright, chained, or in appropriate holders.
- Determine that all electrical equipment in the room is functioning correctly and properly grounded (see Chapter 13). An electrical spark in the presence of oxygen will result in a serious fire.
- Avoid using items that create a spark (e.g., electric razor) with a nasal cannula in use; an electrical or mechanical toy in oxygen tent; or objects of synthetic fabrics that cause static electricity.
- Check the oxygen level of portable tanks before transporting a patient to ensure that there is enough oxygen in the tank.

Safety Guidelines

- 1 Know a patient’s normal range of vital signs and pulse oximetry (SpO₂) values. Hypoxia affects a patient’s vital signs and SpO₂ values.
- 2 Be aware of environmental conditions. Patients with chronic respiratory diseases have difficulty maintaining optimal oxygen levels in polluted environments. If a patient is to receive home oxygen therapy, complete an environmental assessment to determine respiratory hazards in the home such as the use of gas stoves or kerosene space heaters or the presence of smokers in the home.
- 3 Document a patient’s smoking history. Smoking damages the mucociliary clearance mechanism of the lungs and paralyzes the ciliary action, resulting in a decreased ability to clear mucus from the airways. Chronic bronchitis is caused primarily by smoking and results in pooling of mucus in the airways, creating an environment for the development of infections. Long-term chronic bronchitis ultimately results in hypoxia.
- 4 Know a patient’s most recent hemoglobin values and past and current arterial blood gas (ABG) values.
- 5 Oxygen is a medication. Increasing the oxygen liter flow rate for shortness of breath is similar to doubling heart, asthma, or other medications.
- 6 Provide education to patient and family about home oxygen therapy so they understand proper use of the equipment. Safety measures for oxygen use are very important (see Chapter 42) (Box 23-2).
- 7 All oxygen delivery devices fall into three categories, depending on their ability (or inability) to provide enough flow to match a patient’s spontaneous minute volume.
- 8 All oxygen delivery devices are supplemental, high flow, and/or positive pressure.

SKILL 23-1 Applying a Nasal Cannula or Oxygen Mask

Video Clip

Nasal Cannula

A nasal cannula is a simple, effective, and comfortable device for delivering oxygen to a patient (Fig. 23-3). It allows a patient to breathe through the mouth or nose, is available for all age-groups, and is adequate for short- or long-term use. Cannulas are inexpensive, disposable, and easily accepted by most patients. The two tips of the cannula, about 1.5 cm ($\frac{1}{2}$ inch) long, protrude from the center of a disposable tube and are inserted into the nostrils. Oxygen is delivered via the cannula at a flow rate from 1 to 6 L/min. Higher flow rates dry airway mucosa and do not increase the inspired oxygen concentration (FiO_2). You do not use humidification for rates less than 4 L/min. At flow rates greater than 4 L/min, humidification helps prevent drying of nasal and oral mucous membranes. You can estimate approximate FiO_2 by the flow rate (Table 23-1). The delivered oxygen percentage varies, depending on the rate and depth of a patient's breathing.

Oxygen Mask

The simple face mask (Fig. 23-4) is for short-term oxygen therapy. It fits loosely and delivers oxygen concentrations from 40% to 60%. The mask is contraindicated for patients with carbon dioxide retention because it makes the retention worse. The percentage of oxygen delivered with a simple face mask depends on the liter flow and depth of respirations (see Table 23-1).

A plastic face mask with a reservoir bag (Fig. 23-5) and a Venturi mask deliver higher concentrations of oxygen. When used as a nonrebreather, the plastic face mask with a reservoir bag delivers 60% to 90% oxygen at appropriate flow rates (see Table 23-1). This oxygen mask maintains a high-concentration oxygen supply in the reservoir bag. Frequently inspect the bag to make sure that

it is fully inflated. If it is *not fully inflated*, the patient breathes in large amounts of exhaled carbon dioxide.

A Venturi mask is a cone-shaped high-flow device with entrainment ports of various sizes at the base of the mask (Fig. 23-6). The entrainment ports adjust to permit regulation of FiO_2 from 24% to 60%. This mask is useful because it delivers a more precise concentration of oxygen to a patient (see Table 23-1).

The face tent is a shieldlike device that fits under a patient's chin and sweeps around the face (Fig. 23-7). It is used primarily for humidification and for oxygen only when a patient cannot or will not tolerate a tight-fitting mask. Because it is so close to a patient's face, there is no way to estimate how much oxygen is delivered to him or her.

Oxygen hoods and tents are commonly used in the pediatric setting. These devices are able to provide high concentrations of humidified oxygen. This is particularly useful in the child with airway inflammation, epiglottitis (croup), or other respiratory tract infections.

Delegation and Collaboration

The skill of applying a nasal cannula or oxygen mask (not adjusting oxygen flow rate) can be delegated to nursing assistive personnel (NAP). The nurse is responsible for assessing the patient's

FIG 23-3 Nasal cannula adjusted for proper fit.

FIG 23-4 Simple face mask.

FIG 23-5 Plastic face mask with reservoir bag.

TABLE 23-1 Oxygen Delivery Systems

Delivery System	FiO ₂ Delivered	Advantages	Disadvantages
Nasal cannula	1 L/min: 24% 2 L/min: 28% 3 L/min: 32% 4 L/min: 36% 5 L/min: 40% 6 L/min: 44%	Safe and simple Easily tolerated Delivers low concentrations while allowing patient to eat, speak, and drink Does not impede eating or talking Inexpensive, disposable	Unable to use with nasal obstruction Drying to mucous membranes Can dislodge easily May cause skin irritation or breakdown Patient's breathing pattern will affect exact FiO ₂
Oxymizer	1-15 L/min: 24%-60%	Higher concentrations without mask Releases O ₂ only on inhalation Conserves O ₂ , increased portability Does not require humidification	Nasal reservoir may interfere with drinking from cup May be cosmetically unappealing Potential reservoir membrane failure Patient's breathing pattern affects exact FiO ₂
Simple face mask	5-6 L/min: 40% 6-7 L/min: 50% 7-8 L/min: 60%	Can help to provide humidified O ₂	Exact FiO ₂ level difficult to estimate Requires high FiO ₂ levels to prevent rebreathing of CO ₂ Patient inhales room air through side holes in mask
Venturi mask	4 L/min: 24%-28% 8 L/min: 35%-40% 12 L/min: 50%-60%	Controls amount of specified oxygen concentration Delivers percentage of FiO ₂ from 24%-60% Does not dry mucous membranes Delivers humidity with oxygen concentration	Hot and confining; increased levels of humidification may irritate skin A specific flow rate is necessary to deliver a specific FiO ₂ , and the FiO ₂ is decreased if the mask does not fit properly Interferes with eating and talking
Partial nonrebreather— Bag should always remain partially inflated. Therefore flow rate must be high enough to prevent collapse of bag.	10-12 L/min: 80%-90%	Delivers increased FiO ₂ Useful for patients requiring high concentration of O ₂	No inspiratory valve; thus exhaled air mixes with inspired air Hot and confining; may irritate skin; tight seal necessary Interferes with eating and talking Bag may twist and kink
Nonbreathing mask	15 L/min: 60%-90%	Valve closes during expiration; thus exhaled air does not enter reservoir and mix with inhaled air	Requires tight seal; difficult to maintain and uncomfortable May irritate skin <i>Bag should not totally deflate</i>
Face tent	8-12 L/min: 28%-100%	Alternative to aerosol mask Provides high humidity with O ₂	Difficult to keep in place, and FiO ₂ cannot be controlled
Oxygen hood—usually pediatric use	5-8 L/min: 28%-40% 8-12 L/min: 49%-85%	Provides warmed humidified oxygen at a specific temperature	Flow rate of less than 5 L/min may lead to CO ₂ narcosis
Oxygen tent—usually pediatric use	10-15 L/min: up to 50%	Provides humidified O ₂ and can provide cool environment to control body temperature	Can be isolating for the child because every time tent is opened the O ₂ and humidity levels change

Data from Cairo JM, Pilbeam SP: *Mosby's respiratory care equipment*, ed 8, St Louis, 2010, Mosby; and British Thoracic Society Guidelines: Guideline for emergency oxygen use in adult patients: Executive summary, 2008, available at [http://www.brit-thoracic.org.uk/Portals/0/Guidelines/Emergency oxygen guideline/Emergency Oxygen Supplement_web.pdf](http://www.brit-thoracic.org.uk/Portals/0/Guidelines/Emergency%20oxygen%20guideline/Emergency%20Oxygen%20Supplement_web.pdf), accessed August 31, 2012.

FiO₂, Fraction of inspired oxygen concentration.

respiratory system, response to oxygen therapy, and setup of the oxygen therapy and liter flow, including the adjustment of oxygen flow rate. The nurse directs the NAP by:

- Informing how to safely place or adjust the device (e.g., loosening the strap on the oxygen cannula or mask).
- Instructing to inform the nurse immediately about any changes in vital signs; changes in level of consciousness (LOC); skin irritation from the cannula, mask, or straps; or patient complaints of pain or breathlessness.
- Having personnel provide skin care around patient's ears and nose.

Equipment

- Oxygen delivery device as ordered by health care provider
- Oxygen tubing (consider extension tubing)
- Humidifier, if indicated
- Sterile water for humidifier
- Oxygen source
- Oxygen flowmeter
- Appropriate room signs

FIG 23-6 Venturi mask.

FIG 23-7 Face tent for oxygen delivery.

STEP

RATIONALE

ASSESSMENT

1 Assess patient's respiratory status, including symmetry of chest wall expansion, chest wall abnormalities (e.g., kyphosis), temporary conditions (e.g., pregnancy, trauma) affecting ventilation, respiratory rate and depth, sputum production, and lung sounds (see Chapter 6) and for signs and symptoms associated with hypoxia (see Box 23-1).

Changes in ventilation and gas exchange resulting in hypoxia require oxygen therapy.

Clinical Decision Point Patients with sudden changes in their vital signs, LOC, or behavior may be experiencing profound hypoxia. Patients who demonstrate subtle changes over time may have worsening of a chronic or existing condition or a new medical condition (Kaul et al., 2009).

2 Observe for patent airway and remove airway secretions by having patient cough and expectorate mucus or by suctioning (see Chapter 25).

Secretions plug the airway, decreasing the amount of oxygen that is available for gas exchange in lungs.

3 If available, note patient's most recent arterial blood gas (ABG) results or pulse oximetry (SpO₂) value.

Objectively documents patient's pH, arterial oxygen, arterial carbon dioxide, or arterial oxygen saturation.

4 Review patient's medical record for medical order for oxygen, noting delivery method, flow rate, and duration of oxygen therapy.

Ensures safe and accurate oxygen administration. Safe oxygen delivery includes the six rights of medication administration (see Chapter 20).

NURSING DIAGNOSES

- Impaired gas exchange
- Ineffective airway clearance
- Ineffective breathing pattern

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Patient's signs of hypoxia are reduced or eliminated.
- Patient's vital signs remain stable or return to baseline.

Patient demonstrates improved oxygenation.

When there is no underlying cardiovascular disease, patients adapt to decreased oxygen levels by increasing pulse and blood pressure. This is a short-term adaptive response. Once signs of hypoxia are reduced or controlled, patient's vital signs usually return to normal.

- Patient's work of breathing decreases.

Pulmonary conditions such as pneumonia or asthma cause varying degrees of airway narrowing. With improved oxygenation, patient's airways are open, and work of breathing decreases.

STEP	RATIONALE
<ul style="list-style-type: none"> • Patient experiences increased lung expansion. • Patient's LOC returns to baseline. • ABG values or SpO₂ returns to normal or baseline. • Patient's nares and nasal mucosa remain intact. <p>2 Explain procedure to patient and family.</p>	<p>Improved oxygenation helps to resolve collapsed and constricted airways, improves the work of breathing, and thus improves lung expansion.</p> <p>Improvement in oxygenation relieves hypoxia and improves patient's mental status.</p> <p>Documents physiologic response to oxygen therapy.</p> <p>Oxygen cannula applied and monitored correctly.</p> <p>Increases compliance and cooperation of patient and family.</p>

IMPLEMENTATION

<p>1 Perform hand hygiene. Apply face shield if risk of exposure to splashing mucus exists.</p>	<p>Reduces transmission of microorganisms.</p>
<p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p>
<p>3 Attach oxygen delivery device (e.g., cannula, mask) to oxygen tubing and attach end of tubing to humidified oxygen source adjusted to prescribed flow rate (see Fig. 23-1).</p>	<p>Humidity prevents drying of nasal and oral mucous membranes and airway secretions. Ensures correct O₂ delivery.</p>
<p>4 Apply oxygen device:</p> <ul style="list-style-type: none"> a Place the two tips of the cannula into patient's nares. If the tips are curved, they should point downward inside the nostrils. Then loop the cannula tubing up and over patient's ears. Adjust the lanyard so the cannula fits snugly but not too tightly (see Fig. 23-3). b Apply a mask by placing it over patient's mouth and nose. Then bring the straps over patient's head and adjust to form a comfortable but tight seal (see Fig. 23-4). 	<p>Directs flow of oxygen into patient's upper respiratory tract. Patient is more likely to keep device in place if it fits comfortably.</p>
<p>5 Maintain sufficient slack on oxygen tubing and secure to patient's clothes.</p>	<p>Allows patient to turn head without causing mask to shift position or dislodge nasal cannula.</p>
<p>6 Observe for proper function of oxygen delivery device:</p>	<p>Ensures patency of delivery device and accuracy of prescribed oxygen flow rate.</p>
<ul style="list-style-type: none"> a <i>Nasal cannula</i>: Cannula is positioned properly in nares; oxygen flows through tips. 	<p>Provides prescribed oxygen rate and reduces pressure on tips of nares.</p>
<ul style="list-style-type: none"> b <i>Reservoir nasal cannula OXYMIZER</i>: Fit as for nasal cannula. Reservoir is positioned under patient's nose or worn as pendant. 	<p>Delivers higher flow of oxygen with nasal cannula. Delivers a 2:1 ratio (e.g., 6 L/min nasal cannula is approximately equivalent to 3.5 L/min with OXYMIZER device).</p>
<ul style="list-style-type: none"> c <i>Nonbreathing mask</i> (see Fig. 23-5): Apply as regular mask. Valves on mask close; thus exhaled air does not enter reservoir bag. 	<p>Does not allow exhaled air to be rebreathed. Valves on mask side ports permit exhalation but close during inhalation to prevent inhaling room air.</p>
<ul style="list-style-type: none"> d <i>Venturi mask</i> (see Fig. 23-6): Apply as regular mask. Select appropriate flow rate (see Table 23-1). 	<p>It is used when high-flow device is desired.</p>
<ul style="list-style-type: none"> e <i>Face tent</i> (see Fig. 23-7): Apply tent under patient's chin and over mouth and nose. It will be loose, and a mist is always present. 	<p>Excellent source of humidification; however, you cannot control oxygen concentrations, and patient who requires high oxygen cannot use this device.</p>
<p>7 Verify setting on flowmeter and oxygen source for proper setup and prescribed flow rate.</p>	<p>Ensures delivery of prescribed oxygen therapy in conjunction with specific cannula/mask.</p>
<p>8 Check cannula/mask every 8 hours. Keep humidification container filled at all times.</p>	<p>Ensures patency of cannula and oxygen flow. Oxygen is a dry gas; when it is administered via nasal cannula of 4 L/min or more, you must add humidification so patient inhales humidified oxygen (American Thoracic Society, 2012).</p>
<p>9 Post "Oxygen in use" signs on wall behind bed and at entrance to room.</p>	<p>Alerts visitors and care providers that oxygen is in use.</p>
<p>10 Perform hand hygiene.</p>	<p>Reduces transmission of microorganisms.</p>

STEP

RATIONALE

EVALUATION

- 1 Monitor patient's response to changes in oxygen flow rate with SpO₂. **NOTE:** Monitor ABGs when ordered; however, obtaining ABG measurement is an invasive procedure, and ABGs are not measured frequently.
- 2 Perform a physical assessment, listening to lung sounds, palpating chest excursion, inspecting color of skin, and observing for decreased anxiety, improved LOC and cognitive abilities, decreased fatigue, and absence of dizziness. Measure vital signs.
- 3 Assess adequacy of oxygen flow each shift.
- 4 Observe patient's external ears, bridge of nose, nares, and nasal mucous membranes for evidence of skin breakdown.

Continual monitoring with SpO₂ is required for patients on oxygen therapy. Base changes in supplemental oxygen on individual patient's oxygen saturation levels.

Evaluates patient's response to supplemental oxygen. As patient's oxygen level improves, physical signs and symptoms improve.

Ensures patency of oxygen delivery device.

Oxygen therapy sometimes causes drying of nasal mucosa. The delivery device can cause skin breakdown where device comes in contact with face, neck, and ears.

Unexpected Outcomes

- 1 Patient experiences skin irritation or breakdown (e.g., at ears, bridge of nose, nares, other pressure areas), drying of nasal and oral mucosa, sinus pain, or epistaxis.
- 2 Patient experiences continued hypoxia.
- 3 Patient experiences nasal and upper airway mucosa drying.

Related Interventions

- Increase humidification to oxygen delivery system.
- Provide appropriate skin care. Do not use petroleum-based gel around oxygen because it is flammable ([American Lung Association, 2012](#)).
- Notify health care provider.
- Obtain health care provider's orders for follow-up SpO₂ monitoring or ABG determinations.
- Consider measures to improve airway patency, coughing techniques, and oropharyngeal or orotracheal suctioning.
- If oxygen flow rate is greater than 4 L/min, use humidification. When oxygen flow is less than 4 L/min, the humidification system of the body is sufficient ([British Thoracic Society Guidelines, 2008](#)).
- Assess patient's fluid status and increase fluids if appropriate.
- Provide frequent oral care.
- Obtain health care provider order for use of sterile nasal saline intermittently.

Recording and Reporting

- Record the respiratory assessment findings; method of oxygen delivery, flow rate, patient's response; any adverse reactions or side effects; or change in health care provider's orders.
- Report any unexpected outcome to health care provider or nurse in charge.

Special Considerations

Teaching

- If oxygen therapy continues after discharge, teach patient and family the importance of and rationale for it, how to use the oxygen delivery device, how to contact the supplier of medical equipment, and when to contact the health care provider (see [Chapter 42](#)).
- Discuss safety precautions for oxygen use (see [Box 23-2](#)) with patient and family.
- Discuss signs of oxygen toxicity and carbon dioxide retention (e.g., confusion, headache, decreased LOC, somnolence, carbon dioxide narcosis, respiratory arrest) that patient needs to report to the health care provider.

Pediatric

- Some infants and small children are able to tolerate a nasal cannula. Secure the prongs of the cannula with Dermiclear tape or strips of transparent dressing over the child's cheek.
- Typically infants receive oxygen therapy via an oxygen hood. Place the hood over patient's head (sometimes over the

shoulders of a small infant). Sufficient room must exist between the curve of the hood and patient's neck to allow carbon dioxide to escape.

- Inspect toys placed in the tent for safety and suitability. Any source of sparks (e.g., from mechanical or electrical toys) is a potential fire hazard ([Hockenberry and Wilson, 2011](#)).
- Provide comfort and reassurance to the child. Make sure that child is able to see someone nearby ([Hockenberry and Wilson, 2011](#)).

Gerontologic

- Because of the fragility of older adults' skin and mucous membranes, offer oral hygiene and skin care more frequently. Water-based gels such as Aquagel are useful but also dry quickly and need more frequent application.
- Older adults often have a reduced oxygen-carrying capacity if they have a decreased hemoglobin level as a result of cardiac or other underlying illnesses.

Home Care

- Obtain appropriate referrals to determine if patient meets the standards for third-party reimbursement (e.g., PaO₂ 55 mm Hg or less during sleep or exercise). If patients have dependent edema, pulmonary hypertension, or hematocrit greater than 56%, they are eligible with a PaO₂ of 56 to 59 mm Hg ([American Thoracic Society, 2012](#)).

- Oxygen tubing in the home setting is available in lengths of 15 m (50 feet).
- Provide information about a reliable oxygen therapy equipment vendor within the community to determine if patient and family are able to use a home-fill system with an oxygen concentrator, which provides patient opportunity to fill portable canister as needed (Stoller et al., 2010).
- Consider using oxygen-conserving devices (e.g., OXYMIZER) that administer oxygen in a pulse-dosed flow during inhalation only. These reduce the use and cost of long-term oxygen therapy.

SKILL 23-2 Administering Oxygen Therapy to a Patient with an Artificial Airway

Patients with an artificial airway require constant humidification to the airway (see Chapter 25). An artificial airway bypasses the normal filtering and humidification process of the nose and mouth. The two devices that supply humidified gas to an artificial airway are a T tube and a tracheostomy collar.

The T tube, also called a *Briggs adaptor*, is a T-shaped device with a 15-mm (3/5-inch) connection that connects an oxygen source to an artificial airway such as an endotracheal (ET) tube or tracheostomy (Fig. 23-8). The recommended flow rate is 10 L/min with a nebulizer set to the appropriate FiO₂.

A tracheostomy collar is a curved device with an adjustable strap that fits around a patient's neck (Fig. 23-9). There are two ports: an exhalation port that remains patent at all times and the port that connects to the oxygen source with large-bore tubing.

The flow rate is set at 10 L/min with a nebulizer set to the appropriate FiO₂ that provides humidification to the lower airways via the tracheostomy tube opening.

Delegation and Collaboration

The skill of administering oxygen therapy to a patient with an artificial airway cannot be delegated to the nursing assistive personnel (NAP). The nurse directs the NAP about:

- Patient-specific variations for application or adjustment of the T tube or tracheostomy collar (e.g., methods to avoid pressure or pulling on the artificial airway, methods for handling accumulated secretions in devices).
- Immediately reporting to the nurse unexpected outcomes such as increase in anxiety, change in vital signs, and increased secretions associated with the oxygen delivery device.

Equipment

- T tube or tracheostomy collar
- Large-bore oxygen tubing
- Nebulizer
- Sterile water for nebulizer
- Oxygen or gas source
- Clean gloves
- Goggles (if splash risk exists)
- Flowmeter

FIG 23-8 T tube.

FIG 23-9 Tracheostomy collar.

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's respiratory status, including symmetry of chest wall expansion, respiratory rate and depth, sputum production, and lung sounds (see Chapter 6); and assess for signs and symptoms associated with hypoxia (see Box 23-1).
- 2 Observe for patent airway and remove airway secretions by having patient cough and by suctioning (see Chapter 25).
- 3 Monitor pulse oximetry (SpO_2) and, if available, note patient's most recent arterial blood gas (ABG) results.
- 4 Review patient's medical record for medical order for oxygen, noting delivery method, flow rate, and duration of oxygen therapy.

Changes in ventilation and gas exchange resulting in hypoxia require oxygen therapy.

Secretions plug airway, decreasing amount of oxygen available for gas exchange in lung. Secretions also occlude T tube or tracheostomy collar, impeding oxygen delivery to patient.

Objectively documents patient's pH, arterial oxygen, arterial carbon dioxide, or arterial oxygen saturation.

Ensures safe and accurate oxygen administration.

NURSING DIAGNOSES

- Impaired gas exchange
- Ineffective airway clearance
- Ineffective breathing pattern

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Signs of hypoxia are reduced or eliminated.
 - Patient's vital signs return to baseline.
 - Patient's work of breathing decreases.
 - Patient experiences increased lung expansion.
 - Patient's level of consciousness (LOC) returns to baseline.
 - ABG values or arterial oxygen saturation returns to normal or baseline.
 - Tracheal stoma remains intact without irritation or peristomal skin breakdown.
- 2 Explain purpose of T tube or tracheostomy collar to patient and family.

Patient experiences improved oxygenation.

When there is no underlying cardiovascular disease, patient adapts to decreased oxygen levels by increasing pulse and blood pressure. This is a short-term adaptive response. Once signs of hypoxia are reduced or controlled, patient's vital signs usually return to normal.

With improved oxygenation, tissue oxygen demand is met and work of breathing decreases.

Improved oxygenation helps to resolve collapsed and constricted airways, improve work of breathing, and thus improve lung expansion.

Improvement in oxygenation relieves hypoxia and improves patient's mental status.

Documents physiologic response to oxygen therapy.

Tension on tracheal stoma from oxygen therapy equipment has potential to cause pressure on stoma and surrounding skin.

Explanation decreases patient's anxiety and reduces oxygen consumption.

IMPLEMENTATION

- 1 Perform hand hygiene, apply clean gloves, goggles; consider use of barrier gown.
- 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 3 Attach T tube or tracheostomy collar to large-bore oxygen tubing and to humidified room air or oxygen source as indicated.
- 4 If health care provider orders oxygen, adjust flow rate to 10 L/min or as ordered. Adjust nebulizer to proper FiO_2 setting. Attach T tube to ET or tracheostomy tube. Place tracheostomy collar over tracheostomy tube and adjust straps so it fits snugly.

Reduces transmission of microorganisms by preventing contact with pulmonary secretions. Patients with excessive secretions or forceful productive coughs place caregiver at risk for splash contact.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

Provides supplemental humidification to avoid drying of airway.

Flow rate ensures humidification; nebulizer regulates FiO_2 .

STEP	RATIONALE
5 Observe that T tube does not pull on ET or tracheostomy tube. Observe for secretions within T tube or tracheostomy collar and suction as necessary (see Chapter 25).	Pulling effect increases patient's discomfort and causes pressure to side of patient's mouth or tracheal stoma. Maintains patent airway.
6 Observe oxygen tubing frequently for accumulation of fluid. If fluid is present, drain tube away from patient, disconnect from collar or T tube, and discard fluid in proper receptacle.	Excess water is medium for bacterial growth. Draining contaminated water into proper receptacle prevents contamination of entire humidifying unit.
7 Set up suction equipment at patient's bedside.	Some patients experience increased airway secretions resulting from humidification.
8 Remove gloves and goggles; perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Monitor patient's ABG levels or measure SpO ₂ .	Monitoring with SpO ₂ allows for noninvasive, cost-effective trending of patient's arterial oxygen saturation and pulse rate.
2 Observe position of oxygen delivery device to ensure that it is not pulling on artificial airway.	Pulling on artificial airway results in damage to oral cavity or stoma.
3 Measure patient's vital signs, palpate chest excursion, and observe patient's behavior.	Indicates if hypoxia has been relieved.

Unexpected Outcomes

- 1 Patient experiences tracheal stoma irritation; thick, tenacious secretions; pressure areas on neck or near stoma site.
- 2 Patient experiences continued hypoxia.

Related Interventions

- Implement measures to maintain skin integrity (see [Chapter 18](#)).
- Increase frequency of airway care.
- Suction secretions from artificial airway and lungs as indicated.
- Determine if cause of continued hypoxia is oxygen delivery device, plugging of airway, oxygen flow rate, or a new clinical problem.
- Notify health care provider of continued or worsening hypoxia.

Recording and Reporting

- Record the respiratory assessment findings; method of oxygen delivery, flow rate, condition of tracheal stoma, patient's response; any adverse reactions or side effects; and change in health care provider's orders.
- Report any unexpected outcome to health care provider or nurse in charge.

Special Considerations

Teaching

- See Teaching Considerations for [Skill 23-1](#).

Home Care

- Some patients who are at home have both a permanent tracheostomy and a T tube or a tracheostomy collar. The patient or caregiver needs to be physically able to perform tracheostomy care and suctioning techniques, as well as understand how to manage oxygen (see [Chapter 25](#)).

SKILL 23-3 Using Incentive Spirometry

Incentive spirometry helps a patient deep breathe. An incentive spirometer (IS) is most often used following abdominal or thoracic surgery to reduce the incidence of postoperative pulmonary atelectasis. The use of an IS is especially important in patients with underlying pulmonary diseases because of their risk for postoperative pneumonia. Studies demonstrate that, although postoperative deep breathing and coughing are as effective as incentive spirometry, the use of an IS in combination with coughing and other methods for lung expansion (e.g., chest physiotherapy) lowers rates of postoperative pneumonia ([Agostini and Singh, 2009](#)).

Incentive spirometry provides visual feedback to patients about the depth of their breaths. The two types of ISs are flow oriented and volume oriented. Flow-oriented ISs have one or more plastic chambers with freely movable, colored balls. As a patient inhales slowly, the balls are elevated to a premarked area ([Fig. 23-10](#)). A patient's goal is to keep the balls elevated for as long as possible to ensure maximal sustained inhalation; not to snap the balls to the

top of the chamber with a rapid, very brief, low-volume breath. Even if a very slow inspiration does not elevate the balls, this pattern helps a patient improve lung expansion. The advantage of a flow-oriented IS is the slow, steady expansion of the lung.

Volume-oriented devices use a bellows that a patient must raise to a predetermined volume by inhaling slowly ([Fig. 23-11](#)). An achievement light or counter provides feedback to the patient. Some devices have a marker that moves up as a patient inhales. The advantage of the volume-oriented IS is that a patient can achieve a known inspiratory volume and measure it with each breath.

Incentive spirometry encourages patients to breathe deeply and achieve their normal inspiratory capacity. Before surgery it is helpful to determine a patient's baseline inspiratory capacity. An inspiratory volume half to three quarters of baseline is an acceptable postoperative volume. Patients benefiting from incentive spirometry include those using it before surgery, especially before

FIG 23-10 Flow-oriented incentive spirometer.

FIG 23-11 Volume-oriented incentive spirometer.

abdominal, cardiac, or orthopedic surgery; patients with a history of smoking, pneumonia, or chronic respiratory disease; and patients with atelectasis (Agostini and Singh, 2009).

Delegation and Collaboration

The skill of assisting a patient to use incentive spirometry can be delegated to nursing assistive personnel (NAP). The nurse is responsible for patient assessment, monitoring, and evaluating the patient response. The nurse directs the NAP by:

- Informing about the patient's target goal for incentive spirometry.
- Informing to immediately notify the nurse about any unexpected outcomes such as chest pain, excessive sputum production, and fever.

Equipment

- ❑ Flow- or volume-oriented IS

STEP

RATIONALE

ASSESSMENT

- 1 Identify patients who will benefit from incentive spirometry: those who have existing pulmonary disease, are overweight, or have other debilitating chronic illnesses (Agostini and Singh, 2009).
- 2 Assess patient for confusion, malnutrition, cognitive impairment, and decreased necessary motor skills.
- 3 Assess patient's respiratory status, including symmetry of chest wall expansion, respiratory rate and depth, sputum production, and lung sounds (see Chapter 6).
- 4 Assess level of pain at rest and during activity (e.g., coughing) using a 0-to-10 scale.
- 5 Review health care provider's order for incentive spirometry.

Alerts health care personnel to patients at risk for respiratory complications during illness or after surgery.

Determines risks for difficulty performing incentive spirometry.

Decreased chest wall movement, crackles or decreased lung sounds, increased respiratory rate, or increased sputum production can indicate a need for incentive spirometry to improve lung expansion.

Pain decreases effective incentive spirometry by restricting chest expansion.

Health care agencies often require a medical order for incentive spirometry to receive third-party reimbursement.

NURSING DIAGNOSES

- Acute pain
- Impaired gas exchange
- Ineffective airway clearance
- Ineffective breathing pattern

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient demonstrates correct use of IS.
 - Patient achieves target volume and number of repetitions per hour.
 - Patient has improved breath sounds.

Demonstrates learning.

Demonstrates increased lung expansion.

Incentive spirometry helps patient in deep breathing and managing airway secretions.

STEP	RATIONALE
2 Explain procedure to patient and family.	Understanding purpose of incentive spirometry and its proper use improves compliance with use.
3 Indicate to patient where target volume is on IS. NOTE: If possible, demonstrate use of IS.	Encourages patients to “do better” with each breath and meet or exceed target volume. When patients have a visual target, they can gauge their improvement.

IMPLEMENTATION

1 Perform hand hygiene.	Reduces transmission of microorganisms.
2 Position patient in most erect position (e.g., high-Fowler’s if tolerated) (Smeltzer et al., 2009).	Promotes optimal lung expansion during respiratory maneuver.
3 Instruct patient to exhale completely through mouth and place lips tightly around mouthpiece.	Showing patient how to correctly place mouthpiece is reliable technique for teaching psychomotor skill and enables patient to ask questions.
4 Instruct patient to take a slow, deep breath and maintain constant flow, like pulling through a straw. When patient cannot inhale any more, he or she has reached maximal inspiration. Have patient hold breath for at least 3 seconds and then exhale normally.	Maintains maximal inspiration; reduces risk for progressive collapse of individual alveoli.

Clinical Decision Point *Some patients with chronic obstructive pulmonary disease (COPD) are able to hold their breath for only 2 to 3 seconds. Encourage them to do their best and try to extend the duration of breath holding. Allow patients to rest between IS breaths to prevent hyperventilation and fatigue.*

5 Have patient repeat maneuver, encouraging him or her to reach prescribed goal.	Ensures correct use of IS and patient’s understanding of use.
6 Remind patient to perform IS exercises 5 to 10 times followed by controlled coughing every hour while awake or as directed by health care provider. Keep IS within patient’s reach.	Repeated use of IS improves lung expansion and promotes clearing of airways, especially in patients with underlying lung disease (Wilkins et al., 2009). Using controlled cough techniques reduces risk for coughing spasms.
7 Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Observe patient’s ability to use incentive spirometry by return demonstration.	Determines patient’s ability to perform breathing exercise correctly.
2 Assess if patient is able to achieve target volume or frequency.	Measures adherence to therapy and lung expansion.
3 Auscultate chest during respiratory cycle.	Documents lung expansion, identifies any abnormal lung sounds, and determines if airways are clear.

Unexpected Outcomes

- 1 Patient is unable to achieve incentive spirometry target volume.
- 2 Patient has decreased lung expansion and/or abnormal breath sounds.

Related Interventions

- Encourage patient to attempt incentive spirometry more frequently, followed by rest periods.
- Teach cough-control exercises.
- Teach patient how to splint and protect incision sites during deep breathing.
- Administer ordered analgesic if acute pain is inhibiting use of IS.
- Teach patient cough-control exercises.
- Provide assistance with suctioning if patient cannot effectively cough up secretions.

Recording and Reporting

- Record the lung sounds before and after incentive spirometry, the frequency of use, the volumes achieved, and any adverse effects.
- Report any changes in respiratory assessment or patient’s inability to use IS to health care provider.

Special Considerations

Teaching

- Do not let patient use the device if he or she cannot understand or demonstrate proper use.

- Teach patient to examine sputum for consistency, amount, and color changes.

Pediatric

- Incentive spirometry is not typically used in pediatrics except for school-age children; a pediatric patient needs the fine-motor skills and ability to follow instructions to effectively use an IS (Hockenberry and Wilson, 2011).
- Allowing a child to play with and try out the IS helps to decrease his or her anxiety and encourages participation in care.

- Use games or bubbles and balloons to encourage small children to take deep breaths. These activities help achieve the same goals as incentive spirometry in some children.

Gerontologic

- Older adults with chronic illnesses or arthritis have difficulty coordinating the use of the IS. They require additional time to demonstrate the procedure (Sieber and Barnett, 2011).
- COPD, common in the older-adult population, is an important patient-related risk factor; in addition, heart failure, cigarette

use, obesity, obstructive sleep apnea, and decreased cognitive status are also risks for developing postoperative pulmonary complications. Using an IS before and after surgery has the potential to reduce these risks.

- Weakened respiratory muscles and decreased elastic recoil properties of the lungs affect a patient's ability to cough and deep breathe. Therefore it takes an older adult longer to achieve the target volume (Sieber and Barnett, 2011).

SKILL 23-4 Care of a Patient Receiving Noninvasive Positive-Pressure Ventilation

Noninvasive positive-pressure ventilation (NIPPV) maintains positive airway pressure and improves alveolar ventilation without the need for an artificial airway. In addition, this mechanical ventilation alternative reduces and reverses atelectasis, improves oxygenation, reduces pulmonary edema, and improves cardiac function (Frace, 2008). Continuous positive airway pressure (CPAP) keeps the terminal airways (alveoli) partially inflated, reducing the risk for atelectasis; and, if atelectasis has occurred, positive pressure helps in reinflation. Because the alveoli remain partially inflated, there is continued exchange of respiratory gases, and as a result a patient's oxygenation improves (Hoo, 2011). In a cardiac patient NIPPV reduces pulmonary edema because the increased alveolar pressure forces interstitial fluid out of the lungs and back into the pulmonary circulation. In patients with altered cardiac function secondary to sleep apnea, NIPPV provides improved myocardial oxygenation and function.

In selected patients such as those with postpolio syndrome and other neuromuscular diseases, heart failure, sleep disorders, and pulmonary diseases, NIPPV is often the treatment of choice to support ventilation without the hazards associated with endotracheal intubation (Frace, 2008). In addition, there is a reduced risk for pneumonia, gastric aspiration, and ventilator dependency when using NIPPV.

FIG 23-12 Mask suitable for continuous positive airway pressure (CPAP).

NIPPV delivers both inspiratory positive airway pressure (IPAP) and expiratory positive airway pressure (EPAP) (Hoo, 2011). Thus NIPPV has the option of providing CPAP or bi-level positive airway pressure (BiPAP). For most patients it is recommended to try CPAP initially. If this delivery mechanism is not effective, BiPAP is tried.

CPAP maintains a set positive airway pressure measured by centimeters of water (cm H₂O) throughout the patient's inspiratory and expiratory breathing cycles (Fig. 23-12). A CPAP of 5 cm H₂O provides 5 cm of pressure during inspiration and expiration. It is beneficial in patients who retain carbon dioxide such as with obstructive sleep apnea (OSA) or acute exacerbations of chronic

TABLE 23-2 Problems Associated with Continuous Positive Airway Pressure and Bi-level Positive Airway Pressure

Problem	Cause
Discomfort	Mask that fits over patient's nose is tight fitting. Oxygen flow rate causes dry mucous membranes.
Psychosocial	Relationship with sleep partner is difficult. There are possible sensations of claustrophobia.
Risks to skin integrity	Tight fit of mask causes diaphoresis, pressure, and increased risk for skin breakdown. Patients need to remove mask to relieve pressure.
Hypercapnia	Although CPAP improves alveolar function, which increases carbon dioxide clearance from the blood, it also causes air trapping. In some patients this causes a rise in carbon dioxide levels. Initially you need to monitor patient's ABG levels.
Gastric distention	CPAP/BiPAP forces more air into the stomach, which causes distention and discomfort.
Noise	Some patients find the older machines very noisy, interfering with sleep and leisure activities such as watching television or listening to music.

Data from Frace M: Noninvasive ventilation: CPAP and BiPAP on the medical-surgical unit, *Med-Surg Matters* 17(3):12, 2008; and Hoo G: Noninvasive ventilation, June 2011, available at <http://emedicine.medscape.com/article/304235-overview>, accessed March 2, 2012.

ABG, Arterial blood gas; BiPAP, bi-level positive airway pressure; CPAP, continuous positive airway pressure.

obstructive pulmonary disease (COPD) (Hoo, 2011). CPAP keeps the airway open and prevents upper airway collapse. As a result, a patient breathes more normally, sleeps better, and has markedly reduced snoring. In OSA the upper airway collapses during sleep and prevents normal airflow. When the airflow is interrupted, the patient's oxygen saturation drops, and frequent awakenings occur. The usual CPAP pressure is 4 to 10 cm H₂O (Frace, 2008), but it should be determined by a formal sleep study and prescribed accordingly (Table 23-2).

BiPAP is delivered via face mask; thus some patients find it uncomfortable and noisy (see Table 23-2). It works by providing assistance during inspiration and preventing airway closure during expiration. It uses two modes of pressure: one for inspiration and one for expiration. The health care provider designates the pressure during inspiration. BiPAP generates a preset positive-pressure support during inspiration, which increases the patient's tidal volume and ultimately alveolar ventilation. This inspiratory pressure support ends when the patient initiates the expiratory phase. As a result there is an increase in the functional residual capacity (the amount of air remaining in the lungs at the end of expiration), reduced airway closure, reexpansion of atelectatic areas, and improved oxygenation. During expiration BiPAP delivers sufficient expiratory pressure to keep the airways open (Frace, 2008).

The goals for NIPPV include improved oxygenation, decreased carbon dioxide retention, improved sleep, enhanced quality of life, reduced morbidity, improved physical and physiologic function, and cost-effectiveness (Frace, 2008). Patients and families who are candidates for NIPPV are prepared for discharge by a multidisciplinary team, including representatives of nursing, respiratory care,

medicine, dietary service, and social service; the home care nurse; and the home care durable medical equipment company.

Delegation and Collaboration

The skill of caring for a patient receiving noninvasive ventilation cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP by:

- Informing about the need to immediately report to the nurse any changes in patient's vital signs, oxygen saturation, mental status, or skin color.
- Instructing on how to modify care such as how long the mask can be removed, oral care, or any special skin care needs.
- Informing about the prescribed settings on the NIPPV equipment and notifying nurse of any change in settings or patient comfort.

Equipment

(NOTE: When device is used in the home, the home care equipment vendor provides the equipment.)

- Nasal mask/full face mask (with quick-release straps), or nasal pillows
- Oxygen source and tubing
- CPAP/BiPAP per health care provider order
- Humidification source, if needed
- BiPAP and CPAP machines may be used for NIPPV in some critical care areas.
- Delivery tubing
- Pulse oximetry
- Clean gloves
- Gown, mask, and goggles (if splash risk exists)

STEP **RATIONALE**

ASSESSMENT

- 1 Assess patient's respiratory status, including symmetry of chest wall expansion, respiratory rate and depth, oxygen saturation, sputum production, and lung sounds (see Chapter 6). When possible, ask patient about dyspnea and observe for signs and symptoms associated with hypoxia (see Box 23-1).
- 2 Observe patient's skin over bridge of nose, around external ears, back of head.
- 3 Observe patient's ability to clear and remove airway secretions by coughing.
- 4 Obtain pulse oximetry results; when available, note patient's most recent arterial blood gas (ABG) results.
- 5 Obtain vital signs and pulse oximetry before initiation of therapy.

Decreased chest wall movement, crackles or decreased lung sounds, increased respiratory rate, increased sputum production, or signs of worsening hypoxia may make patient a candidate for noninvasive positive pressure ventilation or changes in NIPPV settings.

The mask can place pressure on skin and increase risk for skin breakdown.

Secretions plug the airway, decreasing amount of oxygen that is available for gas exchange in the lung.

Objectively documents patient's pH, arterial oxygen, arterial carbon dioxide, or arterial oxygen saturation.

Provides baseline data to compare desired or untoward vital sign changes resulting from therapy.

Clinical Decision Point NIPPV is contraindicated in cardiac or respiratory arrest, nonrespiratory organ failure, facial surgery or trauma, inability to protect the airway and/or high risk for aspiration, and inability to clear secretions. Controversy surrounding the use of NIPPV in "do-not-resuscitate" or "do not intubate" patients has been addressed by a task force of the Society of Critical Care Medicine, which recommends that it be applied only after careful discussion of goals of care and parameters of treatment with patients and their families (Matzo and Sherman, 2010).

- 6 Review patient's medical record for medical order for CPAP/BiPAP and appropriate settings.

Health care provider's order is necessary for this therapy.

NURSING DIAGNOSES

- Activity intolerance
- Impaired gas exchange
- Sleep deprivation

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient has increased lung expansion.
 - Patient maintains ABG levels or oxygen saturation within normal range or at baseline.

Patient experiences improved oxygenation.
NIPPV delivered appropriately based on patient assessment data.

Clinical Decision Point *When first initiating CPAP/BiPAP, it is important to monitor gas exchange, especially in patients with COPD, cardiogenic pulmonary edema, or acute respiratory failure. You do this to observe for carbon dioxide retention. If patient has “do not resuscitate” orders (for comfort measures only), careful consideration is given before starting noninvasive ventilation (Hoo, 2011).*

- Patient experiences reduction in feelings of dyspnea and work of breathing.
 - Patient’s vital signs and respiratory assessment parameters improve.
 - Patient’s skin around bridge of nose, ears, and back of head remains clear without breakdown.
- 2 Explain to patient and family the purpose and reasons for CPAP/BiPAP.

In patients with acute conditions there is usually an improvement in dyspnea (Filippatos, Mebazaa, and Masip, 2008).
Patients with chronic pulmonary diseases often require nocturnal CPAP/BiPAP indefinitely to achieve long-term benefits.
Reduced pulse and respiratory rate, improved mental status, improved skin color, and decreased use of accessory and abdominal muscles occur because patient’s work of breathing decreases as level of oxygenation improves (Frace, 2008).
Mask applied properly and monitored for pressure occurrence.
Helps reduce sense of claustrophobia from mask. In addition, information reduces anxiety and increases cooperation and adherence to therapy.

IMPLEMENTATION

- 1 Perform hand hygiene; apply clean gloves. Apply mask, gown, and goggles if secretions are projectile.
- 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient’s identification bracelet and/or ask patient to state name.
- 3 Determine correct mask size. Use a masking chart to determine the correct size (S, M, L, XL). *NOTE: It is imperative that mask have quick-release straps.*
- 4 Connect CPAP/BiPAP device delivery tubing to pressure generator.
- 5 Connect patient to pulse oximetry.
- 6 Set CPAP/BiPAP initial settings:
 - a CPAP: 4 to 8 cm H₂O
 - b BiPAP: Inspiratory pressure usually set at 10 to 15 cm H₂O; expiratory pressure usually set at 4 to 10 cm H₂O (Frace, 2008)
- 7 Perform frequent skin assessment to determine presence of pressure, skin irritation, or skin breakdown.
- 8 Dispose of supplies as appropriate, remove gloves and other personal protective equipment, and perform hand hygiene.

Reduces transmission of microorganisms and exposure to pulmonary secretions.
Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
Mask should fit snugly over patient’s nose (CPAP) or nose and/or mouth (BiPAP) to create a tight seal for delivering positive pressure. In case of emergency (e.g., vomiting, respiratory arrest), quick-release straps allow mask to be removed quickly. This system also allows patient to remove mask quickly as needed (Frace, 2008).
Ensures that patient is receiving proper NIPPV as ordered.
It is important to continually monitor patient’s level of oxygenation when initiating NIPPV (Hoo, 2011).
These settings allow health care team to determine initial patient response.
CPAP provides single positive pressure throughout breathing cycle, which helps to keep alveoli open at end-expiration.
BiPAP supplies pressures at both inhalation and exhalation. The inhalation pressure is set according to health care provider’s order and helps to prevent airway closure. Expiratory pressure is set according to health care provider’s order and keeps alveoli open at end-expiration (Frace, 2008).
Mask that is too tight increases risk for skin breakdown over bridge of nose.
Reduces transmission of microorganisms.

STEP

RATIONALE

EVALUATION

<p>1 Observe for decreased anxiety; improved level of consciousness and cognitive abilities; decreased fatigue; absence of dizziness. Measure vital signs, palpate chest excursion, observe skin color, and ask patient to describe sense of dyspnea.</p> <p>2 Monitor pulse oximetry.</p>	<p>Determines patient's response to NIPPV. As hypoxia and hypercapnia are reduced or corrected, the patient's physical assessment parameters improve.</p>
<p>3 Observe skin integrity over bridge of patient's nose.</p>	<p>Documents patient's level of oxygenation. When first initiating NIPPV, it is important to obtain ABG levels in patients in whom abnormal gas exchange is suspected, after the first hour, and per agency protocol.</p> <p>Mask that is too tight causes skin breakdown, and frequent skin assessment is necessary.</p>
<p>4 If NIPPV is planned for use in home, observe and monitor patient's and family's ability to manipulate device and face mask.</p>	<p>Determines patient's ability to perform self-care and adhere to CPAP/BiPAP plan. Success of noninvasive ventilation depends largely on patient acceptance and adherence (Hoo, 2011).</p>

Unexpected Outcomes

- 1 Patient experiences hypoxia.
- 2 Patient experiences hypercapnia.
- 3 Patient states sense of smothering or claustrophobia.

Related Interventions

- Notify health care provider.
- Reassess patient.
- Determine correct settings and integrity of NIPPV.
- Notify health care provider.
- Reassess patient.
- Determine correct settings and integrity of NIPPV.
- Explain system to patient again.
- Demonstrate use of quick-release straps.
- Have patient demonstrate use of quick-release straps.

Recording and Reporting

- Record respiratory assessment findings, CPAP/BiPAP settings, vital signs and pulse oximetry, patient response, patient teaching outcomes.
- Report to charge nurse or health care provider: sudden change in patient's respiratory status and any decline in ABG levels or pulse oximetry values.

Special Considerations

Teaching

- Teach patient and family the best hours to use the machine (e.g., bedtime, watching television); usually patient receives 6 to 8 hours of continual CPAP/BiPAP.
- Teach patient and family how to apply the mask, connect it to the machine, and add oxygen if ordered.

- Instruct family to bring the machine, along with a list of correct settings, to the hospital any time patient is admitted.
- When patients require home NIPPV, instruct in complete care of the CPAP/BiPAP system. Skills include assembling the system, cleaning it, and daily equipment maintenance.

Home Care

- The durable medical equipment provider, the home care nurse, and the primary care nurse develop a teaching plan to ensure that patient and family have working knowledge of the system before discharge.
- Instruct patient and primary caregiver in what to do in case of respiratory distress or power failure.
- Notify appropriate power company so, in the event of a power outage, the home is on priority for restoring power.

PROCEDURAL GUIDELINE 23-1 Use of a Peak Flow Meter

For patients who have measurable changes in the flow of their airways such as patients with asthma or reactive airways disease, peak expiratory flow rate (PEFR) measurements are useful. The PEFR is the maximum flow that a patient forces out during one quick, forced expiration and is measured in liters. Use these measurements as an objective indicator of a patient's current status or the effectiveness of treatment. Decreased PEFR may indicate the need for further interventions such as increased doses of bronchodilators or antiinflammatory medications. Normal PEFR values vary according to a person's age, gender, and size.

Patients with asthma perform PEFR measures in the home to monitor the status of their airways. Health care providers usually recommend that patients measure their PEFR during the following times: every morning, before taking asthma medicines, during asthma symptoms or an asthma attack, after taking medicine for an asthma attack, and other times recommended by their health-care provider. The health care provider will explain how to know if a person's asthma is controlled. A system of asthma zones—green, yellow and red—are commonly used for patients to gauge if their PEFR is well controlled.

Delegation and Collaboration

Initial assessment of a patient's condition cannot be delegated. The skill of follow-up PEFR measurements can be delegated to nursing assistive personnel (NAP).

Equipment

- Peak flow meter
- Patient diary/action plan (if appropriate)

Procedural Steps

- 1 Assess previous PEFR readings and the target set by patient's health care provider.
- 2 Instruct patient about the purpose and rationale.
- 3 Patient should be standing. If patient cannot stand, help him or her to high-Fowler's position or any other position that promotes optimum lung expansion.
- 4 Slide the mouthpiece into base of the numbered scale to zero position.
- 5 Instruct patient to take a deep breath.
- 6 Have patient place meter mouthpiece in the mouth and close lips, making a firm seal.
- 7 Have patient blow out as hard and fast as possible through the mouth only in one single breath.
- 8 Repeat maneuver two additional times. Record the highest number in the chart or patient's diary.
- 9 If patient is to record PEFR at home, have him or her demonstrate PEFR technique independently and assess ability to record PEFR accurately on chart using "traffic light" pattern. Green zone (80% to 100% of personal best number) indicates that no asthma symptoms are present. Yellow zone (50% to 80% of personal best number) signals caution. Red zone (less than 50% of personal best number) signals a medical alert, and patient should call health care provider immediately (Grad et al., 2009).
- 10 Help patient implement an appropriate action plan as prescribed by health care provider.
- 11 Instruct patient to clean unit weekly following manufacturer instructions.

SKILL 23-5 Care of a Patient on a Mechanical Ventilator

Patients requiring mechanical ventilation need support for ventilation and/or oxygenation. Clinical problems such as respiratory failure, exacerbation of chronic obstructive lung disease (COPD), spinal cord trauma, respiratory muscle paralysis, and pneumonia require mechanical ventilation support (Roca et al., 2010). Patients receiving mechanical ventilation are most often in an intensive care unit.

An artificial airway such as an endotracheal (ET) tube or tracheostomy tube is necessary for mechanical ventilation (see Chapter 25). There are two types of mechanical ventilation: positive pressure and negative pressure. Positive-pressure ventilation is the usual method of ventilation that delivers a positive pressure to inflate the lungs. Multiple complications are associated with positive-pressure ventilation: decreased cardiac output, aspiration, tension pneumothorax (see Chapter 25), bronchospasm, laryngeal trauma, sinusitis, and ventilator-associated pneumonia. In addition, as the length of time needed for mechanical ventilation increases, there is an increased risk of failure to wean from the ventilator (Carbery, 2008). Be alert for these side effects. Negative-pressure ventilation is a noninvasive, negative-pressure ventilation technique. It is used for patients with primary neuromuscular illnesses that interfere with normal respiratory muscle function such as multiple sclerosis and muscular dystrophy. You fit a patient with a poncho or shell that is connected to the ventilator. Air is removed from between the patient's chest wall and the interior wall of the poncho or shell, causing the patient to inhale. A patient using negative-pressure ventilation does not need an artificial airway.

The skill described in this chapter focuses on positive-pressure mechanical ventilation frequently used in acute, subacute, and some selective home care settings. Many types of positive-pressure mechanical ventilators are available for acute care use (Fig. 23-13).

Modes of Ventilation

There are many different modes of mechanical ventilation to support different conditions and physiologic processes. Mechanical ventilation controls or assists a patient's respirations when he or she is unable to maintain adequate gas exchange because of respiratory or ventilatory failure (Table 23-3). The ventilator takes over the physical work of moving air into and out of the lungs, but it does not replace or alter the physiologic function of the lung. Mechanical ventilation maintains or improves ventilation, oxygenation, and breathing pattern. Patients with impaired ventilation have low oxygen level (hypoxemia), retain carbon dioxide (hypercapnia), and have difficulty breathing. Invasive mechanical ventilation requires an artificial airway (see Chapter 25).

It is important that patients remain on mechanical ventilation only as long as necessary because there is an increased mortality risk associated with positive-pressure ventilation. Caring for a patient on mechanical ventilation and weaning from it require interdisciplinary collaboration. Nursing care includes providing emotional support, preventing complications (e.g., pneumothorax, atelectasis, decreased cardiac output, pulmonary barotraumas, stress ulcer, or infection), promoting optimal respiratory gas exchange, and monitoring for equipment failure.

FIG 23-13 840 Series ventilator system. (Reprinted by permission from Nellcor Puritan Bennet LLC, Boulder, Colo, Part of Covidien.)

Alarms and Settings

The mechanical ventilator has a number of settings to adjust the amount of oxygen delivered, the amount of tidal volume, the time for inspiration and expiration, and the pressure at which each breath is delivered. The tidal volume, the amount of air per breath, is usually set by the patient’s ideal body weight (5 to 8 mL/kg). If the patient has a restrictive lung disease such as pulmonary fibrosis, a flail chest, or recent thoracic surgery, the tidal volumes are usually set lower.

The respiratory rate is usually set at 10 to 16 breaths/min. Initially the FiO₂ is usually set at 100% and is quickly reduced to less than 40% based on patient arterial blood gas (ABG) levels. The goal of providing oxygenation is to maintain a PaO₂ of >60 mm Hg using an FiO₂ of 40% or less. Table 23-4 lists the ventilator parameters with which you need to become familiar to care for a patient on mechanical ventilation.

There are several alarms on the ventilator to ensure patient safety. Each ventilator is a little different; however, the basic alarms are similar. Alarms common to all ventilators include high-pressure, low-pressure, low-exhaled volume, and oxygen alarms (Table 23-5). You need to know how to respond to the ventilator alarms and which nursing actions are required to preserve the patient’s respiratory status. The two most frequent alarms are the

TABLE 23-3 Overview of Mechanical Ventilation		
Types	Description	Nursing Considerations
Continuous positive airway pressure (CPAP)	Applies positive pressure during entire respiratory cycle.	Used for patients who breathe spontaneously but have hypoxemic respiratory failure; useful during weaning. Patients with COPD may tire after long hours of CPAP and require increased pressure support.
Positive end-expiratory pressure (PEEP)	Applies positive pressure during expiration.	Used for treating hypoxemic respiratory failure.
Volume-targeted	Delivers a preset volume to patient; peak inspiratory pressure varies.	Use in short-term ventilation and with ventilator weaning.
Pressure-targeted	Delivers flow to patient until a preset pressure is reached; tidal volume varies.	Useful when excessive inspiratory pressures could damage lungs, as in neonates; tidal volume varies with airway resistance and lung compliance.
High-Frequency High-frequency jet ventilation (HFJV)	Delivers gas rapidly under low pressure via special injector cannula. Delivers 100-200 breaths/min with tidal volume of 50-400 mL.	Patient on any mode of high-frequency ventilation requires continuous sedation and neuromuscular blocking agent administration.
High-frequency oscillatory ventilation (HFOV)	Delivers over 200 breaths/min with very small tidal volumes. Airway pressure controlled.	Most common of high-frequency types; maintains alveolar ventilation with low airway pressure; useful for treating esophageal or bronchopleural fistulas; helps avert barotraumas in high-risk patients if used early in treatment.
Mode of Use		
Assist-control	Patient initiates breathing, but backup control delivers preset number of breaths at set volume.	
Synchronized intermittent mandatory ventilation (SIMV)	Ventilator delivers set number of breaths at specified volume. Some patients breathe spontaneously between SIMV breaths at volumes differing from those set on the machine.	Requires frequent monitoring during weaning from mechanical ventilation.

COPD, Chronic obstructive pulmonary disease.

TABLE 23-4 Ventilator Parameters

Parameter	Definition	Ventilator Setting
Tidal volume (V_T)	Amount of air inspired and expired with each breath	5-8 mL/kg of ideal body weight (patients with nonrestrictive pulmonary diseases) (Weigand, 2011).
Respiratory rate (R or RR)	Number of breaths delivered per minute	Usual rate is 10-16 breaths/min. However, the rate can be set 4-20 breaths/min, with lower rates used during weaning (Weigand, 2011).
Fraction of inspired oxygen (FiO_2)	Amount of oxygen that patient receives	Ideally less than 40% to maintain $PaO_2 >60$ mm Hg and $SpO_2 >90\%$ (Weigand, 2011).
Positive end-expiratory pressure (PEEP) (see also Table 23-3)	Positive pressure applied at end-expiration to improve oxygenation	5 cm H_2O may be used to approximate physiologic PEEP. May require higher levels (10-20 cm H_2O) in respiratory failure (e.g., refractory hypoxemia).
Sighs	Larger-than-normal breath to provide hyperinflation; helps prevent atelectasis	Usually twice the V_T breath; about 10-15 mL/kg. Rate is usually set at 10-15 times per hour. <i>Sighs are not always used.</i>
Sensitivity	Determines inspiratory effort required to trigger the ventilator	A breath can be triggered by a change in either flow or pressure.
Peak airway pressure	Maximal pressure level achieved during a breath	<40 cm H_2O .
I:E ratio	Comparison of inspiratory (I) to expiratory (E) time	Example: Inspiration 0.5 seconds, expiration 1 second, then I:E = 1 : 2 (Weigand, 2011).
Exhaled minute ventilation (V_E)	Measures the exhaled minute ventilations in liters	Alarm set at 15% greater than patient's average V_E .

PEEP, Positive End Expiratory Pressure.

TABLE 23-5 Troubleshooting Mechanical Ventilation

Ventilator Alarm	Possible Causes	Nursing Interventions
Sudden increase in peak airway pressure (high-pressure alarm)	Coughing Airway plugging Changes in patient position Pneumothorax Incorrect ET tube position Kinked ventilator circuit Excessive water in ventilator circuit	Clear secretions by suctioning. Reposition patient. Assess breath sounds and chest wall movement. Verify placement of ET tube. Assess breath sounds. Verify centimeter level of ET tube. Check circuit; unkink tubing. Drain ventilator tubing.
Gradual increase in peak airway pressure	Decreasing lung compliance Exacerbation of acute process	Evaluate breath sounds; suction. Check for reversible causes: airway plugging, bronchospasm.
Sudden decrease in peak airway pressure (low-pressure alarm)	Patient disconnected from ventilator Leak in ventilator circuit	Check for disconnection. Evaluate circuit connections; tighten loose connections.
Change in minute ventilation or tidal volume	Leak in ET cuff	Check cuff seal.
Decrease	Airway secretions System leak Increased respiratory rate	Suction excessive secretions. Check circuit connections. Evaluate respiratory rate.
Increase	Hypoxia	Evaluate for signs of hypoxia. Evaluate need to obtain ABG sample or monitor pulse oximetry.
Change in respiratory rate	Patient anxiety Increased metabolic demand Hypoxia	Reassure patient. Evaluate body temperature, heart rate, and rhythm. Monitor pulse oximetry.

ABG, Arterial blood gas; ET, endotracheal.

high-pressure and low-pressure alarms. The high-pressure alarm is usually set at 10 to 15 cm greater than the peak airway pressure. When this alarm sounds, it indicates that the ventilator has met resistance to delivering the tidal volume and requires more pressure to inflate the lungs. Some patients have coughed during the inspiratory cycle; some need suctioning or have changed position. More

acute problems that require immediate nursing intervention include the development of a pneumothorax or displacement of the ET or tracheostomy tube. The low-pressure alarm sounds when the ventilator has no resistance to inflating the lung. The patient may be disconnected from the ventilator, or a leak has developed in the ventilator circuit (Weigand, 2011).

Home Mechanical Ventilation

A patient on mechanical ventilation can be managed successfully in the home. Neuromuscular disease such as amyotrophic lateral sclerosis (ALS), muscular dystrophy, brain and spinal cord diseases, chest wall disease, central hypoventilation syndrome, and advanced chronic obstructive pulmonary disease (COPD) are a few of the diseases that can be managed at home on mechanical ventilators. Many factors determine if a patient and family are candidates for home ventilation. Assessment criteria include the desire of the patient and family, the patient's acceptance of ventilator dependence, the patient's and family's ability to understand and perform daily care procedures, the home environment, personal and monetary resources, and technologies for support in the community.

The goals of long-term ventilator care include extension of life, enhancement of the quality of life, provision of an environment that enhances individual potential, reduction of morbidity, improvement of physical and physiologic function, and cost-effectiveness. Patients who are candidates for home mechanical ventilation are prepared for discharge by a multidisciplinary team, including representatives of nursing, medicine, dietary service, and social service; the home care nurse; and the home care durable medical equipment company. The nurse in the hospital needs to be familiar with the home ventilator to help the patient and family with discharge planning and education (Ballangrud et al., 2009).

Delegation and Collaboration

The skill of caring for a patient on a mechanical ventilator cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report immediately to the nurse any change in the patient's respiratory status, vital signs, oxygen saturation and if patient indicates breathlessness.
- Inform the RN immediately if any of the ventilator alarms sound.

Equipment

- Appropriate mechanical ventilator
- Oxygen source
- Pulse oximetry (SpO₂) probe and monitor
- Capnography (EtCO₂) window and monitor (if available)
- Stethoscope
- 10-mL syringe
- Oral airway/bite block
- Manual resuscitation bag (bag-valve-mask) with oxygen connecting tubing and flowmeter
- Clean gloves
- Goggles (if splash risk exists)
- Suction equipment at bedside (in-line/individual catheters)
- Chlorhexidine solution and toothbrush for oral care
- Method for patient communication
- Ventilator flow sheet to document ventilator changes and settings

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's level of consciousness (LOC) and ability to cooperate with mechanical ventilation and need for special positioning such as head of bed at 30 degrees.
- 2 Assess patient's need for sedation (check agency policy).

Determines patient's ability to cooperate and understand aspects of care. Anxious and combative patients may require sedation to tolerate mechanical ventilation.

Sedation is sometimes used in mechanically ventilated patients to reduce respiratory efforts, decrease oxygen demand, and improve ABG and oxygen saturation levels.

Clinical Decision Point When patients on mechanical ventilation become excessively anxious or combative or try to override the ventilator, sedation is often used. Check agency policy for the specific indications for sedation and the specific protocol for administering and monitoring sedation levels for these patients.

- 3 Assess patient's respiratory status, including symmetry of chest wall expansion, respiratory rate and depth, sputum production, and lung sounds (see Chapter 6), and assess for signs and symptoms associated with hypoxia (see Box 23-1).
- 4 Check ventilator, EtCO₂ (if available), SpO₂, and ventilator and cardiac alarms at beginning of each shift and periodically throughout care and compare with health care provider's orders.
- 5 Apply clean gloves and verify placement of artificial airway through auscultation of lung sounds and verification of distal tip marking on ET tube. Determine that tube is placed securely (see Chapter 25).
 - a Auscultate over trachea for presence of air leak. When air leak is present, you will hear movement of air over trachea.
 - b Using minimal occlusive pressure, check inflation of cuff of artificial airway (see Chapter 25).

Decreased chest wall movement, crackles or decreased lung sounds, increased respiratory rate, increased sputum production, or signs of worsening hypoxia indicate need for mechanical ventilation or changes in current ventilator settings to improve oxygenation.

Verifies that ventilator settings are as ordered by health care provider.

Prevents migration of tube into right or left bronchus and accidental extubation.

Cuff of artificial airway needs to be inflated to create a seal for positive-pressure ventilation to occur.

Clinical Decision Point When patients have periodic chest x-ray film examinations, also verify placement of the artificial airway.

STEP	RATIONALE
6 Observe for patent airway and, if necessary, remove airway secretions by suctioning (see Chapter 25). Remove and dispose of gloves and perform hand hygiene.	Secretions plug airway, decreasing amount of oxygen that is available for gas exchange in lung. Secretions also occlude T tube or tracheostomy collar, impeding oxygen delivery to the patient.
7 If available, note patient's most recent ABG results or SpO ₂ . Determine if any factors have changed during mechanical ventilation.	Objectively documents patient's pH, arterial oxygen, arterial carbon dioxide, or arterial oxygen saturation.
8 Determine method for communication with patient. If possible, review previous communication techniques with patient and family.	Patients with an artificial airway and mechanical ventilation cannot communicate verbally. In addition, some of these patients are too weak to use a note pad to communicate their needs. Therefore assessing for and determining communication needs before instituting mechanical ventilation is ideal. However, each time patient has a new caregiver, assess communication preferences.
9 Review patient's medical record for medical order for mechanical ventilation, noting mode of ventilation, respiratory rate, oxygen setting, and tidal volume.	Mechanical ventilation and changes in ventilator settings require health care provider's order.

NURSING DIAGNOSES

- Dysfunctional ventilatory weaning response
- Impaired gas exchange
- Impaired spontaneous ventilation
- Impaired verbal communication
- Ineffective breathing pattern
- Risk for infection
- Ineffective airway clearance

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient has improved lung expansion. • Patient maintains ABG levels and oxygen saturation within normal range or at patient baseline. • Patient's vital signs and respiratory assessment parameters improve. • Patient experiences reduction in feelings of dyspnea and work of breathing. • Patient uses communication board, paper and pencil, or computer to state needs. 	As patient's lungs and lung mechanics improve, lung expansion increases. Verifies that ventilator settings are effective in improving or maintaining patient's level of oxygenation. Reduced pulse and respiratory rate, improved mental status, improved skin color, and decreased use of accessory and abdominal muscles occur because patient's work of breathing decreases as level of oxygenation improves (Carbery, 2008). As pulmonary problem resolves, patient's perceptions of dyspnea and actual work of breathing decline (Hoo, 2011). Appropriate communication system matches patient's abilities.
2 Explain ventilator system to patient and family and be sure to include purpose of and reasons for initiation of mechanical ventilation.	Helps patient express fears and wishes. Plays role in weaning process (Smeltzer et al., 2009).
3 Position patient with head of bed elevated at an angle of 30 to 45 degrees (unless contraindicated). Compare identifiers with information on patient's identification bracelet.	Positioning patients with head of bed elevated at 30 to 45 degrees or higher significantly reduces gastric reflux, thereby decreasing risk for aspiration and ventilator-associated pneumonia (VAP) (AACN, 2011).

IMPLEMENTATION

1 Perform hand hygiene; apply clean gloves. Apply mask, gown, and goggles if secretions are projectile.	Reduces transmission of microorganisms and exposure to pulmonary secretions.
2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
3 Attach mechanical ventilator to ET or tracheostomy tube. Observe for proper functioning of mechanical ventilator.	Connects artificial airway to ventilator and ensures closed system, which enables ventilator to exert appropriate pressure or volume to meet patient's oxygen demands.

Clinical Decision Point *The mechanical ventilator requires programming of accurate settings before attaching to the patient. This is most often the responsibility of the respiratory therapist; however, it is usually a collaborative responsibility of the nurse.*

STEP	RATIONALE
4 Verify that ET or tracheostomy tube is properly positioned during an inspiratory and expiratory cycle by listening to both lungs and assessing chest wall symmetry.	Properly placed artificial airway ensures that both lungs are equally ventilated. Improper airway placement leads to unilateral lung ventilation.
5 Observe patient for synchronization with mechanical ventilation and response to therapy.	Ensures that patient is comfortable using ventilator and has not experienced any adverse hemodynamic effects.
6 Monitor heart rate, blood pressure, respiratory rate, and cardiac rhythm.	Implementation of mechanical ventilation results in decreased venous return and associated hemodynamic changes (Manthous, 2010).
7 Reassess and mark level of ET tube at lips or nares (see Chapter 25).	Provides measure to compare with baseline for depth of tube placement. ET tube must be placed through vocal cords into trachea. Ensures that tube is not too close to carina or in right main stem bronchus.
8 Set up suction equipment, including oral suctioning (see Chapter 25).	Need to provide airway care and suctioning of ET or tracheostomy tube as needed to prevent plugging of airway and reduce risk for infection.
9 Reposition patient regularly to promote best oxygenation and ventilation. This position can be high-Fowler's, lateral, or even prone. Monitor SpO ₂ levels during and after positioning.	Positioning affects oxygenation and ventilation. SpO ₂ drops during position change and recovers once patient is completely positioned. In other patients a change in position (e.g., high-Fowler's to lateral) results in sustained drop in SpO ₂ , thus indicating that patient is unable to tolerate that particular position at that time.
10 Collaborate with health care provider frequently about status of patient, response to therapy, and ongoing monitoring.	Assesses oxygenation status and continued need for mechanical ventilation.
a Monitor SpO ₂ continuously.	Provides ability to continually assess oxygenation levels.
b Monitor EtCO ₂ continually and with serial ABG levels to detect possible overventilation or inadequate alveolar ventilation.	Overventilation causes respiratory alkalosis from decreased carbon dioxide. Inadequate alveolar ventilation causes respiratory acidosis from increased carbon dioxide retention (Carbery, 2008; Wilkins et al., 2009).
c Obtain ABG levels with changes in patient's condition or ventilator changes.	Provides more accurate measure of oxygen saturation and partial pressures of oxygen and carbon dioxide.
11 Perform hourly safety checks on patient and ventilator system:	Provides mechanism for patient to contact health care personnel. Ensures continuous safe and proper functioning of ventilator system. Enables you to identify and correct problems in a timely manner.
a Make sure that patient can reach call light.	Maintains integrity of the system and ensures that all settings are consistent with health care provider's orders.
b Check security of all ventilator connections; make sure that alarms are all turned on, including both high- and low-pressure alarms and volume alarms.	Ensures continuous humidification. Condensation that returns to humidifier can cause possible bacterial contamination.
c Verify that all ventilator settings are correct and correspond to health care provider's orders (Kallus, 2009).	The temperature of inspired gas artificially alters patient's body temperature.
d Check and refill humidifier as needed. Check corrugated tubing for condensation; drain and appropriately discard liquid.	VAP is common, and it is associated with microaspiration of oropharyngeal secretions. Frequent mouth care reduces patient's risk for VAP. Oral care at least 4 times per 24 hours helps reduce risk for pneumonias (AACN, 2009).
e When present, observe temperature gauges on panel of mechanical ventilator, making sure that gas is delivered at correct temperature. Desired temperature of inspired gas is 98.6° F (37° C).	Maintaining activity avoids complications associated with decreased mobility such as pressure ulcers, pneumonia, deep vein thrombosis (DVT), and activity intolerance. Patients receiving mechanical ventilation need help with activity.
12 Perform mouth care at least 4 times per 24 hours (see Chapter 17). Use toothbrush and solution such as chlorhexidine, which is effective in reducing oral bacteria and risk for ventilator-associated pneumonia (Munro et al., 2009).	Apprehension and anxiety occur when patient is not properly informed about progress, changes in care, or changes in ventilator setting. Patients need information and emotional support to successfully tolerate and wean from mechanical ventilation (Carbery, 2008).
13 Perform nursing activities to prevent hazards of immobility (e.g., help patient change position, perform range-of-joint motion exercise, and encourage independence and activity as tolerated).	Reduces transmission of microorganisms and exposure to pulmonary secretions.
14 Keep patient informed on progress and plan for weaning from mechanical ventilator.	
15 Remove gloves and goggles; perform hand hygiene.	

STEP

RATIONALE

EVALUATION

- 1 Reassess and monitor patient's response to mechanical ventilation every 2 to 4 hours.
 - a *Neurologic assessment*: LOC, orientation, sleepiness, changes in anxiety
 - b *Pulmonary assessment*: Lung sounds, airway clearance, work of breathing, breathing pattern, rate of respirations, SpO₂, EtCO₂
 - c *Cardiovascular assessment*: Vital signs, heart rhythm, heart sounds, lower-extremity edema
- 2 Observe SpO₂ and monitor gas exchange.
- 3 Observe integrity of patient ventilator system.
- 4 Observe and evaluate effectiveness of communication methods:
 - a Ask patient if needs and concerns are addressed.
 - b Observe for signs of frustration (e.g., patient shaking head in irritation, crying, withdrawal).
 - c Observe patient/family and health care personnel use communication methods.

Patients requiring mechanical ventilation have unstable physiologic status. It is important to perform key focused evaluation measures frequently as patient's condition warrants.

Documents patient's level of oxygenation and ventilation. Ensures adequate delivery of mechanical ventilation. Communication, or lack of it, increases patient's frustration, sense of powerlessness, and confusion during mechanical ventilation and weaning process (Carbery, 2008).

Unexpected Outcomes

- 1 Patient experiences stiff, noncompliant lung; alveolar edema; pulmonary congestion; chest pain; intraalveolar hemorrhage; substernal chest pain; pneumothorax; continued decrease in blood pressure related to use of positive pressure.
- 2 Patient experiences hypoxia, hypercapnia.
- 3 Patient experiences self-extubation.
- 4 Patient experiences tension pneumothorax, as evidenced by sudden respiratory distress: air hunger, distended neck veins, tracheal/mediastinal shift, hypotension, and tachycardia.
- 5 Pressure alarm sounds.
- 6 Low-volume alarm sounds.

Related Interventions

- Notify health care provider.
- Remain with patient.
- Conduct complete cardiac and pulmonary assessment.
- Notify health care provider.
- Reassess patient.
- Assess integrity of ventilator system.
- Expect ventilator change (increase positive end-expiratory pressure [PEEP] levels).
- Maintain patent airway by suctioning and inserting oral airway.
- Provide oxygen.
- Assess patient's respiratory status and level of oxygenation and ventilation.
- Notify health care provider.
- Remain with patient, remove patient from ventilator, and ventilate with bag-valve-mask (see Chapter 27).
- Notify health care provider.
- Ask NAP to obtain chest tube insertion kit.
- Ask additional personnel to obtain patient's vital signs.
- Assess for airway obstruction (e.g., secretions, patient biting on ET tube).
- Remove obstruction (e.g., ET suctioning, inserting oral airway/bite block).
- Assess integrity of ventilator tubing and reconnect if disconnected.
- Check for airway displacement (e.g., extubation).
- Assess integrity of airway cuff (e.g., deflate and reinflate and determine if seal is present) (see Chapter 25).
- Remain with patient, remove him or her from ventilator, and ventilate with bag-valve-mask.

Recording and Reporting

- Record in progress notes: respiratory assessment findings; mode of mechanical ventilation, oxygen level, actual patient tidal volume, actual patient respiratory rate, peak airway pressure, patient's response to mechanical ventilation, level of the ET, any adverse reactions or side effects.
- Report to nurse in charge or health care provider: sudden change in patient's respiratory status, ventilator-associated problems.

Special Considerations

Teaching

- Teach patient and family about the rationale for mechanical ventilation and the alarms and what they mean.
- Teach patient and family alternative communication techniques to reduce frustration and fear.

Pediatric

- Increasing numbers of children are on home mechanical ventilation. For this reason it is important to include the parent in

the child's care as appropriate. Parents also need to be prepared that, when a readmission to a hospital occurs, because of the chronic nature of the illness the child may not be readmitted to an intensive care unit but rather may remain on the general medical or surgical area.

- Once the child is stable on the mechanical ventilator, promote normal or near-normal activities as the child's condition warrants (e.g., promote play, resume school activities, encourage mobility).

Gerontologic

- Presence of underlying chronic illnesses increase patient's risk for longer intensive care, hospital stays.
- Older adults are usually not able to tolerate the usual sedative, anti-anxiety medications ordered. The prescribed dose is based on patient's baseline kidney and liver functions (Lehne, 2010).

Home Care

- Patients requiring home mechanical ventilation need to learn complete care of the mechanical ventilator system, suctioning, and artificial airway care. Skills include assembling the ventilator circuit, cleaning the circuit, and daily equipment maintenance.
- Use a checklist for ensuring consistency of care for patient on a ventilator.

- Evaluate the following areas during each visit: oxygen flow, alarm system, inspiratory pressure, high-pressure alarm, tidal volume setting, humidifier, respiratory rate, tubing, temperature, resuscitation bag, tracheostomy care, breath sounds, suctioning, and tubing changes.
- The durable medical equipment provider, the home care nurse, and the primary care nurse develop a teaching plan to ensure that patient and family have a complete working knowledge of the ventilator before discharge.
- Teach patient and family caregiver what to do in case of respiratory distress or power failure. Check to determine availability of emergency batteries.
- Instruct family in use of the bag-valve-mask (see Chapter 27).
- Patients who require long-term mechanical ventilation are transferred to a chronic ventilator facility or a long-term ventilator dependency floor within the hospital when they are medically stable. The purpose of such a transfer is to aggressively rehabilitate patient through physical, occupational, and speech therapy. The overall goal is to effectively wean patient from the mechanical ventilator. However, not all patients can be weaned from the ventilator.

Critical Thinking Exercises

You are caring for Mr. Landon, who has a history of chronic obstructive pulmonary disease (COPD) that is well controlled. However, 2 weeks ago he developed an upper respiratory tract infection and was treated with antibiotics. He completed his full course of antibiotics, but his symptoms continued. He has a 4-day history of fever greater than 102.8° F (39.4° C) fatigue, productive cough, worsening dyspnea, and decreased activity tolerance. His health care provider does a complete examination, orders a chest x-ray film examination, and obtains a sputum specimen. Preliminary chest x-ray film results indicate right lower lobe pneumonia. Mr. Landon is admitted to a general medicine floor for treatment with intravenous (IV) antibiotics, supplemental oxygen, and pulmonary hygiene measures.

- 1 You observe Mr. Landon and notice that he is fatigued, has difficulty speaking, and in general looks very uncomfortable. You decide to do a focused assessment. Which systems will you assess, and what information will you obtain? State your rationale for choosing these systems.
- 2 Mr. Landon is started on oxygen therapy via nasal cannula at 2 L/min. What is the approximate FiO_2 level, and what are the hazards for oxygen therapy in this patient?
- 3 Mr. Landon begins to remove the cannula because of discomfort at the nares and ears from the device. What are the causes of this discomfort? What are your interventions to reduce the discomfort?
- 4 One of the nurses suggests a partial rebreather mask for Mr. Landon's oxygen therapy. You do not think this is a good idea, and the rationale for your decision is:
 - a Increased inspired oxygen percentage
 - b Decreased carbon dioxide retention
 - c Decreased oxygen percentage
 - d Increased carbon dioxide retention

REVIEW QUESTIONS

- 1 A patient arrives on the nursing unit because of a sudden onset of dyspnea. Which assessment data would the nurse expect to find?
 - 1 A respiratory rate of 24 breaths/min
 - 2 Cyanosis
 - 3 Clubbing of the fingers
 - 4 A regular breathing pattern
- 2 A patient with an oxygen mask with a reservoir bag is seen while making initial rounds. Which problem might the patient experience if the reservoir bag becomes deflated?
 - 1 Elevated oxygen levels
 - 2 Elevated carbon dioxide levels
 - 3 Drying of the nasal mucous membranes
 - 4 Decrease in the number of respirations
- 3 You are preparing to observe a patient with COPD perform incentive spirometry exercises. With which of the following steps is the patient likely to have difficulty?
 - 1 Placing the mouthpiece correctly
 - 2 Being able to hold breath for 3 seconds after inhalation
 - 3 Being able to blow quickly into the device
 - 4 Performing incentive spirometry three times for each reading
- 4 Humidification is added to a nasal cannula when the flow is set at:
 - 1 1 L/min.
 - 2 2 L/min.
 - 3 3 L/min.
 - 4 4 L/min.
- 5 A patient needs an FiO_2 of 80%. Which of these oxygen delivery devices can deliver oxygen at this FiO_2 level? (Select all that apply.)
 - 1 Nasal cannula at 6 L/min
 - 2 Venturi mask at 12 L/min
 - 3 Nonbreathing mask at 6 L/min
 - 4 Partial rebreathing mask at 6 L/min
- 6 In assessing the adequacy of oxygen therapy, which of the following is most effective?
 - 1 Checking the color of mucous membranes
 - 2 Counting the respiratory rate
 - 3 Measuring pulse oximetry
 - 4 Auscultating lung sounds

- 7 A patient is receiving oxygen by nasal cannula. Which statement by the patient indicates that teaching regarding oxygen therapy has been effective?
- 1 "I was feeling better, so I removed my oxygen."
 - 2 "I asked my spouse not to put Vaseline on my lips."
 - 3 "I can take off my oxygen to walk to the bathroom."
 - 4 "I do not want to be oxygen dependent, so I need continuous pulse oximetry."
- 8 Noninvasive positive-pressure ventilation (NIPPV) _____ and _____ without the need for an artificial airway. Fill in the blank.
- 9 Patients are unable to speak when they have an ET tube in place. What is the recommended method to communicate with these patients?
- 1 Talk to patients as if they have a hearing loss by speaking very loudly.
 - 2 Leave a pen and paper within reach to allow them to write comments.
 - 3 Provide a communication board such as an alphabet board for family to communicate with patient.
 - 4 Ask family members to explain the plan of care to the patient.
- 10 A patient with a tracheostomy tube and humidification collar also has an underlying diagnosis of chronic obstructive pulmonary disease. The nurse hears a bubbling sound on approaching the patient, although the patient is lying calmly and quietly. What is the appropriate action for the nurse to take?
- 1 Suction the patient's tracheostomy tube
 - 2 Liquefy the patient's pulmonary secretions
 - 3 Check the oxygen tubing for fluid accumulation
 - 4 Elevate the patient's head slightly to improve oxygenation

 - Review Questions
 - Audio Glossary

KEY TERMS

Chest physiotherapy (CPT)	Percussion	Shaking
Mucociliary transport	Postural drainage (PD)	Vibration

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Assess for the need to perform chest physiotherapy (CPT) maneuvers.
- Determine the need to modify or discontinue CPT maneuvers, including contraindications and individual variations.
- Explain how to prepare a patient and family for the performance of each CPT maneuver.
- Perform the outlined CPT maneuvers, including standard and modified versions.
- Describe expected and unexpected outcomes of each CPT maneuver.
- Describe discharge teaching and planning related to the use of each CPT maneuver in the home setting.
- Describe approach for use of an acapella device and a vest airway clearance system.

Chest physiotherapy (CPT) is used to mobilize pulmonary secretions. CPT includes physical chest wall maneuvers such as percussion, vibration and shaking, and postural drainage (PD), followed by productive coughing or suctioning. Percussion is a rhythmic force that a caregiver provides by clapping cupped hands against a patient's thorax. It helps to loosen retained secretions from the airway. The maneuvers of vibration and shaking move secretions from the smaller distal airways into the larger central airways. Vibration is a fine, shaking pressure applied to the chest wall only during exhalation. Shaking is a stronger bouncing maneuver supplying a concurrent, compressive force to the chest wall.

Careful patient assessment is a prerequisite for administering any CPT maneuver because the therapy is usually targeted to the affected areas as opposed to all the lung fields (Fleming and Morgan, 2010). PD requires positioning a patient so the position of the lung segment to be drained allows gravity to have its greatest effect. CPT maneuvers move secretions into the large central airways; then these secretions are removed

through coughing or suctioning. Coughing occurs when a patient takes a deep breath, closing the glottis to build up a back pressure, and then forcefully exhales. During the expiratory phase of a cough, the airways compress, causing them to narrow. Airway narrowing and forced exhalation increase the force of airflow in the large central airways, and mucus moves up and out of the trachea. CPT and coughing maneuvers assist with airway clearance of mucus in patients with retained tracheobronchial secretions (Allan et al., 2009).

Secretions accumulate in the airways of patients with bronchitis, asthma, cystic fibrosis (CF), pneumonia, and bronchiectasis. Surgical patients in the postoperative period sometimes have excess secretions because of the effects of anesthesia and ineffective coughing because of incision pain (Allan et al., 2009). Mucus plugs, atelectasis, and lobular collapse occur when secretions accumulate in the airways.

CPT is often used in combination with other therapies, including antibiotics, bronchodilators, mucolytic agents, and systemic hydration. These therapies along with CPT reduce

mucus production and promote airway clearance. The goals of these therapies are (1) to clear the airways of excessive secretions to reduce the work of breathing, and (2) to improve a patient's ability to cough up secretions (Morrison and Agnew, 2011).

In the normal lung the mucociliary transport system clears the airways of excessive mucus and inhaled particles. This system lines the internal lumen of the entire tracheobronchial tree and consists of a thin layer of mucus that is constantly being propelled toward the larynx by cells that have hairlike projections called *cilia*. Inhaled particles are trapped on the mucus, and the cilia act as a conveyor belt to sweep the mucus toward the throat, where it is swallowed or removed by coughing. Airways normally remain clear, and mucus is constantly being cleared almost as fast as it is made. Normal mucus remains thin, white, and watery. When disease causes excessive sputum production, therapeutic interventions help natural airway clearance mechanisms (cough and mucociliary transport) clear the airways of obstructing mucus.

In various disease states mucus clearance slows down, or the cilia are overwhelmed by production of large quantities of mucus. The lungs no longer clear the mucus as fast as it is produced. Secretions stagnate in the airways, change color, and become thick and sticky. The cilia cannot remove large amounts of thick mucus from the lungs. In addition, many people with lung disease cannot cough effectively to clear airways. Therefore it is important to use other maneuvers to aid in clearing excess lung secretions and provide adequate hydration.

The impact of a patient's hydration status on airway clearance remains unclear. However, in some situations an increased fluid intake helps to thin oral secretions so they are easily coughed up and expectorated after CPT. The frequency of CPT depends on patients' conditions (e.g., during an acute pulmonary illness it often takes three or four CPT treatments per day and 2 L or more of fluid a day to clear and thin secretions).

EVIDENCE-BASED PRACTICE

CPT maneuvers are effective in selected patients such as those with CF, bronchiectasis, other chronic pulmonary diseases, and some surgeries (Lester and Flume, 2009). Recent studies compare the effectiveness of newer airway clearance methods (oscillating positive expiratory pressure devices such as the Acapella device [see *Procedural Guideline 24-1*], high-frequency chest wall oscillators such as the Vest airway clearance system (see *Procedural Guideline 24-2*) and intrapulmonary compression ventilators with standard manual CPT (Lester and Flume, 2009; Silva et al., 2009). These studies demonstrate that CPT and the newer devices are safe and effective modalities to aid sputum clearance for a variety of adult and pediatric lung diseases. Although there are few studies on the effectiveness of CPT in adults with chronic obstructive pulmonary disease (COPD) and pneumonia, CPT does help to clear some airway secretions in these patients (Fleming and Morgan, 2010):

- Use assessment findings to determine which lung field(s) require CPT maneuvers.
- Involve patients and families in the CPT plan and selection of mechanical devices. The use of the Acapella device or the Vest often improves patient satisfaction and adherence to CPT (Lester and Flume, 2009; Morrison and Agnew, 2011).
- Patients and families require detailed instructions regarding the mechanical device because it is often self-administered in the home settings (Lester and Flume, 2009).
- Reinforce to patients and families that these devices are easy to use and do not cause any discomfort.

PATIENT-CENTERED CARE

Patients who often require CPT maneuvers are those with chronic illness, postsurgical respiratory complications, or acute respiratory illnesses. Often these patients' physiologic capacities are weakened; they are often anxious because of their illness or surgery; and they may be in pain. Before initiating any CPT maneuvers, it is important to be sure that the patient is comfortable and as pain free as possible. Therefore preprocedure pain assessment and interventions are a priority.

In addition, CPT maneuvers are fatiguing for the acutely ill person, for the person with cardiac disease, and when there is an underlying chronic condition. As a result it is important to plan CPT during short periods interspersed with rest periods, at a time when the patient is rested, and not immediately after a meal. Because these patients are so acutely ill, everything in the hospital setting is new to them, and patient education about the procedure is essential and must be individualized to their needs.

The patient with chronic pulmonary illnesses poses different challenges. Often these patients must devote several hours of their day to activities to assist in airway clearance. As a result CPT maneuvers need to be timed with the patient's routine, personal goals, and social activities (Lester and Flume, 2009). When dealing with patients who have CF, skipping CPT maneuvers is not an option. Often these patients get tired of the daily routine and need assistance in designing an individualized plan for airway clearance.

The skills in this chapter include a great deal of patient touching. Asian and Muslim cultures consider it very poor taste to touch in public. In addition, the skills of physical therapy sometimes involve a gentle percussion or shaking of a patient's rib cage. Patients and families from cultures where violence is an everyday occurrence need detailed information about the procedure so they do not misunderstand the intent and objective of CPT. Always explain which type of touching is involved and what a patient may feel during the treatment, and provide an opportunity for a patient to temporarily stop and rest during the procedure.

BOX 24-1 Contraindications for Postural Drainage

- Increased intracranial pressure
- Head and neck injury until stabilized
- Active hemorrhage with hemodynamic instability
- Recent spinal surgery (e.g., laminectomy) or acute spinal injury
- Active hemoptysis
- Empyema
- Bronchopleural fistula
- Pulmonary edema associated with heart failure
- Large pleural effusions
- Pulmonary embolism
- Aged, confused, or anxious patients who are unable to tolerate position change
- Rib fracture, with or without flail chest
- Surgical wound or healing tissue

Trendelenburg's Position Is Contraindicated for the Following:

- Uncontrolled hypertension
- Distended abdomen
- Esophageal surgery
- Recent gross hemoptysis
- Uncontrolled airway at risk for aspiration

Modified from White G: *Basic clinical lab competencies for respiratory care: an integrated approach*, ed 5, Clifton Park, NY, 2012, Cengage Learning.

Safety Guidelines

- 1 Know a patient's normal range of vital signs. Conditions such as atelectasis and pneumonia requiring CPT can affect a patient's vital signs. The degree of change is related to the level of hypoxia, overall cardiopulmonary status, and tolerance to the procedure.
- 2 Know a patient's current medications. Some medications, particularly diuretics and antihypertensives, cause fluid and hemodynamic changes. These changes affect a patient's tolerance of the positional changes. Steroid medications, age, and malnutrition increase a patient's risk for pathologic rib fractures and often contraindicate rib shaking.
- 3 Know a patient's medical and surgical history. Certain conditions such as increased intracranial pressure, spinal cord injuries, abdominal aneurysm resection, bone metastases, or severe osteoporosis contraindicate the positional changes of postural drainage (Box 24-1). Thoracic trauma contraindicates percussion, vibration, and shaking.
- 4 Know a patient's level of cognitive function. Alteration in mental status often makes it difficult or impossible for a patient to understand the procedure and participate in coughing and expectorating secretions.
- 5 Have suction machine equipment available to assist in clearing airway secretions (see Chapter 25).
- 6 Know a patient's activity tolerance because, when patients are not used to physical activity, their ability to tolerate CPT maneuvers decreases. However, with gradual increases in activity and planned CPT, their tolerance improves.

SKILL 24-1 Performing Postural Drainage

Postural drainage is the use of positioning techniques to drain secretions from specific segments of the lungs and bronchi into the trachea. Each position drains a specific corresponding section of the tracheobronchial tree from the upper, middle, or lower lung field into the trachea. Coughing or suctioning helps remove secretions from the trachea. Fig. 24-1 shows the anatomy of the upper, middle, and lower lobe bronchi. The images in Table 24-1 show the body position used for the corresponding lung segment.

Use patient history and physical assessment findings to select which lung segments require postural drainage. In addition, use

knowledge of a patient's condition and disease process, chest x-ray film examination results, and the extent of the pathologic condition to individualize the postural drainage therapy.

Delegation and Collaboration

The skill of chest physiotherapy (CPT) can be delegated to nursing assistive personnel (NAP). It is the nurse's responsibility to assess the patient, review laboratory and x-ray film examination results, and determine that the patient is stable and able to tolerate the procedure. The nurse directs the NAP to:

- Immediately report to the nurse changes in patient's comfort level, changes in breathing pattern, and tolerance of the procedure.
- Use specific patient precautions related to disease, mobility status, position restrictions, or treatment.

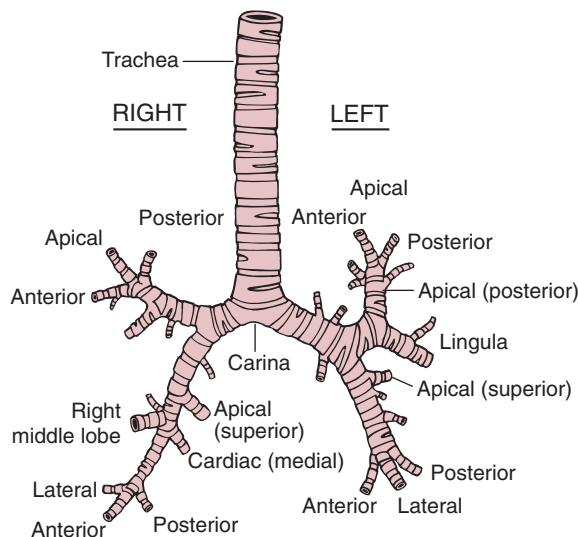

FIG 24-1 Tracheobronchial tree. (Modified from Frownfelter DL, Dean E: Principles and practice of cardiopulmonary therapy, ed 43, St Louis, 2006, Mosby.)

Equipment

- Stethoscope
- Pulse oximeter
- Trendelenburg's hospital bed or tilt table (more common in pediatric agencies)
- Water in pitcher and glass
- Tissues and paper bag
- Chair (for draining upper lobes)
- Extra pillows
- Clear graduated screw-top container
- Oral hygiene care: toothbrush, toothpaste, mouthwash, or chlorhexidine oral rinse if ordered
- Suction equipment (if patient unable to cough and clear own secretions)
- Clean gloves (when there is risk of exposure to patient's respiratory secretions)
- Patient education materials

TABLE 24-1 Positions and Procedures for Drainage, Percussion, Vibration, and Shaking**Area and Procedure****Position of Patient****Left and Right Upper Lobe Anterior Apical Bronchi**

Position patient in chair or high-Fowler's, leaning back. Percuss and vibrate with heel of hands at shoulders and fingers over collarbones (clavicles) in front; do both sides at same time. Position hands for CPT over left and right upper lobe anterior apical bronchi.

**Left and Right Upper Lobe Posterior Apical Bronchi**

Position patient in chair, leaning forward on pillow or table. Percuss and vibrate with hands on either side of upper spine. Do both sides at same time. Position hands for CPT over left and right upper lobe posterior apical bronchi.

**Right and Left Anterior Upper Lobe Bronchi**

Position patient flat on back with small pillow under knees. Percuss and vibrate just below clavicle on either side of sternum. Position hands for CPT over right and left anterior upper lobe bronchi.

**Left Upper Lobe Lingular Bronchus**

Position patient on right side with arm overhead in Trendelenburg's position, with foot of bed raised 30 cm (12 inches), as tolerated.* Place pillow behind back and roll patient one-quarter turn onto it. Percuss and vibrate lateral to left nipple below axilla. Position hands for CPT over left upper lobe lingular bronchus.

**Left and Right Anterior Lower Lobe Bronchi**

Position patient on back, with foot of bed elevated 45 to 50 cm (18 to 20 inches). Have knee bent on pillow. Percuss and vibrate over lower anterior ribs on both sides. Position hands for CPT over left and right anterior lower lobe bronchi.

**Right Lower Lobe Lateral Bronchi**

Position patient on abdomen in Trendelenburg's position with foot of bed raised 45 to 50 cm (18 to 20 inches) as tolerated. Percuss and vibrate on left and right side of chest below shoulder blades (scapulas) posterior to midaxillary line. Position hands for CPT over right lower lobe lateral bronchus.

**Left Lower Lobe Lateral Bronchi**

Position patient on right side in Trendelenburg's position with foot of bed raised 45 to 50 cm (18 to 20 inches) as tolerated. Percuss and vibrate on left side of chest below scapulas posterior to midaxillary line. Position hands for CPT over left lower lobe lateral bronchus.

**Right and Left Lower Lobe Superior Bronchi**

Position patient flat on stomach with pillow under stomach. Percuss and vibrate below scapulas on either side of spine. Position hands for CPT over right and left lower superior bronchi.

CPT, Chest physiotherapy.

*In adult settings Trendelenburg's position is not used as frequently. Verify use with agency policy and health care provider's order.

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <p>1 Assess patient for history of decreased level of consciousness and muscle weakness or disease processes such as pneumonia and chronic obstructive pulmonary disease (COPD) (see Box 24-1).</p> | <p>Conditions that pose risk for impaired airway clearance require CPT.</p> |
|---|---|

Clinical Decision Point *If the use of Trendelenburg's position or other postures causes severe hypertension, severe hypoxemia, or severe shortness of breath, therapy is contraindicated (see Box 24-1). In addition, when patients have a risk for or a history of gastroesophageal reflux (GER), which is regurgitation of stomach contents into the esophagus, the head-down positions should not be used (Lester and Flume, 2009).*

- | | |
|--|---|
| <p>2 Review medical record and assess patient for signs and symptoms, including x-ray film changes consistent with atelectasis, lobar collapse pneumonia, or bronchiectasis; ineffective coughing; thick, sticky, tenacious, and discolored secretions that are difficult to cough up.</p> | <p>Indicates need to perform postural drainage. X-ray film data and signs and symptoms indicate accumulation of pulmonary secretions and ineffective airway clearance.</p> |
| <p>3 Auscultate all lung fields for decreased breath sounds and adventitious lung sounds.</p> | <p>Findings identify bronchial segments needing drainage. Areas of lung congestion and postures for drainage vary, depending on disease process, patient condition, and clinical problems.</p> |
| <p>4 Assess vital signs and pulse oximetry before postural drainage treatment.</p> | <p>Provides baseline to evaluate patient's response to therapy.</p> |
| <p>5 Determine patient's and family caregiver's understanding of and ability to perform home postural drainage.</p> | <p>Identifies potential areas for instruction. Home care CPT is indicated in patients with chronic conditions such as those with cystic fibrosis, chronic bronchitis, or bronchiectasis (Lester and Flume, 2009).</p> |
| <p>6 Use a 0-to-10 pain scale to determine patient's level of comfort.</p> | <p>Determines patient's level of pain and if preprocedure analgesia is needed.</p> |

NURSING DIAGNOSES

- | | | |
|--|---|---|
| <ul style="list-style-type: none"> • Acute pain • Deficient knowledge regarding postural drainage and airway clearance | <ul style="list-style-type: none"> • Impaired gas exchange • Ineffective airway clearance | <ul style="list-style-type: none"> • Ineffective breathing pattern |
|--|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Lung sounds improve or become clear. • Sputum is more easily coughed and expectorated or suctioned out. • Secretions appear more normal in color and consistency. • Pulse oximetry (SpO₂) levels increase and dyspnea decreases. • Chest x-ray film shows improvements: lobar collapse and atelectasis are decreased or eliminated. | <p>Clearing of airways documents effectiveness of procedure. CPT provides mechanical stimulus to loosen secretions from wall of airway; thus secretions are easier to expectorate. When infection is present, returning to normal indicates resolving infection. As secretions are removed, patient exchange of respiratory gases improves, and dyspnea gradually declines. CPT improves atelectasis and facilitates removal of secretions from airways. As a result there is visual improvement on chest x-ray film.</p> |
| <p>2 Prepare patient for procedure:</p> <p>a If patient's pain rating is 4 or greater on assessment, administer analgesia 20 minutes before CPT maneuvers.</p> <p>b Explain purpose and rationale for procedure. Explain positioning, sensations, how long it will take, and any discomforts or side effects.</p> <p>c Encourage high fluid intake program (minimum of 1500 mL) unless contraindicated by other diseases and if health care provider approves. Maintain record of fluid intake and output.</p> <p>d Plan treatments so they do not overlap with meals or tube feeding. Avoid postural drainage 1 to 2 hours before or 1 to 2 hours after meals or bolus tube feedings. Stop all continuous gastric tube feedings for 30 to 45 minutes before postural drainage. Check for residual feeding in patient's stomach; if greater than 100 mL, hold treatment.</p> | <p>Pain control is essential for patient to actively participate in CPT maneuvers and cough forcefully to clear airways. Helps promote cooperation. Well-prepared patient is usually more relaxed and comfortable, which is essential for effective drainage. Fluids thin secretions and make them easier to cough up. Patients need close monitoring and encouragement when first starting high fluid intake program (DeTurk and Cahalin, 2010). Performing postural drainage when patient's stomach is empty helps avoid gastric reflux or vomiting and aspiration of stomach contents.</p> |

STEP

RATIONALE

- | | | |
|---|--|---|
| e | Schedule treatments at appropriate times during day (e.g., coordinate with any bronchodilator therapy, which is usually administered 20 minutes before CPT). | Scheduling of CPT avoids conflict with other interventions and/or diagnostic testing. |
|---|--|---|

Clinical Decision Point *If patient is receiving inhaled bronchodilator, nebulizers, or aerosol treatment, provide postural drainage 20 minutes after such therapy.*

- | | | |
|---|--|--|
| f | Have patient remove any tight or restrictive clothing. | Helps patient relax and promotes deep breathing. |
|---|--|--|

IMPLEMENTATION

- | | | |
|---|--|---|
| 1 | Close room door or pull curtains around patient's bed. Perform hand hygiene and apply clean gloves as indicated. | Maintains privacy. Reduces transmission of microorganisms. |
| 2 | Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). |
| 3 | Use findings from physical assessment and chest x-ray film to select congested areas for draining. Consult with primary health care provider as needed. | Individualized treatment helps relieve specific areas of congestion identified during patient assessment. |
| 4 | Help patient to desired position to drain congested areas (see Table 24-1). Place pillows for support and comfort. Drape patient appropriately. | Proper patient positioning promotes drainage of pulmonary secretions. |
| 5 | Have patient maintain posture for 10 to 15 minutes. | In adults draining each area takes time. |
| 6 | During 10 to 15 minutes of drainage in selected postures, perform chest percussion and vibration and shaking (see Procedural Guideline 24-2) over affected lung region. Table 24-1 shows all postures and hand placement for percussion and vibration and shaking. | Provides mechanical forces to help move airway secretions. |
| 7 | After 10 to 15 minutes of drainage in first posture, have patient sit up and cough. If indicated, save expectorated secretions in clear container. If patient cannot cough, suctioning is necessary (see Chapter 25, Skill 25-2). | Any secretions moved to central airways are removed by cough or suctioning before placing patient into next drainage position. Coughing is most effective when patient is sitting up and leaning forward. |

Clinical Decision Point *Sometimes patients experience transient dyspnea and fatigue because of airway irritation and bronchospasm from the secretions. These patients often benefit from an oscillating or vibrating device such as an Acapella device (see Procedural Guideline 24-1).*

- | | | |
|----|---|--|
| 8 | Have patient rest briefly if necessary. Note pulse oximeter readings. | Short rest periods between postures prevent fatigue and increase tolerance. Pulse oximeter values may fall slightly. |
| 9 | Have patient take sips of water. | Keeping mouth moist aids in expectoration of secretions. |
| 10 | Repeat Steps 4 to 9 until all congested areas selected are drained. Make sure that each treatment does not exceed 30 to 60 minutes. | Postural drainage is used only to drain areas involved and is based on individual assessment. |
| 11 | Offer to help patient with oral hygiene. | Promotes comfort and reduces bad breath. |
| 12 | Remove gloves and perform hand hygiene. | Reduces transmission of microorganisms. |

EVALUATION

- | | | |
|---|--|---|
| 1 | Auscultate lung fields. | Clearance of secretions usually relieves gurgling, early inspiratory crackles, and palpable crepitus. |
| 2 | Inspect character and amount of sputum. | Determines if there are more secretions coughed up and if they are adequately thinned. |
| 3 | Review diagnostic reports, including sputum collections/cultures, chest x-ray films, and blood gas levels. | Provides objective data on improvements in lung function. |
| 4 | Obtain vital signs, pulse oximetry. | Procedure can result in dysrhythmias and decreases in oxygen saturation in some patients. |

Unexpected Outcomes

- 1 Patient experiences severe dyspnea, bronchospasm, hypoxemia, or hypercarbia and/or is unable to tolerate treatment.
- 2 No improvement in chest assessment or chest x-ray film examination results.
- 3 Hemoptysis occurs; or patient develops acute hypotension, severe chest pain, vomiting, aspiration, and/or dysrhythmias.

Related Interventions

- Discontinue, modify, or shorten treatments.
- Administer bronchodilator or nebulizer therapy 20 minutes before CPT.
- Suction and ventilate with bag-valve-mask as needed and closely monitor arterial blood gas (ABG) levels, O₂ saturation, and vital signs.
- Initially increase treatments and encourage and teach coughing exercises.
- Increase hydration.
- Notify health care provider because patient may need sputum culture, change in antibiotics, mucolytics, or a bronchoscopy to remove thick mucus plugs.
- Stop therapy, place patient in high-Fowler's position, and obtain vital signs.
- Call for help and notify health care provider.
- Remain with patient; keep patient comfortable, calm, warm, and quiet.
- If patient vomits or aspirates, suction airway and place him or her on his or her side.
- Prepare for possible oxygen administration.

Recording and Reporting

- Record pretherapy and posttherapy assessment findings and chest x-ray film results; frequency and duration of treatment; postures used and bronchial segments drained; cough effectiveness; need for suctioning; color, amount, and consistency of sputum; hemoptysis or other unexpected outcomes; and patient's tolerance and reactions.
- If patient and family caregiver receive instruction in home care, chart instructions given, understanding of therapy, demonstration of skill, patient acceptance of home care, barriers to learning and implementation, and referrals for home care or rehabilitation.

Special Considerations

Teaching

- Best times for treatments are (1) in the morning before breakfast, when patient can clear secretions that accumulate overnight; and (2) about 1 hour before bedtime, so lungs are clear before sleeping and patient has time after treatment to cough up any mobilized secretions. Frequency depends on need and patient's tolerance and varies from once daily to every 2 to 4 hours in an acute situation.
- Instruct patient's family or caregiver in recognizing when patient's respiratory status requires breathing exercises or postural drainage.

- Teach patient and family caregiver how to assume postures at home. Some postures need modification to meet patient needs. For example, if the patient is very short of breath, place him or her in a supine, side-lying semi-Fowler's or side-lying Trendelenburg's position to drain lateral lower lobes.

Pediatric

- In a child with cystic fibrosis CPT is a cornerstone therapy and is usually performed at least twice daily, on rising in the morning and in the evening (Hockenberry and Wilson, 2011).
- Many cystic fibrosis patients benefit from the use of the Vest airway clearance system (see [Procedural Guideline 24-2](#)) (Hockenberry and Wilson, 2011).

Gerontologic

- Take extra care and thoroughly assess when using postural drainage in older adults. Change positions more slowly and closely assess for any changes in oxygen saturation or vital signs with position changes.
- Older adults with chronic cardiac and pulmonary conditions do not always tolerate a supine or side-lying position for CPT. In these positions patients experience decline in forced vital capacity (FVC) and subsequent decline in oxygen saturation.

Home Care

- If specialized home or outpatient follow-up is needed, refer patient to pulmonary nurse specialist, pulmonary rehabilitation team, or home care personnel (Lester and Flume, 2009).
- Obtain foam wedge or multiple pillows for correct positioning.

PROCEDURAL GUIDELINE 24-1 Using an Acapella Device

The Acapella device is a respiratory rehabilitation device designed to aid sputum clearance (Silva et al., 2009). This device is easy to use as patients are able to perform airway clearance independently. The Acapella is a handheld airway clearance device (Fig. 24-2). It provides positive expiratory pressure (PEP) with oral airway oscillations. PEP stabilizes airways and improves aeration of the distal lung areas. During exhalation pressure from the airways is transmitted to the Acapella device, which helps mucus dislodge from the airway walls and as a result prevents airway collapse, accelerates expiratory flow, and moves mucus toward the trachea.

This device combines resistive features of PEP and vibration to mobilize airway secretions. Patients with chronic conditions

such as cystic fibrosis appear to receive the greatest benefit from this type of treatment.

Delegation and Collaboration

The skill of using an Acapella device can be delegated to nursing assistive personnel (NAP). The nurse is responsible for performing respiratory assessment, determining that the procedure is appropriate and that a patient is able to tolerate it, and evaluating a patient's response to it. The nurse directs the NAP to:

- Be alert for patient's tolerance of procedure such as comfort level and changes in breathing pattern and immediately report changes to the nurse.

PROCEDURAL GUIDELINE 24-1 Using an Acapella Device—cont'd

FIG 24-2 Acapella device. (Used with permission, Smithsmedical.com.)

- Use specific patient precautions such as positioning restrictions related to disease or treatment.

Equipment

- Stethoscope
- Pulse oximeter
- Water and glass
- Chair
- Tissues and paper bag
- Clear graduated screw-top container
- Suction equipment (if patient unable to cough and clear own secretions)
- Acapella device (see Fig. 24-2)
- Clean gloves (optional)
- Patient education materials

Procedural Steps

- 1 Verify the need for a health care provider's order per agency policy.
- 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet (TJC, 2012).

- 3 Assess respirations and auscultate lung sounds for signs and symptoms indicating the need for this treatment.
- 4 Assess patient's and family's understanding of the device and procedure and explain and clarify procedure as needed.
- 5 Prepare Acapella device:
 - a Initial setting: turn Acapella frequency adjustment dial counterclockwise to lowest resistance setting.
 - b As patient improves or is more proficient, adjust the proper resistance level upward by turning the dial clockwise. This initial setting helps patient to adjust to the device.

Clinical Decision Point Determine if aerosol drug therapy is ordered. If so, attach a nebulizer to the end of the Acapella valve.

- 6 Instruct patient to:
 - a Sit comfortably.
 - b Take in a breath that is larger than normal but not to fill lungs completely. Instruct patient to inhale to about 75% of inspiratory capacity.
 - c Place mouthpiece into the mouth, maintaining a tight seal.
 - d Hold breath for 2 to 3 seconds.
 - e Try not to cough and to exhale slowly for 3 to 4 seconds through the device while it vibrates.

Clinical Decision Point If patient cannot maintain an exhalation for this length of time, adjust the dial clockwise. Clockwise adjustment increases the resistance of the vibrating opening, which allows the patient to exhale at a lower flow rate.

- f Repeat cycle for 5 to 10 breaths as tolerated.
- g Remove mouthpiece and perform one to two forceful exhalations and "huff" coughs.
- h Repeat Steps a to g as ordered.
- 7 Auscultate lung fields.
- 8 Obtain vital signs, pulse oximetry.
- 9 Inspect color, character, and amount of sputum.
- 10 Help patient with oral hygiene.
- 11 Review Unexpected Outcomes for Skill 24-1.
- 12 Document procedure and patient's tolerance.

PROCEDURAL GUIDELINE 24-2 Performing Percussion, Vibration, and Shaking

During postural drainage a nurse, respiratory therapist, or trained family member sometimes uses physical maneuvers such as percussion, vibration, and shaking on the rib cage over lung tissue. The clinician uses techniques on specific parts of the rib cage over each affected lung region. Normally the mucociliary escalator and cough transport of the body can effectively clear airway secretions. However, when a patient's ability to clear the airways is reduced, the techniques of percussion, vibration, and shaking are combined with postural drainage.

Percussion involves clapping a patient's chest wall with cupped hands. If done correctly, it painlessly sets up vibrations in the chest to dislodge retained secretions. Vibration is a sustained co-contraction of the upper extremities by the caregiver to produce a vibratory force that is transmitted to the thorax over the involved

lung region. Vibration is only done during exhalation, with the flat part of the palm over the area. It requires all muscles in the caregiver's arm and shoulder to contract and tremble.

Shaking is a more vigorous downward rocking motion on the rib cage done with the flat part of the hand during exhalation. Shaking requires a caregiver to apply controlled pressure from the shoulder and back while slightly leaning on a patient's chest; a rocking motion is created by flexing and extending elbows using the triceps.

Vibration and shaking augment the natural movement of the rib cage during exhalation and help with secretion clearance. Never use the clavicles, breast tissue, sternum, spine, waist, and abdomen for percussion, vibration, and shaking; only perform these maneuvers over the ribs.

PROCEDURAL GUIDELINE 24-2 Performing Percussion, Vibration, and Shaking—cont'd

High-Frequency Chest Wall Oscillation (Compression)

High-frequency chest wall oscillation (HFCWO) or compression consists of a vest linked to an air-pulse generator. One HFCWO device is the Vest airway clearance system, which assists removal of secretions from the lungs (Fig. 24-3). This system is beneficial for patients with neuromuscular diseases, cystic fibrosis, obstructive and restrictive pulmonary diseases, and ineffective coughing ability. In addition, patients with sputum production of 25 to 30 mL/day also benefit from this device because HFCWO decreases the viscosity of mucus, making it easier to cough productively.

Delegation and Collaboration

The skill of performing percussion, vibration, and shaking can be delegated to nursing assistive personnel (NAP). The nurse is responsible for the respiratory assessment and review of the patient's chest x-ray film (with a physician) to determine patient stability, which areas of the lungs are affected, and specific positions for the patient to assume. The nurse directs the NAP to:

- Be alert for patient's tolerance of the procedure, monitor vital signs, and be alert to any patient precautions related to disease or treatment.
- Report any problems with tolerance of the procedure, pain, dyspnea, or changes in vital signs.

Equipment

- Stethoscope
- Hospital bed (tilt table placed in Trendelenburg's position, optional, check agency policy)
- Chair (for upper lobes)
- One-to-four pillows
- Water pitcher and glass
- Tissues and paper bag
- Clear graduated screw-top container
- Mechanical vibrator or percussor (*optional*)
- HFCWO device such as the Vest airway clearance system
- Single layer of clothing

FIG 24-3 High-frequency chest wall oscillation vest for home use. (Copyright © 2012 Hill-Rom Services, Inc. Reprinted with permission. All rights reserved.)

- Clean gloves (if there is a risk for exposure to patient's respiratory secretions)
- Oral hygiene care: toothbrush, toothpaste, mouthwash, or chlorhexidine oral rinse if ordered
- Suction equipment (*optional*)
- Stethoscope, pulse oximeter

Procedural Steps

- 1 Identify patient using at least two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet (TJC, 2012).
- 2 Assess breathing pattern, including muscles used for breathing, respiratory rate and depth, extent of excursion, and chest wall movement.
- 3 Assess patient and review medical record for signs, symptoms, and conditions that indicate need to perform these skills (see Skill 24-1, Assessment).

Clinical Decision Point *Percussion, vibration, and shaking are contraindicated with rib fracture, fracture of other rib cage structures such as clavicle or sternum, pain, severe dyspnea, and severe osteoporosis. Thin, frail patients with osteoporosis are most susceptible to injury and are taught other secretion control measures (e.g., forceful coughing, humidification).*

- 4 Identify and assess area of rib cage over affected bronchial segment for pain, tenderness, abnormal configuration, abnormal excursion or chest wall movement during breathing, and muscle tension. Percussion, vibration, or shaking is contraindicated if one of these assessment findings are present since the treatment has the potential to cause further injury and impair chest wall motion.
- 5 Determine patient's understanding and assess ability to cooperate with therapy, both in hospital and at home.
- 6 Explain procedure in detail: patient's positioning, sensations, how it will be done, how long it will take, and any discomforts or side effects.
- 7 Help patient to relax and deep breathe during procedure. Have patient practice exhaling slowly through pursed lips while relaxing chest wall muscles. Instruct patient to blow out using abdominal muscles, not rib cage muscles.
- 8 Perform hand hygiene and apply clean gloves as appropriate.
- 9 Elevate bed to comfortable working height and stand close to bed with arms directly in front and knees slightly bent.
- 10 Use findings from physical assessment and chest x-ray film to select congested areas of lung. Position patient in appropriate drainage position (see Table 24-1). If a vest airway clearance system (HFCWO) is ordered, progress to Step 15. Place pillows for support and comfort.
- 11 Perform percussion for 3 to 5 minutes in each position as tolerated. Begin on appropriate part of chest wall over draining area (see Table 24-1). Always ask if patient is experiencing any discomfort such as undue pressure or stinging of the skin.
 - a Place hands side by side on chest wall over area to be drained. Cup hands with fingers and thumbs held tightly together. Make sure that entire outer portion of hand makes contact with chest wall to avoid air leaks (see illustration).

PROCEDURAL GUIDELINE 24-2 Performing Percussion, Vibration, and Shaking—cont'd

STEP 11a Chest wall percussion, alternating hand clapping against patient's chest wall.

- b When clapping, most arm movement comes from the elbow and wrist joints. Clapping is often done for 5 minutes without stopping or for 2 to 3 minutes, alternating with vibration and shaking.
 - c Alternately clap chest with cupped hands to create rhythmic popping sound resembling galloping horse. Perform clapping at moderate or fast speed, whichever is most comfortable and effective.
- 12** Perform chest wall vibration and shaking over each affected area (see Table 24-1). Perform vibrations in sets of three followed by coughing so any loosened secretions are expectorated.
- a Place flat portion of hand over area and have patient take slow, deep breath through nose.
 - b Gently resist chest wall as it rises during inhalation.
 - c Have patient hold breath for 2 to 3 seconds and exhale through pursed lips, while contracting abdominal muscles and relaxing chest wall muscles. Chest wall relaxes and falls.
 - d While patient is exhaling, gently push down and vibrate chest wall with flat part of hand.
 - e Repeat vibration 3 times and have patient cascade cough by taking deep breath and doing series of small coughs until end of breath. Instruct patient not to inhale between coughs. Vibrate chest wall as patient coughs. When applying pressure to ribs, always follow natural movement of rib cage. Allow patient to sit up and cough as needed.
- Clinical Decision Point** *When a patient has excessive pulmonary secretions, which occur with cystic fibrosis, a mechanical vibrator instead of manual vibration is more effective in removing them.*
- f Monitor patient's tolerance of vibration and ability to relax chest wall and breathe properly as instructed.
- 13** Perform shaking with vibration:
- a Place flat part of hand over area and have patient inhale slowly through nose.

- b During inhalation apply light pressure on ribs and stretch skin so it is tight.
 - c Have patient hold breath for 2 to 3 seconds.
 - d As patient exhales increase pressure. Maintain pressure while applying intermittent rocking motion on ribs. Pressure is directed toward following natural expiratory rib cage movement.
 - e Instruct patient to exhale through pursed lips and relax chest wall muscles as much as possible.
 - f Repeat shaking 3 times, have patient inhale deeply, and then do rib shaking during cascade cough.
- 14** Perform a total of three or four sets of three vibrations or shaking with vibration followed by coughing over each lung segment as tolerated. Strength and frequency of vibration and shaking will vary.
- 15** Vest Airway Clearance System (HFCWO) device:
- a Position patient in a comfortable body position.
 - b Explain procedure and equipment to patient and family caregiver.
 - c Place Vest on patient and assess for proper fit.
 - (1) With Vest deflated, adjust the closures so it fits comfortably.
 - (2) Vest should rest on the shoulder and extend to the top of the hip bone.
 - (3) Assess chest wall motion. Breathing should not be restricted when Vest is deflated.
 - d Connect the tubing to the generator and the ports of the Vest. Turn on power.
 - e Adjust pressure control as ordered; usually pressure is between 5 and 6.
 - f Adjust frequency; usually set between 10 and 15 Hz.
 - g Administer any aerosol therapy as prescribed.
 - h Depress and maintain pressure on the hand/foot control to initiate Vest therapy.
 - i After 5 to 10 minutes, release hand/foot control.
- 16** Instruct patient to cough or suction if he or she is unable to cough up mucus (see Chapter 25).
- 17** Continue with treatment; usually 15 to 30 minutes.
- 18** Help patient with oral hygiene.
- 19** Remove gloves and perform hand hygiene.
- 20** If long-term therapy is needed, teach patient and significant others the procedure for home use for Acapella or HFCWO devices. If they cannot learn or use, refer for outpatient or home care follow-up.
- 21** Auscultate lung fields.
- 22** Obtain vital signs, pulse oximetry.
- 23** Inspect color, character, and amount of sputum.
- 24** Document procedure and patient's response.

Critical Thinking Exercises

Mr. Meyersohn is a 29-year-old college student with a history of cystic fibrosis. He was admitted to the hospital 3 days ago for pneumonia, with a respiratory rate of 30 beats/min and 90% saturation on 2 L of oxygen via nasal cannula. He has a fever of 38.8° C (101.8° F). Chest x-ray film showed bilateral lower lobe pneumonia and lobar collapse of his right middle lobe.

- 1 Chest physiotherapy (CPT) was ordered. Which positions would you use?
- 2 Based on the chest x-ray film findings, what would you expect to find on physical examination of the chest, and which additional signs and symptoms would you expect to see?
- 3 After 24 hours of aggressive CPT a chest x-ray film examination was repeated. It showed improvement with good expansion of the right middle lobe and improved aeration of the lower lobes. Were the improvements in the x-ray film examination a result of the CPT? What other clinical improvement would you expect?
- 4 What would you document regarding the CPT and clinical assessment?

REVIEW QUESTIONS

- 1 A nurse is caring for the following group of patients who are receiving postural drainage with percussion. Which patient needs the most monitoring for potential side effects as a result of the procedure?
 - 1 A 76-year-old elementary school teacher with diabetes
 - 2 A 42-year-old year stockbroker on long-term steroids
 - 3 A 66-year-old female who plays tennis twice weekly
 - 4 A 58-year-old African-American male businessman
- 2 A patient with pneumonia has a major significant accumulation of thick secretions and requires chest physiotherapy (CPT). Which action by the nurse will help the patient clear respiratory secretions following CPT?
 - 1 Set up a fluid intake schedule with a goal of 1500 mL/day
 - 2 Have patient use his incentive spirometer twice each shift
 - 3 Ambulate patient as much as possible to prevent stasis
 - 4 Encourage patient to take several warm showers every day
- 3 During chest physiotherapy (CPT) the patient's oxygen saturation goes from 96 to 90. Which action should the nurse take initially?
 - 1 Check patient's vital signs
 - 2 Stop the CPT session for that time
 - 3 Stop and ask patient how he feels
 - 4 Listen to patient's lungs
- 4 A patient with continuous gastric tube feedings is due for postural drainage. After aspirating 125 mL residual feeding from the stomach, which action should the nurse take?
 - 1 Elevate the head of the bed
 - 2 Hold the postural drainage treatment
 - 3 Listen to patient's lungs
 - 4 Prepare patient for postural drainage
- 5 A patient with heart failure requires postural drainage. Which intervention should the nurse anticipate to meet patient needs?
 - 1 Providing short rest periods between positions
 - 2 Having patient take sips of water frequently during the treatment
 - 3 Providing mouth care after the postural drainage is finished
 - 4 Listening to each of the lung fields for 1 minute

- 6 A patient is hospitalized with respiratory failure caused by exacerbation of severe emphysema and bronchiectasis. Chest x-ray film examination revealed good lung expansion except for left lower lobe collapse. In which position should you place the patient for the ordered chest physiotherapy?
 - 1 Right side-lying Trendelenburg's
 - 2 Left side-lying Trendelenburg's
 - 3 Right side-lying flat
 - 4 Right side-lying Trendelenburg's with one-quarter turn back onto a pillow
- 7 A patient was admitted with recurrence of bilateral upper lobe lung abscesses caused by tuberculosis. Chest computed tomography examination showed fluid- and air-filled abscesses in bilateral upper lobes anteriorly. How should you position the patient to drain these areas?
 - 1 Sitting up in a chair and leaning backward onto a pillow
 - 2 Sitting up in a chair and leaning forward onto a pillow or table
 - 3 Lying on back flat in bed
 - 4 Lying prone with bed flat
- 8 A patient needing chest physiotherapy finished his lunch at 1 PM. When is the soonest that he should receive postural drainage?
 - 1 30 minutes later
 - 2 At 2 PM
 - 3 Before his next snack
 - 4 Right after dinner
- 9 A frail older adult needs chest physiotherapy because during assessment adventitious lung sounds revealed retained respiratory secretions. Which approach would be most appropriate to help this patient get rid of these secretions?
 - 1 Encouraging him to increase his oral fluid intake
 - 2 Teaching him how to forcefully cough
 - 3 Performing postural drainage on the affected lobes
 - 4 Using vibration and shaking over the affected lobes
- 10 A patient experiences severe dyspnea and hemoptysis during a session of chest physiotherapy (CPT). After stopping the CPT, what is the initial appropriate nursing intervention?
 - 1 Notifying the health care provider
 - 2 Administering a bronchodilator to ease the dyspnea
 - 3 Assessing patient
 - 4 Elevating the head of patient's bed

KEY TERMS

Artificial airway	Endotracheal (ET) tube	Intubation	Respiratory distress
Atelectasis	Hypercapnia	Laryngospasm	Suction
Bronchospasm	Hyperventilation	Obturator	Suction catheter
Closed-system suction catheter	Hypoxemia	Outer and inner cannula	Tracheostomy
	Hypoxia	Preoxygenation	Yankauer suction

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify guidelines for managing a patient's airway.
- Describe the nursing interventions for airway management.
- Discuss the indications for airway suctioning.
- Discuss the indications for tracheostomy care.
- Correctly perform oropharyngeal suctioning, tracheal suctioning, endotracheal care, and tracheostomy tube care.
- Correctly inflate a cuff on an endotracheal or tracheostomy tube.
- Change a tracheostomy tube or inner cannula.

Airway management involves maintaining the patency of a patient's nose, upper airway, trachea, and lower airway of the respiratory system. The primary goal is to maintain adequate tissue oxygenation. Many courses of action are available to promote an open or patent airway, which has the potential to become obstructed by mucus, mechanical obstruction (i.e., soft tissue in upper airway), or a foreign body. These actions do not always require a health care provider's order. Consult a health care provider if there are any concerns about the appropriateness of an intervention or when an airway obstruction is present, even when treatment relieves the obstruction. Hydration, positioning, nutrition, chest physiotherapy techniques,

suctioning, deep breathing, coughing, humidity, incentive spirometry, and aerosol therapy are noninvasive techniques that are helpful in maintaining a patent airway.

When patients are unable to clear airway secretions with coughing, chest physiotherapy, or other noninvasive techniques, more invasive measures such as suctioning or inserting an artificial airway are needed. An artificial airway is a plastic or rubber device (such as a tracheostomy or endotracheal tube) that is inserted into the upper or lower respiratory tract to facilitate ventilation or the removal of secretions. These additional measures are necessary, especially in weak, confused, or critically ill patients.

EVIDENCE-BASED PRACTICE

Preoxygenation and deep breathing, sometimes referred to as *hyper-ventilation*, help to reduce suction-induced hypoxemia (AARC, 2010). Hyperinflation is the process of providing 100% oxygen to a patient before airway suctioning:

- Preoxygenation provides a patient with a short-term increase in supplemental oxygen. Techniques include increasing oxygen flow rate on a nasal cannula or oxygen mask, increasing the percent of inspired oxygen of breaths delivered by a mechanical ventilator, or increasing oxygen flow rates to artificial airways.
- Not all patients require preoxygenation unless they are hypoxemic before suctioning.
- Following suctioning, return a patient's oxygen level to pre-suctioning levels to avoid increased risk for oxygen toxicity (AARC, 2010).

The practice of normal saline instillation (NSI) into artificial airways is no longer recommended as standard practice. Initially this instillation was believed to improve secretion removal. However, the research on this practice is inconclusive. The following items identify the lack of evidence for support or the potential side effects of the practice:

- Clinical studies comparing the results of suctioning using NSI with those of standard suctioning do not show any clinical or significant results (AARC, 2010; Halm and Krisko-Hagel, 2008).
- Suctioning with or without isotonic normal saline (INS) produces similar amounts of secretions and significant decreases in oxygen saturation.
- Potential side effects are increases in heart rate for 4 to 5 minutes after suctioning with INS as opposed to dry suctioning.
- Level of a patient's dyspnea after suctioning with or without INS was not significantly different.
- Use of INS with suctioning has the potential to increase ventilator-associated pneumonia because INS can dislodge bacteria from the upper airway to the lower portions of the airway (AARC, 2010; Halm and Krisko-Hagel, 2008).

PATIENT-CENTERED CARE

Artificial airways alter patients' ability to communicate, possibly causing feelings of fear, frustration, and vulnerability. Recommendations to improve communication for patients with an altered airway include developing alternate means of communication and to "acknowledge the lack of voice to the patient" (Foster, 2010). If nurses identify anger and frustration in their patients, they need to consider the need for improved communication methods. Nurses also need to thoroughly educate patients and make sure that they understand any procedures or tests. Regular pain medication administration for tracheostomy site soreness and before suctioning or dressing changes is helpful in promoting comfort and trust.

Collaboration with families is essential when providing alternative means of communication for patients. Patients and families who have English as their second language or do not speak English require additional attention from nurses and other health care providers to prevent misunderstanding treatment options. As a nurse, obtain translators or other communication aids so patients and families understand the need for an artificial airway and the

subsequent treatments. Once communication is established, a patient and family will have more trust in the care provided, which will promote cooperation and rapport (Gill et al., 2009).

Safety Guidelines

- 1 Know a patient's normal range of vital signs and oxygen saturation levels. Baseline physiologic measures serve as a means to identify individual abnormalities and recognize the worsening of an illness.
- 2 Know a patient's medical history. Smoking alters normal mucociliary clearance. Certain disorders such as chronic obstructive pulmonary disease (COPD), asthma, cystic fibrosis, pneumonia, thoracic surgery, chest trauma, and abdominal surgery place patients at increased risk for an obstructed airway.
- 3 Identify conditions that increase a patient's risk for aspiration of gastric contents into the lung, resulting in airway obstruction. These include the presence of enteral feeding tubes or other nasal or oral gastric tubes, a decreased level of consciousness, and a decreased swallowing ability.
- 4 Use caution when suctioning patients with a head injury. The suction procedure causes an elevation in intracranial pressure (ICP). Reduce this risk by presuctioning hyperventilation, which results in hypocarbia. This in turn induces vasoconstriction, thereby reducing the risk of ICP.
- 5 Determine if a patient has a history of nasal problems such as nasal trauma, nasal polyps, deviated nasal septum, or chronic sinusitis. Allergy problems may cause mucosal swelling that narrows nasal passages, which affects the ability to easily pass a suction catheter.
- 6 Review a patient's respiratory assessments from the past 12 or 24 hours. These are relative baseline measurements that help to distinguish between gradual and acute changes in a patient's status.
- 7 Perform a systematic respiratory assessment of upper and lower airways, including identifying respiratory rate, respiratory pattern, respiratory muscles used, breath sounds, ability to cough effectively, integrity of the rib cage, and the characteristics of sputum production.
- 8 Identify and become familiar with the use of equipment available at the agency. Many types of artificial airways, suction catheters, and suction machines are available. Knowing how to operate the equipment before use promotes positive outcomes.
- 9 Test all equipment before use. Have adequate supplies on hand at the bedside. Equipment must work properly to provide safe nursing care. Determine that the suction machine is generating adequate negative suction pressure and that there are suction catheters and appropriate equipment at the bedside.
- 10 Know the side effects of medications and other therapies. Some medications such as beta-adrenergic blockers have the side effect of bronchospasm. An adverse effect of opioids and sedatives is respiratory depression. Similarly, too much oxygen reduces the drive to breathe in patients with chronic hypercapnia (elevated arterial carbon dioxide tension). Some position changes affect a patient adversely. For example, in patients with impaired spinal cord innervations of the respiratory muscles, supine positions place the diaphragm at a mechanical disadvantage and increase the risk for aspiration.

SKILL 25-1 Performing Oropharyngeal Suctioning

NSO Airway Management Module / Lesson 3

Video Clip

A Yankauer, or tonsillar tip, suction device is used for oropharyngeal suctioning (i.e., the removal of pharyngeal secretions through the mouth) (Fig. 25-1). A Yankauer suction catheter is made of rigid, minimally flexible plastic. The tip of this suction catheter usually has one large and several small openings through which the mucus enters with application of negative pressure. The Yankauer suction catheter is angled to facilitate removal of secretions through a patient's mouth. This catheter is used instead of a standard suction catheter when oral secretions are extremely copious and thick because it handles large volumes of secretions better than a standard suction catheter. The Yankauer catheter is not used to suction the nares or trachea because of its size.

The Yankauer suction device is useful in the removal of secretions from the mouth. Yankauer suctioning is used when the patient is able to cough effectively but is unable to clear secretions. In addition, patients who benefit most are those who have had oral and maxillofacial surgery, trauma to the mouth, neurovascular injury, and cerebrovascular accident causing hemiparesis and

drooling or impaired swallowing. Patients with artificial airways and impaired swallowing require use of the Yankauer suction device to provide oral hygiene.

Delegation and Collaboration

The skill of performing oropharyngeal (Yankauer) suctioning can be delegated to nursing assistive personnel (NAP). Do not routinely delegate this skill for patients with oral or neck surgery in the immediate postoperative period. The nurse is responsible for assessing the patient's respiratory status. The nurse directs the NAP about:

- Appropriate suction limits for oropharyngeal suctioning for a particular patient (e.g., the appropriate suction pressure, expected frequency of suctioning, and expected color and volume of secretions).
- The risks of applying excessive or inadequate suction pressure.
- Avoiding mouth sutures, applying suction against sensitive tissues, and dislodging tubes in the patient's nose or mouth.
- Avoiding stimulation of the gag reflex.
- Immediately reporting to the nurse change in vital signs, pulse oximetry, sputum (i.e., bloody), difficulty breathing, or discomfort during or after the procedure.

FIG 25-1 Oropharyngeal suctioning.

Equipment

- Yankauer or tonsillar tip suction catheter
- Clean gloves
- Towel, cloth, or disposable paper drape
- Mask, goggles, or face shield
- Disposable cup or nonsterile basin
- Tap water or normal saline (about 100 mL)
- Suction machine or wall suction device
- Connecting tubing (6 feet)
- Oral airway (if indicated)
- Washcloth (if indicated)
- Pulse oximeter, stethoscope

STEP

RATIONALE

ASSESSMENT

- 1 Identify risk factors for airway obstruction: impaired cough or gag reflex, weakened respiratory muscles, impaired swallowing, and decreased level of consciousness.
- 2 Assess for signs and symptoms of hypoxia (low oxygen use at cellular or tissue level), hypoxemia (low oxygen tension in blood), or hypercapnia (elevated carbon dioxide tension in blood): apprehension, anxiety, decreased ability to concentrate, lethargy, decreased level of consciousness (especially acute), increased fatigue and dizziness, behavioral changes (e.g., irritability and restlessness), tachycardia, tachypnea, decreased depth of breathing, elevated blood pressure, cardiac dysrhythmias, pallor, cyanosis, dyspnea, and use of accessory muscles for breathing.
- 3 Obtain patient's oxygen saturation level via pulse oximetry (SpO₂) (see Chapter 5). Keep oximeter in place.

Risk factors prevent patient from protecting airway from aspiration or clearing secretions safely.

Suctioning of airways is indicated with alterations in oxygenation associated with secretion accumulation.

Provides an objective baseline measure of oxygen saturation and an early indication of changes in oxygenation status.

STEP	RATIONALE
4 Determine patient's ability to hold or manipulate catheter and his or her knowledge about use of suction catheter and procedure.	Encourages cooperation; minimizes risks and anxiety. Identifies teaching needs. Physical factors such as impaired mobility of upper extremities prevent patient from using catheter to help control oral secretions.
5 Assess for signs and symptoms of upper airway obstruction: gurgling on inspiration or expiration, restlessness, obvious excessive oral secretions, drooling, gastric secretions or vomitus in mouth, or coughing without clearing secretions from upper airway.	Secretions pool in upper airway, which can cause total airway obstruction and hypoxia. The risk for aspiration of gastric contents and airway obstruction is increased in patients with vomiting, delayed gastric emptying, and impairment in esophageal sphincter control, cough, swallowing, or gag reflex.
6 Auscultate for presence of adventitious sounds (see Skill 25-2).	Determines if lower airway secretions are present and establishes baseline.

NURSING DIAGNOSES

- | | | |
|---|--|---|
| <ul style="list-style-type: none"> • Deficient knowledge regarding use of suction • Impaired gas exchange | <ul style="list-style-type: none"> • Impaired swallowing • Ineffective airway clearance • Ineffective breathing pattern | <ul style="list-style-type: none"> • Risk for aspiration • Risk for infection |
|---|--|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • No gurgling sounds are heard in patient's pharynx on inspiration and expiration. • Drooling is diminished or absent. • Vomitus or gastric secretions are absent from mouth. • SpO₂ improves or remains the same. 	<p>Suctioning is effective. Secretions are removed from large upper airway.</p> <p>Excessive drooling indicates that patient is unable to handle oral secretions.</p> <p>Gastric secretions retained in oral cavity increase patient's risk for aspiration pneumonia.</p> <p>Removal of secretions helps to improve oxygen saturation level.</p>
--	--

Clinical Decision Point *In patients with chronic pulmonary disease, the SpO₂ value may remain the same after oropharyngeal suctioning.*

<p>2 Explain to patient how procedure helps clear airway secretions and relieves some breathing problems. Explain that coughing, gagging, or (less commonly) sneezing is normal and lasts only a few seconds. Encourage patient to cough out secretions and show how to splint painful areas during procedure. Practice coughing if able.</p>	<p>Gagging or coughing occurs when posterior pharynx is suctioned or as a result of excess secretions. Coughing secretions out of lower airway or posterior pharynx decreases amount of suctioning required. Splinting reduces abdominal incision discomfort during coughing or gagging.</p>
<p>3 Position patient in semi-Fowler's or sitting position. Place towel, cloth, or paper drape across patient's neck and chest.</p>	<p>Promotes patient comfort and removal of airway secretions. Towel protects gown and bed linen from contamination by secretions.</p>

IMPLEMENTATION

<p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number according to agency policy). Compare identifiers with information on patient's identification bracelet.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p>
<p>2 Perform hand hygiene and apply clean gloves. Apply mask or face shield if splashing is likely.</p>	<p>Reduces transmission of microorganisms.</p>
<p>3 Fill cup or basin with approximately 100 mL of water or normal saline.</p>	<p>Aids in cleaning catheter after suctioning and assesses that equipment functions.</p>
<p>4 Connect one end of connecting tubing to suction machine and other to Yankauer suction catheter. Turn on suction machine; set vacuum regulator to appropriate setting (see manufacturer instructions).</p>	<p>Prepares suction apparatus. Elevated pressure settings increase risk for trauma to oral mucosa.</p>
<p>5 Check that suction machine is functioning properly by placing tip of catheter in water or saline and suctioning small amount from cup or basin.</p>	<p>Ensures equipment function and lubricates catheter.</p>
<p>6 Remove patient's oxygen mask if present. Nasal cannula may remain in place. Keep oxygen mask near patient's face.</p>	<p>Allows access to mouth. Reduces chance of hypoxia.</p>

STEP

RATIONALE

Clinical Decision Point *Be prepared to quickly reapply supplemental oxygen if SpO₂ value falls below 90% or respiratory distress develops during or at the end of oropharyngeal suctioning.*

- | | | |
|---|--|--|
| 7 | Insert catheter into mouth along gum line to pharynx. Move catheter around mouth until secretions have cleared. Encourage patient to cough. Replace oxygen mask. | Movement of catheter prevents suction tip from invaginating oral mucosal surfaces and causing trauma. Coughing moves secretions from lower airway into mouth and upper airway. |
|---|--|--|

Clinical Decision Point *Be careful using a Yankauer tip with a patient who had recent oral or head/neck surgery.*

- | | | |
|----|---|---|
| 8 | Rinse catheter with water in cup or basin until connecting tubing is cleared of secretions. Turn off suction. Wash face if secretions are present on patient's skin. | Rinses catheter and reduces probability of transmission of microorganisms. Clean suction tubing enhances delivery of set suction pressure. Prevents skin breakdown. |
| 9 | Observe respiratory status. Repeat procedure if indicated. May need to use standard suction catheter to reach into trachea if respiratory status not improved (see Skill 25-2). | Directs nurse to continue or cease intervention or choose another intervention. |
| 10 | Remove towel, cloth, or disposable drape and place in trash or in laundry if soiled. Reposition patient; Sims' position encourages drainage and should be used if patient has decreased level of consciousness. | Reduces transmission of microorganisms. Facilitates drainage of oral secretions. |
| 11 | Discard remainder of water into appropriate receptacle. Rinse basin in warm soapy water and dry with paper towels. Discard disposable cup into appropriate receptacle. Place catheter in clean, dry area. | Reduces transmission of microorganisms and maintains medical asepsis. Moist environment encourages microorganism growth. |

Clinical Decision Point *Keep catheter in nonairtight container such as brown paper or plastic bag attached to bedrail or in suction canister area. Do not store the catheter where it will come in contact with secretions or excretions, which promote bacterial growth.*

- | | | |
|----|---|---|
| 12 | Remove gloves, mask, or face shield and dispose of in appropriate receptacle. Perform hand hygiene. | Reduces transmission of microorganisms to other patients and equipment. |
| 13 | Position patient and provide oral hygiene as needed. | Promotes patient's comfort. |

EVALUATION

- | | | |
|---|---|---|
| 1 | Compare assessment findings before and after procedure. | Identifies physiologic response to suction procedure. |
| 2 | Auscultate chest and airways for adventitious sounds. | Presence of lower airway adventitious sounds suggests need for lower airway suctioning. |
| 3 | Inspect mouth for any vomitus. | Clear oral airway is necessary to prevent aspiration. |
| 4 | Obtain postsuction SpO ₂ measure. Compare with presuction level. | Provides objective measure of effectiveness of suction procedure (AARC, 2004). |
| 5 | Observe patient or family perform Yankauer suctioning. | Demonstrates learning. |

Unexpected Outcomes

- 1 Patient's respiratory distress increases.

- 2 Bloody secretions are suctioned.

Related Interventions

- Suction further or implement nasal or tracheal suctioning.
- Evaluate need for other means to protect airway (e.g., oral intubation, oral airway, positioning).
- Provide supplemental oxygen.
- Notify health care provider.

- Assess oral cavity for trauma or lesions.
- Reduce amount of suction pressure used.
- Observe catheter tip for nicks, which cause mucosal trauma.
- Increase frequency of oral hygiene.

Recording and Reporting

- Record the amount, consistency, color, and odor of secretions; number of times suctioned, patient's response to suctioning; and presuction and postsuction cardiopulmonary assessment findings (see [Chapter 6](#)).
- Record instructions given to caregivers and note their ability to correctly perform procedure.
- Report any unresolved outcomes such as worsening respiratory distress to the health care provider.

Special Considerations

Teaching

- Instruct patient and family caregiver not to allow catheter to fall to the floor. If this occurs, teach patient and caregiver how to clean or obtain a clean catheter (see [Home Care Considerations](#)).
- Provide information regarding signs and symptoms of worsening respiratory status.

Pediatric

- Airways of infants and children are smaller than those of an adult; even small amounts of mucus cause airway obstruction.
- Position infants with breathing problems or excessive vomitus in supine or side-lying position ([Hockenberry and Wilson, 2011](#)).
- Suction should be completed for only 5 seconds because of risk of deoxygenation. Allow 30 to 60 seconds for patient to reoxygenate ([Hockenberry and Wilson, 2011](#)).

- Complete oral suctioning first and then nasal suctioning to decrease the risk of aspiration ([Hockenberry and Wilson, 2011](#)).
- Use bulb syringe. Compress syringe before insertion to prevent forcing secretions into infant's bronchi. Within the hospital replace the bulb every 24 hours ([Hockenberry and Wilson, 2011](#)).

Gerontologic

- Patients with dysphagia may benefit from oral suctioning before, during, and after meals.
- Oral mucosa in older adults is fragile; use a lower suction pressure.
- Older adults are prone to aspiration of oral secretions because of decreased cough and gag reflexes ([Meiner and Lueckenotte, 2011](#)).

Home Care

- Make sure that patient and family caregiver know how to clean and disinfect or change the secretion collection container every 24 hours according to home care protocol. Many agencies seal and dispose of the entire disposable secretion collection canister as biohazardous material.
- Assess knowledge level of patient and family caregiver to determine amount of instruction required and frequency of home health visits necessary to reach goals.
- Assess home for the presence of respiratory irritants, including cigarette smoke, dust, pollen, animal dander, mold, and chemicals.

SKILL 25-2 Airway Suctioning

NSO Airway Management Module / Lessons 1, 5, and 6

Nasopharyngeal and Nasotracheal Suctioning

Nasopharyngeal and nasotracheal suctioning help to maintain a patent airway by removing secretions from the nares, pharynx, throat, and trachea by introducing a suction catheter through the nares. This type of suctioning is used when oral suctioning (see [Skill 25-1](#)) is ineffective or inappropriate or when the lower airway requires removal of secretions. It involves inserting a small rubber or soft plastic tube into the nares to the pharynx or trachea and applying negative pressure to withdraw mucus.

Artificial Airway Suctioning

Endotracheal (ET) tubes and tracheostomy tubes (TTs) are artificial airways inserted to relieve airway obstruction, provide a route for mechanical ventilation, permit easy access for secretion removal, and protect the airway from gross aspiration in patients with impaired cough or gag reflexes.

Endotracheal Tubes

NSO Airway Management Module / Lesson 7

ET intubation is a procedure performed by a health care provider or specially trained personnel (e.g., certified registered nurse anesthetist, respiratory therapist, or rescue personnel). An ET tube is inserted through the nares (nasal ET tube) or the mouth (oral ET tube) past the epiglottis and vocal cords into the trachea ([Fig. 25-2, A and B](#)).

The major differences between oropharyngeal and tracheal airway suctioning are the depth suctioned, the potential for complications, and the need for it to be a sterile procedure. Oropharyngeal suctioning only removes secretions from the back of the throat. Tracheal airway suctioning extends into the lower airway and is indicated to remove respiratory secretions and maintain optimum ventilation and oxygenation in patients who are unable to independently remove these secretions. When a patient's oxygen saturation falls below 90%, this is a good indicator of the need for suctioning. Assess patients to determine frequency and depth of suctioning. Some patients require suctioning every hour or two, whereas others need it only once or twice a day ([AARC, 2004](#)).

If the secretions are only in the nose and mouth, only the pharynx requires suctioning. However, in most instances you will suction both the pharynx and the trachea. Suction secretions from the pharynx as often as necessary using oropharyngeal or nasopharyngeal suctioning. Secretions that are not removed are more likely to be aspirated into the lungs, increasing the risk for infection and respiratory failure. This requires tracheal suction.

Tracheal suctioning has many risks, including hypoxemia, which often results in cardiac dysrhythmias, laryngeal spasm, or bradycardia. Bradycardia is associated with stimulation of the vagus nerve. Nasal trauma and bleeding can develop from trauma from a suction catheter introduced through the nares ([AARC, 2004](#)).

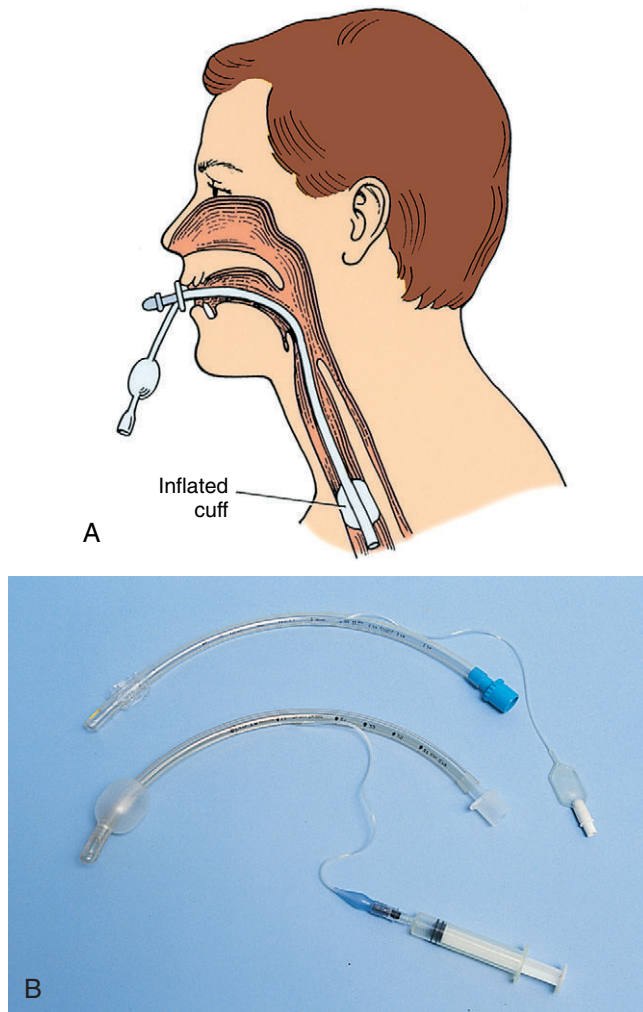

FIG 25-2 A, Endotracheal (ET) tube with inflated cuff. B, ET tubes with uninflated and inflated cuffs and syringe for inflation.

The length of time that an ET tube remains in place is somewhat controversial; however, in most cases after 2 to 4 weeks, if a patient still requires an artificial airway, a TT is inserted (AARC, 2010). Oral ET tubes are usually made of plastic or rubber. Adult sizes of ET tubes have a cuff molded onto the tube to prevent the aspiration of oral secretions or gastric contents into the lung and/or to obstruct the escape of air from mechanical ventilator breaths through the upper airway.

Tracheostomy Tubes

A TT can be temporary or permanent, depending on a patient's condition. It is inserted directly into the trachea through a small incision made in a patient's neck. TTs are made of several different materials, including polyvinyl chloride- or silicone-based plastics

and stainless steel or metallic compounds. Metal tracheostomy tubes are thermal sensitive and must be protected from extreme heat and cold to prevent tissue injury in the patient. Most metal and plastic TTs contain an inner cannula that is temporarily withdrawn for cleaning airway-occluding mucus without removing the entire TT (see Skill 25-4) (White et al., 2010).

A cuff on a TT serves the same purpose as one on an ET tube. Cuffs are made of a balloonlike inflatable plastic; usually you manually inflate one with air (see Skill 25-5). Plastic-covered foam cuffs are self-air-inflating if the inflation port is left open to the atmosphere (Frace, 2010; Regan and Dallachiesa, 2009).

Some agencies use a closed suction catheter system or in-line suction catheter device to minimize infections, especially in critically ill or immunosuppressed patients (Pedersen et al., 2009). Use of a closed-system catheter (in-line) allows quicker lower airway suctioning without applying sterile gloves or a mask and does not interrupt ventilation and oxygenation in critically ill patients (see Procedural Guideline 25-1). With a closed-system method the patient's artificial airway is not disconnected from the mechanical ventilator (Jongerden et al., 2011).

Delegation and Collaboration

The skills of nasotracheal and new artificial airway suctioning cannot be delegated to nursing assistive personnel (NAP). When the patient has an established tracheostomy and you determine that he or she is stable, you can delegate suctioning. The nurse directs the NAP about:

- Any unique modifications of the skill such as the need for supplemental oxygen or the use of a clean-versus-sterile suction technique.
- Appropriate suction limits for suctioning TT and risks of applying excessive or inadequate suction pressure.
- Signs and symptoms of hypoxemia such as change in patient's respiratory status, confusion, and restlessness and to report these signs immediately to the nurse.
- Reporting any change in secretion quality, quantity, and color.

Equipment

- Appropriate-size suction catheter (smallest diameter that will remove secretions effectively)
- Nasal or oral airway (if indicated)
- Two sterile gloves or one sterile and one clean glove
- Clean towel or paper drape
- Suction machine/source
- Mask, goggles, or face shield
- Connecting tubing (6 feet)
- Small Y-adapter (if catheter does not have a suction control port)
- Water-soluble lubricant
- Sterile basin
- Sterile normal saline solution or water, about 100 mL
- Pulse oximeter and stethoscope

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| <p>1 Assess for risk factors for upper or lower airway obstruction, including obstructive lung disease, pulmonary infections, impaired mobility, sedation, decreased level of consciousness, seizures, presence of feeding tube, decreased gag or cough reflex, and decreased swallowing ability.</p> <p>2 Determine presence of apprehension, anxiety, decreased ability to concentrate, lethargy, decreased level of consciousness (especially acute), increased fatigue, dizziness, behavioral changes (especially irritability), pallor, cyanosis, dyspnea, or use of accessory muscles.</p> <p>3 Assess vital signs, including pulse oximetry (SpO₂) and, if on ventilator, peak inspiratory pressure and tidal volume.</p> <p>4 Assess signs and symptoms of upper and lower airway obstruction requiring airway suctioning, including wheezing, crackles, or gurgling on inspiration or expiration; restlessness; ineffective coughing; absent or diminished breath sounds; tachypnea; hypertension or hypotension; cyanosis; decreased level of consciousness, especially acute; or excess nasal secretions, drooling, or gastric secretions or vomitus in mouth (AARC, 2004).</p> <p>5 Assess for additional factors that anatomically influence upper or lower airway function: recent surgery; head, chest, or neck tumors; facial or nasal trauma; and neuromuscular diseases.</p> <p>6 Assess factors that affect volume and consistency of secretions.</p> <p style="padding-left: 20px;">a Fluid balance</p> <p style="padding-left: 20px;">b Lack of humidity</p> <p style="padding-left: 20px;">c Infection (e.g., pneumonia)</p> <p style="padding-left: 20px;">d Allergies, sinus drainage</p> <p>7 For endotracheal suctioning assess patients' peak inspiratory pressure when on volume-controlled ventilation or tidal volume during pressure-controlled ventilation.</p> <p>8 Weigh a patient's need for suction and consider contraindications to nasotracheal suctioning (AARC, 2004):</p> <p style="padding-left: 20px;">a Facial or neck trauma/surgery</p> <p style="padding-left: 20px;">b Acute head injuries</p> <p style="padding-left: 20px;">c Bleeding disorders</p> <p style="padding-left: 20px;">d Nasal bleeding</p> <p style="padding-left: 20px;">e Epiglottitis or croup</p> <p style="padding-left: 20px;">f Laryngospasm</p> <p style="padding-left: 20px;">g Irritable airway</p> <p style="padding-left: 20px;">h Gastric surgery</p> | <p>Presence of these risk factors can impair patient's ability to clear secretions from airway, increase risk for retaining secretions, and necessitate nasopharyngeal or nasotracheal suctioning.</p> <p>Signs and symptoms indicate hypoxia (low oxygen at cellular or tissue level), hypoxemia, or hypercapnia. Anxiety and pain consume oxygen and in turn worsen signs of hypoxia. Patients with conditions such as acute respiratory distress syndrome, pulmonary edema, and heart failure are at particular risk for hypoxia.</p> <p>Establishes baseline. Signs of hypoxia include decreased oxygen saturation, increased pulse rate, increased rate of breathing, decreased depth of breathing, elevated blood pressure, and cardiac dysrhythmias.</p> <p>Physical signs and symptoms result from decreased oxygen to tissues and pooling of secretions in upper and lower airways. Assessment is necessary before and after suction procedure (AARC, 2004).</p> <p>Abnormal anatomy impairs normal drainage of secretions (e.g., nasal swelling, deviated septum, or facial fractures). Tumors in or around lower airway impair secretion removal by occluding or externally compressing lumen of airway.</p> <p>Thickened or copious secretions increase risk for airway obstruction. Fluid overload increases amount of secretions. Dehydration promotes thicker secretions. The environment influences secretion formation and gas exchange. Airway suctioning is needed when patient cannot clear secretions effectively.</p> <p>Patients with respiratory infections are prone to increased secretions that are thicker and sometimes more difficult to expectorate. Increases volume of secretions in pharynx.</p> <p>Increased peak inspiratory pressure or decreased tidal volume may indicate airway obstruction (AARC, 2010).</p> <p>Consider these conditions only if suctioning appears to be hazardous. Passage of catheter through nasal route causes additional trauma, increases nasal bleeding, or causes severe bleeding in presence of bleeding disorders. In presence of epiglottitis, croup, laryngospasm, or irritable airway, entrance of suction catheter via nasal route causes intractable coughing, hypoxemia, and severe bronchospasm; this may necessitate emergency intubation or tracheostomy.</p> |
| <p>9 Examine sputum microbiology data.</p> <p>10 Assess patient's understanding of procedure.</p> | <p>Certain bacteria are easier to transmit or require isolation because of virulence or antibiotic resistance.</p> <p>Reveals need for instruction.</p> |

Clinical Decision Point ET suctioning is necessary for patients with artificial airways. Most contraindications are relative to a patient's risk of developing adverse reactions or a worsening clinical condition as a result of the procedure. The decision to withhold suctioning to avoid a possible adverse reaction may in fact be lethal (AARC, 2010).

STEP

RATIONALE

NURSING DIAGNOSES

- Deficient knowledge regarding suctioning
- Fatigue
- Impaired gas exchange
- Impaired spontaneous ventilation
- Impaired swallowing
- Ineffective airway clearance
- Ineffective breathing pattern
- Risk for aspiration
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Upper and lower airways demonstrate absent or diminished adventitious sounds, including gurgles, crackles, wheezes on inspiration and expiration.
 - Heart rate, blood pressure, respiratory rate and effort, and SpO₂ readings are within normal range.
 - Absence of drooling, gastric secretions, or vomitus in mouth; nasal secretions.
 - Patient verbalizes easier breathing if able.
- 2 Explain to patient how procedure will help clear airway and relieve breathing difficulty. Explain that temporary coughing, sneezing, gagging, or shortness of breath is normal during procedure.
- 3 Explain importance of and encourage coughing to remove secretions during procedure. Practice coughing, using splinting if appropriate (see Chapter 36).
- 4 Have patient assume position comfortable for nurse and patient (usually semi-Fowler's or sitting upright with head hyperextended unless contraindicated).
- 5 Place pulse oximeter on patient's finger. Take reading and leave oximeter in place.

Airways are cleared of secretions.

When airway secretions are removed and oxygenation improves, patient's vital signs, SpO₂ readings, and respiratory assessment findings improve as well (AARC, 2004).

Secretions retained in oral cavity increase patient's risk for pneumonia.

Patent airway reduces work of breathing.

Encourages cooperation and minimizes risks, anxiety, and pain of procedure.

Facilitates secretion removal and reduces frequency and duration of future suctioning.

Reduces stimulation of gag reflex, promotes patient comfort and secretion drainage, and prevents aspiration. Reduces strain on nurse's back. Hyperextension facilitates insertion of catheter into trachea.

Provides continuous SpO₂ value to determine patient's response to suctioning.

IMPLEMENTATION

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.
- 2 Perform hand hygiene and apply mask, goggles, or face shield if splashing is likely.
- 3 Connect one end of connecting tubing to suction machine and place other end in convenient location near patient. Turn suction device on and set suction pressure to as low a level as possible and yet able to effectively clear secretions (AARC, 2010). Occlude end of suction tubing to check pressure.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

Reduces transmission of microorganisms.

Excessive negative pressure damages nasal pharyngeal and tracheal mucosa and induces greater hypoxia. Lowest possible suction pressure is recommended; less than 150 mm Hg in adults (AARC, 2010; Pedersen et al., 2009).

Clinical Decision Point After suctioning, readjust ventilator settings to preprocedural levels to avoid increased risk for oxygen toxicity and absorption, atelectasis from prolonged administration of high concentrations of oxygen, and increased carbon dioxide retention in patients with chronic obstructive lung disease (Pedersen et al., 2009).

- 4 Prepare suction catheter.
 - a **One-time-use catheter:**
 - (1) Using aseptic technique, open suction kit or catheter. If sterile drape is available, place it across patient's chest or on over-bed table. Do not allow suction catheter to touch any nonsterile surfaces.
 - (2) Unwrap or open sterile basin and place on bedside table. Be careful not to touch inside of basin. Fill with about 100 mL sterile normal saline solution or water (see illustration).

Prepares catheter, maintains asepsis, and reduces transmission of microorganisms. Provides sterile surface on which to lay catheter between passes.

Saline or water is used to clean tubing after each suction pass.

STEP

RATIONALE

- (3) Open lubricant. Squeeze small amount onto open sterile catheter package without touching package.
NOTE: Lubricant is not necessary for artificial airway suctioning.

b Closed (in-line) suction catheter: see Procedural Guideline 25-1.

- 5 Apply sterile glove to each hand or apply nonsterile glove to nondominant hand and sterile glove to dominant hand.
 6 Pick up suction catheter with dominant hand without touching nonsterile surfaces. Pick up connecting tubing with nondominant hand. Secure catheter to tubing (see illustration).
 7 Check that equipment is functioning properly by suctioning small amount of normal saline solution from basin.
 8 Suction airway:

a Nasopharyngeal and nasotracheal suctioning:

- (1) Increase oxygen flow rate for face masks as ordered by health care provider (Lewis et al., 2011). Have patient deep breathe slowly, if possible.
 (2) Lightly coat distal 6 to 8 cm (2.4 to 3.2 inches) of catheter with water-soluble lubricant.
 (3) Remove oxygen delivery device, if applicable, with nondominant hand. Without applying suction and using dominant thumb and forefinger, gently but quickly insert catheter into nares. Instruct patient to deep breathe and insert catheter following natural course of nares. Slightly slant catheter downward or through mouth. Do not force through nares (see illustration).

Prepares lubricant while maintaining sterility. Using water-soluble lubricant helps avoid lipid aspiration pneumonia. Excessive lubricant occludes catheter.

Reduces transmission of microorganisms and maintains sterility of suction catheter.

Maintains catheter sterility. Connects catheter to suction.

Ensures equipment function. Lubricates internal catheter and tubing.

Hyperoxygenation is recommended, especially in patients who are hypoxemic (AARC, 2010).

May help reduce suction-induced decline in oxygenation.

Lubricates catheter for easier insertion.

Application of suction pressure while introducing catheter into trachea increases risk for damage to mucosa and increases risk for hypoxia. Passing catheter during inhalation improves likelihood of entering trachea.

Clinical Decision Point Be sure to insert catheter during patient inhalation, especially if inserting it into trachea, because epiglottis is open. Do not insert during swallowing or catheter will most likely enter esophagus. Never apply suction during insertion. Patient should cough. If patient gags or becomes nauseated, catheter is most likely in esophagus, and you need to remove it.

- (a) *Nasopharyngeal* (without applying suction): In adults insert catheter about 16 cm (6.4 inches); in older children, 8 to 12 cm (3 to 5 inches); in infants and young children, 4 to 7.5 cm (1.6 to 3 inches). Rule of thumb is to insert catheter distance from tip of nose (or mouth) to angle of mandible.
 (i) Apply intermittent suction for no more than 15 seconds by placing and releasing nondominant thumb over catheter vent. Slowly withdraw catheter while rotating it back and forth between thumb and forefinger.

Ensures that catheter tip reaches pharynx for suctioning.

Intermittent suction removes pharyngeal secretions.

STEP 4a(2) Pouring sterile saline into tray.

STEP 6 Attaching catheter to suction.

STEP

RATIONALE

(b) *Nasotracheal* (without applying suction): In adults insert catheter about 20 cm (8 inches); in older children about 16 to 20 cm (6 to 8 inches); and in young children and infants, 8 to 14 cm (3 to 5½ inches).

Ensures that catheter tip reaches trachea.

Clinical Decision Point When using the nasal approach, perform tracheal suctioning before pharyngeal suctioning whenever possible. The mouth and pharynx contain more bacteria than the trachea. If copious oral secretions are present before beginning the procedure, suction mouth with oral suction device first.

Clinical Decision Point When there is difficulty passing the catheter, ask patient to cough or say “ahh” or try to advance the catheter during inspiration. Both measures help to open the glottis to permit passage of the catheter into the trachea.

(i) Apply intermittent or continuous suction for no more than 10 seconds by placing non-dominant thumb over vent of catheter and slowly withdrawing catheter while rotating it back and forth between dominant thumb and forefinger. Encourage patient to cough. Replace oxygen device, if applicable, and have patient deep breathe.

Both intermittent and continuous suction can cause tracheal tissue damage (Lynn-McHale Wiegand, 2011; Pederson et al., 2009). Suctioning longer than 10 seconds causes cardiopulmonary compromise, usually from hypoxemia or vagal overload (AARC, 2010).

(4) Positioning: In some instances turning patient’s head helps you suction more effectively. If you feel resistance after insertion of catheter, use caution; it has probably hit carina. Pull catheter back 1 to 2 cm (0.4 to 0.8 inches) before applying suction (AARC, 2004).

Turning patient’s head to side elevates bronchial passage on opposite side. Turning head to right helps with suctioning of left main-stem bronchus; turning head to left helps you suction right main-stem bronchus. Suctioning too deep may cause tracheal mucosa trauma.

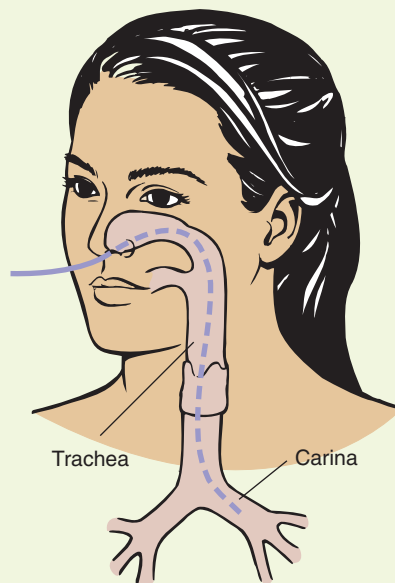

Clinical Decision Point Monitor patient’s vital signs and oxygen saturation throughout suction procedure. If the patient’s pulse drops more than 20 beats/min or increases more than 40 beats/min or if SpO₂ falls below 90% or 5% from baseline, stop suctioning.

(5) Rinse catheter and connecting tubing with normal saline or water until cleared.

Secretions that remain in suction catheter or connecting tubing decrease suctioning efficiency.

(6) Assess for need to repeat suctioning procedure. Do not perform more than two passes with catheter. Observe for alterations in cardiopulmonary status. When possible, allow adequate time (at least 1 minute) between suction passes for ventilation and oxygenation. Encourage patient to deep breathe with oxygen mask in place (if ordered) and cough.

Suctioning can induce hypoxemia, dysrhythmias, laryngospasm, and bronchospasm. Deep breathing ventilates and reoxygenates alveoli. Repeated passes clear airway of excessive secretions but can also remove oxygen and may induce laryngospasm (Higgins, 2009a).

STEP 8a(3) Pathway for nasotracheal catheter progression.

STEP

RATIONALE

b Artificial airway suctioning:

- (1) Hyperoxygenate patient with 100% oxygen for 30 to 60 seconds before suctioning by adjusting fractional inspired oxygen (FiO_2) setting on a mechanical ventilator or using an oxygen-enrichment program on microprocessor ventilators (AARC, 2010). Manual ventilation of a patient is not recommended; it is ineffective for providing FiO_2 of 1.0 (AARC, 2010).
- Preoxygenation converts large proportion of resident lung gas to 100% oxygen to offset amount used in metabolic consumption while ventilation or oxygenation is interrupted and volume is lost during suctioning (Lewis et al., 2011; Pedersen et al., 2009).

Clinical Decision Point Suctioning can cause elevations in intracranial pressure (ICP) in patients with head injuries. Reduce this risk by presuction hyperoxygenation, which results in hypocarbia, which in turn induces vasoconstriction. Vasoconstriction reduces the potential for an increase in ICP. Limit suctioning to 2 times with each suctioning procedure (AARC, 2004).

- (2) If patient is receiving mechanical ventilation, open swivel adapter or, if necessary, remove oxygen or humidity delivery device with nondominant hand. Exposes artificial airway.
- (3) Without applying suction, gently but quickly insert catheter into artificial airway using dominant thumb and forefinger (it is best to try to time catheter insertion into artificial airway with inspiration) until you meet resistance or patient coughs; then pull back 1 cm (0.4 inch) (Pedersen et al., 2009). Application of suction pressure while introducing catheter into trachea increases risk for damage to tracheal mucosa and increased hypoxia. Pulling back stimulates cough and removes catheter from mucosal wall so catheter is not resting against tracheal mucosa during suctioning. Shallow suctioning is recommended to prevent tracheal mucosa trauma (AARC, 2010).

Clinical Decision Point If unable to insert catheter past the end of the ET tube, the catheter is probably caught in the Murphy eye (i.e., side hole at the distal end of the ET tube that allows for collateral airflow in the event of tracheal main-stem intubation). If this happens, rotate the catheter to reposition it away from the Murphy eye or withdraw it slightly and reinsert with the next inhalation. Usually the catheter meets resistance at the carina. One indication that the catheter is at the carina is acute onset of coughing because the carina contains many cough receptors. Pull the catheter back 1 cm (0.4 inch) (AARC, 2004).

- (4) Apply continuous suction by placing nondominant thumb over vent of catheter; slowly withdraw catheter while rotating it back and forth between dominant thumb and forefinger (see illustration). Encourage patient to cough. Watch for respiratory distress. Continuous suction and rotation of catheter are recommended because studies show that tracheal tissue damage from intermittent and continuous suctioning is similar (Pedersen et al., 2009). If catheter “grabs” mucosa, remove thumb to release suction.

Clinical Decision Point If patient develops respiratory distress during the suction procedure, immediately withdraw catheter and supply additional oxygen and breaths as needed. In an emergency, administer oxygen directly through the catheter. Disconnect suction and attach oxygen at prescribed flow rate through the catheter.

- (5) If patient is receiving mechanical ventilation, close swivel adapter or replace oxygen delivery device. Reestablishes artificial airway.

STEP 9b(4) Suctioning tracheostomy.

STEP	RATIONALE
(6) Rinse catheter and connecting tubing with normal saline until clear. Use continuous suction.	Removes catheter secretions. Secretions left in tubing decrease suctioning efficiency and provide environment for microorganism growth.
(7) Assess patient's vital signs, cardiopulmonary status, and ventilator measures for secretion clearance. Repeat Steps (1) through (6) once or twice more to clear secretions. Allow adequate time (at least 1 full minute) between suction passes.	Suctioning can induce dysrhythmias, hypoxia, and bronchospasm and impair cerebral circulation or adversely affect hemodynamic stability (Higgins, 2009a).
(8) Encourage patient to deep breathe if able. Hyperoxygenate for at least 1 minute following same technique used to preoxygenate (AARC, 2010).	Reoxygenates and reexpands alveoli. Suctioning causes hypoxemia and atelectasis. Hyperventilation should not be used routinely (AARC, 2010).
(9) When pharynx and trachea are sufficiently cleared of secretions, perform oropharyngeal suctioning to clear mouth of secretions. Do not suction nose again after suctioning mouth.	Removes upper airway secretions. More microorganisms generally are present in mouth. Upper airway is considered "clean," and lower airway is considered "sterile." You can use same catheter to suction from sterile to clean areas (e.g., tracheal suctioning to oropharyngeal suctioning) but not from clean to sterile areas. Seals contaminants in gloves. Reduces transmission of microorganisms (Higgins, 2009a).
9 When suctioning is complete, disconnect catheter from connecting tubing. Roll catheter around fingers of dominant hand. Pull glove off inside out so catheter remains coiled in glove. Pull off other glove over first glove in same way. Discard in appropriate receptacle. Turn off suction device.	Reduces transmission of microorganisms. Promotes comfort.
10 Remove towel, place in laundry or appropriate receptacle, and reposition patient. (Apply clean gloves to continue personal care.)	Prevents absorption atelectasis (i.e., tendency for airways to collapse if proximally obstructed by secretions). Prevents oxygen toxicity while allowing patient time to reoxygenate blood.
11 If indicated, readjust oxygen to original level because patient's blood oxygen level should have returned to baseline.	Reduces transmission of microorganisms.
12 Discard remainder of normal saline into appropriate receptacle. If basin is disposable, discard into appropriate receptacle. If basin is reusable, rinse it out and place it in soiled utility room.	Reduces transmission of microorganisms.
13 Remove face shield and discard into appropriate receptacle. Perform hand hygiene.	Provides immediate access to suction catheter for next procedure.
14 Place unopened suction kit on suction machine table or at head of bed.	
15 Help patient to a comfortable position and provide oral hygiene as needed.	

EVALUATION

1 Compare patient's vital signs, cardiopulmonary assessments, and SpO ₂ values before and after suctioning. If on ventilator, compare FiO ₂ and tidal volumes.	Identifies physiologic effects of suction procedure to restore airway patency.
2 Ask patient if breathing is easier and if congestion is decreased.	Provides subjective confirmation that suctioning procedure has relieved airway.
3 Observe character of airway secretions.	Provides data to document presence or absence of respiratory tract infection or thickened secretions.

Unexpected Outcomes

- 1 Patient's respiratory status does not improve.
- 2 Bloody secretions are returned after suctioning.
- 3 Unable to pass suction catheter through naris at first attempt.
- 4 Patient has paroxysms of coughing.
- 5 No secretions obtained during suctioning.

Related Interventions

- Limit length of suctioning.
- Determine need for more frequent suctioning, possibly of shorter duration.
- Determine need for supplemental oxygen. Supply oxygen between suctioning passes.
- Notify health care provider.
- Determine amount of suction pressure used. May need to be decreased.
- Ensure that suction is completed correctly using intermittent suction and catheter rotation.
- Evaluate suctioning frequency.
- Provide more frequent oral hygiene.
- Try other naris or oral route.
- Increase lubrication of catheter.
- Insert nasal airway, especially if suctioning through patient's nares frequently.
- If obstruction is mucus, apply suction to relieve obstruction but not to mucosa. If you think obstruction is a blood clot, consult with health care provider.
- Administer supplemental oxygen.
- Allow patient to rest between passes of suction catheter.
- Consult with health care provider regarding need for inhaled bronchodilators or topical anesthetics.
- Evaluate patient's fluid status and adequacy of humidification on oxygen delivery device.
- Assess for signs of infection.
- Determine need for chest physiotherapy (see [Chapter 24](#)).

Recording and Reporting

- Record the amount, consistency, color, and odor of secretions; size of catheter; route of suctioning; and patient's response to suctioning.
- Document patient's presuctioning and postsuctioning vital signs, cardiopulmonary status, and ventilation measures (see [Chapter 6](#)).

Special Considerations**Teaching**

- Instruct patient that coughing increases during the procedure.
- Explain why supplemental oxygen is given before and after suctioning if indicated.

Pediatric

- Small-diameter suction catheters required in pediatrics should be half the diameter of the child's TT ([Gardner and Shirland, 2009](#); [Hockenberry and Wilson, 2011](#)).
- Hyperoxygenate with 100% oxygen in pediatric patients and 10% increase of baseline in neonates before suctioning ([AARC, 2010](#)).
- Perform ET suctioning only when clinically indicated in infants and neonates. Clinical signs are notable changes in respiratory rate and breath sounds, increased secretions, bradycardia, or restlessness ([Gardner and Shirland, 2009](#)).
- Thick secretions are more difficult to remove because of small diameter of suction catheter.
- Make sure that distance suctioned is not greater than 0.5 cm (0.2 inches) beyond the tip of the artificial airway. To determine

distance, place catheter near a sample artificial airway ([Hockenberry and Wilson, 2011](#)).

- Infant airways have less cartilage and may collapse easily, especially in premature infants or those with reactive airways.
- Suctioning should not last beyond 5 seconds ([Hockenberry and Wilson, 2011](#)), and negative pressure should not exceed 100 mm Hg ([AARC, 2010](#); [Gardner and Shirland, 2009](#)).

Gerontologic

- Older adults lose some properties of elastic recoil and gas exchange.
- Capillaries of older adults are often fragile, predisposing patient to bleeding problems.
- Patients with coronary artery disease are at greater risk for cardiopulmonary compromise.

Home Care

- Although most patients with airway clearance problems at home have a tracheostomy, some require nasal pharyngeal suctioning. Catheters are often used for a 24-hour period and then cleaned and disinfected; or they are cleaned with soapy water after each use and discarded after 24 hours.
- Instruct patient and family caregiver to clean and disinfect or change the secretion collection container every 24 hours according to home care or agency protocol.
- In the home setting stress the importance of brief intervals of applying suction pressure. Instruct those performing suctioning to hold their breath during the application of negative suction pressure to help them remember to not suction too long.

PROCEDURAL GUIDELINE 25-1 Closed (In-Line) Suction

NSO Airway Management Module / Lesson 6

Delegation and Collaboration

The skill of airway suction with a closed (in-line) suction catheter cannot be delegated to nursing assistive personnel (NAP). In special situations such as suctioning a permanent tracheostomy, this procedure may be delegated to NAP. The nurse is responsible for cardiopulmonary assessment and evaluation of patient. The nurse directs the NAP about:

- Any individualized aspects of patient care that pertain to suctioning (e.g., position, duration of suction, pressure settings).
- Expected quality, quantity, and color of secretions and to inform the nurse immediately if there are changes.
- Patient's anticipated response to suction and to immediately report to the nurse changes in vital signs, complaints of pain, shortness of breath, confusion, or increased restlessness.

Equipment

- Closed-system or in-line suction catheter
- Suction machine
- Connecting tubing (6 feet)
- Two clean gloves (*optional*)
- Mask, goggles, or face shield
- Pulse oximeter and stethoscope

Procedural Steps

- 1 Perform assessment as in Skill 25-2.
- 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.
- 3 Explain the procedure to patient and the importance of coughing during the suctioning procedure. Even if patients cannot speak, they deserve to have information regarding the procedure.
- 4 Help patient assume a position of comfort for both patient and nurse, usually semi- or high-Fowler's position. Place towel across patient's chest.
- 5 Perform hand hygiene, apply clean gloves and face shield, and attach suction.
 - a In many agencies a respiratory therapist attaches the catheter to the mechanical ventilator circuit. If catheter is not already in place, open suction catheter package using aseptic technique and attach closed suction catheter to ventilator circuit by removing swivel adapter and placing closed suction catheter apparatus on ET or TT. Connect Y on mechanical ventilator circuit to closed suction catheter with flex tubing (see illustrations A and B).
 - b Connect one end of connecting tubing to suction machine; connect other end to the end of a closed-system or in-line suction catheter. Turn suction device on, set vacuum regulator to appropriate negative pressure, and check pressure. Many closed-system suction catheters require slightly higher suction pressures (consult manufacturer guidelines).
- 6 Hyperoxygenate patient (usually 100% oxygen) by adjusting the FiO₂ setting on the ventilator or by using a temporary oxygen-enrichment program available on microprocessor

ventilators (AARC, 2010). Manual ventilation is not recommended.

- 7 Pick up suction catheter enclosed in plastic sleeve with dominant hand.
- 8 Wait until patient inhales to insert catheter. Use a repeating maneuver of pushing catheter and sliding (or pulling) plastic sleeve back between thumb and forefinger until resistance is felt or patient coughs. Pull back 1 cm (0.5 inches) before applying suction to avoid tissue damage to carina.
- 9 Encourage patient to cough and apply suction by squeezing on suction control mechanism while withdrawing catheter. Apply continuous suction for no longer than 10 seconds as you remove the suction catheter. Be sure to withdraw catheter completely into plastic sheath so it does not obstruct airflow.
- 10 Reassess cardiopulmonary status, including pulse oximetry and ventilator measures, to determine need for subsequent suctioning or complications. Repeat Steps 5 to 9 one more time to clear secretions. Allow adequate time (at least 1 full minute) between suction passes for ventilation and reoxygenation.
- 11 When airway is clear, withdraw catheter completely into sheath. Be sure that colored indicator line on catheter is visible in the sheath. Squeeze vial or push syringe while applying suction to rinse inner lumen of catheter. Use at least 5- to 10-mL of saline to rinse the catheter until it is clear of retained

STEP 5a **A**, Closed-system suction catheter attached to endotracheal tube. **B**, Suctioning tracheostomy with closed-system suction catheter.

PROCEDURAL GUIDELINE 25-1 Closed (In-Line) Suction—cont'd

secretions, which can cause bacterial growth and increase the risk for infection. Lock suction mechanism if applicable and turn off suction.

- 12 Hyperoxygenate for at least 1 minute by following the same technique used to preoxygenate (AARC, 2010).
- 13 If patient requires oral or nasal suctioning, perform Skill 25-1 or 25-2 with separate standard suction catheter.
- 14 Reposition patient. Remove gloves and face shield, discard into appropriate receptacle, and perform hand hygiene.

- 15 Compare patient's respiratory assessments before and after suctioning, observe airway secretions, and document findings.

Clinical Decision Point *Based on research, closed (in-line) suctioning does not decrease the risk of ventilator-associated pneumonia (VAP) when compared to open suctioning (Jongerden et al., 2011; Subirana et al., 2010).*

SKILL 25-3 Performing Endotracheal Tube Care**NSO** Airway Management Module / Lesson 7

Endotracheal (ET) tubes are flexible, plastic tubes placed in the mouth or through the nose and advanced down into the trachea to establish short-term artificial airways to administer mechanical ventilation, relieve upper airway obstruction, protect against aspiration, and clear secretions. Routine care maintains correct position of the tube and good hygiene.

After insertion of an ET tube, the cuff is inflated. Preventing cuff-related problems is a critical component of nursing care and depends on securing the tube and inflating the cuff properly. In many agencies these functions are shared by nursing and respiratory therapy staff. Allowing an ET tube to slip lower into the airway can prevent ventilation of a lung, usually the left lung. Allowing it to slide too far up the tracheobronchial tree can allow air to escape through or damage the vocal cords. Properly securing an ET tube prevents incidental extubation from coughing or pulling on the tube. Additional risks of movement of an artificial airway are tracheal stenosis, tracheomalacia, erosion of the innominate artery, and tracheoesophageal fistula, particularly when the cuff is overinflated. Proper nursing care reduces risks for each of these complications (Stonecypher, 2010).

Once a tube is inserted, confirmation of placement is achieved using a chest x-ray film or capnography. Capnography is the non-invasive measurement of the partial pressure of carbon dioxide (CO₂) in exhaled breath expressed as the CO₂ concentration over time. It is recommended as a reliable way to validate the correct placement of an ET tube (AARC, 2011). The carbon dioxide monitor measures CO₂ directly from the airway, with the sensor located on the airway adapter at the hub of the ET.

After a tube is inserted and secured and the cuff is inflated (see Skill 25-5), your chief concern is to maintain patency of the ET tube. In patients who cannot clear their secretions, periodic suctioning of the artificial airway achieves airway patency.

Ventilator-associated pneumonia (VAP) occurred in 10% to 20% of ventilated patients who ventilated for more than 2 days (Browne et al., 2011; Scherzer, 2010). VAP causes 90% of health care-acquired infections in ventilated patients and causes an increase in hospital length of stay by 5 to 7 days and a 50% higher mortality rate (Oleska & Muscedere, 2011; Scherzer, 2010). VAP is defined as developing after 48 hours following intubation (Niël-Weise et al., 2011). Best-practice guidelines indicate that the following interventions are advantageous in preventing VAP:

- Elevate the head of the bed at 30 to 45 degrees to prevent aspiration (Selvaraj, 2010; Stonecypher, 2010).
- Change patient position every 2 hours to decrease risk for atelectasis, pulmonary infections, pressure ulcers, discomfort, and urinary stasis (Winkelman and Chiang, 2010).
- Provide oral care with chlorhexidine by swab every 8 hours. If chlorhexidine is contraindicated, a toothbrush can be used to remove dental plaque organisms. Toothettes are not adequate to clean the dental plaque, but they may be used between brushing for comfort (Ames, 2011; Browne et al., 2011; Rewa and Muscedere, 2011).
- Maintain the ET cuff pressures at 20 cm H₂O to decrease movement of secretions to the lower airways (Stonecypher, 2010).
- Carefully monitor patient for aspiration when enteral feedings are infusing.
- Change ventilator circuits every 48 hours because of potential bacteria within tubing condensation (Stonecypher, 2010).
- Remove subglottal secretions every 4 to 6 hours or before position changes (Browne et al., 2011; Scherzer, 2010; Stonecypher, 2010).

Delegation and Collaboration

This skill of performing ET care cannot be delegated to nursing assistive personnel (NAP). NAP may assist the nurse with ET care. The nurse directs the NAP to:

- Immediately report any signs of respiratory problems or increased airway secretions.
- Immediately report if the ET tube appears to have moved or become obstructed or dislodged.
- Immediately report changes in patient's mood, level of consciousness, irritability, vital signs, or decreased pulse oximetry value.

Equipment

- Towel
- ET and oropharyngeal suction equipment
- 1- or 1½-inch-wide adhesive or waterproof tape (do not use paper or silk tape) or commercial ET tube holder and mouth guard (follow manufacturer instructions for securing)
- Clean gloves (two pairs)
- Adhesive remover swab or acetone on cotton ball
- Chlorhexidine swabs, nonalcohol mouthwash or toothpaste
- Toothbrush, toothette, and shaving supplies

- One wet and one soapy washcloth or paper towels
- Clean 2 × 2-inch gauze
- Tincture of benzoin, liquid adhesive, or skin preparation pads
- Tongue blade (*optional*)
- Mask, goggles, face shield (if indicated)
- Stethoscope

STEP

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <p>1 Auscultate lungs and observe respiratory rate and depth.</p> <p>2 Observe for soiled or loose tape; pressure sore on nares, lips, or corner of mouth; excess nasal or oral secretions; patient moving tube with tongue, biting tube or tongue; tube repositioned by health care provider or other specially trained personnel; foul-smelling mouth.</p> <p>3 Observe for factors that increase risk for complications from ET tube: type and size of tube, movement of tube up and down trachea (in and out), cuff overinflation or underinflation, duration of tube placement, presence of facial trauma, malnutrition, and neck or thoracic radiation.</p> <p>4 Determine proper ET tube depth as noted by centimeters at lip or gum line. This line is marked on tube and recorded in patient's record at time of intubation.</p> <p>5 Assess patient's knowledge of procedure.</p> | <p>Provides baseline measure of ventilation.</p> <p>Presence of ET tube impairs ability of patient to swallow oral secretions. Patient is at increased risk for developing pressure areas from impaired circulation as tube is pulled or pressed against mucosal tissues.</p> <p>Tube rotating from side to side can cause pressure sores. Tube moving up and down trachea predisposes patient to develop tracheoesophageal fistula or tracheomalacia. Tube can become dislodged from lower airway (incidental extubation), or it can enter main-stem bronchus. Cuff underinflation increases risk for aspiration, whereas overinflation may cause ischemia or necrosis of tracheal tissue from obstruction of capillary bed. Patient can “tongue” oral tube easily and dislodge it. Longer duration of intubation is associated with increased risk for lower airway complications, as in facial trauma.</p> <p>Ensures that tube is proper depth to adequately ventilate both lungs and that it is not too high, which causes vocal cord damage, or too low, which results in right main-stem intubation, in which only the right lung is ventilated.</p> <p>Encourages cooperation, minimizes risks and anxiety. Identifies teaching needs.</p> |

|---|--|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • ET tube remains in correct position in patient's trachea evidenced by depth of tube same as when started or as ordered (same centimeter marking at gums or lips); bilateral breath sounds are equal. • Patient's skin around mouth and oral mucous membranes does not have pressure areas or other injury from biting. <p>2 Explain procedure and patient's need to participate, including not biting or moving ET tube with tongue; trying not to cough when tape is off ET tube; keeping hands down and not pulling on tubing.</p> | <p>Maintaining ET position promotes adequate ventilation of lungs. Complications of lower airway and vocal cord trauma prevented.</p> <p>ET tube does not place undue pressure against corners of mouth, causing pressure area. Patient is not able to bite inner cheeks or tongue.</p> <p>Reduces anxiety, encourages cooperation, and reduces risks.</p> |
|---|--|

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Perform hand hygiene. Apply clean gloves and mask, goggles, or face shield if indicated.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Reduces transmission of microorganisms.</p> |
|---|--|

STEP	RATIONALE
<p>3 Administer endotracheal, nasopharyngeal, or oropharyngeal suction (see Skills 25-1 and 25-2 and Procedural Guideline 25-1).</p>	<p>Removes secretions. Diminishes patient's need to cough during procedure.</p>
<p>4 Connect oral suction catheter to suction source. Help patient to comfortable position.</p>	<p>Prepares patient for oropharyngeal suctioning.</p>
<p>5 Prepare securement option:</p> <p>a <i>Tape method:</i> Cut piece of tape long enough to go completely around patient's head from naris to naris plus 15 cm (6 inches): adult, 30 to 60 cm (12 to 24 inches). Lay tape adhesive-side up on bedside table. Cut and lay 8 to 15 cm (3 to 6 inches) of second piece of tape, adhesive sides together, in center of the long strip to prevent tape from sticking to hair. Smaller strip of tape should cover area between ears around back of head.</p>	<p>Preparing tape ahead allows you to have one hand positioned on ET tube throughout procedure. Adhesive tape needs to encircle head below ears with sufficient tape left to wrap around tube.</p>
<p>b <i>Commercially available ET tube holder:</i> Open package per manufacturer instructions. Set device aside with head guard in place and Velcro strips open.</p>	<p>Commercial devices are latex free, fast, and convenient. These devices avoid need for tape and resultant skin breakdown and are easily applied in presence of facial hair.</p>
<p>6 Instruct assistant to apply pair of gloves and hold ET tube firmly at patient's lips or nares. Note number marking on ET tube at gum line or lips.</p>	<p>Reduces transmission of microorganisms. Maintains proper tube position and prevents incidental extubation.</p>
<p>Clinical Decision Point Do not allow assistant to hold the tube away from the lips or nares. Doing so allows too much "play" in the tube and increases the risk for tube movement and accidental extubation. Never let go of the ET tube because it could become dislodged.</p>	
<p>7 Remove old tape or device.</p> <p>a <i>Tape:</i> Carefully remove tape from ET tube and patient's face. If tape is difficult to remove, moisten with (soapy) wet washcloth, water, or adhesive tape remover. Discard tape in appropriate receptacle if nearby.</p>	<p>Provides access to skin under tape for assessment and hygiene. Reduces transmission of microorganisms.</p>
<p>b <i>Commercially available device:</i> Remove Velcro strips from ET tube and remove ET tube holder from patient.</p>	<p>Velcro adhesive strips hold ET tube in place and provide marker to measure distance to patient's lips or gums. These devices all permit access to patient's mouth and lips for ease in oropharyngeal suctioning and oral hygiene.</p>
<p>8 Remove any secretions or adhesive from patient's face.</p> <p>a Use adhesive remover swab to remove excess adhesive left on face after tape removal. Wash adhesive remover from face.</p>	<p>Promotes hygiene. Adhesive causes damage to skin. Prevents poor adhesion of new tape.</p>
<p>9 Remove oral airway or bite block, if present, and place on towel.</p>	<p>Provides access to and complete observation of patient's oral cavity.</p>
<p>Clinical Decision Point Do not remove oral airway if patient is actively biting ET tube. Wait until tape is partially or completely secured to ET tube.</p>	
<p>10 Clean mouth, gums, and teeth opposite ET tube with 5 mL of 0.12% chlorhexidine swabs every 8 hours unless contraindicated; brush teeth thoroughly and rinse with nonalcohol mouthwash. Administer oropharyngeal suctioning with Yankauer suction catheter during brushing and rinsing.</p>	<p>Promotes hygiene and reduces risk for VAP. Chlorhexidine swabs provide oral decontamination associated with lower risk of VAP (Browne et al., 2011). Alcohol-based mouthwashes dry oral mucosa (Lewis et al., 2011). Suctioning removes pooled secretions.</p>
<p>11 <i>Oral ET tube only:</i> Remembering "cm" ET tube marking at level of gums or lips, with help of assistant move ET tube to opposite side or center of mouth. Do not change tube depth. Reposition tube on opposite side or center of mouth at least every 24 to 48 hours according to agency protocol (oral ET tube only).</p>	<p>Prevents formation of pressure sores at sides of patient's mouth. Ensures correct position of tube. Measuring tube at lip line can be distorted from edema, trauma, or disease process.</p>
<p>12 Repeat oral cleaning as in Step 10 on opposite side of mouth.</p>	<p>Removes secretions from mouth and oral pharynx.</p>
<p>13 Clean face and neck with soapy washcloth, rinse, and dry. Shave male patient as necessary.</p>	<p>Moisture and beard growth prevent adhesive tape adherence.</p>
<p>14 Pour small amount of skin protectant or liquid adhesive on clean 2 × 2-inch gauze and dot on upper lip (oral ET tube) or across nose (nasal ET tube) and cheeks to ear. Allow to dry completely.</p>	<p>Protects skin from tape burns and makes more adherent.</p>

STEP

RATIONALE

15 Secure ET tube.

a Tape method:

- (1) Slip tape under patient's head and neck, adhesive side up. Take care not to twist tape or catch hair. Do not allow tape to stick to itself. It helps to gently stick end of tape to tongue blade, which serves as guide. Then slide tongue blade under patient's neck. Center tape so double-faced tape extends around back of neck from ear to ear.
- (2) On one side of face secure tape from ear to nares (nasal ET tube) or over lip to ET tube (oral ET tube). Tear remaining tape in half lengthwise, forming two pieces that are 2 cm (0.8 inch) wide. Secure bottom half of tape across upper lip (oral ET tube) or across top of nose (nasal ET tube) to opposite ear (see illustration A). Wrap top half of tape around tube and up from bottom (see illustration B). Tape should encircle tube at least 2 times for security.
- (3) Gently pull other side of tape firmly to pick up slack and secure to opposite side of face and ET tube same as first piece (see illustration). **NOTE:** ET tube is secured. Assistant can release hold. (You may want assistant to help reinsert oral airway.)

Positions tape to secure ET tube in proper position.

Secures tape to face. Using top tape to wrap prevents downward drag on ET tube.

Secures tape to face and tube. ET tube should be at same depth at lips or gum line. Check earlier assessment for verification of tube depth in centimeters.

STEP 15a(2) A, Securing bottom half of tape across patient's upper lip. B, Securing top half of tape around tube.

STEP 15a(3) Tape securing endotracheal tube.

STEP

RATIONALE

b Commercially available device:

- | | |
|---|---|
| <ul style="list-style-type: none"> (1) Thread ET tube through opening designed to secure it. Be sure that pilot balloon is accessible. (2) Place strips of ET holder under patient at occipital region of head. (3) Verify that ET tube is at established depth using lip or gum line marker as guide. (4) Attach Velcro strips at base of patient's head. Leave 1 cm (0.5 inch) slack in strips (see illustration). (5) Verify that tube is secure, it does not move forward from patient's mouth or backward down into patient's throat, and there are no pressure areas on oral mucosa or occipital region of head. | <p>Commercially available holders have a slit in front of holder designed to secure ET tube.</p> |
| <p>16 Remove and clean oral airway in warm soapy water and rinse well. Half hydrogen peroxide and half normal saline solution aids in removal of crusted secretions. Nonalcohol mouthwash freshens patient's mouth. Shake excess water from oral airway. Be sure to rinse hydrogen peroxide mixture from airway.</p> | <p>Ensures that ET tube remains at correct depth as determined during assessment.</p> |
| <p>17 Reinsert oral airway without pushing tongue into oropharynx and secure with tape (see Chapter 27).</p> | <p>Tube must be secure so it remains at correct depth. It can be secured without being tight and causing pressure.</p> |
| <p>18 Discard soiled items in appropriate receptacle. Remove towel and place in laundry.</p> | <p>Promotes hygiene. Reduces transmission of microorganisms.</p> |
| <p>19 Reposition patient.</p> | <p>Prevents patient from biting ET tube and allows access for oropharyngeal suctioning.</p> |
| <p>20 Remove gloves and mask, goggles, or face shield; discard in receptacle; and perform hand hygiene. (Assistant performs same steps.) Place clean items (e.g., tincture of benzoin, mouthwash, excess swabs) in place of storage.</p> | <p>Reduces transmission of microorganisms. Reduces transmission of microorganisms. Ensures that contaminated gloves and hands do not touch clean items.</p> |

STEP 15b(4) Endotracheal tube holder in place with pilot balloon accessible and Velcro strips secured. (Courtesy Dale Medical Products, Plainville, Mass.)

EVALUATION

- | | |
|---|---|
| <p>1 Compare respiratory assessments before and after ET tube care.</p> | <p>Identifies any changes in presence and quality of breath sounds after procedure.</p> |
| <p>2 Observe depth and position of ET tube according to health care provider recommendation.</p> | <p>Position of ET tube should not be altered.</p> |
| <p>3 Assess security of tape by gently tugging at tube.</p> | <p>Tape should remain attached to face. Patient may cough during tugging.</p> |
| <p>4 Assess skin around mouth and oral mucous membranes for intactness and pressure sores.</p> | <p>Tape should not tear skin. Pressure areas should be absent.</p> |

Unexpected Outcomes

- 1 Patient is accidentally extubated.
- 2 ET tube moves in airway.
- 3 Patient has unequal breath sounds.
- 4 Patient has pressure sores from tube.
- 5 Air escapes around tube.

Related Interventions

- Remain with patient while calling for assistance.
- Ventilate with bag-valve-mask as needed.
- Assess patient for airway patency, spontaneous breathing, and vital signs.
- Prepare for reintubation.
- Repeat taping or securing procedure.
- In very active patients without facial injury who are at risk for self-extubation, consider applying second piece of tape around back of head.
- Evaluate ET tube for proper depth before and after tube care. If it is deeper or shallower, notify health care provider, who may order a chest x-ray film. Then reposition tube only if allowed by agency and you have received appropriate instructions.
- Suction patient.
- Increase frequency of ET tube care.
- Apply antimicrobial ointment per agency protocol.
- Align oxygen and humidity supply tubing so they do not pull ET tube, creating pressure sores.
- Monitor for infection. If skin tear is present on cheeks or over nose or upper lip, apply protective barrier such as stoma adhesive patch or hydrocolloid dressing and apply tape to this.
- Verify position of tube and check for proper cuff inflation. If tube position is incorrect, reposition according to protocol or notify health care provider (see Skill 25-5).

Recording and Reporting

- Document respiratory assessments before and after care, patient's tolerance of procedure, ordered and actual depth of ET tube, frequency of ET tube care, integrity of oral and nasal mucosa, pressure sore care, and frequency and extent of ET tube care.
- Report unequal breath sounds, accidental extubation, or respiratory distress to the health care provider.

Special Considerations

Teaching

- Instruct patient and family caregivers not to manipulate the ET tube, tape, or ET tube holder. If patient is complaining or appears uncomfortable, instruct family caregiver to ask for the nurse.

- Instruct patient and family caregiver to inform the nurse if the tube causes gagging. Repositioning of the tube and/or sedation are options for reducing gagging.

Pediatric

- Neonatal and pediatric procedures for securing ET tubes and suctioning airways vary (Hockenberry and Wilson, 2011).
- Infant skin is more prone to tearing when removing tape (Hockenberry and Wilson, 2011).
- Because of infants' delicate skin, you will not always use skin preparation before securing ET tube. ET tube holders are best used in this population.

Gerontologic

- Older adult skin is more prone to tearing when removing tape.
- Older adults with tendency toward inadequate nutrition are more prone to complications (e.g., infection, breakdown of oral mucosa).

SKILL 25-4 Performing Tracheostomy Care

NSO Airway Management Module / Lesson 8

A tracheostomy is a 51- to 76-mm (2- to 3-inch) curved metal or plastic tube inserted into a stoma through the neck and into the trachea to maintain a patent airway. It is placed in patients who require long-term airway management because of airway obstruction, airway clearance needs, and long-term intubation (Regan and Dallachiesa, 2009). A tracheostomy offers advantages over long-term endotracheal (ET) tube placement such as decreased laryngeal and tracheal tissue injury, ease of breathing, and access for better oral hygiene (White et al., 2010). Some patients with a tracheostomy tube are able to cough secretions out of the tube completely, whereas others are only able to cough secretions up into it.

A tracheostomy tube has a flange that fits against a patient's neck and an outer cannula or primary airway. It may have a removable inner cannula for cleaning and an inflatable cuff that

surrounds the outer cannula (Fig. 25-3, A). An inflation tube and valve connect to the cuff for inflation. The pilot balloon expands and contracts on inflation and deflation. An inflated cuff keeps the tube stable within the trachea.

Standards for care include properly securing the tube, inflating the cuff to an appropriate pressure, maintaining patency by suctioning, and providing oral hygiene. A tracheostomy tube can cause granulation tissue to form on the vocal cords, epiglottis, or trachea secondary to inappropriate cuff inflation. (See Cuff inflation in Skill 25-5.)

An intubated patient is unable to speak because of placement of a tracheostomy tube which prevents normal airflow over and vibration of the vocal cords. Use verbal and nonverbal communication skills when you care for an intubated patient. Alphabet

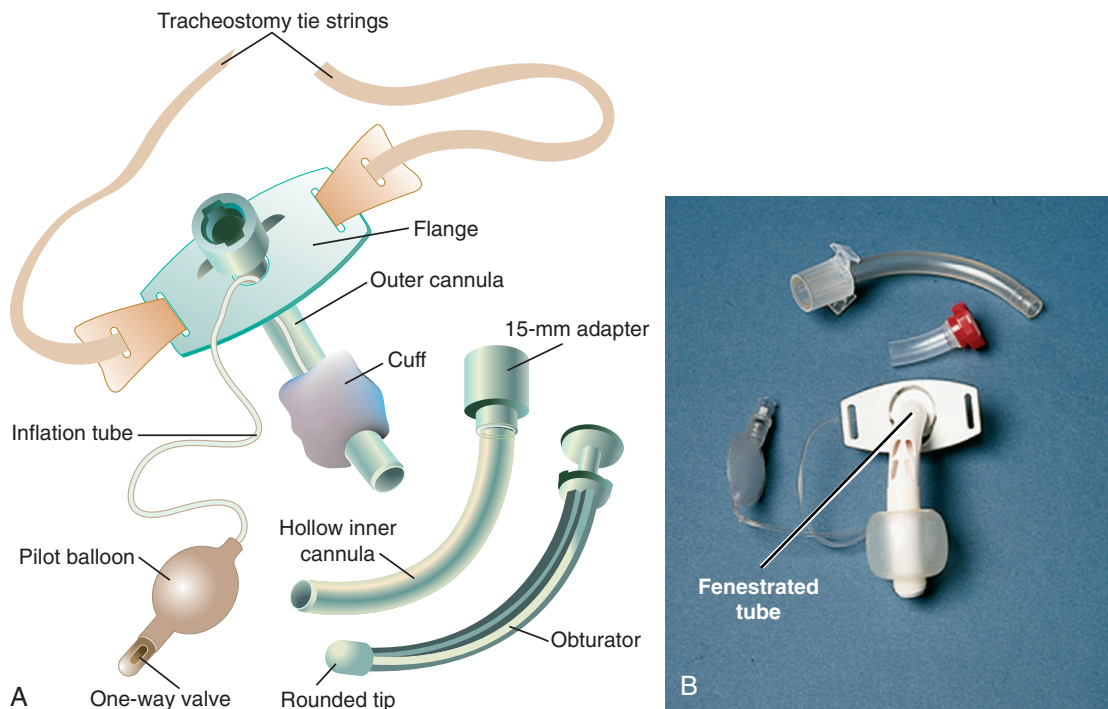

FIG 25-3 A, Parts of tracheostomy tube. B, Fenestrated tracheostomy tube with cuff, inner cannula, decannulation plug, and pilot balloon. (From Lewis SL: Medical-surgical nursing: assessment and management of clinical problems, ed 8, St Louis, 2011, Mosby.)

charts, pen and paper, slates or chalkboards, or magnetic pen doodle boards are some common communication tools. You may place a speaking valve over some tracheostomy tubes, which allows a patient to speak (Regan and Dallachiesa, 2009). One type of tracheostomy tube is fenestrated, which means that the outer cannula has precut openings (see Fig. 25-3, B). When the inner cannula is removed and the cuff is deflated, patients can speak. A speech pathologist must evaluate patients for aspiration risk before cuff deflation and inner cannula removal.

Delegation and Collaboration

The skill of performing tracheostomy care is not routinely delegated to nursing assistive personnel (NAP). In some settings patients who have well-established tracheostomy tubes may have the care delegated to NAP. The nurse is responsible for assessing a patient and evaluating for proper artificial airway care. The nurse directs the NAP to:

- Immediately report any changes in patient’s respiratory status, level of consciousness, confusion, restlessness or irritability, or in level of comfort.
- Immediately report any dislodgement or excessive movement of the tracheostomy tube.

- Immediately report abnormal color of the tracheal stoma and drainage.

Equipment

- Bedside table
- Towel
- Tracheostomy suction supplies (see Skill 25-2)
- Sterile tracheostomy care kit, if available (be sure to collect supplies listed that are not available in kit), or two sterile 4 × 4-inch gauze pads
 - Sterile cotton-tipped applicators
 - Sterile tracheostomy dressing (precut and sewn surgical dressing)
 - Sterile basin
 - Normal saline
 - Small sterile brush (pipe cleaner) (or disposable inner cannula)
 - Roll of twill tape, tracheostomy ties, or tracheostomy holder
 - Scissors
- Pulse oximeter
- Clean gloves (two pair)
- Mask, goggles, or face shield

STEPS

RATIONALE

ASSESSMENT

- 1 Observe for excess peristomal secretions, excess intratracheal secretions, soiled or damp tracheostomy ties, soiled or damp tracheostomy dressing, diminished airflow through tracheostomy tube, or signs and symptoms of airway obstruction requiring suctioning (see Skill 25-2).

Indicate need for tracheostomy care caused by presence of secretions at stoma site or within tracheostomy tube.

STEPS	RATIONALE
2 Assess patient's hydration status, humidity delivered to airway, status of existing infection, patient's nutritional status, and ability to cough.	Determines factors that affect amount and consistency of secretions in tracheostomy and patient's ability to clear airway.
3 Assess vital signs, oxygen saturation, lung sounds, and patient's ability to clear airway.	Provides baseline to determine patient response to therapy.
4 Assess patient's understanding of and ability to perform own tracheostomy care.	Allows you to identify potential need for instruction.
5 Check when tracheostomy care was last performed.	Tracheostomy care is provided at least every 4 to 8 hours and more often if indicated (e.g., increased airway or stoma secretions, infection [airway or stoma]) (Regan and Dallachiesa, 2009).

NURSING DIAGNOSES

- Deficient knowledge regarding tracheostomy care
- Impaired gas exchange
- Impaired spontaneous ventilation
- Ineffective airway clearance
- Ineffective breathing pattern
- Risk for aspiration
- Risk for impaired skin integrity
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> Inner and outer cannulas of tracheostomy tube are free of secretions; ties are clean, secured snugly, and tied in double square knot. Stoma site is pink, does not bleed, and is free of secretions and signs of infection. 	Tracheostomy tube is patent and secure, optimizing amount of oxygen delivered to patient and limiting risk of infection from retained secretions. Indicates absence of infection at stoma site. Dry, intact tracheostomy stoma reduces risk for subsequent systemic infection. Prevents accidental extubation of tracheostomy tube.
2 Have another nurse or NAP assist in this procedure (Lewis et al., 2011).	
3 Explain procedure and patient's participation.	Encourages cooperation, minimizes risks, and reduces anxiety.
4 Help patient to position comfortable for both nurse and patient (usually supine or semi-Fowler's).	Promotes patient comfort and prevents nurse muscle strain.
5 Place towel across patient's chest.	Reduces transmission of microorganisms.

IMPLEMENTATION

1 Identify patient using two identifiers (i.e. name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2 Perform hand hygiene. Apply clean gloves and face shield if applicable.	Reduces transmission of microorganisms.
3 Apply pulse oximeter sensor.	Provides monitoring for oxygen desaturation during procedure.
4 Suction tracheostomy (see Skill 25-2). Before removing gloves, remove soiled tracheostomy dressing and discard in glove with coiled catheter.	Removes secretions to avoid occluding outer cannula while inner cannula is removed. Reduces need for patient to cough.
5 Perform hand hygiene. Prepare equipment on bedside table. <ol style="list-style-type: none"> Open sterile tracheostomy kit. Open two 4 × 4-inch gauze packages using aseptic technique and pour normal saline on one package. Leave second package dry. Open two cotton-tipped swab packages and pour normal saline on one package. Do not recap normal saline. Open sterile tracheostomy dressing package. Unwrap sterile basin and pour about 0.5 to 2 cm (½ to 1 inch) of normal saline into it. Open small sterile brush package and place aseptically into sterile basin. Prepare length of twill tape long enough to go around patient's neck 2 times, about 60 to 75 cm (25 to 30 inches) for an adult. Cut ends on diagonal. Lay aside in dry area. 	Prepares equipment and allows for smooth, organized completion of tracheostomy care. Cutting ends of tie on diagonal aids in inserting tie through eyelet.

STEPS

RATIONALE

- f If using commercially available tracheostomy tube holder, open package according to manufacturer directions.
- 6 Hyperoxygenate patient using ventilator settings or by applying oxygen source loosely over tracheostomy.
- 7 Apply sterile gloves. Keep dominant hand sterile throughout procedure.

Required if patient has oxygen saturation levels below 92% (Higgins, 2009b). Helps to reduce amount of oxygen desaturation.
Reduces transmission of microorganisms.

Clinical Decision Point For tracheostomy tube with no inner cannula or Kistner button, continue with Step 9.

8 Care of tracheostomy with inner cannula:

- a While touching only outer aspect of tube, unlock and remove inner cannula with nondominant hand following line of tracheostomy. Drop inner cannula into normal saline basin.
- b Replace tracheostomy collar, T tube, or ventilator oxygen source over outer cannula. (NOTE: May not be able to attach T tube and ventilator oxygen devices to all outer cannulas when inner cannula is removed.)
- c To prevent oxygen desaturation in affected patients, quickly pick up inner cannula and use small brush to remove secretions inside and outside inner cannula (see illustration).
- d Hold inner cannula over basin and rinse with normal saline, using nondominant (clean) hand to pour normal saline.
- e Replace inner cannula (see illustration) and secure “locking” mechanism. Reapply ventilator after hyperoxygenating patient if needed.

Removes inner cannula for cleaning. Normal saline loosens secretions from inner cannula.

Maintains supply of oxygen to patient as needed.

Tracheostomy brush provides mechanical force to remove thick or dried secretions.

Removes secretions and normal saline from inner cannula.

Secures inner cannula and reestablishes oxygen supply.

9 Tracheostomy with disposable inner cannula:

- a Remove new cannula from manufacturer packaging.
- b While touching only outer aspect of tube, withdraw inner cannula and replace with new cannula. Lock into position.
- c Dispose of contaminated cannula in appropriate receptacle and reconnect to ventilator or oxygen supply.
- 10 Using normal saline-saturated cotton-tipped swabs and 4 × 4-inch gauze, clean exposed outer cannula surfaces and stoma under faceplate extending 5 to 10 cm (2 to 4 inches) in all directions from stoma (see illustration). Clean in circular motion from stoma site outward using dominant hand to handle sterile supplies.
- 11 Using dry 4 × 4-inch gauze, pat lightly at skin and exposed outer cannula surfaces.
- 12 Secure tracheostomy.

Prevents transmission of infection. Restores oxygen delivery.

Aseptically removes secretions from stoma site. Moving in outward circle pulls mucus and other contaminants from stoma to periphery.

Dry surfaces prohibit formation of moist environment for microorganism growth and skin excoriation (Higgins, 2009b).

STEP 8c Cleaning tracheostomy inner cannula.

STEP 8e Reinserting inner cannula.

STEPS

RATIONALE

a Tracheostomy tie method:

- (1) Instruct assistant, if available, to apply clean gloves and securely hold tracheostomy tube in place. With assistant holding tracheostomy tube, cut old ties.

Promotes hygiene and reduces transmission of microorganisms.
Secures tracheostomy tube to prevent incidental extubation.

Clinical Decision Point Assistant must not release hold on tracheostomy tube until new ties are firmly tied. If working without an assistant, do not cut old ties until new ties are in place and securely tied (Lewis et al., 2011).

- (2) Take prepared tie, insert one end of tie through faceplate eyelet, and pull ends even (see illustration).
- (3) Slide both ends of tie behind head and around neck to other eyelet and insert one tie through second eyelet.
- (4) Pull snugly.
- (5) Tie ends securely in double square knot, allowing space for only one loose or two snug finger widths in tie (see illustration).

Secures tracheostomy tube.

One finger width of slack prevents ties from being too tight when tracheostomy dressing is in place and also prevents movement of tracheostomy tube into lower airway (Frace, 2010).

Critical Decision Point Do not use scissors to cut gauze pads as they may shed fibers that could be inhaled by patient. Use a manufactured pad for this purpose (Frace, 2010; Higgins, 2009b).

- (6) Insert fresh 4 × 4-inch tracheostomy dressing under clean ties and faceplate (see illustration).

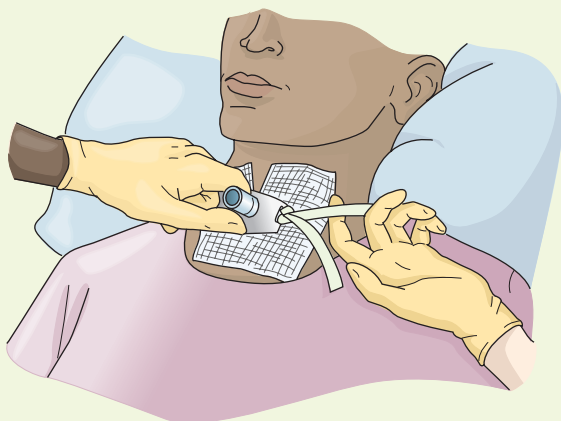

Absorbs drainage. Dressing prevents pressure on clavicle heads (Frace, 2010; Regan and Dallachiesa, 2009).

STEP 10 Cleaning around stoma.

STEP 12a(2) Replacing tracheostomy ties. Do not remove old tracheostomy ties until new ones are secure.

STEP 12a(5) Tracheostomy ties properly placed. (From Sorrentino SA: Mosby's textbook for nursing assistants, ed 8, St Louis, 2013, Mosby.)

STEP 12a(6) Applying tracheostomy dressing.

STEPS

RATIONALE

b Tracheostomy tube holder method:

- (1) While wearing gloves, maintain secure hold on tracheostomy tube. This can be done with an assistant; or, when an assistant is not available, leave old tracheostomy tube holder in place until new device is secure.
- (2) Align strap under patient's neck. Be sure that Velcro attachments are on either side of tracheostomy tube.
- (3) Place narrow end of ties under and through faceplate eyelets. Pull ends even and secure with Velcro closures (see illustration).
- (4) Verify that there is space for only one loose or two snug finger widths under neck strap.

- 13 Position patient comfortably and assess respiratory status.
- 14 Be sure that oxygen or humidification delivery sources are in place and set at correct levels.
- 15 Remove gloves and face shield and discard in appropriate receptacle.
- 16 Replace cap on normal saline bottles. Store reusable liquids, date container, and store unused supplies in appropriate place.
- 17 Perform hand hygiene.

Prevents incidental dislodgement of tube.

Promotes comfort. Some patients require posttracheostomy care suctioning.

Humidification provides moisture for airway, makes it easier to suction secretions, and decreases risk of mucus plugs (Frace, 2010; Regan and Dallachiesa, 2009).

Reduces transmission of microorganisms.

Once opened, normal saline is considered free of bacteria for 24 hours.

Reduces transmission of microorganisms among patients.

STEP 12b(3) Tracheostomy tube holder in place. (Courtesy Dale Medical Products, Plainville, Mass.)

**EVALUATION**

- 1 Compare assessments before and after tracheostomy care.
- 2 Assess fit of new tracheostomy ties and ask patient if tube feels comfortable.
- 3 Inspect inner and outer cannulas for secretions.
- 4 Assess stoma for inflammation, edema, or discolored secretions.

Determines effectiveness of tracheostomy care.

Tracheostomy ties are uncomfortable and place patient at risk for tissue injury when they are too loose or too tight.

Presence of secretions on cannulas indicates need for more frequent tracheostomy care.

Broken skin places patient at risk for infection.

Stoma infection requires change in tracheostomy skin care plan.

Unexpected Outcomes

- 1 Excessively loose or tight tracheostomy ties/tracheostomy holder.
- 2 Inflammation of tracheostomy stoma.
- 3 Patient has pressure area around tracheostomy tube.
- 4 Accidental decannulation.
- 5 Respiratory distress from mucus plug in cannula.

Related Interventions

- Adjust ties or apply new ties/tracheostomy holder.
- Increase frequency of tracheostomy care.
- Apply topical antibacterial solution, allow it to dry, and apply bacterial barrier.
- Apply hydrocolloid or transparent dressing just under stoma to protect skin from breakdown. Consult with skin care specialist.
- Increase frequency of tracheostomy care and keep dressing under faceplate at all times.
- Consider using double dressing or applying hydrocolloid or stoma adhesive dressing around stoma.
- Call for assistance.
- Replace old tracheostomy tube with new tube. Some experienced nurses or respiratory therapists may be able to quickly reinsert tracheostomy tube.
- Keep spare tracheostomy tube of same size and kind at bedside in event of emergency replacement (Weber-Jones, 2010).
- Same-size ET tube can be inserted in stoma in an emergency.
- Insert suction catheter to confirm that new tube is in trachea.
- Be prepared to manually ventilate patients in whom respiratory distress develops with Ambu bag until tracheostomy is replaced.
- Notify health care provider.
- Remove inner cannula if applicable for cleaning or suction cannula.
- Notify health care provider if tracheostomy tube requires replacement (Weber-Jones, 2010).

Recording and Reporting

- Record respiratory assessments before and after care; type and size of tracheostomy tube; frequency and extent of care; type, color, and amount of secretions; patient tolerance and understanding of procedure; and special care in event of unexpected outcomes.
- Report accidental decannulation or respiratory distress to the health care provider.

Special Considerations

Teaching

- Different types of tracheostomy tubes have different faceplates. Some are rigid; others are not. Instruct caregivers not to lift up rigid faceplates or they will dislodge tube.
- Some commercial tracheostomy tube holders require removal of excess tie material to fit properly.
- If you anticipate long-term placement of tracheostomy, plan to teach patient and family tracheostomy care.

- Patients with new tracheostomy frequently have bloody secretions for 2 to 3 days after procedure and for 24 hours after each tracheostomy tube change (Frace, 2010).

Pediatric

- Children generally have shorter necks, making the stoma more difficult to clean.
- Pediatric tracheostomy tubes (smaller than size 4) do not contain an inner cannula.
- Nurses perform routine tracheostomy tube changes weekly after a tract has formed, generally 5 days (Hockenberry and Wilson, 2011).

Gerontologic

- Some older adults may have more fragile skin and are more prone to skin breakdown from secretions or pressure (Meiner and Lueckenotte, 2011).
- Some older adults with impaired nutrition do not heal well.

SKILL 25-5 Inflating the Cuff on an Endotracheal or Tracheostomy Tube

A cuff on a tracheal tube prevents the escape of air between the tube and the walls of the trachea and reduces aspiration when a patient is receiving mechanical ventilation. The goals of correctly inflating the cuff on an artificial airway are to promote lung inflation for mechanical ventilation, prevent aspiration of gastric contents, and at the same time allow drainage of secretions that accumulate between the epiglottis and the cuff (Box 25-1). The amount of air inserted in a cuff is based on several factors (i.e., the size of the patient's trachea and the external diameter of the artificial airway). If the cuff pressures are too high, permanent damage to the tracheal mucosa occurs (Frace, 2010). Maintain cuff pressures between 20 and 25 mm Hg or less (Lewis et al., 2011).

No recommendation exists for a preferred method for cuff inflation. Most patients have a low-pressure cuff with a cuff manometer. The manometer allows for accurate monitoring of cuff pressures by respiratory therapists.

Delegation and Collaboration

The skill of inflating the cuff on an endotracheal or tracheostomy tube cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Immediately report any change in vital signs, respiratory status, confusion, restlessness, or discomfort.

BOX 25-1 Indications for Cuff Inflation

Mechanical Ventilation

- Continuous airway pressure
- Positive end expiratory pressure (PEEP)
- Inability to meet ventilatory requirements with cuff down
- Inability to meet oxygen requirements with cuff down

Risk of Aspirating Gastric Contents

- Feeding tube, especially large bore, in stomach
- Gastroesophageal reflux disease
- Hiatal hernia
- During and after meals
- Impaired gastric emptying
- Decreased gag reflex
- Impaired swallowing

- Immediately report any indication of the artificial airway moving or appearing loose.

Equipment

- Endotracheal (ET)/tracheostomy suction equipment (see Skill 25-2)
- Stethoscope
- 5- or 10-mL syringe
- Alcohol wipe
- Mask, goggles, face shield (if indicated)
- Clean gloves (if indicated)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| <p>1 Observe for signs and symptoms of gurgling on expiration, decreased exhaled tidal volume (mechanically ventilated patient), spasmodic coughing, tense test balloon on tube, flaccid test balloon on tube, and unexpected phonation.</p> <p>2 Assess vital signs; respiratory effort; and, if on ventilator, tidal volume.</p> <p>3 If patient is to be discharged with cuffed tracheostomy tube, determine family caregiver's understanding of and ability to perform procedure.</p> | <p>Partially deflated cuff allows secretions to enter trachea and permits vocalization. High cuff pressure can result in necrosis, tracheomalacia, or tracheoesophageal fistula. Overinflated cuff may cause patient to cough (Frace, 2010).</p> <p>Assesses respiratory status and provides baseline to determine response to therapy.</p> <p>Identifies teaching needs.</p> |
|--|---|

NURSING DIAGNOSES

- | | | |
|--|---|---|
| <ul style="list-style-type: none"> • Deficient knowledge about cuff inflation • Impaired spontaneous ventilation | <ul style="list-style-type: none"> • Ineffective breathing pattern • Risk for infection | <ul style="list-style-type: none"> • Risk for aspiration |
|--|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Mechanically ventilated patient receives prescribed tidal volume. • Minimal leak is auscultated at end of inspiration. • No evidence of excessive phonation, aspiration of gastric or mouth contents, tracheoesophageal fistula, or tracheomalacia is present. <p>2 Explain procedure and how patient can participate. Explain that some coughing during procedure is normal.</p> | <p>Proper inflation of cuff ensures that ventilator delivers correct tidal volume.</p> <p>Allows drainage of secretions during inhalation when airway is at widest but prevents gross aspiration during exhalation when airway is narrower. Prevents continuous contact of tracheal mucosa with cuff.</p> <p>Proper level of cuff inflation is maintained consistently. Aspiration and phonation occur when cuff is underinflated. Tracheoesophageal fistula and tracheomalacia occur when cuff is overinflated (Frace, 2010).</p> <p>Encourages cooperation, minimizes risks, and reduces anxiety.</p> |
|---|---|

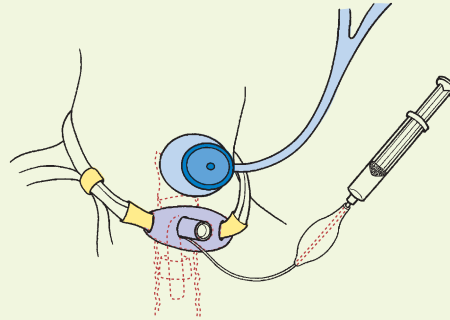

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Perform hand hygiene. Apply clean gloves and a face shield if indicated.</p> <p>3 Help patient to position of comfort (generally semi-Fowler's).</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Reduces transmission of microorganisms.</p> <p>Promotes patient comfort and facilitates drainage.</p> |
|--|--|

STEP

RATIONALE

- | | |
|---|---|
| <p>4 Suction secretions through ET or tracheostomy tube and also mouth (see Skills 25-1 and 25-2 or Procedural Guideline 25-1).</p> <p>5 Connect syringe to pilot balloon.</p> <p>6 Place stethoscope in sternal notch or above tracheostomy tube and listen for minimal amount of air leak at end of inspiration (see illustration).</p> | <p>Ensures patent airway and facilitates hearing airflow with stethoscope. Prevents aspiration of oral secretions during cuff deflation.</p> <p>Allows immediate access to equipment for adjusting cuff pressure. Assesses proper cuff inflation.</p> |
|---|---|

STEP 6 Inflating cuff on tracheostomy while listening with stethoscope.

- | | |
|---|--|
| <p>7 If you do not hear an air leak, remove all air from cuff.</p> <p>8 Reinflate cuff according to agency policy.</p> <p>9 If you hear excessive air leak, slowly add air as in Step 8.</p> <p>10 Remove stethoscope and wipe diaphragm with alcohol wipe.</p> <p>11 Remove syringe and discard into appropriate receptacle or store per policy. Do not leave attached to pilot balloon valve.</p> <p>12 Reposition patient.</p> <p>13 Remove gloves and face shield. Discard into appropriate receptacle. Perform hand hygiene.</p> | <p>Releases excessive cuff pressure, which can reduce capillary blood flow and increase tissue necrosis.</p> <p>Inflates cuff to minimal leak. If air leak is audible with ear, it is too large. If you do not hear an air leak, cuff is overinflated.</p> <p>Excess air leak may prevent adequate lung expansion and increase risk for aspiration.</p> <p>Reduces transmission of microorganisms.</p> <p>Reduces transmission of microorganisms. Prevents accidental deflation of cuff.</p> <p>Promotes comfort.</p> <p>Reduces transmission of microorganisms.</p> |
|---|--|

EVALUATION

- | | |
|---|--|
| <p>1 Compare respiratory assessments before and after cuff care.</p> <p>2 Observe exhaled tidal volume from mechanical ventilator. Exhaled tidal volume should not be less than 50 mL of delivered tidal volume.</p> <p>3 Auscultate for audible air leak.</p> <p>4 Observe for excessive phonation, presence of gastric secretions in airway secretions, or tracheoesophageal fistula.</p> | <p>Determines effectiveness of cuff care procedure and patient tolerance.</p> <p>Ensures appropriate ventilation of lungs.</p> <p>Air leak should be heard only with stethoscope.</p> <p>Occurs with inadequate or excessive cuff inflation.</p> |
|---|--|

Unexpected Outcomes

- 1 Cuff pressure is excessive.
- 2 Excessive volume is required to inflate cuff.
- 3 Excessive air leak is present.
- 4 Cuff requires increased amounts of air to maintain minimal leak.

Related Interventions

- Remove air from cuff.
- Reinflate with appropriate minimal leak technique.
- Notify health care provider.
- Patient may need insertion of larger tube.
- Reposition patient or tubing.
- Reinflate cuff per protocol.
- Prepare for insertion of new tube by health care provider or trained personnel if cuff ruptures.
- Prepare to manually ventilate patient if needed.
- Reassess position of tube.
- Cuff of ET tube is sometimes higher in trachea (where airway is wider) than previously.
- Withdraw all air from cuff so pilot balloon is completely deflated (flat).
- Remove syringe from pilot balloon. Watch to see if air reenters pilot balloon (cuff). If so, the cuff is leaking, and tube requires replacement.
- Fill cuff appropriately.

Recording and Reporting

- Document presence of minimal leak at end of inspiration, volume of air injected into cuff, secretions obtained when suctioning, frequency of cuff care, patient tolerance of procedures, and safe cuff pressure levels.

Critical Thinking Exercises

You are assigned to care for Mrs. Karlowski, a 55-year-old bank manager. You receive the following information in report: Past medical history—she has a history of chronic lung disease with a long history of smoking. She has no medication allergies. She complains of occasional bouts of bronchitis, which are treated with antibiotics on an outpatient basis. Current complaint includes a 1-week history of upper respiratory symptoms with increasing shortness of breath; and a 2-day history of fever, cough, malaise, nausea, and worsening shortness of breath. Focused assessment: Alert and oriented; VS: 140/86, 110, 34, temp orally 39.2°C (102.6°F). Oxygen saturation baseline is 89%; now at 86%. Respiratory assessment: decreased breath sounds with crackles throughout the lower lobes.

- Mrs. Karlowski complains of thick secretions in her mouth. She feels that she can cough up the pulmonary secretions, but the secretions still remain in her mouth, and they make her nauseous. Which intervention would you select to help her clear oral secretions? Explain your choice.
 - Yankauer suctioning
 - Nasotracheal suctioning
 - Orotacheal suctioning
 - When you are performing airway management interventions, the risk for health care–associated pneumonia is always present. What can you do to reduce this risk when using a suction technique to clear tracheal secretions? (Select all that apply.) Explain your choice(s).
 - Perform hand hygiene
 - Use sterile suction technique
 - Use clean suction technique
 - Use humidified oxygen
 - While suctioning Mrs. Karlowski, you observe that the returned sputum is thicker and brown tinged. This is very different from earlier sputum. Which action would you take? (Select all that apply.) Explain your choice(s).
 - Notify health care provider or nurse in charge
 - Decrease humidification
 - Increase fluids
 - Obtain artificial airway
 - Obtain sputum specimen
- A patient needs both the trachea and the oral pharynx suctioned. In which order should the nurse suction these areas and why? Place in correct order.
 - Suction the oral cavity last
 - Suction the oral cavity first
 - Suction nasotracheally first
 - Suction nasotracheally last
 - A patient is in the intensive care unit after a thoracotomy and has subsequent hypoxia. Which of the following manifestations is an associated symptom of hypoxia?
 - Increased mentation
 - Feeling of calm
 - Normal heart rate and rhythm
 - Lethargy
 - The nurse is caring for a patient with an artificial airway whose pulse oximeter reading drops from 90% to 85%. What is the priority nursing action?
 - Check for the presence of a pulse
 - Assess for an adequate blood pressure
 - Check for a patent airway
 - Check the connections of the oxygen supply
 - A patient with an endotracheal tube has unequal breath sounds, even after being suctioned and repositioned. Which nursing intervention is indicated at this time?
 - Notify the health care provider
 - Call for help
 - Suction the airway
 - Reposition patient's endotracheal tube deeper
 - You are assigned a patient with a tracheostomy, and you need to change the patient's dressing because you note that the dressing is moist. Place the following steps to secure the tracheostomy in the correct order.
 - Slide both ends of tie behind head and around neck to other eyelet and insert one tie through second eyelet.
 - Ask for assistance from the NAP to hold the tracheostomy tube.
 - Secure ties.
 - Cut old ties.
 - Take prepared tie and insert one end of tie through faceplate eyelet and pull ends even.
 - Insert fresh dressing under clean ties and faceplate.
 - Mr. Stone has a tracheostomy with an inner cannula that needs to be cleaned. He is receiving 40% humidified oxygen via a tracheotomy mask. Which intervention should the nurse take to prevent desaturation?
 - Have Mr. Stone sit upright.
 - Use hydrogen peroxide on the 4x4s to clean Mr. Stone's inner cannula.
 - Quickly clean Mr. Stone's inner cannula.
 - Reinsert the inner cannula; you do not have to lock it down after the initial cleaning.
 - Place the steps for securing an oral endotracheal (ET) tube with tape in the correct order after completing suctioning.
 - Remove old tape from patient's face.
 - Apply clean gloves.
 - Cut piece of tape long enough to go completely around patient's head from naris to naris plus 15 cm (6 inches).
 - Remove any secretions or adhesive from patient's face.
 - Instruct helper to apply pair of gloves and hold ET tube firmly at patient's lips or nares.

REVIEW QUESTIONS

- A patient hospitalized for acute pneumonia has a 10-year history of chronic lung disease and cannot clear her respiratory secretions from the posterior pharynx even with coughing. Which suctioning intervention is appropriate?
 - Oropharyngeal
 - Nasopharyngeal
 - Endotracheal
 - Tracheal

Pediatric

- Pediatric tracheostomy tubes and neonatal and many pediatric ET tubes do not contain cuffs.

- 9 Which of the following intervention(s) help to preventing ventilator-associated pneumonia? (Select all that apply.)
- 1 Elevating the head of the bed at 10 degrees to prevent aspiration
 - 2 Changing patient position every 4 hours to decrease risk for atelectasis, pulmonary infections, pressure ulcers, discomfort, and urinary stasis
 - 3 Providing oral care with chlorhexidine by swab every 8 hours
 - 4 Maintaining endotracheal cuff pressures at 20 cm H₂O to decrease movement of secretions to the lower airways
- 10 Managing a patient's airway requires several safety guidelines. Which of the following statements is (are) true in maintaining airways safely? (Select all that apply.)
- 1 Respiratory assessment only needs to include the respiratory rate and oxygen saturation levels.
 - 2 The risk of aspiration is important to assess when enteral feeding tubes are present.
 - 3 Evaluate all airway equipment for functionality before use.
 - 4 Review of baseline or previous shift information is not necessary to your care of the patient.

KEY TERMS

Air leak	Intrapleural pressure	Pneumothorax	Tension pneumothorax
Atmospheric pressure	Mediastinal shift	Positive pressure	Tidaling
Chest tube	Negative pressure	Subcutaneous emphysema	Visceral pleura
Hemothorax	Parietal pleura		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Explain the physiology of normal respiration.
- List three common sites for chest tube placement.
- List three conditions requiring chest tube insertion.
- Describe closed chest drainage systems: water-seal and waterless systems.
- Describe principles and mechanisms of chest tube suction.
- Discuss measures to maintain patient safety during chest tube insertion, maintenance, and removal.
- Describe methods of troubleshooting chest tube systems.
- Discuss the nursing principles in caring for patients with chest tubes.
- Describe autotransfusion.

The chest cavity is a closed structure bound by muscle, bone, connective tissue, vascular structures, and the diaphragm. This cavity has three distinct sections, each sealed from the others: one section for each lung and a third section for the mediastinum, which surrounds structures such as the heart, esophagus, trachea, and great vessels.

The lungs are covered with a membrane called the *visceral pleura*. The interior chest wall is lined with a membrane called the *parietal pleura* (Fig. 26-1). The space between the visceral and parietal pleura is called the *pleural space* and is filled with approximately 7-to-20 mL of lubricating fluid to help the pleura slide during respiration (Twedell, 2009). During inspiration the intercostal muscles pull outward, and the diaphragm contracts and pulls downward, thereby increasing the size of the chest cavity. As a result an increase in the amount of negative pressure (vacuum effect) is exerted in the intrapleural space.

During inspiration increased negative pressure pulls the lungs against the expanded chest cavity, increasing their size.

The expanding lungs cause the intrapulmonic (alveolar) pressure to fall lower than atmospheric pressure, thus increasing the negative pressure within the lungs. This change in pressure causes air to rush into the lungs until the intrapulmonic pressure is equal to the pressure in the atmosphere. When the chest cavity stops expanding and the lungs are full of air, the respiratory muscles and diaphragm relax and return the chest cavity to its resting stage. Expiration (exhalation) is a passive process that results from relaxation of the inspiratory muscles that decrease the space in the chest cavity.

Trauma, disease, or surgery can result in air, blood, pus, or lymph fluid leaking into the intrapleural space, creating a positive pressure that collapses lung tissue (Durai et al., 2010). Small leaks (24% or less) are sometimes absorbed spontaneously and may not require a chest tube. The usual intervention for larger leaks is a chest tube to remove air and fluid from the pleural space, prevent air and/or fluid from reentering the pleural space, and reestablish normal intrapleural and intrapulmonary pressures.

FIG 26-1 Partial structures of lungs.

A number of clinical conditions such as cancer, infection, pancreatitis, connective tissue disease, autoimmune diseases, asbestos exposure, certain drugs, or collagen vascular diseases increase pleural fluid entry or decrease fluid exit from the lung. This is called a *pleural effusion*; and, when present, a patient usually needs a diagnostic thoracentesis and pleural fluid analysis to determine the cause of the exudate (see Chapter 44) (Twedell, 2009). Patients usually need one or more chest tubes to promote drainage of the excess fluid and lung expansion (Mertin et al., 2009; Twedell, 2009).

A pneumothorax is collapse of the lung caused by a collection of air in the pleural space. The loss of negative intrapleural pressure causes the lung to collapse. A variety of mechanisms cause a pneumothorax. A traumatic pneumothorax develops as a result of penetrating chest trauma such as a stabbing (open) or the chest striking the steering wheel in an automobile accident (closed). A spontaneous or primary pneumothorax sometimes occurs from the rupture of a small bleb (blister) on the surface of the lung or an invasive procedure such as insertion of a subclavian intravenous (IV) line. Secondary pneumothorax occurs because of underlying disease such as emphysema. A patient with a pneumothorax usually feels sharp chest pain that worsens on inspiration or coughing because atmospheric air irritates the parietal pleura. As a pneumothorax worsens, a patient will experience easy fatigue, a rapid heart rate, and low blood pressure (U.S. National Library of Medicine, 2011).

A tension pneumothorax, a life-threatening situation, occurs from rupture in the pleura when air accumulates in the pleural space more rapidly than it is removed. The pleural space functions as a one-way valve, causing an increase in the amount of air and pressure. If left untreated, the lung on the affected side collapses; and the mediastinum shifts to the opposite (unaffected side), leading to tracheal deviation, reduced venous return, and subsequent decrease in cardiac output. Tracheal deviation is a late sign and may be absent in some cases (Bethel, 2008). A patient has sudden chest pain, a fall in blood pressure, tachycardia, acute pleuritic pain, diaphoresis, dry cough, and cardiopulmonary arrest can occur. Patients with chest trauma, fractured ribs, invasive thoracic bedside procedures (e.g., insertion of central lines), and those on high-pressure mechanical ventilation are at risk for tension pneumothorax (Bethel, 2008). If emergent treatment is required, a needle decompression is achieved with a large-gauge needle (14 or 16 gauge) inserted into the second intercostal space, midclavicular line. A “hissing” sound is noted, followed by a rapid stabilization of the patient’s vital signs and respiratory status (Briggs, 2010).

FIG 26-2 Pleural chest tube in place following thoracic surgery.

A hemothorax is collapse of the lung caused by an accumulation of blood and fluid in the pleural cavity between the chest wall and the lung, usually as a result of trauma. It produces a counterpressure and prevents the full expansion of the lung. A hemothorax is also caused by rupture of small blood vessels from inflammatory processes such as pneumonia or tuberculosis. In addition to pain and dyspnea, signs and symptoms of shock can develop if blood loss is severe (Mertin et al., 2009).

Chest tube insertion is the treatment for most types of effusions, pneumothorax, hemothorax, and postoperative chest surgery or trauma. A chest tube is a large catheter inserted through the thorax to remove fluid (effusions), blood (hemothorax), and/or air (pneumothorax). Small-bore chest tubes (12 to 20 Fr) are sufficient to remove air, and large-bore (24 to 32 Fr) tubes are needed to remove fluid and blood. In some settings the traditional reusable glass three-bottle system is still used but rarely. Clear, plastic, disposable containers are most common (Durai et al., 2010). The newest system available is the mobile chest drain, which allows a patient to move about with less restriction. Regardless of the system used, the principles of patient management are the same. A pleural chest tube (Fig. 26-2) is inserted when air or fluid enters the pleural space, compromising oxygenation or ventilation. A closed chest drainage system with or without suction is attached to the chest tube to promote drainage of air and fluid. Lung reexpansion occurs as the fluid or air is removed from the pleural space (Briggs, 2010; Twedell, 2009).

The location of the chest tube indicates the type of drainage expected. Apical (second or third intercostal space) and anterior chest tube placement promotes removal of air. Because air rises, these chest tubes are placed high, allowing evacuation of air from the intrapleural space and lung reexpansion (Fig. 26-3). The air is discharged into the atmosphere, and there is little or no drainage in the collection chamber.

Chest tubes placed low (usually in the fifth or sixth intercostal space) and posterior or lateral drain fluid (see Fig. 26-3). Fluid in the intrapleural space is affected by gravity and localizes in the lower portion of the lung cavity. Tubes placed in these positions drain blood and fluid. Frequently applying suction helps with this

FIG 26-3 Diagram of sites for chest tube placement.

FIG 26-4 Mediastinal chest tube.

drainage. Fluid drainage is expected after open-chest surgery and with some chest trauma (Briggs, 2010).

A mediastinal chest tube is placed in the mediastinum, just below the sternum (Fig. 26-4), and is connected to a drainage system. This tube drains blood or fluid, preventing its accumulation around the heart. A mediastinal tube is commonly used after open-heart surgery.

Occasionally in emergency situations and for a small pneumothorax a catheter is inserted through the chest wall, and a rubber flutter one-way valve (e.g., a Heimlich valve) is attached to the catheter (Fig. 26-5, A and B). As a patient exhales, the positive pressure generated by the air leaving the chest enters the tubing, causing the valve to open so air is released. During inspiration the tube collapses on itself, preventing air from reentering the chest. No drainage chamber is used with this device; therefore it is not used when patients need fluid drained such as from a hemothorax or a pleural effusion (Lewis et al., 2011).

Smaller “pigtail catheters” are also used and are less traumatic than the large-bore tubes. In addition, if they occlude the health care provider can irrigate them with sterile water. However, because these tubes are small, the size of the tube lumen does not promote

A

B

FIG 26-5 A, Heimlich chest drain valve is a specially designed flutter valve that is used in place of a chest drainage unit for small uncomplicated pneumothorax with little or no drainage and no need for suction. The valve allows for escape of air but prevents reentry of air into the pleural space. (Image courtesy Becton, Dickinson and Company, Franklin Lakes, New Jersey. All rights reserved.) B, Placement of valve between chest tube and drainage bag, which can be worn under clothing.

drainage of blood, and they are not used for chest trauma (Lewis et al., 2011).

Mobile chest drains are devices that are lighter and self-contained and allow patients to move with less restriction. As a result there is a decreased risk for deep vein thrombosis, pulmonary embolism, and other complications associated with immobility. In addition, because the system is lighter, a patient has less pain. These mobile systems rely on gravity or dry suction for drainage. They are ideal for patients with persistent drainage or air leaks requiring prolonged need for a chest tube (Varela et al., 2010). Patients who require a mobile chest drainage system at home need sufficient discharge planning and patient teaching directed toward safe operation of the system (see Home Care Considerations for Skill 26-1).

The disposable systems such as an Atrium or Pleur-Evac chest drainage system are one-piece molded plastic units that provide for a single- or multiple-chamber closed drainage system (Fig. 26-6). A single-chamber system allows air from a pneumothorax to bubble out of the water seal and escape through the air outlet while preventing air from reentering the intrapleural space. This system is not recommended for the evacuation of fluid because drainage would raise the level of the water-seal liquid. An increased height of fluid in the water seal increases the resistance to drainage on expiration and eventually stops the drainage entirely.

A two- or three-chamber system drains both a hemothorax and a pneumothorax effectively. The two-chamber system permits liquid to flow into the collection chamber, and air flows into the water-seal chamber. A three-chamber system promotes the drainage of fluid and air with controlled suction. In both systems the first chamber provides a compartment for fluid or blood drainage, and a second compartment for either a water seal or a one-way

FIG 26-6 Disposable chest drainage systems. (Pleur-Evac images courtesy Teleflex Medical, Research Triangle Park, NC.)

valve. In the three-chamber system, the third compartment is for suction control, which may or may not be used. The disposable units appear to be the system of choice because they are cost-effective and some facilitate autotransfusion, a common practice in open-heart surgeries.

EVIDENCE-BASED PRACTICE

Small chest tubes often become blocked by blood clots and fibrin. Milking and stripping a chest tube are processes used to clear the clots. Milking is the manual compression of a chest tube in an attempt to move the chest tube drainage toward the collection device. Milking involves squeezing the chest tube back and forth intermittently with the hands along the length of the tube. Stripping a chest tube involves using continuous pressure on the tube while running the hands down from the site of insertion to the drainage container.

The evidence has changed related to the use of stripping. It causes a dangerous increase in intrathoracic pressure, which damages the lung tissue (Durai et al., 2010). Milking does not alter intrathoracic pressure as much as stripping (Briggs, 2010). However, it is used only in select situations (e.g., when chest tube drainage becomes acutely occluded from multiple clots).

Careful management of chest tube drainage prevents the need to milk chest tubes:

- Avoid dependent loops of the drainage tube; or, when these loops cannot be avoided (such as when the patient is sitting), lift and clear the tube every 15 minutes.
- Tailor the length of the drainage tube to a patient. The tubing must be long enough to allow a patient to move but not so long that dependent loops hang down the side of the bed. If the tubing is coiled, looped, or clotted, the drainage is impeded and can result in a tension pneumothorax (Briggs, 2010).

PATIENT-CENTERED CARE

Health care–acquired infections (HAIs) occur at the rate of 13 per 1000 patient days in U.S. intensive care units (ICUs). As patient advocates, nurses need to know the factors leading to infections. HAIs often cost over \$40,000 per patient and burden patients and families with higher mortality rates and prolonged hospitalizations. Invasive procedures such as mechanical ventilation, central venous catheters, and chest tubes can all increase the risk for HAIs. Oldfield et al. (2009) studied 120 ICU patients who had one or

more chest tubes to identify their risk for HAIs. The researchers found that patients with chest tubes for longer than 20 days had a six-times greater risk of developing an HAI than those with chest tubes for fewer than 20 days. Based on this information, nurses must be vigilant for patient assessment findings that indicate the need for a chest tube and encourage deep-breathing exercises and early mobility, use of appropriate analgesia to promote activity, and patient education regarding these practices (Oldfield et al., 2009).

Safety Guidelines

- 1 Document patient's baseline vital signs, oxygen saturation, lung sounds, and respiratory status. Changes in vital signs or respiratory status often indicate a malfunction of a chest drainage system.
- 2 Observe the water seal for intermittent bubbling from its U tube or a rise and fall of fluid that is synchronous with respirations (Briggs, 2010). For example, in a nonmechanically ventilated patient the fluid level rises during inspiration and falls during expiration. When a patient is on a mechanical ventilator, the opposite occurs.
 - a Constant bubbling in the water seal or a sudden, unexpected stoppage of water-seal activity is considered abnormal and requires immediate attention (Briggs, 2010).
 - b Unexpected stoppage of activity may indicate a blockage or reexpansion. In these situations immediate attention and correction are indicated. After 2 to 3 days, tidaling or bubbling on expiration is expected to stop, indicating that the lung has reexpanded (Briggs, 2010).
- 3 In a waterless system look for a rise and fall of fluid in the diagnostic air-leak indicator synchronous with respirations. Constant left-to-right bubbling (when facing the indicator) or violent rocking is considered abnormal and indicates an air leak.
- 4 Note the expected amount of chest tube drainage, and monitor drainage on a regular basis (e.g., every hour initially and then every 4 hours). At the end of the shift, make a mark to indicate the fluid level with the date and time on the side of the drainage collection chamber. Note the drainage amount as output.
 - a A sudden decrease in the amount of chest tube drainage can indicate a possible clot or obstruction in the chest tube.
 - b Notify a health care provider when there is a sudden increase of more than 250 mL of drainage over 1 hour, which can indicate fresh bleeding from the thorax (Durai et al., 2010).
 - c Drainage from a pneumothorax is generally limited. Any fluid buildup is caused by chest tube insertion trauma. The chest tubes promote the removal of air from the intrapleural space.
- 5 Know the expected color of the drainage. Drainage from recent open-chest surgery is initially bright red and gradually becomes serous as the postoperative course continues. Blood-tinged fluid usually indicates malignancy, pulmonary infarction, or severe inflammation. Frank blood indicates a hemothorax. Pus indicates an empyema, which is a collection of pus in the pleural cavity (Briggs, 2010).
- 6 In the water-seal system observe for constant, gentle bubbling in the suction control chamber when it is connected to suction. In the waterless system a designated amount of suction is maintained by setting the suction source and dialing the prescribed suction level in the float ball column.
- 7 Assess both types of systems for air leaks. If an air leak exists, determine whether it is in the patient (patient-centered air

leak) or in the chest tube system (system-centered air leak). To rule out an air leak as patient-centered, you assess the patient's respiratory status. Document and report any changes in lung sounds, pulse oximetry, respiratory rate, or mentation.

Remember that continuous bubbling in the water-seal chamber with an absence of bubbles in the suction control chamber indicates that there is a leak in the system (Briggs, 2010). Ensure that all tubing connections are tight.

SKILL 26-1 Managing Closed Chest Drainage Systems

NSO Chest Tubes Module / Lessons 1 and 3

There are two types of commercial drainage systems: the water-seal and the waterless systems (Table 26-1). This skill reviews the nursing responsibilities and interventions related to the safe management of chest tubes. Review the roles and responsibilities of the health care provider for chest tube placement (Table 26-2).

Water-Seal Systems

NSO Chest Tubes Module / Lesson 2

Two-Chamber Water-Seal System

On expiration fluid or air is forced out of the intrapleural space. Suction pulls air or fluid through the chest tube into the drainage collection chamber. On entering the drainage collection chamber, this fluid or air displaces the air present in the chamber by pushing it through the water seal and out of the system into the atmosphere. The water-seal chamber is left open to air to drain. If the tubing is clamped, there is no mechanism for air to vent. To maintain the water-seal system, the chest tube system must remain upright. When it is tipped or overturned, the water seal is disrupted.

Three-Chamber Water-Seal System

If suction is used, the three-chamber water-seal system (Fig. 26-7) is set up with the suction control chamber added. A prescribed amount of sterile fluid (e.g., 20 cm of water) is poured into the suction control chamber, which is then attached to a suction source by tubing. The amount of sterile water added depends on manufacturer recommendations. The chamber is filled to the set volume for the prescribed amount of suction. Sterile water is added several times a day because of evaporation. As the fluid level decreases, the amount of suction also declines. The wall or portable suction device is turned up until the water in the suction control bottle exhibits a continuous, gentle bubbling. This provides the prescribed amount of suction (negative pressure).

If the suction source delivers more negative pressure than the suction control chamber water level allows, there is no danger because atmospheric air is pulled into the suction control chamber through an inlet, causing the excess suction to dissipate. The extra

FIG 26-7 Disposable water-seal chest drainage system with suction. (Used with permission, Atrium Medical Corp.)

TABLE 26-1 Comparison of Chest Tube Drainage Systems

Drainage System Type	Function	Advantage	Disadvantage
Water-seal system (see Fig. 26-7)	Two-chamber provides one-way valve for chest drainage. Water seal prevents reentry of air into lung. Three-chamber adds a chamber to aid evacuation of chest drainage.	Easy set-up and use Cost-effective	System must be kept upright to maintain seal. Drainage chamber may fill up quickly if patient has large amount of drainage. Sterile water must be added several times a day to maintain suction and water seal because of evaporation.
Waterless system (see Fig. 26-8)	Also provides three chambers, but no water is required to establish a seal.	Water seal maintained even if system is knocked over More space provided for drainage	Water must be added to system if patient requires evaluation of an air leak.
Dry suction system (see Fig. 26-9)	Also provides three chambers, but no water is required to establish a seal.	Easy set up Quiet operation Can be used when higher levels of suction are required	Sterile water must be added to system if patient requires suction.

air pulled into the chamber causes vigorous bubbling. If this occurs, lower the suction source setting to reduce noise and evaporation of the fluid. The absence of bubbling indicates that no suction is being exerted into the system. Raise the suction setting to restore gentle bubbling.

The middle chamber of a traditional chest drainage system is the water seal. The water seal allows air to exit from the pleural space on exhalation and prevent it from entering the pleural cavity or mediastinum on inhalation. When the appropriate amount of sterile water is added, a 2-cm water seal is established. To maintain effective water seal the chest drainage unit must remain upright, and you must monitor the water level in the water-seal chamber to check for evaporation. Bubbling in the water-seal chamber indicates an air leak.

Waterless Systems

Two-Chamber Waterless System

The principles of the waterless system are similar to those of the water-seal system except that fluid is not required for setup. Because water is not used, accidentally tipping the system does not compromise the patient's condition.

The water seal is replaced by a one-way valve (Fig. 26-8) located near the top of the system. Most of the container serves as the drainage chamber. The suction chamber does not depend on water. Instead it contains a float ball, which is set by a suction control dial after the suction source is turned on. A diagnostic air-leak indicator is located on the face of the unit. It requires the addition of 15 mL of fluid for visualization. The function of the indicator is to identify one of the following:

TABLE 26-2 Process for Insertion of Chest Tubes

Role	Purpose
Explain purpose, procedure, and possible complications to patient and have patient sign consent form.	Provides informed consent.
Have pain medication available to administer before or immediately after chest tube insertion as appropriate according to patient's condition.	Analgesia improves patient comfort throughout procedure and helps patient take appropriate deep breaths to promote lung reexpansion and drainage of fluid in pleural space.
Perform hand hygiene. Clean chest wall with antiseptic.	Reduces transmission of microorganisms.
Apply mask and gloves.	Maintains surgical asepsis.
Drape area of chest tube insertion with sterile towels. Inject local anesthetic and allow time to take effect.	Maintains surgical asepsis. Decreases pain during procedure.
Make a small incision over the rib space where tube is to be inserted. Thread a clamped chest tube through the incision. Health care provider clamps chest tube until system is connected to water seal.	Inserts chest tube into intrapleural space. Clamping prevents entry of atmospheric air into chest and worsening of pneumothorax.
Suture chest tube in place if suturing is policy or health care provider preference.	Secures chest tube in place.
Cover chest tube insertion site with sterile 4 × 4-inch gauze and large dressing to form an occlusive dressing supported with an elastic bandage (Elastoplast). Sterile petrolatum gauze is used around the tube.	Holds chest tube in place and occludes site around it. Helps stabilize chest tube and holds dressing tightly in place. Sterile petrolatum gauze helps prevent air leak.
<p>Water-Seal System</p> <p>Remove connector cover from patient's end of chest drainage tubing with sterile technique. Secure drainage tubing to chest tube and drainage system.</p>	Health care provider is responsible for making certain that system is set up properly, proper amount of water is in the water seal, dressing is secure, and chest tube is securely connected to drainage system.
<p>Water-Seal Suction</p> <p>Connect system to suction or supervise a nurse connecting it to suction if suction is to be used.</p>	Health care provider is responsible for determining and checking amount of fluid that is to be added to suction control chamber and prescribing suction setting.
<p>Waterless System</p> <p>Remove connector cover from patient's end of chest drainage tubing with sterile technique. Secure drainage tubing to chest tube and drainage system.</p>	Health care provider is responsible for making certain that system is set up properly and chest tube is securely connected to drainage system.
<p>Waterless Suction</p> <p>Turn on suction source. Set float ball level to prescribed setting.</p>	Health care provider is responsible for prescribing level of float ball and suction setting.
Health care provider or nurse adds sterile water or normal saline to diagnostic indicator.	Allows quick assurance that system is functioning properly. Connects chest tube to drainage.
Unclamp chest tube.	Verifies correct chest tube placement.
In both systems health care provider orders and reviews chest x-ray film studies.	

- 1 The lung is expanding normally. This is indicated by a gentle tidaling of the fluid in the diagnostic indicator.
- 2 The lung is probably reexpanded if after 2 or 3 days the tidaling has stopped.
- 3 There is an air leak in the system if, when facing the system, the observer sees the fluid bubbling left to right. Locate and correct the source of the air leak.

FIG 26-8 Disposable waterless chest drainage system with suction.

Three-Chamber Waterless System

When suction is ordered, attach the suction chamber port to the suction source by tubing, turn the suction on, and set the float ball to the prescribed setting. If the float ball does not rise to the prescribed level, increase the suction source setting until it does. The system is now functioning with suction.

There are usually two suction settings: one at either the suction control chamber or the float ball setting and the other at the suction source. The chamber or float ball setting is a safety factor to reduce the possibility that the intrapleural tissues receive too much suction, causing injury.

Dry Suction System

Dry suction control systems provide many advantages (Fig. 26-9), including higher suction pressure levels, easy setup, and the lack of continuous bubbling, which provides for quiet operation. There is no fluid to evaporate, which decreases the amount of suction necessary. A self-compensating regulator controls dry suction units. A dial is set to the prescribed suction control setting. These units are preset to -20 cm of water pressure, but they are adjustable from -10 to -40 cm. However, the dry suction control systems require or have pre-sealed sterile water in the water-seal chamber (Atrium, 2010).

Delegation and Collaboration

The skill of chest tube management cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Proper positioning of the patient with chest tubes to facilitate chest tube drainage and optimal functioning of the system.
- How to ambulate and transfer patient with chest drainage.
- Measuring vital signs and reporting any abnormal changes in vital signs, complaints of chest pain or sudden shortness of breath, or excessive bubbling in water-seal chamber to the nurse immediately.

FIG 26-9 Dry suction chest drainage system. (Used with permission, Atrium Medical Corp.)

- The danger of any disconnection of system, change in type and amount of drainage, sudden bleeding, or sudden cessation of bubbling. Notify the nurse immediately.

Equipment

- Prescribed chest drainage system
- Suction source and setup (wall canister or portable)
 - *Water-seal system:* Add sterile water or normal saline (NS) solution to cover the lower 2.5 cm (1 inch) of the water-seal U tube. Or pour sterile water or NS into the suction control chamber if suction is to be used (see manufacturer directions)
 - *Waterless system:* Add vial of 30- to 45-mL sterile sodium chloride or water (for diagnostic air-leak indicator), 20-mL syringe, 21-gauge needle, and antiseptic swab
 - Dry suction system
- Clean gloves
- Sterile gauze sponges
- Local anesthetic, if not an emergent procedure
- Chest tube tray (all items are sterile): Knife handle (1), chest tube clamp, small sponge forceps, needle holder, knife blade No. 10, 3-0 silk sutures, tray liner (sterile field), curved 8-inch Kelly clamps (2), 4 × 4-inch sponges (10), suture scissors, hand towels (3), sterile gloves
- Dressings: Petrolatum gauze, split chest-tube dressings, several 4 × 4-inch gauze dressings, large gauze dressings (2), and 4-inch tape or elastic bandage (Elastoplast)
- Head cover
- Facemask/face shield
- Sterile gloves
- Two rubber-tipped hemostats (shodded) for each chest tube
- 1-inch adhesive tape for taping connections or plastic zip ties
- Stethoscope, sphygmomanometer, and pulse oximeter

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <p>1 Measure vital signs and pulse oximetry.</p> <p>2 Perform a complete respiratory assessment.</p> <p>a Signs and symptoms of increased respiratory distress and hypoxia (e.g., decreased breath sounds over affected and nonaffected lungs, marked cyanosis, asymmetric chest movements, displaced trachea, shortness of breath, and confusion).</p> <p>b Assess for sharp, stabbing chest pain or chest pain on inspiration, hypotension, and tachycardia. If possible, ask patient to rate level of comfort on a scale of 0 to 10.</p> <p>3 Assess patient for known allergies. Ask patient if he or she has had a problem with medications, latex, or anything applied to skin.</p> <p>4 Review patient's medication record for anticoagulant therapy, including aspirin, warfarin (Coumadin), heparin, or platelet aggregation inhibitors such as ticlopidine (Ticlid) or dipyridamole (Persantine).</p> <p>5 Review patient's hemoglobin and hematocrit levels.</p> <p>6 For patients who have chest tubes, observe:</p> <p>a Chest tube dressing and site surrounding tube insertion.</p> <p>b Tubing for kinks, dependent loops, or clots.</p> <p>c Chest drainage system should remain upright and below level of tube insertion.</p> <p>7 Assess patient's knowledge of procedure.</p> | <p>Provides baseline to determine patient's response to chest tube.</p> <p>Patients in need of chest tubes have impaired oxygenation and ventilation.</p> <p>Signs and symptoms associated with respiratory distress are related to type and size of pneumothorax, hemothorax, or preexisting illness. Signs of hypoxia are related to inadequate oxygen to tissues.</p> <p>Sharp stabbing chest pain with or without decreased blood pressure and increased heart rate may indicate tension pneumothorax. Presence of pneumothorax or hemothorax is painful, frequently causing sharp inspiratory pain. In addition, there is discomfort associated with presence of a chest tube, not just with its insertion. As a result, patients tend to not cough or change position in an effort to minimize this pain (Durai et al., 2010).</p> <p>Povidone-iodine or chlorhexidine are antiseptic solutions used to clean skin before tube insertion (Durai et al., 2010). Lidocaine is a local anesthetic administered to reduce pain. The chest tube will be held in place with tape.</p> <p>Anticoagulation therapy can increase procedure-related blood loss.</p> <p>Parameters reflect if blood loss is occurring, which may affect oxygenation.</p> <p>Ensures that dressing is intact and occlusive seal remains without air or fluid leaks and that area surrounding insertion site is free of drainage or skin irritation.</p> <p>Maintains patent, freely draining system, preventing fluid accumulation in chest cavity. Subcutaneous emphysema can occur if tubing is blocked or kinked. When tubing is coiled, looped, or clotted, drainage is impeded, and there is an increased risk for a tension pneumothorax or surgical emphysema (Briggs, 2010). If chest tube remains in place for some time, patient's risk for infection increases (Oldfield et al., 2009).</p> <p>An upright drainage system facilitates drainage and maintains water seal.</p> <p>Encourages cooperation, minimizes risks and anxiety. Identifies teaching needs.</p> |
|--|--|

STEP

RATIONALE

NURSING DIAGNOSES

- Anxiety
- Acute pain
- Impaired gas exchange
- Risk for Infection

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Patient is oriented and less anxious.
- Vital signs are stable.
- Patient reports no chest pain.
- Breath sounds are auscultated in all lobes. Lung expansion is symmetric, pulse oximetry (SpO₂) is stable or improved, and respirations are nonlabored.
- Chest tube remains in place, and chest drainage system remains airtight.
- Gentle tidaling (fluctuations or rocking) is evident in water-seal or diagnostic indicator.

Hypoxia is relieved.
Decreased hypoxia improves vital sign measures.
Reexpansion of lung reduces chest pain.
Reexpansion of lung promotes normal respirations.

Indicates correct placement and patency of chest tube drainage system.

Indicates that system is functioning normally. Reflects changes in intrapleural pressure.

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

2 Check agency policy and determine whether informed consent is needed.

Invasive medical procedures typically require informed consent.

3 Review health care provider's order for chest tube placement.

Insertion of a chest tube requires health care provider order.

4 Perform hand hygiene.

Maintains sterility of system for use under sterile operating room conditions.

5 Set up water-seal system (or dry system with suction); see manufacturer guidelines.

a Obtain chest drainage system. Remove wrappers and prepare to set up a two- or three-chamber system.

b While maintaining sterility of drainage tubing, stand system upright and add sterile water or NS to appropriate compartments.

Reduces possibility of contamination.

(1) *Two-chamber system (without suction)*: Add sterile solution to water-seal chamber (second chamber), bringing fluid to required level as indicated.

Water-seal chamber acts as one-way valve so air cannot enter pleural space (Briggs, 2010).

(2) *Three-chamber system (with suction)*: Add sterile solution to water-seal chamber (middle chamber). Add amount of sterile solution prescribed by health care provider to suction control (third chamber), usually 20 cm water pressure. Connect tubing from suction control chamber to suction source. Tailor length of drainage tube to patient (see illustration).

Depth of rod below fluid level dictates highest amount of negative pressure that can be present within system. For example, 20 cm of water is approximately 20 cm of water pressure. Any additional negative pressure applied to the system is vented into the atmosphere through suction control vent. This safety device prevents damage to pleural tissues from an unexpected surge of negative pressure from suction source. Excessively long drainage tube may result in occlusions.

(3) *Dry suction system*: Fill water-seal chamber with sterile solution. Adjust suction control dial to prescribed level of suction; suction ranges from -10 to -40 cm of water pressure. Suction control chamber vent is never occluded when suction is used. **NOTE:** On a dry suction system, **DO NOT** obstruct positive-pressure relief valve. This allows air to escape.

Automatic control valve on dry suction control device adjusts to changes in patient air leaks and fluctuation in suction source and vacuum to deliver the prescribed amount of suction.

6 Set up waterless system (see manufacturer guidelines).

a Remove sterile wrappers and prepare to set up.

Maintains sterility of system for use under sterile operating room conditions.

b For two-chamber system (without suction), nothing is added or needs to be done to system.

Waterless two-chamber system is ready for connecting to patient's chest tube after opening wrappers.

STEP

- c For three-chamber system (with suction), connect tubing from suction control chamber to suction source.
 - d Instill 15 to 45 mL of sterile water or NS into diagnostic indicator injection port located on top of system.
- 7 Secure all tubing connections with tape in double-spiral fashion using 2.5-cm (1-inch) adhesive tape or use zip ties (nylon cable) with a clamp (Bauman and Handley, 2011). Check system for patency by:

RATIONALE

Suction source provides additional negative pressure to system.

Allows observation of rise and fall in water in diagnostic air leak window. Constant left-to-right bubbling or rocking is abnormal and indicates an air leak. This is not necessary for mediastinal drainage because there is no tidaling. In an emergency, system *does not* require water for set up.

Prevents atmospheric air from leaking into system and patient's intrapleural space. Provides chance to ensure airtight system before connection to patient.

STEP 5b(2) Top, Pleur-Evac drainage system, a commercial three-chamber chest drainage device. Bottom, Schematic of drainage device.

STEP	RATIONALE
<ul style="list-style-type: none"> a Clamping drainage tubing that will connect to patient's chest tube. b Connecting tubing from float ball chamber to suction source. c Turning on suction to prescribed level. <p>8 Turn off suction source and unclamp drainage tubing before connecting patient to system. Make a second check to be sure that drainage tubing is not excessively long. Suction source is turned on again after patient is connected.</p> <p>9 Administer premedication such as sedatives or analgesics as ordered.</p>	<p>Having patient connected to suction when it is initiated could damage pleural tissues from sudden increase in negative pressure. Tubing that is coiled or looped may become clotted and cause a tension pneumothorax.</p> <p>Reduces patient anxiety and pain during procedure.</p>
<p>Clinical Decision Point <i>During procedure carefully monitor patient for changes in level of sedation.</i></p>	
<p>10 Provide psychological support to patient (Durai et al., 2010).</p> <ul style="list-style-type: none"> a Reinforce preprocedure explanation. b Coach and support patient throughout procedure. <p>11 Perform hand hygiene and apply clean gloves. Position patient for tube insertion so side in which tube is to be inserted is accessible to health care provider.</p> <p>12 Help health care provider with chest tube insertion by providing needed equipment and local analgesic. Health care provider will anesthetize skin over insertion site, make a small skin incision, insert a clamped tube, suture it in place, and apply occlusive dressing.</p> <p>13 Help health care provider attach drainage tube to chest tube; remove clamp. Turn on suction to prescribed level.</p> <p>14 Tape or zip-tie all connections between chest tube and drainage tube. (NOTE: Chest tube is usually taped by health care provider at time of tube placement; check agency policy).</p> <p>15 Check systems for proper functioning. Health care provider will order a chest x-ray film.</p> <p>16 After tube placement position patient:</p> <ul style="list-style-type: none"> a Use semi-Fowler's or high-Fowler's position to evacuate air (pneumothorax). b Use high-Fowler's position to drain fluid (hemothorax). <p>17 Check patency of air vents in system.</p> <ul style="list-style-type: none"> a Water-seal vent must have no occlusion. b Suction control chamber vent is not occluded when suction is used. c Waterless systems have relief valves without caps. <p>18 Position excess tubing horizontally on mattress next to patient. Secure with clamp provided so it does not obstruct tubing.</p> <p>19 Adjust tubing to hang in straight line from chest tube to drainage chamber.</p>	<p>Reduces patient anxiety and helps complete procedure efficiently.</p> <p>Reduces transmission of microorganisms.</p> <p>Ensures smooth insertion.</p> <p>Connects drainage system and suction (if ordered) to chest tube.</p> <p>Secures chest tube to drainage system and reduces risk for air leak that causes breaks in airtight system.</p> <p>Verifies intrapleural placement of tube.</p> <p>Permits optimum drainage of fluid and/or air.</p> <p>Permits displaced air to pass into atmosphere.</p> <p>Provides safety factor of releasing excess negative pressure into atmosphere.</p> <p>Provides safety factor of releasing excess negative pressure.</p> <p>Prevents excess tubing from hanging over edge of mattress in dependent loop. Drainage collected in loop can occlude drainage system, which predisposes patient to a tension pneumothorax (Briggs, 2010).</p> <p>Promotes drainage and prevents fluid or blood from accumulating in pleural cavity.</p>
<p>Clinical Decision Point <i>Frequent gentle lifting of the drain allows gravity to assist blood and other viscous material to move to the drainage bottle. Patients with recent chest surgery or trauma need to have the chest drain lifted based on assessment of the amount of drainage; some patients might need chest tube drains lifted every 5 to 10 minutes until drainage volume decreases. However, when coiled or dependent looping of tubing is unavoidable, the tubing is lifted every 15 minutes at a minimum to promote drainage (Briggs, 2010).</i></p>	
<p>20 Place two rubber-tipped hemostats (for each chest tube) in an easily accessible position (e.g., taped to top of patient's headboard). These should remain with patient when ambulating.</p>	<p>Chest tubes are double clamped under specific circumstances: (1) to assess for an air leak (Table 26-3), (2) to empty or quickly change disposable systems, or (3) to assess if patient is ready to have tube removed.</p>
<p>Clinical Decision Point <i>In the event of a chest tube disconnection and risk of contamination, submerge the tube 2 to 4 cm (1 to 2 inches) below the surface of a 250-mL bottle of sterile water or NS until a new chest tube unit can be set up (Bauman and Handley, 2011).</i></p>	

STEP	RATIONALE
21 Dispose of sharps in proper container, dispose of used supplies, then perform hand hygiene.	Reduces transmission of microorganisms.
22 Care of patient after chest tube insertion: <ul style="list-style-type: none"> <li data-bbox="139 296 773 436">a Perform hand hygiene and apply clean gloves. Assess vital signs, oxygen saturation; skin color; breath sounds; rate, depth, and ease of respirations; and insertion site every 15 minutes for the first 2 hours, then at least every shift (see agency policy). <li data-bbox="139 441 773 850">b Monitor color, consistency, and amount of chest tube drainage every 15 minutes for first 2 hours. Indicate level of drainage fluid, date, and time on write-on surface of chamber. <ul style="list-style-type: none"> <li data-bbox="159 558 773 642">(1) Expect less than 100 mL/hr from a mediastinal tube immediately after surgery and no more than 500 mL in first 24 hours. <li data-bbox="159 646 773 787">(2) Expect between 100 and 300 mL in the first 3 hours after insertion of posterior chest tube, with total of 500 to 1000 mL expected in first 24 hours. Drainage is grossly bloody during first several hours after surgery and changes to serous. <li data-bbox="159 791 773 850">(3) Expect little or no output from anterior chest tube that is inserted for a pneumothorax. <li data-bbox="139 854 537 879">c Observe chest dressing for drainage. <li data-bbox="139 884 773 938">d Palpate around tube for swelling and crepitus (subcutaneous emphysema) as noted by crackling. <li data-bbox="139 970 773 1024">e Check tubing to ensure that it is free of kinks and dependent loops. <li data-bbox="139 1029 773 1113">f Observe for fluctuation of drainage in tubing and water-seal chamber during inspiration and expiration. Observe for clots or debris in tubing. <li data-bbox="139 1236 773 1291">g Keep drainage system upright and below level of patient's chest. <li data-bbox="139 1295 773 1436">h Check for air leaks by monitoring bubbling in water-seal chamber: Intermittent bubbling is normal during expiration when air is being evacuated from pleural cavity, but continuous bubbling during both inspiration and expiration indicates leak in system. <li data-bbox="139 1440 773 1495">i Remove gloves and dispose of used soiled equipment in appropriate biohazard container. Perform hand hygiene. 	Provides immediate information about procedure-related complications such as respiratory distress and leakage. Provides baseline for continuous assessment of type and quantity of drainage. Ensures early detection of complications. Sudden gush of drainage may result from coughing or changing patient's position, releasing pooled/collected blood rather than indicating active bleeding. Acute bleeding indicates hemorrhage. Health care provider should be notified if there is more than 250 mL of bloody drainage in an hour (Durai et al., 2010). Drainage around tube may indicate blockage. Indicates presence of air trapping in subcutaneous tissues. Small amounts are commonly absorbed. Large amounts are potentially dangerous. Promotes drainage. If fluctuation or tidaling stops, it means that either the lung is fully expanded or system is obstructed (Bauman and Handley, 2011). In nonmechanically ventilated patient, fluid rises in water-seal or diagnostic indicator (waterless system) with inspiration and falls with expiration. The opposite occurs in patient who is mechanically ventilated. This indicates that system is functioning properly (Lewis et al., 2011). Promotes gravity drainage and prevents backflow of fluid and air into pleural space. Absence of bubbling may indicate that lung is fully expanded in patient with a pneumothorax. Check all connections and locate sources of air leak as described in Table 26-3. Prevents accidents involving contaminated equipment.

EVALUATION

1 Evaluate patient for decreased respiratory distress and chest pain. Auscultate patient's lungs and observe chest expansion.	Determines status of lung expansion.
2 Monitor vital signs and pulse oximetry.	Determines if level of oxygenation has improved.
3 Reassess patient's level of comfort on scale of 0 to 10, comparing level with comfort before chest tube insertion.	Indicates need for analgesia. Patient with chest tube discomfort hesitates to take deep breaths and as a result is at risk for pneumonia and atelectasis.
4 Evaluate patient's ability to use deep-breathing exercises while maintaining comfort.	Indicates patient's ability to promote lung expansion and prevent complications.
5 Monitor continued functioning of system as indicated by reduction in amount of drainage, resolution of air leak, and complete reexpansion of the lung.	Detects early signs of system complications or indicates possible removal of chest tube.

TABLE 26-3 Problem Solving with Chest Tubes

Assessment	Intervention
Air leak can occur at insertion site, at connection between tube and drainage device, or within drainage device itself. Determine when air leak occurs during respiratory cycle (e.g., inspiration or expiration). Continuous bubbling is noted in water-seal chamber that is attached to suction (Briggs, 2010). If water-seal unit is not attached to suction, a total absence of bubbling and drainage would indicate a leak.	Check all connections between chest tube and drainage system. Locate leak by clamping tube at different intervals along the tube. Leaks are corrected when constant bubbling stops. If present on a chest drainage system such as the Sahara S 1100a Pleur-Evac, observe the air-leak meter to determine the size of the leak.
Assess for location of leak by clamping chest tube with two rubber-shod or toothless clamps close to chest wall. If bubbling stops, air leak is inside patient's thorax or at chest insertion site.	Unclamp tube, reinforce chest dressing, and notify health care provider immediately. Leaving chest tube clamped can cause collapse of lung, mediastinal shift, and eventual collapse of other lung from buildup of air pressure within the pleural cavity.
If bubbling continues with the clamps near the chest wall, gradually move one clamp at a time down drainage tubing away from patient and toward suction control chamber. When bubbling stops, leak is in section of tubing or connection between clamps.	Replace tubing or secure connection and release clamps.
If bubbling still continues, it indicates that leak is in the drainage system.	Change the drainage system.
Assess for tension pneumothorax: <ul style="list-style-type: none"> • Severe respiratory distress • Low oxygen saturation • Chest pain • Absence of breath sounds on affected side • Tracheal shift to unaffected side • Hypotension and signs of shock • Tachycardia 	Make sure that chest tubes are patent: remove clamps, eliminate kinks, or eliminate occlusion. Notify health care provider immediately and prepare for another chest tube insertion. A one-way flutter (Heimlich) valve or large-gauge needle may be used for short-term emergency release of pressure in the intrapleural space. Have emergency equipment, oxygen, and code cart available because condition is life threatening.
Water-seal tube is no longer submerged in sterile fluid because of evaporation.	Add sterile water to water-seal chamber until distal tip is 2 cm (1 inch) under surface level.

Unexpected Outcomes

- 1 Patient develops respiratory distress. Chest pain, a decrease in breath sounds over affected and nonaffected lungs, marked cyanosis, asymmetric chest movements, presence of subcutaneous emphysema around tube insertion site or neck, hypotension, tachycardia, and/or mediastinal shift, are critical and indicate a severe change in patient status such as excessive blood loss or tension pneumothorax.
- 2 Air leak is unrelated to patient's respirations.
- 3 There is no chest tube drainage.
- 4 Chest tube is dislodged.
- 5 Substantial increase in bright red drainage is observed.

Related Interventions

- Notify health care provider immediately.
 - Collect set of vital signs and pulse oximetry.
 - Prepare for chest x-ray.
 - Provide oxygen as ordered.
-
- See Table 26-3 for determining source of an air leak and problem solving.
 - Notify health care provider.
 - Observe for kink in chest drainage system.
 - Observe for possible clot in chest drainage system.
 - Observe for mediastinal shift or respiratory distress (medical emergency).
 - Notify health care provider.
 - Immediately apply pressure over chest tube insertion site.
 - Have assistant obtain sterile petroleum gauze dressing. Apply as patient exhales. Secure dressing with tight seal.
 - Notify health care provider.
 - Obtain vital signs.
 - Monitor drainage.
 - Assess patient's cardiopulmonary status.
 - Notify health care provider.

Recording and Reporting

- Record respiratory assessment, type of drainage device, amount of suction if used, amount of drainage in chamber, and presence of absence of an air leak. Record patient teaching and validation of understanding in nurses' notes and electronic health record (EHR).
- Record level of patient comfort and baseline vital signs, including oxygen saturation. If postoperative patient, record vital signs and oxygen saturation every 15 minutes for at least 2 hours after surgery.
- Record integrity of dressing and presence of drainage on dressing.
- Report any unexpected outcomes immediately to nurse in charge or health care provider.

Special Considerations

Teaching

- Instruct patient and family caregivers regarding proper functioning of chest tube and drainage system.
- Inform patient to remain in bed if chest tube is attached to suction (Maliakal, 2011).
- Instruct patient to not lie on the tubing or allow it to get kinked to promote drainage (Maliakal, 2011).
- Instruct patient to immediately report any changes in chest comfort.

Pediatric

- If possible, using pictures and special dolls, familiarize child and family with equipment before inserting chest drainage system (Hockenberry and Wilson, 2011).

- Chest tube drainage greater than 3 mL/kg/hr for more than 3 consecutive hours is excessive and may indicate postoperative hemorrhage. Notify the health care provider immediately (Hockenberry and Wilson, 2011).

Gerontologic

- Fragility of the older adult's skin requires special care and planning for management of chest tube dressing. Frequently assess surrounding skin for signs of skin breakdown.

Home Care

- Patients with chronic conditions (e.g., uncomplicated pneumothorax, effusions, empyema) that require long-term chest tube may be discharged with smaller mobile drains (Varela et al., 2010).
- Instruct patient how to ambulate and remain active with a mobile chest tube drainage system.
- Instruct patient and family caregivers about when to contact health care provider regarding changes in the drainage system (e.g., chest pain, breathlessness, change in color or amount of drainage, leakage on the dressing around the chest tube).
- Provide patient and family caregiver information specific to the type of drain; when possible have patient demonstrate proper maintenance of the mobile drainage system. Most of these systems do not have a suction control chamber and use a mechanical one-way valve instead of a water-seal chamber (Varela et al., 2010).

SKILL 26-2 Assisting with Removal of Chest Tubes

NSO Chest Tubes Module / Lesson 4

Actual removal of a chest tube is most often the function of a physician or health care provider such as a physician's assistant or nurse practitioner. If you are to remove a chest tube, this procedure must be part of agency policy and procedure standards, and you must be competent in the skill. You will complete a designated number of removals under the observation of the health care provider. This skill details nursing responsibilities and health care provider actions for chest tube removal (Briggs, 2010).

Prepare a patient for chest tube removal by assessing the need for pre-removal analgesia, obtaining the required medication orders, and instructing a patient about the process and what will be requested of him or her. During removal of the chest tube, it is important to instruct a patient to take a deep breath and hold it (Valsalva maneuver) until the tube is removed. This maneuver prevents air from being sucked into the chest as the tube is pulled out and an occlusive dressing is applied (Bauman and Handley, 2011; Briggs, 2010; Durai et al., 2010).

Delegation and Collaboration

The skill of assisting with removal of chest tubes cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Immediately report to the nurse any patient sensations of shortness of breath, increased chest pain, dizziness, or increased anxiety.
- Report to the nurse any drainage on the dressing placed over the chest tube site.

Equipment

- Suture set
- Sterile scissors
- Sterile forceps
- Clean gloves
- Sterile gloves
- Facemask/face shield
- Prepared sterile dressing: petrolatum-impregnated gauze, 4 × 4 inch–gauze dressings, and large dressings
- 4-inch adhesive tape or elastic bandage (Elastoplast) cut into strips
- Stethoscope, sphygmomanometer, pulse oximeter
- Disposable bed pad

STEP

RATIONALE

ASSESSMENT

<p>1 Assess status of patient's lung re-expansion.</p> <p>a Provide health care provider with results of chest x-ray film.</p> <p>b Note trend in water-seal fluctuation over last 24 hours. Determine if bubbling is present.</p> <p>c Confirm that drainage has decreased to less than 100-to-150 mL/day (Briggs, 2010; Hunter, 2008).</p> <p>d Percuss lung for resonance (see Chapter 6).</p> <p>e Auscultate lung sounds.</p> <p>2 Assess patient's level of comfort using a scale of 0 to 10 and determine when last analgesic medication was given.</p> <p>3 Determine patient's understanding of chest tube removal procedure.</p> <p>4 Do not clamp chest tube before removal. Assess for changes in vital signs, oxygen saturation, chest pain, apprehension, and symptoms of tension pneumothorax.</p>	<p>Reveals position of lung tissue in chest cavity and whether sufficient lung reexpansion has occurred (Briggs, 2010; Durai et al., 2010).</p> <p>Pleura of expanded lung seals holes on internal tip of chest tube, halting fluctuation in water seal. Halt in fluctuation for 24 hours indicates that lung is expanded. When bubbling is present, it usually indicates that lung has not fully expanded (Briggs, 2010; Durai et al., 2010).</p> <p>Pleural drainage was removed, allowing lung to reexpand.</p> <p>Normal resonance occurs with reexpansion.</p> <p>Normal breath sounds are heard bilaterally with reexpansion.</p> <p>Chest tube removal is painful; additional analgesia or breathing exercises are often necessary (Briggs, 2010; Durai et al., 2010).</p> <p>Encourages cooperation and minimizes risks and anxiety. Identifies teaching needs.</p> <p>Clamping chest tube before removal to assess patient's tolerance is no longer recommended because there is no benefit to the practice. If a chest tube that was continuing to bubble is clamped, a tension pneumothorax may occur (Briggs, 2010; Hunter, 2008).</p>
--	--

NURSING DIAGNOSES

- Acute pain
 - Anxiety
 - Risk for impaired gas exchange
- Related factors are individualized based on patient's condition or needs.*

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Lung reexpansion is maintained. • Patient does not experience discomfort. • Spontaneous healing of chest tube insertion site occurs after removal of tube without infection or other complications. <p>2 Explain procedure to patient.</p>	<p>Source of air or fluid loss is sealed or has healed.</p> <p>Pain management is achieved.</p> <p>Large, nonporous occlusive dressing at puncture site promotes uncomplicated healing.</p> <p>Reduces anxiety and promotes patient cooperation.</p>
--	--

IMPLEMENTATION

<p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Administer prescribed medication for pain relief about 30 minutes before procedure.</p> <p>3 Perform hand hygiene and apply clean gloves and face shield if needed.</p> <p>4 Help patient to sitting position on edge of bed, lying supine or on side without chest tubes. Place pad under chest tube site.</p> <p>5 Health care provider prepares an occlusive dressing of petrolatum-impregnated gauze on a pressure dressing, sets it aside on sterile field, and applies sterile gloves.</p> <p>6 Support patient physically and emotionally while health care provider removes dressing and clips sutures.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Reduces discomfort and relaxes patient. Medication reaches peak effect at time of tube removal. Patients report sensations ranging from pain to pulling when chest tube is removed (Durai et al., 2010; Hunter, 2008).</p> <p>Reduces transmission of microorganisms.</p> <p>Health care provider prescribes patient's position to facilitate tube removal. Pad absorbs any drainage associated with tube removal.</p> <p>Essential to prepare in advance for quick application to wound on tube withdrawal.</p> <p>Patients state that, when they know that the tube is being pulled, they can mentally prepare themselves for the procedure. Support from health care team reduces anxiety and promotes cooperation.</p>
--	---

STEP	RATIONALE
7 Health care provider asks patient to perform Valsalva maneuver (take deep breath and hold it) or exhale completely and hold it.	Prevents air from being sucked into chest as tube is removed (Bauman and Handley, 2011; Durai et al., 2010). A complication associated with removal of chest tubes is recurrent pneumothorax, which results from atmospheric air reentering pleural cavity. This occurs when patient inhales during tube removal.
8 Health care provider quickly pulls out chest tube and tightens and ties purse-string suture if present, after which patient is instructed to breathe normally.	This forms an airtight seal and prevents entry of air through chest wound. Sutures aid in skin closure (Briggs, 2010; Durai et al., 2010; Hunter, 2008).
9 Health care provider applies sterile occlusive dressing over wound and firmly secures it in position with elastic bandage (Elastoplast) or wide tape.	Keeps wound aseptic. Prevents entry of air into chest. Wound closure occurs spontaneously.
10 Help patient to upright position supported by pillows.	Restores patient's comfort. Patients report that proper positioning following chest tube removal helps to relieve procedure-related sensations of pain and pulling (Hunter, 2008).
11 Remove used equipment from bedside. Dispose in appropriate receptacle.	Prevents spread of microorganisms.
12 Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Auscultate lung sounds.	Helps to confirm lung remains expanded.
2 Palpate skin over area where tube was inserted for subcutaneous emphysema.	Subcutaneous emphysema results from entrance of air into subcutaneous space. It is painful, and as a result patients may not take full lung expansion (Briggs, 2010; Durai et al., 2010).
3 Evaluate for signs of respiratory distress immediately after tube removal and during first few hours after removal.	Provides for early notification of health care provider if adverse symptoms occur. Chest tubes may need reinsertion.

Critical Decision Point *If air is heard escaping from the chest tube site, reinforce the occlusive dressing and immediately notify health care provider.*

4 Evaluate patient's vital signs, oxygen saturation, pulmonary status, and psychological status.	Detects early signs and symptoms of complications.
5 Review chest x-ray film.	Identifies early signs of incomplete lung expansion. If complications are noted, a computed tomography (CT) scan, which is better at identifying chest tube location, should be recommended (Lewis et al., 2011).
6 Ask about patient's level of pain or comfort. Observe for nonverbal cues of pain and assess level of discomfort on scale of 0 to 10.	Indicates that wound did not close well. Determines patient's tolerance of procedure.
7 Check chest dressing for drainage and patency. When changing dressing, note wound for signs of healing.	Ensures occlusion and proper healing of chest wound.

Unexpected Outcomes

- 1 Dyspnea and labored respirations noted after chest tube removal; potential recurrence of pneumothorax, hemothorax, or effusion.
- 2 Infection is noted at insertion site.

Related Interventions

- Notify health care provider.
- Obtain vital signs and oxygen saturation.
- Stay with patient.
- Prepare for possible chest tube reinsertion.
- Assess patient's vital signs for elevated temperature, tachypnea, and tachycardia. Assess wound for drainage, odor, erythema, or increased pain.

Recording and Reporting

- Record removal of tube, amount and appearance of drainage in the collection bottle, appearance of wound and dressing, and patient's response in nurses' notes and EHR.
- Record vital signs and respiratory assessment on flow sheet.
- Record patient teaching and validation of understanding in nurses' notes and EHR.

- Report unexpected outcomes to nurse in charge or health care provider.

Special Considerations

Teaching

- Instruct patient and family caregiver to immediately report signs of chest pain, shortness of breath, or sensations of chest discomfort.

Pediatric

- Pediatric patients usually require analgesia (e.g., morphine sulfate 0.1 mg/kg in combination with midazolam [Versed]) before chest tube removal (Hockenberry and Wilson, 2011).

- EMLA (locally applied anesthetic patch) placed under the occlusive dressing at the chest tube insertion site 1 hour before tube removal reduces pain of procedure. However, child may still feel the “pulling” sensation (Hockenberry and Wilson, 2011).

SKILL 26-3 Autotransfusion of Chest Tube Drainage

In autotransfusion blood lost from trauma, injury, or surgery is infused back into a patient’s circulatory system. When reinfusion is linked with chest drainage, it is a relatively risk-free, inexpensive, and easy method of replacing blood. Benefits of autotransfusion include an immediate blood supply, no risk of transfusion reaction, and more oxygen supplied to vital organs (Bauman and Handley, 2011). Patients must also have a patent intravenous (IV) line in place (see Chapter 28). Reinfusion is contraindicated in patients with coagulation disorders, infections, cancer, and pre-existing liver or kidney dysfunction (Atrium, 2010; Bauman and Handley, 2011).

Delegation and Collaboration

The skill of reinfusion of chest tube drainage cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Immediately inform nurse of changes in patient’s vital signs or pulse oximetry (SpO₂) levels.
- Immediately inform nurse about increased or decreased drainage from chest tube.

Equipment

- Adult/pediatric single-use chest drainage and autotransfusion unit (Fig. 26-10)
- Optional:* Continuous autotransfusion system (ATS) with a blood-compatible infusion pump (check agency policy)
- Microaggregate blood filter (40-µm filter, see manufacturer instructions)

FIG 26-10 Example of autotransfusion unit.

- Nonvented blood-compatible IV administration set
- Antiseptic swab
- Infusion pump (see manufacturer instructions)
- Replacement bag
- Gown, clean gloves, and mask as needed

STEP **RATIONALE**

ASSESSMENT

- | | |
|--|---|
| <p>1 See Assessment for Skill 26-1.</p> <p>2 Determine presence of active bleeding (at least 50-to-100 mL/hr), through chest tube.</p> | <p>Indicates need for possible reinfusion of chest tube drainage.</p> |
|--|---|

Clinical Decision Point *Collected blood never remains in the chest drain or ATS blood bag for more than 6 hours before autotransfusion. Immediate use is preferred (Atrium, 2010; Bauman and Handley, 2011).*

- | | |
|---|--|
| <p>3 Assess IV site (see Chapter 28); note size of IV catheter. 18-gauge angiocatheter preferred.</p> <p>4 Obtain baseline laboratory data (e.g., hemoglobin and hematocrit).</p> | <p>Determines presence of adequate and patent IV site for administration of blood products.</p> <p>Provides data to measure effectiveness of reinfusion of chest drainage on patient’s circulating blood volume.</p> |
|---|--|

NURSING DIAGNOSES

- Decreased cardiac output
- Ineffective peripheral tissue perfusion
- Risk for infection

Related factors are individualized based on patient’s condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Vital signs, hematocrit, and hemoglobin stabilize. • Drainage system functions correctly and lung reexpands in 48 to 72 hours. • IV line remains patent. | <p>Reinfusion reduces significant blood loss associated with closed chest drainage.</p> <p>Negative pressure is reestablished in intrapleural space.</p> <p>Patent IV is necessary for reinfusion of cleansed mediastinal tube drainage.</p> <p>Reduces anxiety and promotes patient cooperation.</p> |
| <p>2 Explain procedure to patient.</p> | |

IMPLEMENTATION

- | | |
|--|---|
| <p>1 System setup:</p> <p>a Set up ATS according to technique that maintains sterility of unit and following the three steps printed on front of unit.</p> <p>b Make certain that all connections are tight and all clamps are open.</p> <p>c A 200-μm double-sided mesh filter is located in ATS bag to filter drainage.</p> <p>d ATS collection bag has capacity of 1000 mL marked in increments of 25 mL and an area for marking times and amounts.</p> | <p>Contamination of unit provides ready source of infection to patient.</p> <p>Tight connections ensure an airtight system, and open clamps allow chest drainage to enter ATS bag.</p> <p>Filtering drainage removes extraneous materials and microemboli.</p> <p>Dark-red drainage is expected only during immediate postoperative period. This drainage turns serous over time.</p> |
|--|---|

Clinical Decision Point *Continuous ATS is prescribed following cardiac surgery. This is a closed system with a specific infusion pump and IV circuit. This system requires specific education and is used in selected situations (Atrium, 2010). Check agency policy.*

- | | |
|---|---|
| <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> |
| <p>3 Perform hand hygiene and apply clean gloves.</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>4 Prepare chest drainage for reinfusion.</p> <p>a Following manufacturer directions, open replacement bag and close the two white clamps.</p> <p>b Use high-negativity relief valve to reduce excessive negativity.</p> <p>c Bag transfer:</p> <ol style="list-style-type: none"> (1) Close clamp on chest drainage tubing. (2) Close clamps on top of initial ATS collection bag. (3) Connect chest drainage tube to new ATS bag. (4) Make certain that all connections are tight. (5) Open all clamps on chest drainage tube and replacement bag. <p>d Connect connectors on top of initial collection bag and remove bag by lifting it from the side hook and then from the foot hook.</p> <p>e Secure replacement bag by connecting the foot hook, replacing the metal frame into the side hook of the chest drainage unit, and pushing down to secure the frame onto the hook.</p> <p>f Place thumbs on top of metal frame and push up with fingers to slide bag out; remove replacement bag.</p> | <p>Contamination of unit provides ready source of contamination to patient. Closed clamps maintain closed system during replacement.</p> <p>This eases removal of initial collection bag from metal support stand.</p> <p>Prevents air from entering chest cavity through tube and collapsing lung.</p> <p>Maintains closed system for reinfusion, preventing contamination of the blood.</p> <p>Establishes new ATS.</p> <p>Ensures an airtight system.</p> <p>Reestablishes an autotransfusion collection system.</p> |
| <p>5 Reinfuse chest drainage.</p> <p>a Use new microaggregate filter to reinfuse each autotransfusion bag.</p> | <p>Maintains closed system within bag and removes it for use in autotransfusion.</p> <p>Provides safe attachment of replacement bag to chest drainage unit.</p> <p>Prevents infusion of microemboli and provides maximal filtration for each bag.</p> |

STEP	RATIONALE
<p>b Access bag by inverting it, wiping off port with antiseptic swab, and spiking through the port with the microaggregate filter and twisting.</p>	<p>Connects autotransfusion bag to transfusion tubing.</p>
<p>c With bag upside down, gently squeeze it to remove air and prime filter with blood.</p>	<p>Gentle pressure is used to prevent hemolysis.</p>
<p>d Hang bag on an IV pole and continue to prime tubing until all air is gone. Clamp tubing, attach it to patient's IV access, and adjust clamp to deliver reinfusion at appropriate rate.</p>	<p>Removes all air from transfusion tubing. Reinfusion is delivered either by gravity, application of a blood cuff (not to exceed 150 mm Hg pressure), or blood-compatible IV pump (see Chapter 29).</p>
<p>e If ordered, anticoagulants (Anticoagulant Citrate Dextrose Solution-A or Citrate Phosphate Dextrose Solution, USP) are added to reinfusion through self-sealing port in autotransfusion connector.</p>	<p>Prevents clotting in autotransfusion. Reversing heparin with protamine to preoperative levels or collection of nonheparinized blood following emergency chest trauma may require a citrate anticoagulant (Atrium, 2010).</p>
<p>f Monitor patient's vital signs and SpO₂ according to patient condition and agency policy. For some patients this may be as frequent as every 15 minutes; for other patients it may be every hour.</p>	<p>Patients who require autotransfusion usually have complex physiologic needs, and their vital signs change quite rapidly. Consistent, frequent monitoring allows for timely identification of changes and initiation of appropriate interventions to restore physiologic stability.</p>
<p>6 Discontinue autotransfusion.</p> <p>a Clamp chest drainage tube only briefly and only if ordered by health care provider and connect it directly to chest drainage unit with red and blue connectors.</p>	<p>Clamping chest tube for any length of time can cause a tension pneumothorax (Hunter, 2008; Lewis et al., 2011).</p>
<p>b Open chest drainage tube clamp.</p>	<p>All drainage will be collected directly in drainage unit and appropriately discarded.</p>
<p>7 Discard used supplies and perform hand hygiene.</p>	<p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Monitor vital signs, hematocrit, and hemoglobin.</p>	<p>Helps determine effects of treatment.</p>
<p>2 Monitor chest drainage system and patient's lung sounds.</p>	<p>Helps determine proper functioning of system and its effectiveness.</p>
<p>3 Evaluate IV infusion site for infiltration and phlebitis.</p>	<p>Patent IV infusion site is maintained.</p>

Unexpected Outcomes

- 1 Chest tube is dislodged.
- 2 Patient has dyspnea, chest pain, and labored respirations.
- 3 Patient has signs of infection, fever, and chills.

Related Interventions

- Immediately apply pressure over chest tube insertion site.
- Have assistant apply sterile petrolatum-impregnated occlusive dressing.
- Notify health care provider.
- Verify that chest tube is patent and draining.
- Obtain vital signs.
- Notify health care provider.
- Obtain wound cultures as ordered.
- Obtain vital signs.

Recording and Reporting

- Record drainage and reinfusion with times and amounts of each; include patient's response to reinfusion. Describe condition of IV infusion site. Record patient teaching and validation of understanding in nurses' notes and EHR.

Special Considerations

Teaching

- Prepare patient and family caregivers for the procedure so they will understand when the patient's blood is reinfused. Patients and their families may have had this instruction before surgery but need reinforcement.

Critical Thinking Exercises

Mr. Moberly is in his first postoperative day following open heart surgery. He has a right pleural and mediastinal chest tube to drainage. His last vital signs were blood pressure (BP) 110/64 mm Hg; pulse 126 beats/min; respirations on mechanical ventilator 16 breaths/min; SpO₂, 90%; temperature, 99.0° F (rectally). The last hourly chest tube drainage was 75 mL from the pleural tube and 100 mL from the mediastinal tube.

- Why is it important to check vital signs, check for air leaks, and note the amount of chest drainage every 15 to 30 minutes for at least 2 hours after Mr. Moberly returns from surgery?
- Mr. Moberly's chest tube drainage ranged from 75 to 100 mL from both chest tubes over the last 3 hours. Which measures do you take to maintain chest tube patency?
- It is now 12 hours after surgery, and Mr. Moberly is transferred from bed to chair. Immediately following this transfer you note drainage of 50 mL of dark red fluid. What are your actions?

REVIEW QUESTIONS

- The nurse is caring for a patient with a new chest tube. The patient is anxious and fearful of taking pain medications because he knows that he needs to be active, take deep breaths, and cough. Which action is the best for the nurse to take to address this fear?
 - Tell him that the medication will make him sleepy
 - Explain that by controlling pain he will be able to be active and cough well
 - Notify the health care provider
 - Give him the medication anyway
- A postoperative thoracotomy patient complains of increased sharp chest pain. The nurse's assessment reveals an increased respiratory rate, increased pulse rate, and increased anxiety. When assessing the chest tube system, the nurse notes that the water-seal chamber of the collection tubing is empty. What is causing the patient's chest pain?
 - Improper function of the chest tube system
 - Improved pneumothorax
 - Tension pneumothorax
 - Incisional pain
- Patients with chest tubes that remove bloody drainage from the chest cavity usually are at risk for respiratory problems. These patients have many care priorities. What are two important priorities related to management of the chest tube system?
 - Monitoring chest tube drainage and maintaining chest tube patency
 - Monitoring chest tube drainage and promoting activity
 - Promoting airway clearance and maintaining chest tube patency
 - Promoting activity and airway clearance
- Patients who have a pneumothorax have which type of chest tube?
 - Pleural tubes placed in the second or third intercostal space
 - Pleural tubes placed in the fifth or sixth intercostal space
 - Pleural tubes placed laterally
 - Pleural tubes placed posteriorly
- The nurse is caring for a patient with a chest tube to treat a pneumothorax. The tube and occlusive dressing become dislodged. What should be the nurse's immediate action?
 - Call for help and take vital signs
 - Take vital signs and perform a pulmonary assessment
 - Secure an occlusive dressing over chest tube site and take vital signs
 - Notify the health care provider and prepare to insert a new chest tube

- When caring for a patient with a chest tube, which activities can a nurse delegate to nursing assistive personnel (NAP)? (Select all that apply.)
 - Caring for a patient with a chest tube connected to a disposable drainage system
 - Helping to remove chest tubes
 - Reinfusion of chest tube drainage
 - None of the above
- A patient comes through the emergency department after an automobile accident 6 hours ago. He has had a chest tube inserted at a small community hospital. He is transferred immediately to the intensive care unit. The nurse's assessment finds that the 18 Fr chest tube is draining serosanguineous fluid, with approximately 75 mL draining over the last hour. The medical record indicates the patient has a hemothorax. The patient's SpO₂ is 90, and respirations are 18 per minute. Based on the nurse's findings the most important action would be:
 - Monitoring the patient's vital signs
 - Notifying the health care provider about the appearance of the drainage
 - Providing analgesic for the patient's pain
 - Frequently checking the position of the chest drainage tube and note if it stays patent
- The nurse is assisting the health care provider with removal of a chest tube. Which of the following statements is incorrect?
 - The patient must be in a prone position to complete the chest tube removal.
 - The nurse administers the ordered analgesia 30 minutes before the procedure.
 - The nurse provides emotional support during tube insertion.
 - The nurse has suction available.
- Mr. Rifas is a 39-year-old who presented to the emergency department with a tension pneumothorax following a motorcycle accident. He is now on your medical-surgical floor with a chest tube in place at 20 cm of suction. The prior shift reported that Mr. Rifas had a total of 180 mL serous drainage. When you go to assess Mr. Rifas, you notice 250 mL of bright red blood in the chest drainage system. You assess his vital signs: blood pressure, 102/56; heart rate, 142; respiratory rate, 28/min; and oxygen saturation, 89%. In addition, Mr. Rifas is complaining of dyspnea. Which of the following actions is the priority?
 - Do nothing; this is normal for a patient following a tension pneumothorax.
 - Continue to monitor Mr. Rifas' vital signs.
 - Notify the health care provider immediately.
 - Notify the charge nurse to let her know that you will need to have a new canister ordered.
- Stripping the chest tube is no longer best practice because it causes increased _____, which can lead to lung tissue injury.

KEY TERMS

Advance directive	Bag-mask device	Code event	Endotracheal intubation
Automated external defibrillator (AED)	Cardiopulmonary resuscitation (CPR)	Do not resuscitate (DNR)	Manual defibrillator
		Dysrhythmia	Oral airway

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss indications for oral airway insertion.
- Identify need for automated external defibrillator (AED) application and indications for use.
- State indications for cardiopulmonary resuscitation (CPR).
- Discuss code management.
- State the end points for CPR.
- Demonstrate in a laboratory or clinical situation: insertion of an oral airway, use of an AED, and performance of CPR.

Cardiopulmonary arrests are emergency situations that you must be prepared to handle at any time. Cardiac arrest is the cessation of circulating blood flow, which eliminates oxygen transport and perfusion. Many cardiac arrests are caused by irregular heart rhythms known as dysrhythmias. The causes of dysrhythmias may include electrolyte disturbances (potassium, magnesium, or calcium), heart damage, and certain prescribed or recreational medications. A dysrhythmia causes symptoms that vary in severity from minor to lethal. Lethal dysrhythmias include ventricular tachycardia (VT) and ventricular fibrillation (VF) and require a medically delivered electrical shock for treatment. Early defibrillation or shock may quickly return the heart to normal without further deterioration of a patient's status. The majority of arrests involve the collapse of both the respiratory and cardiovascular systems. This is defined as a *cardiopulmonary arrest*. Unless otherwise indicated within a patient's advance directive or a do-not-resuscitate (DNR) health care provider's order, all patients receive cardiopulmonary resuscitation (CPR) in the event of an arrest.

In addition to initiating CPR, you must anticipate and recognize prearrest indications such as tachycardia,

hypotension, tachypnea, decreasing oxygen saturation below 90% despite provision of supplemental oxygen, and a decreasing urine output of less than 50 mL in 4 hours (Ehlenbach et al., 2009). Each agency has policies for initiating the rapid-response team before a code occurs.

You will learn to approach a resuscitation attempt in a systematic and organized fashion to ensure the most expeditious care. Within most hospitals this arrest situation is referred to as a "code" (e.g., "code blue," "code 7"). Each agency has a specific code or signal to summon immediate assistance in the event of a cardiac and/or respiratory arrest. The goal is to provide resuscitation in a timely manner to restore cardiopulmonary function and avoid poor neurologic outcomes or death. Most nurses and nursing students are required to be certified in basic life support (BLS) measures.

EVIDENCE-BASED PRACTICE

The Committee on Emergency Cardiac Care (Berg et al., 2010a) reviews and conducts research on cardiac arrest treatment and outcomes and has created evidence-based guidelines for both initial care (BLS) and ongoing measures (advanced

cardiovascular life support [ACLS]) (Neumar et al., 2010). The 2010 American Heart Association (AHA) resuscitation guidelines emphasize the importance of high-quality CPR, which includes continuous chest compression for bystanders, a new emergency medical services (EMS) algorithm, and aggressive postresuscitation care (AHA, 2010). These new methods have shown to dramatically improve survival in patients with witnessed arrest and shockable rhythm (Ewy and Kern, 2009). The method suggests use of continuous chest compression without mouth-to-mouth ventilations for witnessed cardiac arrest. For bystanders with access to automated external defibrillators (AEDs) and EMS personnel who arrive during the first 4 to 5 minutes of the arrest, the delivery of a defibrillator shock is recommended. The updated CPR guidelines from the AHA include a hands-only approach (continuous chest compressions) for the untrained lay rescuer. The sequence of actions has changed from A B C (airway, breathing, circulation) to C A B (circulation, airway, breathing). Methods to improve survival after cardiopulmonary arrest include:

- Immediate recognition and activation of emergency medical response.
- Early CPR that emphasizes chest compressions.
- Rapid defibrillation if indicated.
- Effective advanced cardiac life support
- Integrated postcardiac care such as cooling to preserve neurologic function (Peberdy et al., 2010). Many hospitals have developed protocols for using external cooling techniques and intravascular cooling devices.

Many hospitals now allow family members and significant others to remain in a patient's room during resuscitative efforts and invasive procedures. Evaluation of these programs confirms a remarkable level of approval and gratitude by participating family members (AACN, 2010). Survey of family members noted a significant reduction in posttraumatic stress and self-reports of a greater sense of resolution and fulfillment among witnesses of resuscitative efforts compared with nonwitnesses.

PATIENT-CENTERED CARE

Whenever a patient requires resuscitation, his or her family is also a prime nursing concern. When caring for patients from diverse cultures and religions, consider an individual's meaning and interpretation of life support and resuscitation. You can perform many

interventions to help families during emergency situations. Use a professional language interpreter to explain the patient's status to them. In addition, use cultural and religious support personnel to facilitate understanding of the events by family members and accommodate the patient's religious and cultural practices. Be prepared to handle large numbers of visitors who may remain at the bedside to provide support for the family and/or pray for the patient. Collaborate with the family decision maker and leader to plan rotating visits at the bedside. It is helpful to designate a waiting area to accommodate the group.

Advance directives offer valuable information concerning a patient's resuscitation status and individual patient decisions regarding resuscitation efforts. Although advance directives are often addressed before or during a patient's hospitalization, you play an important role in encouraging patients to complete the document.

Although individuals may be part of a specific cultural or religious group, an individual may not follow all aspects of that culture or religion. Therefore it is essential that you consider each individual's interpretation and wishes to ensure the right of self-determination.

Safety Guidelines

- 1 Know a patient's baseline vital signs, noting any irregularities in cardiac rhythm. Dysrhythmias can precipitate a cardiopulmonary arrest. Cardiovascular conditions that place a patient at risk for dysrhythmias include coronary artery disease, myocardial infarction, open-heart surgeries, acid-base imbalances, and toxicities.
- 2 Know a patient's most recent serum electrolyte values. Electrolyte imbalances (e.g., potassium, magnesium, and calcium) can precipitate cardiopulmonary arrest.
- 3 When a patient has been exposed to a chemical or drug, attempt to determine the type and amount of the substance involved. Certain chemicals (e.g., ethanol, tranquilizers, opiates) depress the respiratory center and can result in a respiratory arrest. Oversedation involving the use of patient-controlled analgesia (PCA) pumps or epidural administration can also contribute to respiratory depression. Overdoses of some drugs can cause ventricular dysrhythmias and cardiopulmonary arrest.

SKILL 27-1 Inserting an Oropharyngeal Airway

An oropharyngeal airway is a semicircular, minimally flexible, curved piece of hard plastic (Fig. 27-1). When inserted, it extends from just outside the lips, over the tongue, and to the pharynx (Fig. 27-2). Oral airways allow you to suction through a central core or along the side of the airway and maintain airway patency in an unconscious patient.

Oral airways vary in length and width (Table 27-1). Choose the size of an oral airway based on a patient's age and the width and length of his or her mouth. Size is correct if, when the flange is held parallel to the front teeth with the airway against the patient's cheek, the end of the curve reaches the angle of the jaw.

Delegation and Collaboration

The skill of inserting an oropharyngeal airway cannot be delegated to nursing assistive personnel (NAP). Respiratory therapists have the training to insert an oral airway. The nurse directs the NAP to:

FIG 27-1 Oral airways.

FIG 27-2 Placement of oral airway.

- Immediately report to the nurse any signs of airway distress, vomiting, or change in level of consciousness.

Equipment

- Appropriate-size oral airway (see Table 27-1)
- Clean gloves
- Tissues or washcloths
- Suction equipment if indicated
- Nonallergenic tape (*optional*)
- Face shield if indicated
- Tongue blade
- Stethoscope

TABLE 27-1 Oral Airway Guidelines for Size* by Age

Size	Age
30-34 mm or size 000	Premature neonates
40 mm or size 00	Newborn
50 mm or size 0	Newborn to 1 yr
60 mm or size 1	1 to 2 yr
70 mm or size 2	2 to 6 yr
80 mm or size 3	6 to 18 yr
90 mm or size 4	Adult medium
100 mm or size 5	Adult large
110 mm or size 6	Adult extra large

*Measure from the corner of the mouth to the angle of the jaw just below the ear for size estimation.

STEP

RATIONALE

ASSESSMENT

- 1 Identify need to insert an oral airway. Signs and symptoms include upper airway gurgling with breathing, absent cough or gag reflex, increased oral secretions, excessive drooling, grinding teeth, clenched teeth, biting of orotracheal or gastric tubes, labored respirations, and increased respiratory rate.
- 2 Determine factors that may contribute to upper airway obstruction such as age (children have a proportionally larger tongue) or presence of a nasal or oral airway and drainage tubes (swallowing is more difficult with tubes in place).
- 3 Assess for presence of gag reflex; gently place tongue blade on back of patient's tongue.
- 4 Ensure that patient does not have dentures in place before attempting an oral airway insertion.

These conditions place patient at risk for obstruction of the upper airway. Use oral airways only in unconscious patients. They may stimulate vomiting or laryngospasm if inserted in a semiconscious or conscious patient.

Allows you to accurately assess need for oral airway placement. Patients at greater risk for upper airway obstruction are infants, children, and adults with upper airway congestion, loss of consciousness, seizure disorders, neuromuscular diseases, increased oral secretions, or facial trauma.

Provides guide as to when oral airway can be safely removed in postoperative patient.

Oral airway insertion can dislodge dentures and cause worsening airway obstruction.

Clinical Decision Point Never insert an oral airway in a conscious patient or a patient with recent oral trauma, oral surgery, or loose teeth. Never force an airway into place.

- 5 Assess family member's knowledge of procedure.

Identifies learning needs of family. Patient will be unconscious.

NURSING DIAGNOSES

- Ineffective airway clearance
- Risk for aspiration

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient's respiratory status improves, as evidenced by respirations with normal rate, easier removal of secretions, and lack of gurgling noise in throat with respirations.
 - Patient is not able to grind teeth or bite tubes.
 - Patient's tongue does not obstruct airway.
- 2 Family members can verbalize understanding of need for oropharyngeal airway.

Airway is clear of secretions.

Oral airway prevents tooth contact with other teeth or with tubes. Oral airway keeps tongue in correct position to maintain patent airway.

Teaching was successful.

STEP

RATIONALE

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Position unconscious patient in semi-Fowler's position if possible.</p> | <p>Provides easy access to oral cavity.</p> |
| <p>2 Perform hand hygiene and apply clean gloves and face shield (when possible).</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>3 Whenever possible, use padded tongue blade to open patient's mouth; if necessary, use thumb and forefinger of nondominant hand to open jaws and teeth.</p> | <p>Provides access to oral cavity. To avoid a bite, do not insert your fingers into patient's mouth. Use extreme caution if manually opening patient's jaw and teeth.</p> |
| <p>4 Insert oral airway.</p> <p style="margin-left: 20px;">a Hold oral airway with curved end up and insert distal end until airway reaches back of throat; then turn airway over 180 degrees and follow natural curve of tongue. <i>Option:</i> Hold airway sideways, insert halfway, and then rotate airway 90 degrees while gliding it over natural curvature of tongue. Make sure that outer flange is just outside patient's lips.</p> | <p>When inserting airway, take care not to push patient's tongue into pharynx.</p> <p>Proper insertion of airway prevents displacement of patient's tongue into posterior oropharynx.</p> |

Clinical Decision Point In a *pediatric patient*, **DO NOT rotate** the oral airway on insertion because the airway tip will damage the soft palate.

- | | |
|---|---|
| <p>5 Suction secretions as needed.</p> | <p>Removes secretions; maintains patent airway.</p> |
| <p>6 Reassess patient's respiratory status; auscultate lungs.</p> | <p>Verifies respiratory status and patent airway.</p> |
| <p>7 Clean patient's face with soft tissue or washcloth.</p> | <p>Promotes hygiene.</p> |
| <p>8 Discard tissue into appropriate receptacle, place washcloth in dirty or soiled linen bag, remove gloves and face shield and discard in appropriate receptacle; perform hand hygiene.</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>9 Administer mouth care frequently.</p> | <p>Increases patient comfort and removes debris. It also provides moisture to oral mucosal tissues.</p> |

Clinical Decision Point Do not use lemon glycerin swabs for oral care because they are drying to mucosal tissues and promote bacterial growth. Oral airway will need to be removed, cleaned or discarded, and replaced in patients with excessive oral secretions. Frequent suctioning of the oral cavity may be required. Oral airways are not a long-term solution. They can cause significant lip and tongue erosion.

EVALUATION

- | | |
|--|---|
| <p>1 Observe patient's respiratory status and compare respiratory assessments before and after insertion of oral airway.</p> | <p>Identifies patient's response to insertion of airway.</p> |
| <p>2 Evaluate that airway is patent and that patient's tongue does not obstruct airway.</p> | <p>Ensures route for oxygen delivery to patient.</p> |
| <p>3 Observe for patient pushing airway out with tongue or coughing.</p> | <p>Patient's ability to clear his or her own airway may have returned. Indicates reassessment of need for an oral airway.</p> |

Unexpected Outcomes

- 1 Patient continually coughs and gags when airway is inserted.
- 2 Airway obstruction not relieved.
- 3 Patient pushes airway out of place or out of mouth.
- 4 Unable to insert oral airway; patient is combative or you are unable to pry mouth open.

Related Interventions

- Do not continue inserting airway if patient begins to gag. Stimulation of gag reflex can cause vomiting and aspiration.
- Remove oral airway and position patient on side.
- Reassess need for artificial airway prn.
- Obtain immediate assistance.
- Reinsert airway or determine from physician if another form of airway is needed.
- Assess for other causes of obstruction.
- Patient may be at point where he or she is able to breathe on own. Reassess patient's need for oral airway.
- Obtain assistance.
- Reassess patient's need for oral airway.
- Provide sedation as ordered.

Recording and Reporting

- Record in nurses' notes and electronic health record (EHR) assessment findings while inserting oral airway; size of oral airway; other interventions performed at same time, especially positioning and suctioning; and patient's response to procedure.

Special Considerations

Pediatric

- Oral airways are seldom used in treatment of airway obstruction in infants and children. Because the airway is narrow, they are often more occlusive than beneficial (Hockenberry and Wilson, 2011).

SKILL 27-2 Use of an Automated External Defibrillator

Defibrillation is the electrical attempt to stop a lethal arrhythmia such as ventricular fibrillation. An automated external defibrillator (AED) allows for individuals trained only in basic life support to defibrillate. AEDs eliminate the need for training in rhythm interpretation and make early defibrillation practical and achievable. The AED is a defibrillator that incorporates a rhythm analysis system. The device attaches to a patient by two adhesive pads and connecting cables. Most AEDs are stand-alone boxes with a very simple three-step function (Fig. 27-3) and verbal prompts to guide the responder. All AEDs offer automated rhythm analysis, whereby the rhythm is compared to thousands of other rhythms stored in the AED computer software. On rhythm identification, some AEDs automatically provide the electrical shock after a verbal warning (fully automated). Other AEDs recommend a shock, if needed, and then prompt the responder to press the shock button.

Delegation and Collaboration

Basic life support certification provides hands-on training with an AED for laypersons, nursing assistive personnel (NAP), and licensed health care professionals. Most hospitals using AEDs have given the authority to use an AED to all cardiopulmonary resuscitation (CPR)-certified personnel, including NAP. Refer to specific hospital policies for use of the AED.

Equipment

- ❑ AED
- ❑ Pair of AED adhesive pads

FIG 27-3 Automated external defibrillator device. (Courtesy Philips Medical Systems.)

STEP

RATIONALE

ASSESSMENT

- Establish person's unresponsiveness and call for help. (In community settings have someone call 9-1-1.)
- Establish absence of respirations and lack of circulation: no pulse, no respirations, no movement.

This information helps to determine if the individual is unresponsive rather than asleep, intoxicated, hearing impaired, or postictal. Rapid response by qualified professionals ensures ongoing resuscitation support.

Indicates need for emergency measures, including AED.

Clinical Decision Point An AED should be applied only to a patient who is unconscious, not breathing, and pulseless. For children younger than 8 years old, AED pads designed for children should be used. When child pads are not available, use adult AED pads (Berg et al., 2010b).

NURSING DIAGNOSES

- Decreased cardiac output
- Ineffective breathing pattern
- Ineffective tissue perfusion
- Impaired spontaneous ventilation

Related factors are individualized based on patient's condition or needs.

PLANNING

- Expected outcomes following completion of procedure:
 - Patient's cardiac rhythm is converted back to stable rhythm.
 - Patient regains pulse and respirations.

Defibrillation provides electrical shock to convert a lethal dysrhythmia. CPR and defibrillation were successful.

STEP

RATIONALE

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Assess patient for unresponsiveness, not breathing and pulselessness.</p> | <p>These are indicators of cardiopulmonary arrest.</p> |
| <p>2 Activate code team in accordance with hospital policy and procedure.</p> | <p>First available person brings resuscitation cart and AED.</p> |
| <p>3 Start chest compressions and continue until AED is attached to patient and verbal prompt of device advises you, “Do not touch the patient.”</p> | <p>To minimize interruption time of chest compressions, continue CPR while AED is being applied and turned on.</p> |
| <p>4 Place AED next to patient near chest or head.</p> | <p>Ensures easy access to device.</p> |

Clinical Decision Point *If the AED is immediately available, attach it to patient as soon as possible. The faster defibrillation is delivered, the better the survival rate (Ewy and Kern, 2009).*

- | | |
|---|--|
| <p>5 Turn on power (see illustration).</p> | <p>Turning on the power will begin the verbal prompts to guide you through the next steps.</p> |
| <p>6 Attach the device. Place the first AED pad on the upper right sternal border directly below the clavicle. Place the second AED pad lateral to the left nipple with the top of the pad a few inches below the axilla (see illustration). Ensure that cables are connected to the AED.</p> | <p>Alternative pad placement of AED pads is not recommended. AEDs analyze most heart rhythms using lead II. If the AED pads are placed as directed, patient’s heart rhythm will be analyzed in lead II.</p> <p>Patients with large amounts of chest hair may require shaving to obtain adequate pad contact.</p> |

Clinical Decision Point *Do not attach pads to a wet surface, over a medication patch, or over a pacemaker or implanted defibrillator. Wet surfaces, implanted defibrillators, and medication patches reduce the effectiveness of the defibrillation attempt and result in complications.*

STEP 5 Power panel with AED prompts. (Courtesy Philips Medical Systems.)

STEP 6 Placement of AED pads with device next to patient.

STEP	RATIONALE
<p>7 Do NOT touch patient when AED prompts you. Direct rescuers and bystanders to avoid touching patient by announcing “Clear!” Allow the AED to analyze the rhythm. Some devices require that an analysis button be pressed. The AED takes approximately 5 to 15 seconds to analyze the rhythm.</p>	<p>Each brand of AED is different; thus familiarity with the specific model that you are using is important. Not touching patient when directed prevents artifact errors, avoids all movement during analysis (Link et al., 2010), and prevents shock from being delivered to bystanders.</p>
<p>8 Before pressing the shock button, announce loudly to clear the victim and perform a visual check to ensure that no one is in contact with him or her.</p>	<p>Clearing patient ensures safety for those involved in rescue efforts.</p>
<p>9 Immediately begin chest compression after the shock and continue for 2 minutes. Do NOT remove the pads.</p>	<p>Continues cardiac perfusion.</p>
<p>10 Deliver two breaths using mouth-to-mouth with barrier device or mouth-to-mask device or bag-mask device. Watch for chest rise and fall. Deliver 10-to-12 breaths/min.</p>	<p>In a hospital setting where protected methods of artificial ventilation are available, mouth-to-mouth without a barrier device is not recommended because of risk for microbial contamination.</p>
<p>11 After 2 minutes of CPR, the AED will prompt you not to touch patient and will resume analysis of patient’s rhythm. This cycle will continue until patient regains a pulse or physician determines death.</p>	

EVALUATION

- | | |
|---|--|
| <p>1 Inspect pad adhesion to chest wall. If pads are not in good contact with chest wall, remove them and apply a new set. Attach new set of pads to the AED.</p> | <p>Poor pad-skin contact reduces the effectiveness of the shock, causes skin burns, or increases chance of shocking those involved in the rescue efforts. Always apply a new set of pads. Do NOT reuse.</p> |
| <p>2 Check for a palpable pulse. Continue resuscitative efforts until patient regains pulse or the physician determines death.</p> | |

Unexpected Outcomes

- 1 Patient’s heart rhythm does not convert into a stable rhythm with pulse after defibrillation.
- 2 Patient’s skin has burns under AED pads.

Related Interventions

- Assess pad contact on patient’s chest wall.
- Do not touch patient during AED rhythm analysis.
- Avoid placing AED pads over medication patches, pacemaker, or implantable defibrillator generators.
- Assess AED pad contact on chest.
- Ensure that chest is dry before applying pads to chest.
- Apply skin care as indicated if patient is resuscitated successfully.

Recording and Reporting

- Immediately report arrest via the hospital-wide communication system, indicating exact location of victim.
- Cardiopulmonary arrest requires precise documentation. Most hospitals use a form designed specifically for in-hospital arrests.
- Record in nurses’ notes and EHR or on designated CPR worksheet: onset of arrest, time and number of AED shocks (you will not know the exact energy level used by the AED), time and energy level of manual defibrillations, medications given, procedures performed, cardiac rhythm, use of CPR, and patient’s response.

Special Considerations

Teaching

- If patient is at risk for cardiopulmonary arrest, instruct the family or caregivers in CPR or encourage them to obtain certification through an instructor from the hospital, American Red Cross, or American Heart Association.

- Patient and family should keep emergency numbers taped to the phone or consider programming them into speed dial function on both home and mobile phones. Stress the use of 9-1-1.
- It is extremely helpful if family has list of medications that patient is presently taking.

Pediatric

- Most AEDs are specifically designed for adult use only and are therefore not recommended for use in children younger than 8 years old or less than 25 kg body weight (Link et al., 2010). Adult pads can be used if child pads are not available; be sure not to overlap pads. Manual defibrillation performed by health care personnel using lower energy settings (2 to 4 joules/kg) is the most common method of pediatric defibrillation (Link et al., 2010).

Home Care

- AEDs are available for use in the community and home setting.

SKILL 27-3 Code Management

All who respond to cardiopulmonary arrests should follow a simple, standardized, easy-to-remember approach. Initially a code is managed by the first responder performing the basic skills of cardiopulmonary resuscitation (CPR), which includes the primary survey of *C* (circulation), *A* (airway), *B* (breathing), *D* (early defibrillation). These interventions continue until the code team arrives. The initial process also includes notification of the hospital resuscitation or code team. Most of the code team members have been trained in the advanced cardiac life support (ACLS) guidelines and the performance of the secondary survey: *C* (rhythm analysis of cardiac rhythm), *A* (airway intubation), *B* (confirmation of airway and ventilation) and *D* (differential diagnosis of the cause). Both surveys must be reassessed continually and managed as appropriate throughout the code situation.

The hospital response team usually includes a physician, intensive care nurse, respiratory therapy personnel, anesthesiology personnel, and possibly radiology and laboratory technologists. A pastoral care representative is often available to be with the family.

The ability of a non-ACLS-certified nurse to initiate resuscitative efforts can prevent lethal dysrhythmias such as ventricular fibrillation from deteriorating to asystole (absence of cardiac

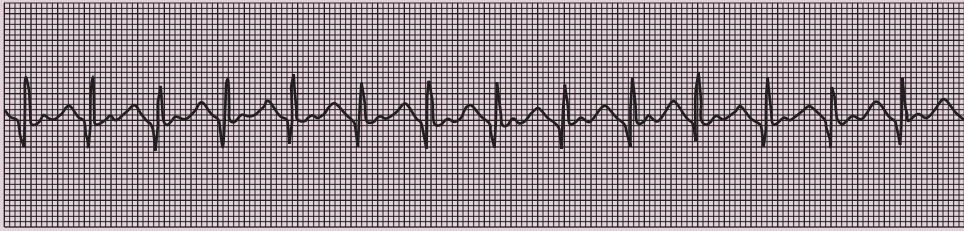

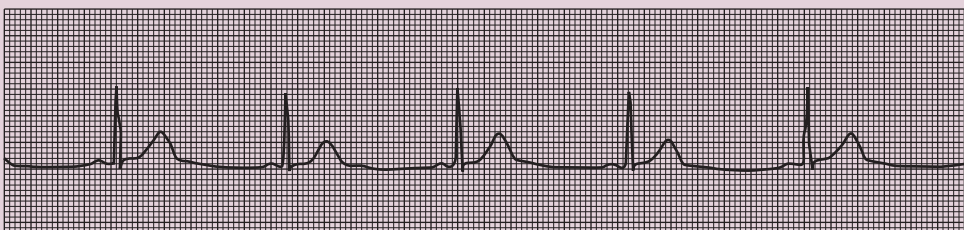

electrical activity) and provide a chance for the heart to return to its normal rhythm. Table 27-2 summarizes basic cardiac arrhythmias. Early CPR and defibrillation delivered within the primary survey optimizes heart and brain function, leading to improved survivability. Equipment may be readily available at the bedside or in a designated area of the hospital unit. It is the nurse's responsibility to know how to use this equipment and to know its location and the contents of the resuscitation or crash cart.

CPR certification is a requirement of nurses and nursing students. Therefore CPR will not be covered in detail within this chapter. Table 27-3 summarizes some points regarding CPR skills, including differences in adult, child, and infant techniques.

Delegation and Collaboration

The skill of code management cannot be delegated to nursing assistive personnel (NAP). However, NAP who are certified in basic life support (BLS) techniques can perform the basic skills of CPR. Most NAP are certified in BLS and can use an automated external defibrillator (AED). Most hospitals reserve the skill of manual defibrillation for licensed personnel who are ACLS certified or have received competency validation to perform manual

TABLE 27-2 Common Cardiac Dysrhythmias

Rhythm Characteristics and Etiology	Clinical Significance and Management
<p>Sinus Tachycardia</p>  <p>Regular rhythm, rate 100-180 beats/min (higher in infants), normal P wave, normal QRS complex.</p> <p>Rate increase is often normal response to exercise, emotion, or stressors such as pain, fever, pump failure, hyperthyroidism, and certain drugs (e.g., caffeine, nitrates, epinephrine, nicotine).</p>	<p>Some patients with heart disease are unable to increase their heart rate to meet increased oxygen demands.</p> <p>Correct underlying factors; discontinue drugs producing the side effect.</p>
<p>Sinus Bradycardia</p>  <p>Regular rhythm, rate less than 60 beats/min, normal P wave, normal PR interval, normal QRS complex.</p> <p>Rate decrease is normal response to sleep or in well-conditioned athlete; diminished blood flow to SA node, vagal stimulation, hypothyroidism, increased intracranial pressure, or pharmacologic agents (e.g., digoxin, propranolol, quinidine, procainamide) sometimes cause abnormal drops in rate.</p>	<p>No clinical significance unless associated with signs and symptoms of reduced cardiac output such as dizziness or syncope or presence of chest pain.</p> <p>Bradycardia with hypotension and decreased cardiac output is treated with atropine; pacemaker is sometimes necessary.</p>

Continued

TABLE 27-2 Common Cardiac Dysrhythmias—cont'd**Rhythm Characteristics and Etiology****Clinical Significance and Management****Atrial Fibrillation (A-fib)**

Chaotic, irregular atrial activity resulting in an irregular ventricular response. No identifiable P waves. Irregular ventricular response resulting in an irregular cardiac rate and rhythm. The conduction of the multiple atrial impulses across the atrioventricular (AV) node determines the rate.

Caused by aging, calcification of the sinoatrial (SA) node, or changes in myocardial blood supply.

There is loss of the atrial kick (portion of the cardiac output squeezed in the ventricles with a coordinated atrial contraction), pooling of blood in the atria, and development of microemboli. The patient often complains of fatigue, a fluttering in the chest, or shortness of breath if the ventricular response is rapid. Commonly occurring dysrhythmia in the aging and older adult.

Ventricular Tachycardia

Rhythm slightly irregular, rate 100-200 beats/min, P wave absent, PR interval absent, QRS complex wide and bizarre, >0.12 second.

Caused by changes in the normal pacemaker of the heart such as decrease in blood flow, ischemia, or embolus.

Results in decreased cardiac output caused by decreased ventricular filling time; often leads to severe hypotension and loss of pulse and consciousness.

Acute loss of pulse and respiration. Immediate chest compressions and defibrillation are required.

Ventricular Fibrillation

Uncoordinated electrical activity. No identifiable P, QRS, or T wave. Causes include sudden cardiac death, electrical shock, acute myocardial infarction, drowning, or trauma.

Acute loss of pulse and respiration. Immediate chest compressions and defibrillation are required. Availability of AED is recommended in public and/or private places where large numbers of people gather or where people who are at high risk for heart attack live.

TABLE 27-3 Adult, Child, and Infant Cardiopulmonary Resuscitation Techniques (Health Care Providers)

Technique	Adult	Child (1-8 Years Old)	Infant (Under 1 Year) Does Not Include Newborns
Chest compressions: Push hard and fast to allow complete recoil	Begin compressions if no pulse Lower half of sternum, between nipples 3.75 to 5 cm (1½ to 2 inches) One to two rescuers: 100/min at a rate of 30 compressions to 2 breaths (30:2)	Begin compressions if no pulse or pulse <60/min Lower half of sternum, between nipples Heel of one hand or as for adults At least ⅓ depth of chest One rescuer: 30 compressions, 2 breaths (30:2) Two rescuers: 15 compressions, 2 breaths (15:2)	Begin compressions if no pulse or pulse <60/min Just below nipple line (lower half of sternum) Two fingers, two thumbs (encircling hands) One rescuer: 30 compressions, 2 breaths (30:2) Two rescuers: 15 compressions, 2 breaths (15:2)
Defibrillation using AED	Use adult pads Provide 5 cycles of CPR before shock if response time is greater than 4 to 5 minutes and arrest was not witnessed Otherwise, AED should be applied as soon as available, and shock as soon as advised Resume compressions immediately after shock	Use child pads whenever possible If none, use adult pads but do not overlap them Apply AED as soon as available, and shock as soon as advised	If there is a shockable rhythm, manual defibrillation is used
Airway	Head tilt–chin lift (HCP: Suspected trauma, use jaw thrust)	Head tilt–chin lift (HCP: Suspected trauma, use jaw thrust)	Head tilt–chin lift (HCP: Suspected trauma, use jaw thrust)
HCP: Rescue breathing mouth-to-mask or bag-mask without chest compressions	10 to 12 breaths/min (approximately 1 breath every 5-6 seconds)	12 to 20 breaths/min (approximately 1 breath every 3 seconds)	12 to 20 breaths/min (approximately 1 breath every 3 seconds)
HCP: Rescue breaths for CPR with advanced airway (endotracheal tube/tracheotomy)	8 to 10 breaths/min (approximately 1 breath every 6-8 seconds)	8 to 10 breaths/min (approximately 1 breath every 6-8 seconds)	8 to 10 breaths/min (approximately 1 breath every 6-8 seconds)
Foreign body airway obstruction	Abdominal thrusts	Abdominal thrusts	Back slaps and chest thrusts

Data from Berg RA et al: 2010 American Heart Association Guidelines for cardiopulmonary resuscitation and emergency cardiovascular care. Part 5: Adult basic life support, *Circulation* 122(suppl 3):S685, 2010a; and Berg MD et al: 2010 American Heart Association Guidelines for cardiopulmonary resuscitation and emergency cardiovascular care. Part 13: Pediatric basic life support, *Circulation* 122(suppl 3):S862, 2010b.
AED, Automated external defibrillator; CPR, cardiopulmonary resuscitation; HCP, health care provider.

FIG 27-4 Emergency resuscitation cart.

defibrillation. All other skills in the code situation are directed by the code team leader and performed by nurses, respiratory therapists, and other health care professionals.

Equipment

❑ Crash cart (Fig. 27-4)—Most adult carts have the following equipment:

- Clean and sterile gloves, gown, protective eyewear
- Oxygen source
- Bag-mask device or resuscitation bag
- Oral airways
- Laryngoscope, handle, and laryngoscope blades, straight and curved
- Endotracheal (ET) tubes, various sizes (5-to-9 mm for adults; 0-to-4 mm for pediatrics)

- Carbon dioxide detector to confirm ET tube placement
 - Tape or commercial ET tube holder
 - Backboard
 - AED and/or manual defibrillator with AED/defibrillator pads
 - Intravenous (IV) needles (sizes for adults and pediatrics)
 - Central vascular access kit
 - IV tubing and fluids (normal saline [NS] and 5% dextrose in water [D₅W])
 - Syringes
 - Laboratory specimen tubes
 - Arterial blood gas kit
 - Emergency medications
 - ACLS guidelines or algorithms
- ❑ Suction source and suction equipment if not with crash cart

STEP

RATIONALE

ASSESSMENT

1 Determine if patient is unconscious by shaking him or her and shouting, “Are you OK?” Assess patient unresponsiveness.

Confirms that patient is unresponsive rather than intoxicated, sleeping, or hearing impaired. Substance abuse, hypoglycemia, toxicities, seizures, trauma, ketoacidosis, and shock can also cause unconsciousness.

Clinical Decision Point *If an unresponsive person has adequate respirations and pulse, remain until further assistance is present. Place victim in a modified lateral recovery position (see illustration). Continue to assess for the presence of respirations and pulse because a recurrent arrest may develop.*

STEP 1 Recovery position.

NURSING DIAGNOSES

- Decreased cardiac output
- Impaired spontaneous ventilation
- Ineffective tissue perfusion
- Impaired gas exchange
- Ineffective breathing pattern

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure:

- Patient regains pulse and respirations.
- Patient receives postresuscitation care:
 - Transport to intensive care unit (ICU).
 - Continue ongoing care in the ICU.

CPR was successful.

Ongoing treatment and support needed.

2 Immediately activate the hospital code team or emergency medical services (EMS). Tell co-workers to bring AED (if available) and crash cart to bedside.

Ensures timely application of defibrillation, CPR, and ACLS to arrest victim.

STEP

RATIONALE

IMPLEMENTATION

Primary survey: C (Circulation)

- 1 Check carotid pulse on adult or child; use brachial or femoral pulse in an infant. Palpate for no more than 10 seconds (Berg et al., 2010a).
- 2 Place victim on hard surface such as floor, ground, or backboard. Victim must be flat. Logroll victim to flat, supine position using spine precautions if trauma is suspected.

Carotid pulse is the easiest to locate in adults and children. Femoral pulse may also be palpated in a child or infant.

External compression of heart is facilitated. Heart is compressed between sternum and spinal vertebrae, which must be on hard and firm surface. Do NOT delay the start of CPR. Positioning patient on hard surface may take more than one or two rescuers. You may need to wait to safely move him or her. Place backboard or position patient as soon as appropriate assistance is present.

Primary survey: A (Airway)

- 3 Apply clean gloves and face shield.
- 4 Open airway.
 - a Head tilt–chin lift (no trauma) (see illustration) or
 - b Jaw thrust (cervical trauma is suspected) (see illustration)

Reduces transmission of microorganisms.

Determine if patient has spontaneous respirations. Tongue is most common cause of blocked airway in unresponsive patient. Suspect spinal cord injury in patients with trauma. Jaw-thrust maneuver prevents head extension and neck movement and further paralysis or spinal cord injury. Apply rigid cervical collar and immobilize patient as soon as possible to reduce cervical spine motion.

Primary survey: B (Breathing)

- 5 Attempt to ventilate patient with slow breaths using one of these methods.
 - a Mouth-to-mouth using barrier device.
 - b Mouth-to-mask using pocket mask (see illustration).
 - c Bag-mask device (see illustrations).
- 6 If available, insert oral airway (see Skill 27-1).
- 7 Suction secretions if necessary or turn victim's head to one side unless trauma is suspected.

Slow breaths deliver air at low pressure to reduce risk of gastric distention.

Forms airtight seal to prevent air from escaping through nose.

Provides secure seal and permits use of supplemental oxygen.

Gives breaths with enough force to make the chest rise.

Maintains tongue on anterior floor of mouth and prevents obstruction of posterior airway by tongue.

Suctioning prevents airway obstruction. Turning patient's head to one side allows gravity to drain any secretions, decreasing risk of aspiration.

STEP 4a Head tilt–chin lift. (From Sorrentino S: Mosby's textbook for nursing assistants, ed 7, St Louis, 2008, Mosby.)

STEP 4b Jaw thrust without head tilt.

STEP 5b Pocket mask.

STEP

RATIONALE

Primary survey: D (Defibrillation)

- 8 If pulse is absent and AED is available, apply AED immediately as appropriate.
 - a After one shock, resume CPR for 5 cycles and begin rhythm analysis and shock sequence again.
- 9 If pulse is absent and an AED is unavailable, immediately initiate chest compressions.
 - a Assume correct hand position and compression ratio for patient (see illustrations).

Most successful defibrillation rates occur when AED is applied and used within 5 minutes following collapse. Survival rates decline when defibrillation is delayed.

One shock followed by chest compressions for 5 cycles provides sufficient blood flow and perfusion before another set of shocks is delivered (Berg et al., 2010a).

Specific hand position, compression depth, and ratio are different for adults, children, and infants to avoid injury to heart, lung, or liver (see Table 27-3).

Clinical Decision Point Ensure that fingers are off the ribs and lowermost part of the xiphoid process. This minimizes the chance of rib fracture that could result in punctured lung or liver laceration, which further compromises cardiopulmonary status. Continue chest compressions, ventilation, and AED use.

Secondary survey: Implementation

- 1 Give code leader brief verbal report on events performed before code team's arrival (i.e., code, vital signs, medical diagnosis, and code intervention).
- 2 On arrival of sufficient personnel, delegate tasks as appropriate while core group continues with resuscitation efforts.

This information is critical in selection of appropriate treatment for patient.

Delegation of duties is essential to meet critical needs of patient and his or her family in timely matter.

STEP 5c A, Bag-mask device. B, Two-rescuer breathing with bag-mask device. (Courtesy Ambu USA.)

STEP 9a A, Proper hand position—adult. B, Proper hand position—child. C, Proper hand position—infant.

STEP

RATIONALE

- a Assist victim's roommate or visitors away from code scene. Assign pastoral care or other nurses to communicate with family.
- b Delegate someone to remove excess furniture or equipment from room.
- c Have someone bring patient's chart to bedside or have access to patient's electronic health record (EHR).
- d Assign nurse as recorder to record/document events of code.
- e Assign another nurse to get medications and supplies from crash cart to hand off to code team members. The bedside nurse is involved in tasks such as medication administration, vital signs, and helping with procedures.

Clarifies patient's medical condition, code status, and presence of any allergies.
Ensures accurate documentation of events of code, medications, and treatments administered.
Provides code personnel with appropriate medication and equipment in timely fashion.

Secondary survey: C (Analysis of cardiac rhythm)

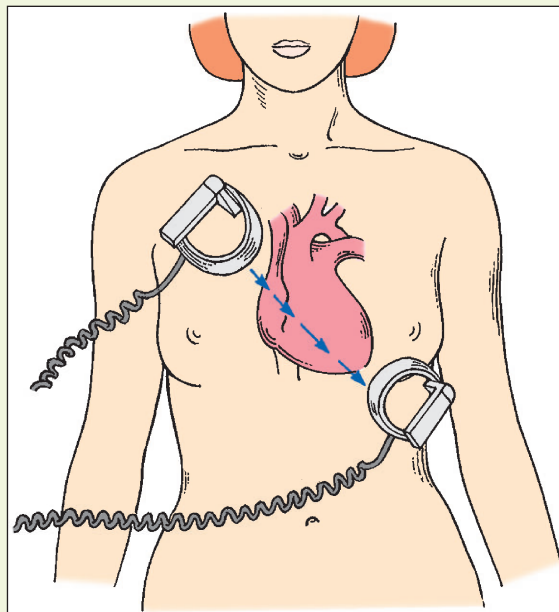

- 3 Attach manual defibrillator/monitor to patient using electrocardiogram (ECG) electrodes, quick-look paddles with gel pads, or "hands-off" defibrillation electrode to visualize cardiac rhythm (see illustration).
- 4 If cardiac rhythm is "shockable," continue CPR and assist code team with manual defibrillation.
 - a Turn on defibrillator and select proper energy level following agency policy and equipment directions.
 - b Apply conductive gel or gel pads to patient's chest where defibrillator paddles will be placed. Some defibrillators use "hands-off pads" that are applied to patient's chest and directly connect to manual defibrillator.
 - c Place paddles or pads on patient's chest wall.
 - d Verify that no one is in physical contact with patient, bed, or any item contacting patient during defibrillation. A warning must be called out before initiating charge.
- 5 Establish IV access with large-bore IV needle (14- to 22-gauge) and begin infusion of 0.9% NS.
 - a If you cannot obtain peripheral IV access, physician may pursue central venous access.

Cardiac rhythm monitor devices provide immediate rhythm display for analysis without disruption of rescue breathing and chest compression.

Manual defibrillation is performed by ACLS-certified personnel.
Energy is delivered in prescribed doses. Manual biphasic devices deliver shocks at a lower level (200 joules); monophasic waveforms use 360 joules.
Good skin-to-paddle/pad contact ensures appropriate discharge of current and decreases chance of skin burns (Link, 2010).

Ensures appropriate discharge of current.
Prevents accidental delivery of shock or injury to personnel.

Provides a route for rapid drug administration and access for blood samples and fluid administration. Physiologic saline is isotonic. Rapid fluid infusion facilitates dispersal of medication throughout cardiovascular system.

STEP 3 Paddle placement for defibrillation.

STEP	RATIONALE
<p>6 Help with procedures as needed.</p> <p>7 Continue CPR until relieved, until victim regains spontaneous pulse and respiration, rescuer is exhausted and unable to perform CPR effectively, or physician discontinues CPR.</p>	<p>Most equipment needed for special procedures during code is on the crash cart. Knowledge of crash cart contents is very helpful in the code to provide personnel with the appropriate equipment. Interruptions in CPR are planned and organized. They usually occur during change of CPR personnel, defibrillation, and intubation. An interruption should not exceed 10 seconds (Berg et al., 2010a).</p>
Secondary survey: A (Intubate airway)	
<p>8 If respirations are absent, help the code team with ET intubation.</p> <p>a Have available laryngoscope handle, laryngoscope blades, curved and straight blades, ET tubes, stylet, suction, and tape or ET tube holder. Ensure that light source on laryngoscope is functional.</p>	<p>Intubation provides a patent airway and facilitates pulmonary ventilation. Laryngeal mask airway or esophageal-tracheal Combitube can also be used to provide advanced airway support. Light is necessary on laryngoscope to visualize vocal cords and intubate trachea. Batteries may need to be changed.</p>
Secondary survey: B (Confirmation of airway and ventilation)	
<p>9 Assist in confirmation of ET tube placement or advanced airway support by auscultating lungs for bilateral breath sounds. Carbon dioxide (CO₂) detector or esophageal detector devices are used as secondary methods to confirm correct airway placement (Neumar et al., 2010).</p> <p>10 Ventilate using bag device on intubation.</p>	<p>Auscultation of lungs and exhaled CO₂ monitoring or esophageal detector device further verifies correct airway placement and adequacy of ventilation and gas exchange. Chest x-ray film is usually obtained after patient has been stabilized to confirm placement of ET tube and central venous catheters. Avoid hyperventilation. Increased intrathoracic pressure caused by incomplete exhalation results in reduced cardiac output (Neumar et al., 2010).</p>
Secondary survey: D (Differential diagnosis)	
<p>11 Help physician obtain laboratory and diagnostic studies.</p>	<p>Helps in determining cause of the arrest.</p>

EVALUATION

<p>1 Reassess primary and secondary surveys throughout the code event.</p>	<p>This keeps the process organized and addresses immediate needs of the patient.</p>
<p>2 Palpate carotid pulse at least every 5 minutes after first minute of CPR.</p>	<p>Documents adequacy of external cardiac compressions.</p>
<p>3 Observe for spontaneous return of respirations or heart rate every 2 minutes.</p>	<p>Assessment of pulse, respiration, heart rate, and cardiac rhythm can occur after chest compressions and ventilation have been interrupted briefly every 2 minutes.</p>
<p>4 Ensure that interruptions in CPR are minimized.</p>	<p>Interruptions are associated with reduced coronary artery perfusion pressure and lower mean coronary perfusion pressure (Berg et al., 2010a).</p>

Unexpected Outcomes

- 1 Patient develops skeletal injury such as fractured ribs or sternum or internal organ injury such as lacerated lung or liver as a result of chest compressions.
- 2 Patient's CPR is unsuccessful.
- 3 Rescuer is unassisted, tires, and is unable to continue.

Related Interventions

- Obtain appropriate diagnostic tests to document injuries.
- Assess patient's postarrest breathing for symmetry and pain.
- Assess for intrathoracic or intraabdominal bleeding (hematomas, increasing abdominal girth).
- Contact chaplain services.
- Contact social worker.
- Complete postmortem care on patient (see Chapter 16).
- Notification of coroner and organ procurement agency needs to be made in accordance with local hospital or state law.
- Provide for privacy for patient's family to say their good-byes to patient.
- Obtain assistance.

Recording and Reporting

- Immediately report arrest, indicating exact location of victim. In hospital setting follow hospital policy. In community setting activate the emergency response system.
- Record in nurses' notes and EHR or on designated CPR worksheet: onset of arrest, time and number of AED shocks (you will not know the exact energy level used by the AED), time and

energy level of manual defibrillations, medications given, procedures performed, cardiac rhythm, use of CPR, and patient's response.

Special Considerations

Teaching

- See Skill 27-2 for teaching considerations.

Pediatric

- All persons involved in administering CPR must understand different breathing/compression ratios, hand (fingers) placement, and depth of compression in children and infants compared with adults.
- Infants and children experience respiratory arrest much more frequently than full cardiopulmonary arrest.
- Quick reference, color-coded guides are frequently used in pediatric codes to quickly determine appropriate drug doses and equipment sizes.

Gerontologic

- In older adults compressions often result in rib or cartilage fractures.
- Remove loose-fitting dentures to avoid obstructing the airway. If dentures fit securely, leave them in to provide a tight seal when providing ventilations.

Home Care

- In the community and long-term care settings, patients may have implanted cardioverter defibrillators (ICDs) and/or pacemakers. For these patients, families need to know how to administer CPR and the specific capabilities of the patient's ICD/pacemaker. Placement of defibrillator or AED pads/paddles may need to be altered to avoid placement directly on top of an ICD or pacemaker generator. Remove medication patches from chest.
- Soft surfaces such as a mattress, car seat, or grassy surface decrease efficiency of external cardiac compressions.

Critical Thinking Exercises

You are the charge nurse for night shift on a general medical floor. On your rounds you find your patient, Ethel Waters, lying unresponsive on the floor of the bathroom. She is 85 years old and was admitted with heart failure. An automated external defibrillator (AED) is available down the hall.

- 1 What should you do first? Explain your choice.
 - 1 Apply the AED
 - 2 Call for help
 - 3 Check for a pulse
 - 4 Open airway and provide two breaths
- 2 Your co-worker arrives to Mrs. Water's room with the AED. What is your next step? Explain your choice.
 - 1 Check for a pulse
 - 2 Start chest compressions
 - 3 Apply the AED
 - 4 Continue with 8 to 10 breaths/min
- 3 Your co-worker has started chest compressions on Mrs. Waters. Under which of the following circumstances should you interrupt performance of the chest compressions? Explain your choice.
 - 1 Arrival of the code team
 - 2 AED advises, "Do NOT touch the patient."
 - 3 Initiation of bag-mask ventilation
 - 4 Intravenous (IV) line insertion
- 4 Cardiopulmonary resuscitation (CPR) continues for Mrs. Waters. Which of the following action(s) should occur every 2 minutes?
 - 1 Checking IV fluids
 - 2 Interrupting chest compression to assess for spontaneous pulse/respirations
 - 3 Continuing chest compression uninterrupted
 - 4 AED reanalyzing the cardiac rhythm
- 5 The code team has arrived to continue resuscitation attempts on Mrs. Waters. Which activities will be involved in the code team's work? How can you participate?

REVIEW QUESTIONS

- 1 Which of the following is(are) the goal(s) of resuscitation?
 - 1 Return of pulse
 - 2 Providing oxygen to the victim as soon as possible
 - 3 Restoring cardiopulmonary function and avoid poor neurologic outcomes
 - 4 Restoring cardiopulmonary function or avoid poor neurologic outcomes
- 2 The primary purpose of a hospital team is/are to: (Select all that apply.)
 - 1 Intervene early to prevent cardiac arrest.
 - 2 Transfer the patient to the intensive care unit (ICU).
 - 3 Reduce hospital mortality rate.
 - 4 Remove the need for the code team.
- 3 Which of the following is a nursing concern for the family of an arrest victim?
 - 1 Accommodate families' religious and cultural practices.
 - 2 Do not allow family in patient's room at any time.
 - 3 Question families' reasons for refusing organ donation.
 - 4 Have multiple health care providers speak to the family.
- 4 A nurse is reviewing the procedure for insertion of an oropharyngeal airway. Which of the following is true about an oral airway?
 - 1 It eliminates the need to position the head of the unconscious patient.
 - 2 It eliminates the possibility of an upper airway obstruction.
 - 3 It needs to be inserted even when a patient has had recent oral trauma.
 - 4 It may stimulate vomiting or laryngospasm if inserted in the semiconscious patient.
- 5 A visitor suffers a cardiac arrest, and resuscitation is begun. The nurse would be correct doing CPR and operating an AED if which of the following sequence of steps were followed?
 - 1 Check for a pulse, provide chest compressions until the AED arrives, attach the AED, open the airway, provide two breaths if needed.
 - 2 Wait for the AED, open the airway, provide two breaths if needed, check for a pulse, and attach the AED if no pulse.
 - 3 Call for help, get the AED, open the airway, provide two breaths if needed, check for a pulse, continue compressions if no pulse is present, attach the AED.
 - 4 Provide two breaths, check for a pulse, call for the AED, provide chest compressions until the AED arrives, attach the AED.
- 6 You need to open the airway of a suspected trauma victim. Which technique would you use to open the airway in this patient?
 - 1 Head tilt
 - 2 Chin lift
 - 3 Jaw thrust
 - 4 Lateral lying position
- 7 Which of the following are appropriate personnel to use an AED?
 - 1 Only licensed providers
 - 2 Any basic life support (BLS) provider
 - 3 Only physicians
 - 4 Only charge nurses

- 8 The nurse is participating in a code on an adult and waiting for the AED to arrive. At what rate should the compressions and breaths be delivered?
- 1 60/min at a ratio of 30 compressions to 2 breaths
 - 2 60/min at a ratio of 15 compressions to 2 breaths
 - 3 80/min at a ratio of 15 compressions to 2 breaths
 - 4 100/min at a ratio of 30 compressions to 2 breaths
- 9 The nurse is involved in resuscitating a patient. The AED has just delivered a shock. What should be done immediately after the shock has been delivered?
- 1 Continue CPR for another minute until the AED recharges
 - 2 Start an IV line of normal saline with a large-size IV catheter
 - 3 Reposition patient's head for better respiratory effort
 - 4 Continue CPR for 2 minutes
- 10 Which of the following indicates that your artificial breaths are adequate?
- 1 The seal on the barrier device leaks air whenever the breath is given.
 - 2 The bag-mask device is connected to oxygen.
 - 3 The oral airway is in place.
 - 4 Artificial breathing has enough force to make the chest rise.

KEY TERMS

Biohazard container	Electrolyte	Implanted venous port	Peripherally inserted central catheter (PICC)
Catheter	Electronic infusion device (EID)	Infiltration	Phlebitis
Catheter-related bloodstream infection (CRBSI)	Embolus (emboli)	Infusion pump	Saline lock
Central vascular access device (CVAD)	Exit site	Injection cap	Sharps container
Central line-associated bloodstream infection (CLABSI)	Fluid volume deficit (FVD)	Isotonic	Smart pump
Drop factor	Fluid volume excess (FVE)	Noncoring needle	Subcutaneous tunnel
	Heparin lock	Nontunneled central vascular catheters	Thrombosis
	Hypertonic	Over-the-needle catheter (ONC)	Tunneled central vascular catheter
	Hypotonic	Percutaneous	Venipuncture

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss patient conditions requiring intravenous (IV) therapy.
- Explain how to prepare a patient and family caregiver for IV therapy.
- Discuss complications of IV therapy.
- Identify individualized outcomes for patients requiring IV therapy.
- Explain techniques for preventing transmission of infection for a patient receiving IV therapy.
- Demonstrate initiating IV therapy, regulating IV flow rate, changing IV solutions, changing IV tubing, changing IV dressings, and discontinuing a short peripheral IV.
- Identify common types of central vascular access devices (CVADs) and describe their care and maintenance.
- Identify the educational needs of patients with CVADs.

The goal of intravenous (IV) therapy is to maintain or prevent fluid and electrolyte imbalances, administer continuous or intermittent solutions or medications, replenish blood volume, and assist in pain management. Assessments of a patient's anatomy and physiology of the circulatory system, fluid and electrolyte balance, disease pathophysiology, type and duration of prescribed therapy, allergies, and patient's response to illness play a key role in decision making to ensure safe delivery of infusion solutions or medications. Evidence-based practice guides the safe, efficient, quality care necessary to provide infusion therapy. For the skills in this chapter, follow the six rights of administering parenteral solutions or medications: Right drug/solution, Right dose/concentration, Right patient, Right route, Right date/time, and Right documentation (Alexander et al., 2010; INS, 2011; Policy and Procedures INS, 2011). Defined further, these rights include knowledge of the correct solution and equipment; and how to initiate an infusion, regulate infusion rate, care for and maintain the infusion equipment, identify and correct any infusion-related complications, and discontinue an infusion. To safely and correctly provide infusion therapy, you need astute clinical management and specialized IV therapy skills in addition to your knowledge and professional accountability.

INTRAVENOUS SOLUTIONS

The use of IV therapy for a patient with an alteration in fluid and electrolyte balance is common in nursing practice. Many prepared IV solutions are available for use (Table 28-1). IV solutions fall into several categories: isotonic, hypotonic, and hypertonic. Isotonic fluids have the same osmolality as body fluids and are used to replace extracellular volume (e.g., prolonged vomiting). They effectively mimic the fluid loss of the body in the absence of an electrolyte imbalance. Hypotonic solutions are those that have an effective osmolality less than that of body fluids and are used most often to hydrate cells (e.g., hypertonic dehydration, required water replacement). Hypertonic solutions are those that have an effective osmolality greater than body fluids and are used most often to increase extracellular fluid volume (e.g., replace electrolytes, treat shock). A patient's specific fluid and electrolyte imbalance and serum electrolyte values guide the need for administration of the appropriate IV fluid (Alexander et al., 2010).

Administer all IV fluids carefully; isotonic solutions could cause increased fluid overload in patients with renal or cardiac disease; hypotonic solutions could exacerbate a hypotensive state in a patient with low blood pressure; and hypertonic solutions are irritating to the vein and have the potential to cause increased risk of heart failure and pulmonary edema.

Premixed solutions are available in which medications or electrolytes have been added by the manufacturer. Advantages are the increased stability of the solution, selection of the correct medication, and diluents. Disadvantages are that admixtures come in more than one dosage, leading to potential medication errors. As the choices of premixed solutions increase, so does the risk of related complications. Conduct a complete assessment of a patient's history, physical assessment, and review of laboratory findings before initiating any solutions or medications. When initiating IV therapy you must verify that the order is complete. Elements of a complete order include patient identification, type of solution or medication, volume, rate of infusion, frequency of infusion, route, dosage (medication), and any special considerations. The nurse administering IV solutions or medications should be aware of the indications for the prescribed therapy, any adverse reactions,

TABLE 28-1 Intravenous Solutions

Solution	Concentration	Other Names
Dextrose in Water Solutions		
Dextrose 5% in water*	Isotonic	D ₅ W
Dextrose 10% in water	Hypertonic	D ₁₀ W
Dextrose 50% in water	Hypertonic	D ₅₀ W
Saline Solutions		
0.45% sodium chloride (half NS)	Hypotonic	½ NS 0.45% NS
0.33% sodium chloride (one-third NS)	Hypotonic	⅓ NS
0.9% sodium chloride† (NS)	Isotonic	NS 0.9% NS 0.9% NaCl
3%-5% sodium chloride	Hypertonic	3%-5% NS 3%-5% NaCl
Dextrose in Saline Solutions		
Dextrose 5% in 0.9% sodium chloride	Hypertonic	D ₅ 0.9%NaCl D ₅ 0.9%NS D ₅ NS
Dextrose 5% in 0.45% NaCl sodium chloride	Hypertonic	D ₅ 0.45%NaCl D ₅ 0.45%NS D ₅ ½NS
Multiple Electrolyte Solutions		
Lactated Ringer's‡	Isotonic	LR
Dextrose 5% in Lactated Ringer's	Hypertonic	D ₅ LR

LR, Lactated Ringer's; NS, normal saline.

*Dextrose is quickly metabolized, leaving free water to be distributed evenly in all fluid compartments (Alexander et al., 2010).

†Although it is isotonic because the total concentration of electrolytes equals plasma concentration, it contains 154 mEq of both sodium and chloride, which is a higher concentration of these electrolytes than is found in the plasma, which can cause fluid volume excess (Alexander et al., 2010).

‡Contains sodium, potassium, calcium, chloride, and lactate.

special monitoring (laboratory values, vital signs, intake and output [I&O]), and appropriate interventions (INS, 2011).

INTRAVENOUS CATHETERS

To administer IV solutions and medications, a venous access device (VAD) is inserted into a vein with the final tip residing in a location that is appropriate for the pH and osmolality of the solution or medication (INS, 2011). Solutions and medications with a pH of less than 5.0 or greater than 9.0 and an osmolality greater than 600 mOsm/L are infused with a central vascular access device (CVAD) with final tip placement in the superior or inferior vena cava. Solutions and medications with a pH between 5.0 and 9.0 and an osmolality less than 600 mOsm/L may be infused via a short peripheral or midline catheter (Alexander et al., 2010; INS, 2011). Solutions or medications with low or high pH and high osmolality have the potential to cause infusion-related complications such as phlebitis when administered with a short peripheral or midline catheter (Alexander et al., 2010). Table 28-2 outlines the vascular access device (VAD) options for peripheral administration.

The choice of VADs can be overwhelming because there are a variety of sizes, number of lumens, and materials used to

Type	Use	Types of Infusions
Winged infusion butterfly needle	One-time infusion, IV push administration	Solutions or medications with pH between 5.0 and 9.0 Osmolarity less than 600 mOsm/L (INS, 2011)
Short, over-the-needle catheter (ONC) (7.5 cm [less than 3 inches])	Continuous infusion, intermittent infusion, short-term duration (INS, 2011)	Solutions or medications with pH between 5.0 and 9.0 Osmolarity less than 600 mOsm/L (INS, 2011)
Midline peripheral catheters (7.5 to 20 cm [3 to 8 inch])	Continuous infusion and intermittent infusion (1 to 4 weeks) (INS, 2011)	Solutions or medications with pH between 5.0 and 9.0 Osmolarity less than 600 mOsm/L (INS, 2011)

IV, Intravenous.

manufacture the devices (Fig. 28-1). When selecting the appropriate VAD, consider a patient’s prescribed therapy, length of treatment, duration the device remains in place, vascular integrity, patient preference, and resources available to care for the device (INS, 2011). Table 28-3 indicates the appropriate uses for the more common catheter sizes.

EVIDENCE-BASED PRACTICE

Research suggests that a dedicated, nurse-driven IV team that implements the most current technologies, maintains infusion therapy knowledge, uses infection-prevention practices, and incorporates current standards and guidelines will improve patient outcomes and reduce complications (Ackley et al., 2008; Alexander et al., 2010; INS, 2011).

Evidence-based practice (EBP) in the prevention of infusion-related complications such as catheter-related bloodstream infections (CRBSIs) and central line–associated bloodstream infections (CLABSIs) could significantly reduce patient morbidity and mortality (Alexander et al., 2010; Policy and Procedures INS, 2011). Placement of a VAD, infusion of solutions and medications, and manipulation of infusion equipment all contribute to an increased risk of infection. It is imperative that you follow established infection-prevention strategies.

- Perform hand hygiene before or after touching a patient, before handling an invasive device, before donning and after removing gloves, and after contact with inanimate objects near a patient.
- Clean skin site before venipuncture with an appropriate single-use antiseptic solution.
- Routine site care and dressing changes are not required on short peripheral catheters unless the dressing is soiled or not intact.
- Chlorhexidine solution is preferred for skin antisepsis (INS, 2011). Povidone-iodine, 70% alcohol, or tincture of iodine (1% or 2%) may also be used. Chlorhexidine is not recommended for infants under 2 months of age.
- Use a catheter stabilization device that allows for visual inspection of an insertion site.

Catheter Size (Gauge)	Clinical Indication
14, 16, 18	Trauma, surgery, blood transfusion
20	Continuous or intermittent infusions, blood transfusion
22	Continuous or intermittent infusions, children and elderly patients Administration of blood or blood product in pediatrics and neonates
24	Fragile veins for intermittent or continuous infusions; administration of blood or blood product in pediatrics or neonates

Modified from Alexander M et al: *Infusion nursing evidence based approach*, ed 3, St Louis, 2010, Mosby.

FIG 28-1 Intravenous access device options. **A**, Over-the-needle catheter (ONC) device. **B**, Steel butterfly needle.

- Primary and secondary continuous administration sets used to administer fluids other than lipid, blood, or blood products should be changed no more often than every 96 hours.

PATIENT-CENTERED CARE

Communication, comfort, and education are essential components of patient-centered care when delivering infusion therapy.

Educating patients and family caregivers about the prescribed IV therapy and goals of therapy may be difficult unless you give attention to patients' cultural and linguistic needs. Education includes clear and concise terms for all aspects of IV therapy and individualized training that include self-care practices (INS, 2011). Nursing interventions used during the insertion of the VAD to help alleviate anxiety and fear would include preparing a patient before insertion of the short peripheral IV catheter by placing him or her in a comfortable position, speaking directly to him or her, and answering questions as honestly as possible. Ask patients if they have had IV therapy in the past. Know what are their concerns and expectations. When you prepare for insertion, use techniques that minimize discomfort. Your ability to recognize diversity in patients, whether it is cultural, linguistic, or religious or caused by past experiences, will prepare you to be confident in providing infusion therapy to patients.

Safety Guidelines

- 1 Know a patient's baseline vital signs before initiating IV therapy. Fluid and electrolyte imbalances affect vital signs. Dehydration

sometimes produces hypotension and tachycardia. Fluid overload results in hypertension and bounding pulses.

- 2 Know a patient's medical history, current medications, and therapies. Medications affect fluid and electrolyte balance (e.g., diuretics or steroids). Determine his or her previous experience with IV therapy.
- 3 Beware of prolonged environmental conditions that affect a patient's fluid status (e.g., exposure to hot, humid weather), leading to fluid and electrolyte imbalances, particularly in the infant, older adult, and chronically ill.
- 4 Ensure that an IV system is intact and there is no evidence of phlebitis or infiltration. An intact system ensures that you have maintained sterility and that no fluid or medication has been lost.
- 5 Note the date of the last IV administration set and dressing change (Box 28-1).
- 6 Maintain sterility of a patent IV system using INS standards (see Box 28-1).
- 7 Know the standard precautions for infection control and the Occupational Safety and Health Administration (OSHA) standards for occupational exposure to bloodborne pathogens (Box 28-2).

BOX 28-1 INS Standards to Decrease Intravascular Infection Related to Intravenous Therapy

- Palpate catheter insertion site for tenderness daily through the intact dressing.
- Directly inspect a catheter site if patient develops tenderness at site, fever without obvious source, or symptoms of local or bloodstream infection.
- Perform hand hygiene before and after palpating, inserting, replacing, or dressing any intravascular device.
- Clean skin site before venipuncture with an appropriate single-use antiseptic solution.
- Allow site to air-dry before proceeding with procedure: 2% chlorhexidine 30 seconds, povidone-iodine at least 2 minutes.
- Do not palpate insertion site after skin has been cleaned with single-use antiseptic solution.
- Use catheter stabilization device that allows visual inspection of access site.
- Change gauze dressings that cover a catheter site every 48 hours.
- Intravenous tubing administration sets can remain sterile for 96 hours.
- Replace dressing over peripheral venous catheters when replacing catheter or when dressing becomes damp, loosened, or soiled.
- Clean injection ports with single-use antiseptic solution before accessing system.
- Replace short, peripheral venous catheters and rotate sites based on clinical assessment indicating signs or symptoms of IV-related complications.

Modified from Infusion Nurses Society: Infusion nursing standards of practice, *J Intraven Nurs* 34(suppl 1):S1, 2011.
INS, Infusion Nurses Society.

BOX 28-2 Standards for Reducing Occupational Exposure to Bloodborne Pathogens

- 1 Gloves are necessary when there is a reasonable expectation that the employee may contact blood (e.g., during vascular access procedures or while changing IV administration sets).
- 2 Immediately place contaminated needles, needleless devices, and other sharps in puncture-resistant, leak-proof containers properly labeled as a biohazard; when the containers are full, seal and dispose of them properly.
- 3 Do not bend, shear, recap, or remove contaminated needles from the syringe after use.
- 4 Occupational Safety and Health Administration (OSHA) requires reports of needlestick injuries, and the health care agency must provide medical evaluation and follow-up.
- 5 Hepatitis B vaccinations should be made available to all employees who have occupational exposure.
- 6 Training and education about exposure prevention and use of protective equipment must be offered to high-risk workers who initiate IV therapy.
- 7 Each agency must have an infection control plan, including methods to reduce health care worker's exposure to biohazardous wastes.
- 8 Agencies must have engineering and work practice controls to eliminate or minimize employee exposure. Controls may include sharps disposal containers and self-sheathing needles.

Modified from Occupational Safety and Health Administration (OSHA): Occupational exposure to bloodborne pathogens, needlestick, and other sharps injuries: final rule, CFR 29, part 1910, *Fed Reg* 66:5317, 2001, updated April 2011, available at http://www.osha.gov/pls/oshaweb/owadisp.show_document?p_table=FEDERAL_REGISTER&p_id=16265, accessed 8/21/12.

SKILL 28-1 Initiating Intravenous Therapy

NSO IV Fluid Administration Module / Lessons 1 and 2

Infusion therapy provides access to the venous system to deliver solutions and medications or blood and blood products. Reliable venous access for infusion therapy administration is essential.

Your role is to select the appropriate vascular access device (VAD) needed to place a short peripheral intravenous (IV) catheter or to assist clinicians with placement of a midline or central vascular access device (CVAD). In addition, skills are needed to prepare the infusion equipment and become familiar with the various infusion systems used during an infusion. Some solutions and medications can be administered continuously, whereas others are given intermittently. Various types of administration sets, needleless devices, extension sets, flushes, and pumps and the knowledge and skills for their correct and safe use are required. Know and follow INS standards, your agency policy and procedures, and state or government practice guidelines when providing IV therapy.

Delegation and Collaboration

The skill of initiating IV therapy cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. The nurse instructs the NAP to:

- Inform the nurse if the patient complains of any IV site-related complications such as pain, redness, swelling, bleeding.
- Inform the nurse if the patient's IV dressing becomes wet.
- Inform the nurse if the solution of fluid in the IV bag is low or the electronic infusion device (EID) alarm is sounding.

Video Clip

Equipment

- Appropriate short peripheral IV catheter for venipuncture (see Table 28-3) (Select the smallest gauge and length possible to administer the prescribed therapy [INS, 2011].)
- IV start kit supplies (available in some agencies): May contain a sterile drape to place under patient's arm, tourniquet, tape, transparent dressing, cleansing agents(s) (2% chlorhexidine preferred or povidone-iodine and 70% alcohol) and 2 × 2-inch gauze pads
- Clean gloves (latex free for patients with latex allergy)
- Extension set with needleless connection device (also called saline lock, heparin lock, IV plug or adapter)
- Prefilled 5-mL syringe with flush agent (preservative-free normal saline [NS] 0.9% normal saline solution [NSS] [INS, 2011])
- Alcohol pads
- Stabilization device (optional) and skin protectant
- Prescribed intravenous solution
- Administration set, either macrodrip or microdrip, depending on prescribed rate; if using EID, appropriate administration set
- 0.2-micron filter for nonlipid (fat emulsions) solutions (may be incorporated into the infusion set)
- Protective equipment: Goggles and mask (optional, check agency policy)
- IV pole, rolling or ceiling mounted
- EID if available
- Watch with second hand to calculate drip rate
- Special patient gown with snaps at shoulder seams if available (makes removal with IV tubing easier)
- Needle disposal container (also called *sharps container* or *biohazard container*)

STEP

RATIONALE

ASSESSMENT

- 1 Review accuracy and completeness of health care provider's order for type and amount of IV fluid, medication additives, infusion rate, and length of therapy. Follow six rights of medication administration (see Chapter 20).
 - a Check approved online database, drug reference book, or pharmacist about IV fluids composition, purpose, potential incompatibilities and side effects.
- 2 Assess patient's knowledge of procedure, reason for prescribed therapy, and arm placement preference.
- 3 Assess for clinical factors/conditions that will respond to or be affected by administration of IV solutions.
 - a Body weight
 - b Clinical markers of vascular volume:

Before administering solutions or medications an order from a licensed independent practitioner (LIP) is needed (Alexander et al., 2010; INS, 2011; Policy and Procedures INS, 2011).

Ensures safe and correct administration of IV therapy and appropriate selection of vascular access device (VAD).

Provides patient-centered care by determining level of emotional support and instruction needed (Policy and Procedures INS, 2011).

Provides baseline to determine effectiveness of prescribed therapy. A systems approach is recommended to assess for fluid and electrolyte imbalances (Alexander et al., 2010; LeFever et al., 2010).

Changes in body weight reflect fluid loss or gain. One kilogram or 2.2 lbs of body weight is equivalent to gain or loss of 1 L of fluid (Alexander et al., 2010).

STEP	RATIONALE
(1) Urine output (decreased, dark yellow).	Kidneys respond to extracellular volume (ECV) deficit by reducing urine production and concentrating urine. Kidney disease can also cause oliguria.
(2) Vital signs: Blood pressure, respirations, pulse, temperature.	Changes in blood pressure may be associated with fluid volume status (fluid volume deficit [FVD]) seen in postural hypotension. Respirations can be altered in presence of acid-base imbalances. Temperature elevations increase need for fluid requirements (a temperature of 101° F [38.3° C] and 103° F [39.4° C] requires at least 500 mL of fluid replacement within a 24-hr period) (Alexander et al., 2010).
(3) Distended neck veins. (Normally veins are full when person is supine and flat when person is upright.)	Indicator of fluid volume status: flat or collapsing with inhalation when supine with ECV deficit; full when upright or semi-upright with ECV excess.
(4) Auscultation of lungs.	Crackles or rhonchi in dependent portions of lung may signal fluid buildup caused by ECV excess.
(5) Capillary refill	Indirect measure of tissue perfusion (sluggish with ECV deficit).
c Clinical markers of interstitial volume	
(1) Skin turgor (Pinch skin over sternum or inside of forearm.)	Failure of skin to return to normal position within 3 seconds indicates ECV deficit. This is called <i>tenting</i> (Alexander et al., 2010).
(2) Dependent edema (pitting or nonpitting) 1+ indicates barely detectable edema; 4+ indicates deep pitting (see Chapter 6).	Pitting edema is seen with a weight gain of 10 to 15 lbs (4.5-6.8 kg) of retained fluid (Alexander et al., 2010).
(3) Oral mucous membrane between cheek and gum	More reliable indicator than dry lips or skin. Dry between cheek and gums indicates ECV deficit.
d Thirst	Occurs with hypernatremia and severe ECV deficit. Not a reliable indicator for older adults (Meiner, 2011).
e Behavior and level of consciousness:	
(1) Restlessness and mild confusion	Occurs with FVD or acid-base imbalance.
(2) Decreased level of consciousness (lethargy, confusion, coma)	Occurs with severe ECV deficit.
4 Determine if patient is to undergo any planned surgeries or procedures.	May occur with osmolality and acid-base imbalances. Allows anticipation and placement of appropriate VAD for infusion and avoids placement in an area that will interfere with medical procedures (INS 2011).
5 Assess laboratory data.	Helps determine priority assessments and establishes baseline for determining if therapy is effective.
6 Assess patient's history of allergies, especially to iodine, adhesive, or latex.	Equipment used during VAD insertion may contain substances to which patient is allergic.

NURSING DIAGNOSES

- Anxiety
- Deficient knowledge regarding IV therapy
- Risk for electrolyte imbalance
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1** Expected outcomes following completion of procedure:
 - Fluid and electrolyte balance returns to normal.
 - Vital signs are stable and within normal limits for patient.
 - No redness, drainage, swelling, or pain present at venipuncture site.
 - Patient is able to explain purpose and risks of IV therapy.
- Proper solution is infused at proper rate and monitored, resolving fluid and electrolyte imbalance (Alexander et al., 2010).
- Demonstrates response of circulatory system to fluid and electrolyte replacement (Alexander et al., 2010).
- Ensures that catheter is without infusion-related complications (INS, 2011).
- Demonstrates learning (Alexander et al., 2010; INS, 2011).

STEP

RATIONALE

IMPLEMENTATION

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name. 2 Instruct patient about rationale for infusion, including solution and medications ordered, procedure for initiating an IV, and signs and symptoms of complications. 3 Help patient to comfortable sitting or supine position. Provide adequate lighting. 4 Perform hand hygiene. Gather and organize equipment on clean, clutter-free bedside stand or over-bed table. 5 Change patient's gown to more easily removed gown with snaps at shoulder if available. 6 Open sterile packages using sterile aseptic technique (see Chapter 8). 7 <i>Option:</i> Prepare short extension tubing with needleless connector or stand-alone saline lock (injection cap) to attach to VAD catheter hub. | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Provides patient with information about procedure and promotes compliance (Policy and Procedures INS, 2011).</p> <p>Promotes comfort and relaxation of patient. Aids in successful vein location.</p> <p>Reduces transmission of infection and contamination of equipment (INS, 2011).</p> <p>Use of this gown decreases risk of inadvertently dislodging VAD or administration set when changing gown.</p> <p>Maintains sterility of equipment and reduces spread of microorganisms.</p> <p>Short extension tubing prevents traction on VAD. Many agencies use short extension tubing for continuous infusions and stand-alone saline locks (capped catheters).</p> |
|--|---|

Clinical Decision Point Short extension sets may be used on short peripheral catheters. Will decrease potential contact with hub and reduce blood contact. Must be of Luer-Lok connection (Alexander et al., 2010; INS, 2011; Policy and Procedures INS, 2011).

- | | |
|--|--|
| <ol style="list-style-type: none"> a Remove protective cap from needleless connector. Swab injection cap with antiseptic swab. Attach syringe with sterile 0.9% normal saline solution (NS) flush and inject through cap into short extension set, keeping syringe attached. b Maintain sterility of end of connector and set aside for attaching to catheter hub after successful venipuncture. <ol style="list-style-type: none"> 8 Prepare IV tubing and solution for continuous infusion. <ol style="list-style-type: none"> a Check IV solution using six rights of medication administration (see Chapter 20). If using bar code, scan code on patient's wristband and then on IV fluid container. Be sure that prescribed additives such as potassium and vitamins have been added. Check solution for color, clarity, and expiration date. Check bag for leaks. | <p>Removes air from tubing, preventing it from being introduced into vein (Alexander et al., 2010; Policy and Procedures INS, 2011).</p> <p>Prevents touch contamination.</p> <p>IV solutions are medications and need to be checked carefully to reduce risk of error. Bar code system reduces medication errors (Poon et al., 2010). Do not use solutions that are discolored, contain particles, or are expired. Do not use leaking bags because the integrity has been compromised and they present an opportunity for infection (Alexander et al., 2010; Policy and Procedures INS, 2011; INS, 2011).</p> |
|--|--|

STEP 8d A, Roller clamp in open position. B, Roller clamp in closed position.

STEP 8e Removing protective sheath from IV bag port.

STEP

RATIONALE

- | | |
|--|--|
| <p>b Open infusion set, maintaining sterility of both tubing ends. Electronic infusion devices (EIDs) sometimes have a special dedicated administration set.</p> <p>c Removing appropriate end caps, attach extension tubing (if used) with injection port to distal end of infusion set, maintaining sterility. Leave end cap on distal end of extension tubing.</p> <p>d Place roller clamp (see illustration A) about 2 to 5 cm (1 to 2 inches) below drip chamber and move roller clamp to “off” position (see illustration B).</p> <p>e Remove protective sheath over IV tubing port on plastic IV solution bag (see illustration) or top of bottle.</p> <p>f Remove protective cap from tubing insertion spike (not touching spike) and insert spike into port of IV bag (see illustration). Clean rubber stopper on glass-bottled solution with single-use antiseptic and insert spike into black rubber stopper of IV bottle. Bottles need special vented tubing.</p> | <p>Prevents touch contamination, which allows microorganisms to enter infusion equipment and bloodstream.</p> <p>Distal end of extension tubing with injection port attaches to IV catheter hub after venipuncture.</p> <p>Close proximity of roller clamp to drip chamber allows more accurate regulation of flow rate. Moving clamp to “off” prevents accidental spillage of IV solution during priming.</p> <p>Provides access for insertion of infusion tubing into solution using sterile technique.</p> <p>Flat surface on top of bottled solution may contain contaminants, whereas opening to plastic bag is recessed. Prevents contamination of bottled solution during insertion of spike.</p> |
|--|--|

Clinical Decision Point Do not touch spike because it is sterile. If contamination occurs (e.g., spike is accidentally dropped on the floor), discard that IV tubing and obtain a new one.

- | | |
|---|---|
| <p>g Compress drip chamber and release, allowing it to fill one-third to one-half full (see illustration).</p> <p>h Prime infusion tubing by filling with IV solution: Remove protective cap on end of tubing (you can prime some tubing without removal) and slowly open roller clamp to allow fluid to travel from drip chamber through tubing to needle adapter. Invert Y connector to displace air. Return roller clamp to “off” position after priming tubing (filled with IV fluid). Replace protective cap on end of infusion tubing.</p> <p>i Be certain that tubing is clear of air and air bubbles. To remove small air bubbles, firmly tap IV tubing where air bubbles are located. Check entire length of tubing to ensure that all air bubbles are removed (see illustration).</p> <p>j If using optional long extension tubing (not short tubing in Step 7), remove protective cap and attach it to distal end of IV tubing, maintaining sterility. Then prime long extension tubing.</p> | <p>Creates suction effect; fluid enters drip chamber to prevent air from entering tubing.</p> <p>Priming ensures that tubing is clear of air before connection with VAD. Slow fill of tubing decreases turbulence and chance of bubble formation. Closing clamp prevents accidental loss of fluid.</p> <p>Maintains sterility.</p> <p>Large air bubbles act as emboli.</p> <p>Priming removes air from tubing so it does not enter patient’s vascular system.</p> |
|---|---|

STEP 8f Inserting spike into IV bag.

STEP 8g Squeezing drip chamber to fill with fluid.

STEP 8i Removing air bubbles from tubing.

STEP

RATIONALE

9 Perform hand hygiene and apply clean gloves. Wear eye protection and mask (see agency policy) if splash or spray of blood is possible.

Reduces transmission of microorganisms. Decreases exposure to human immunodeficiency virus (HIV), hepatitis, and other bloodborne organisms (INS, 2011). Prevents spraying blood from contacting your mucous membranes.

Clinical Decision Point *Gloves are not necessary to locate vein but must be applied before preparing the site.*

10 Apply tourniquet around arm above antecubital fossa 10 to 15 cm (4 to 6 inches) above proposed insertion site (see illustration). Do not apply tourniquet too tightly to avoid injury, bruising skin, or occluding artery. Check for presence of radial pulse.

Tourniquet should be tight enough to impede venous return but not occlude arterial flow (Alexander et al., 2010; Policy and Procedures INS, 2011).

(Option a: Apply tourniquet on top of a thin layer of clothing such as a gown sleeve to protect fragile or hairy skin.)

If patient has fragile veins, tourniquet should be applied loosely or not at all to prevent damage to veins and bruising.

(Option b: Blood pressure cuff may be used in place of tourniquet: Inflate cuff to just below patient's diastolic pressure [less than 50 mg Hg].)

11 Select vein for VAD insertion (see illustration). Veins on dorsal and ventral surfaces of arms (e.g., cephalic, basilic, or median) are preferred in adults. Avoid lateral surface of wrist (10 to 12.5 cm [4 to 5 inches]) because of potential for nerve damage (INS, 2011).

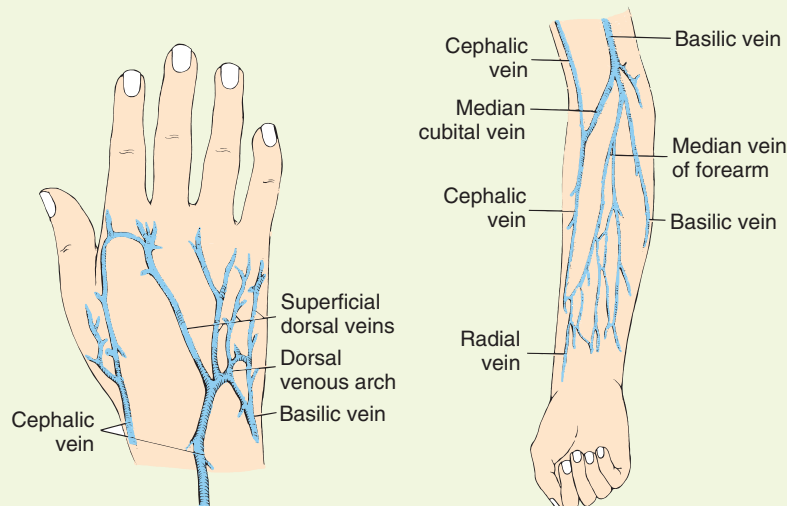

Ensures adequate vein that is easy to puncture and less likely to rupture. Veins of lower extremities should not be used for routine IV therapy in adults because of risk of tissue damage and thrombophlebitis (INS, 2011).

a Use most distal site in nondominant arm if possible.

Patients with VAD placement in their dominant hand have decreased ability to perform self-care.

STEP 10 Tourniquet placed on arm for initial vein selection.

STEP 11 Cephalic, basilic, and median cubital veins are best for IV placement in adults.

STEP	RATIONALE
<p>b Select a well-dilated vein. Methods to improve venous distention:</p> <ol style="list-style-type: none"> (1) Place extremity in dependent position and stroke from distal to proximal below proposed venipuncture site. (2) Apply warmth to extremity for several minutes (e.g., warm washcloth or dry heat). 	<p>Increased volume of blood in vein at venipuncture site makes vein more visible. Promotes venous filling. Heat increases blood supply through vasodilation (INS, 2011).</p>
<p>Clinical Decision Point Vigorous friction and multiple tapping of a vein, especially in older adults, causes hematoma and/or venous constriction.</p>	
<p>12 Select a vein large enough for VAD insertion:</p> <ol style="list-style-type: none"> a With your index finger, palpate vein by pressing downward. Note resilient, soft, bouncy feeling while releasing pressure (see illustration). b Avoid vein selection in: <ol style="list-style-type: none"> (1) Areas with tenderness, redness, rash, pain, or infection. (2) Extremity affected by previous cerebrovascular accident (CVA), paralysis, dialysis shunt, or mastectomy. (3) Site distal to previous venipuncture site, sclerosed or hardened veins, infiltrate site, areas of venous valves, or phlebotic vessels. (4) Fragile dorsal veins in older adults. c Choose site that will not interfere with patient's activities of daily living (ADLs), use of assist devices, or planned procedures. 	<p>Fingertip is more sensitive and better for assessing vein location and condition. It would be difficult to assess for any signs or symptoms of complications if an IV device were inserted in an area already compromised (INS, 2011). Increases risk for complications such as infection, lymphedema, or vessel damage (INS, 2011). Such sites cause infiltration around newly placed VAD site and vessel damage. Veins have increased risk for infiltration. Keeps patient as mobile as possible.</p>
<p>13 Release tourniquet temporarily and carefully.</p> <p><i>Option:</i> Clip arm hair with scissors if necessary (explain to patient). <i>Option:</i> You may apply topical local anesthetic to IV site 30 minutes before insertion. Monitor for allergic reaction.</p>	<p>Restores blood flow and prevents venospasm when preparing for venipuncture. Hair impedes venipuncture or adherence of dressing. Local anesthetic reduces discomfort (must have health care provider order for use of local anesthetic).</p>
<p>Clinical Decision Point If hair removal is needed, do not shave area with a razor. Shaving may cause microabrasions that increase risk of infection (INS, 2011).</p>	
<p>14 Apply clean gloves if not done in Step 9.</p> <p>15 Place adapter end of short infusion tubing (prepared in Step 7) or extension/injection cap for saline lock nearby in sterile package.</p> <p>16 If area of insertion appears to need cleaning, use soap and water first and dry. Use chlorhexidine antiseptic swab or applicator to clean insertion site, using friction in a horizontal plane with first swab, in a vertical plane with second swab, and in a circular motion moving outward with third swab (see illustration). Allow to dry completely. Refrain from touching cleaned site unless using sterile technique. Allow drying time between agents if agents are used in combination (alcohol and betadine).</p>	<p>Reduces transmission of microorganisms. Permits smooth, quick connection of infusion to short peripheral catheter once vein is accessed. Mechanical friction in this pattern allows penetration of antiseptic solution to epidermal layer of the skin (Alexander et al., 2010; INS, 2011; Policy and Procedures INS, 2011). Allowing antiseptic solution to air-dry completely effectively reduces microbial counts (INS, 2011). 2% Chlorhexidine dries in 30 seconds (INS, 2011). Touching cleaned area introduces microorganisms from your finger to site. If this happens, prepare site again.</p>

STEP 12a Palpate vein.

STEP 16 Clean site with 2% chlorhexidine.

STEP

RATIONALE

- 17 Reapply tourniquet 10 to 15 cm (4 to 6 inches) above anticipated insertion site. Check presence of radial pulse.
- 18 Perform venipuncture. Anchor vein below site by placing thumb over vein and gently stretching skin against direction of insertion 4 to 5 cm (1½ to 2 inches) distal to the site (see illustration). Instruct patient to relax hand.
 - a Warn patient of a sharp, quick stick. Insert VAD with bevel up at 10- to 30-degree angle slightly distal to actual site of venipuncture in direction of vein (see illustration).

Diminished arterial flow prevents venous filling. Pressure of tourniquet causes vein to engorge.

Stabilizes vein for needle insertion and prevents vein from rolling. Skin becomes taut, decreasing drag on insertion of device.

Places needle at a 10- to 30-degree angle to vein. When vein is punctured, risk for puncturing posterior vein wall is reduced. Superficial veins require smaller angle. Deeper veins require greater angle.

Clinical Decision Point Use each VAD only once for each insertion attempt.

- 19 Observe for blood return through flashback chamber of catheter, indicating that bevel of needle has entered vein (see illustration A). Lower catheter until almost flush with skin. Advance catheter approximately 0.6 cm (¼ inch) into vein and loosen stylet of over-the-needle catheter (ONC). Continue to hold skin taut while stabilizing needle and advance catheter off needle to thread just the catheter into vein until hub rests at venipuncture site (see illustration B). Do not reinsert stylet once it is loosened. Advance catheter while safety device automatically retracts stylet (technique will vary by product type). Follow manufacturer guidelines.

Increased venous pressure from tourniquet increases backflow of blood into catheter or tubing.

Allows for full penetration of vein wall, placement of catheter in inner lumen of vein, and advancement of catheter off stylet. Reduces risk for introduction of microorganisms along catheter. Advancing entire stylet into vein may penetrate wall of vein, resulting in hematoma.

Reinsertion of stylet causes catheter shearing in vein and potential catheter embolization (INS, 2011).

Clinical Decision Point A single nurse should not make more than two attempts at initiating IV access (INS, 2011). After two attempts the nurse should have another nurse attempt the insertion.

STEP 18 Stabilize vein below insertion site.

STEP 18a Puncture skin with catheter at 10- to 30-degree angle.

A

B

STEP 19 A, Observe for blood return in flashback chamber. B, Advance catheter into vein until hub rests at venipuncture site.

STEP	RATIONALE
<p>20 Stabilize catheter with nondominant hand and release tourniquet or blood pressure cuff with other. Apply gentle but firm pressure with middle finger of nondominant hand 3 cm (1¼ inches) above insertion site. Keep catheter stable with index finger.</p>	<p>Permits venous flow, reduces backflow of blood, and allows connection with administration set with minimal blood loss (INS, 2011).</p>
<p>21 Quickly connect Luer-Lok end of prepared extension set, or saline lock of primary administration set, to end of catheter. Do not touch point of entry of connection. Secure connection.</p>	<p>Prompt connection of infusion set maintains patency of vein and prevents risk of exposure to blood. Maintains sterility.</p>
<p>22 Flush VAD. Slowly flush a primed extension set with remaining saline from attached prefilled syringe (see illustration A) or begin a primary infusion by slowly opening slide clamp or adjusting roller clamp of IV tubing. Observe for swelling. <i>Option:</i> Remove syringe. Attach distal end of primary IV tubing to needleless connector on short extension tubing that is attached to catheter (see illustration B).</p>	<p>Positive-pressure flushing allows fluid to displace removed stylet, creates positive pressure in catheter, and prevents reflux of blood into catheter lumen (Policy and Procedures INS, 2011). Initiates flow of fluid through IV catheter, preventing clotting of device. Swelling indicates infiltration, and catheter would need to be removed.</p>
<p>23 Secure catheter (procedures differ; follow agency policy). a <i>Manufactured catheter stabilization device:</i> Wipe selected area with single-use skin protectant and allow to dry. Apply sterile adhesive strip over catheter hub. Slide device under catheter hub and center hub over device. Holding catheter in place, peel off half of liner, press to adhere to skin. Repeat on other side. Holding catheter in place, pull tab out from center of device to create opening, insert catheter into slit. This frames IV site (see illustration). Then apply dressing.</p>	<p>Use of manufactured stabilization device preserves integrity of access device, minimizes catheter movement at hub, and prevents catheter dislodgement or loss of access (INS, 2011).</p>

STEP 22 A, Flush primed end of extension set. B, Connect IV tubing to the short extension set that is attached to the catheter.

STEP 23a Catheter stabilization device in place. (Image Courtesy C.R. Bard, Inc., All rights reserved.)

STEP 23c Tape over catheter hub.

STEP

- b Transparent dressing:** Secure catheter with nondominant hand while preparing to apply dressing.
- c Sterile gauze dressing:** Place narrow piece 1.27 cm ($\frac{1}{2}$ inch) of sterile tape over catheter hub (see illustration). Place tape only on catheter, *never* over insertion site. Secure site to allow easy visual inspection. Avoid applying tape or gauze around arm.
- 24 Apply sterile dressing over site.**
- a Transparent dressing (TSM):**
- (1) Carefully remove adherent backing. Apply one edge of dressing and gently smooth remaining dressing over IV site, leaving connection between IV tubing and catheter hub uncovered. Remove outer covering and smooth dressing gently over site (see illustration).
 - (2) Take a 2.5 cm (1-inch) piece of tape and place it over extension or administration set tubing (see illustration). **Do not apply tape on top of transparent dressing.**
- b Sterile gauze dressing:**
- (1) Place 2 × 2-inch gauze pad over insertion site and catheter hub. Secure all edges with tape. Do not cover connection between IV tubing and catheter hub (see illustration).
 - (2) Fold 2 × 2-inch gauze in half and cover with 2.5-cm (1-inch)-wide tape extending about an inch from each side. Place under tubing/catheter hub junction (see illustration).

RATIONALE

- Prevents accidental dislodgement of catheter.
- Use sterile tape under sterile dressing to prevent site contamination. Regular adhesive tape is potential source of pathogenic bacteria (INS, 2011).
- Prevents back-and-forth motion of catheter.
- Occlusive dressing protects site from bacterial contamination. Allows for visualization of insertion site and surrounding area for signs and symptoms of IV-related complications (INS, 2011). Connection between administration set and hub needs to be uncovered to facilitate changing tubing if necessary.
- Removal of tape from transparent dressing can cause accidental removal of catheter.
- Tape on top of transparent dressing prevents moisture from being carried away from skin.
- Optional method of securing device if patient is allergic to transparent dressing. It is not the preferred method to cover and secure IV device because gauze prevents visualization of insertion site (INS, 2011).
- Tape on top of gauze makes it easier to access hub/tubing junction. Gauze pad elevates hub off skin to prevent pressure area.

STEP 24a(1) Apply transparent dressing.

STEP 24a(2) Place tape over administration set tubing.

STEP 24b(1) Place 2 × 2-inch gauze over insertion site and catheter hub.

STEP 24b(2) Apply 2 × 2-inch gauze dressing under tubing junction.

STEP	RATIONALE
25 Loop the short extension tubing or the continuous infusion administration tubing alongside arm and place second piece of tape directly over tubing and secure (see illustration).	Securing administration set or extension set reduces risk for dislodging catheter if IV tubing is pulled (i.e., loop comes apart before catheter dislodges).
26 For continuous infusion, insert tubing of IV administration set into electronic infusion device (EID). Check ordered rate of infusion, then turn on EID, program it, and begin infusion at correct rate. If infusing by gravity drip, adjust flow rate to correct drops per minute (see Skill 28-2)	Manipulation of catheter during dressing application alters flow rate. EID maintains correct rate of flow for IV solution. Flow fluctuates; thus it must be checked at intervals for accuracy.
27 Label dressing per agency policy. Include date and time of IV insertion, VAD gauge size and length, and your initials (see illustration).	Allows for recognition of type of device and length of time that device has been in place.
28 Dispose of used stylet or other sharps in appropriate sharps container. Discard supplies. Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms; prevents accidental needlestick injuries.
29 Instruct patient in how to move or turn without dislodging VAD.	Prevents accidental dislodgement of catheter.

STEP 25 Loop and secure tubing.

STEP 27 Label IV dressing.

EVALUATION

1 Routine site care and dressing changes are not performed on short peripheral catheters unless dressing is soiled or no longer intact.	An occlusive transparent dressing is changed at time of site rotation (Alexander et al., 2010; INS, 2011; Policy and Procedures INS, 2011). Gauze dressings are changed every 48 hours (INS, 2011).
2 Observe patient every 1 to 2 hours or at established intervals per agency policy and procedure for the following: a Correct type/amount of IV solution that has infused by observing fluid level in IV container. b Check infusion rate on EID or count drip rate (if gravity drip). c Check patency of VAD.	Correct administration of fluid volume prevents fluid imbalance. Accurate monitoring of drip rate further ensures correct volume administration. Flow rate is slowed or stopped.
Clinical Decision Point <i>If IV is positional, fluid will run slowly or stop, depending on position of patient's arm; if this continues, you may have to restart IV.</i>	
d Observe patient during palpation of vessel (over TSM) for signs of discomfort.	Tenderness is an early sign of phlebitis (INS, 2011).

STEP	RATIONALE
<p>e Inspect insertion site, note color (e.g., redness or pallor). Inspect site for presence of swelling (which is sign of infiltration) or pain and tenderness (which is a sign of phlebitis) (Table 28-4). Palpate temperature of skin above dressing.</p> <p>3 Observe patient to determine response to therapy (e.g., laboratory values, I&O, weights, vital signs, postprocedure assessments).</p>	<p>Redness, inflammation, tenderness, and warmth indicate vein inflammation or phlebitis. Use a standard scale for assessing and documenting infiltration (INS, 2011).</p> <p>IV fluids and additives maintain or restore fluid and electrolyte balance. Early recognition of complications leads to prompt treatment.</p>

Unexpected Outcomes	Related Interventions
<p>1 FVD as manifested by decreased urine output, dry mucous membranes, decreased capillary refill, a disparity in central and peripheral pulses, tachycardia, hypotension, shock.</p> <p>2 FVE as manifested by crackles in lungs, shortness of breath, edema.</p> <p>3 Electrolyte imbalances indicated by abnormal serum electrolyte levels, changes in mental status, alterations in neuromuscular function, cardiac arrhythmias, and changes in vital signs.</p> <p>4 Infiltration is indicated by slowing of infusion; insertion site is cool to touch, pale, and painful.</p> <p>5 Phlebitis is indicated by pain and tenderness at IV site with erythema at site or along path of vein. Insertion site is warm to touch, and rate of infusion may be altered.</p> <p>6 Bleeding occurs at venipuncture site.</p> <p>7 IV site infection. Monitor site for signs and symptoms of infection, which may include redness, pain, edema, induration, temperature, and drainage.</p>	<ul style="list-style-type: none"> • Notify health care provider. • Requires readjusting infusion rate. • Reduce IV flow rate if symptoms appear. • Notify health care provider. • Adjust additives in IV or type of IV fluid per order. • Stop infusion and discontinue IV (see Procedural Guideline 28-1). • Elevate affected extremity. • Restart new IV above previous location of infiltrate or opposite extremity if continued therapy is necessary. • Document degree of infiltration and nursing intervention. • Stop infusion immediately and discontinue IV (see Procedural Guideline 28-1). • Restart new IV if continued therapy is necessary in area above previous location or opposite extremity. • Place moist warm compress over area of phlebitis. • Continue to monitor site for 48 hours after catheter is removed for postinfusion phlebitis (INS, 2011). • Document degree of phlebitis and nursing interventions per agency policy and procedure (see Table 28-4). • Verify that system is intact and replace dressing if loosened. • Restart new IV if bleeding from site does not stop or if IV is dislodged. • Notify health care provider for appropriate interventions such as culturing of device or site. • Restart new IV if continued therapy is necessary in area above location or opposite extremity. • Document presence and severity of infection and interventions.

Grade	Clinical Criteria
0	No symptoms
1	Erythema at access site with or without pain
2	Pain at access site with erythema and/or edema
3	Pain at access site with erythema and/or edema Streak formation Palpable venous cord
4	Pain at access site with erythema and/or edema Streak formation Palpable venous cord >1 inch (2.5 cm) in length Purulent drainage

From Infusion Nurses Society: Infusion nursing standards of practice, *J Intraven Nurs* 34(1S):S65, 2011.

- ### Recording and Reporting
- Record in nurses' notes and electronic health record (EHR) the number of attempts and sites of insertion; precise description of insertion site (e.g., cephalic vein on dorsal surface of right lower arm, 2.5 cm [1 inch] above wrist); flow rate; method of infusion (gravity or EID), size and type, length, and brand of catheter; and time infusion started and patients response to insertion. Use an infusion therapy flow sheet when available.
 - If using an EID, document type and rate of infusion and device identification number.
 - Record patient's status, IV fluid, amount infused, and integrity and patency of system according to agency policy.
 - Report to oncoming nursing staff: type of fluid, flow rate, status of VAD, amount of fluid remaining in present solution, expected time to hang subsequent IV container, and patient condition.

- Report to health care provider any signs and symptoms of IV-related complications.

Special Considerations

Teaching

- Instruct patient in signs and symptoms of IV-related complications (e.g., infiltration, phlebitis, and inflammation).
- Instruct patient to inform nurse or NAP if rate slows or stops or if patient sees blood in the tubing or on the dressing.
- Teach patient how to ambulate with IV pole or stand.
- Instruct patient to protect IV when performing hygiene activities.

Pediatric

- Perform venipuncture in a neutral space to allow the child's room to be a safe place.
- In addition to the usual venipuncture sites, the four scalp veins and dorsum of the foot are used in infants.
- Needle selection is based on age: 26- to 24-gauge for neonates, 24- to 22-gauge for children (Hockenberry and Wilson, 2011; INS, 2011).
- Use local anesthetics and distraction strategies to minimize distress associated with venipuncture (Alexander et al., 2010).
- Apply latex-free tubing or rubber band or use a blood pressure cuff inflated to just below diastolic blood pressure. In accessing scalp veins aim the catheter downward toward the heart so the flow of infusion can follow venous return (INS, 2011).
- Allow older children to select IV site to increase cooperation so they believe that they have some control over their treatment.
- To maintain safety in positioning, have extra help when starting an IV on a child. Use therapeutic hugging, usually in a sitting position, to provide close contact (Hockenberry and Wilson, 2011). NAP can help with positioning.
- Choose age-appropriate activities compatible with the maintenance of the IV infusion to maintain normal growth and development.

Gerontologic

- Veins of the older population are very fragile; they have less subcutaneous support tissue, and their skin is thinning (Alexander et al., 2010). Avoid sites that are easily moved or bumped. Use a commercial protective device to protect the site and reduce manipulation (Fig. 28-2).
- In older patients the use of a 22- or 24-gauge catheter is appropriate for most therapies. Smaller-gauge catheters are less traumatizing to the vein but still allow blood flow to provide increased hemodilution of the IV fluids or medications (Alexander et al., 2010).

FIG 28-2 I.V. House Protective Device. (Courtesy I.V. House.)

- If possible, avoid the back of the older adult's hand or the dominant arm for venipuncture because use of these sites interferes with their independence.
- As older adults lose subcutaneous tissue, the veins lose stability and roll away from the needle. To stabilize the vein, pull the skin taut and toward you with your nondominant hand and anchor the vein with your thumb.
- Reduce the angle of insertion (e.g., 5 to 15 degrees on insertion) to accommodate more superficial veins.
- Some older adults do not complain of pain at the insertion site; however, a large amount of fluid may infiltrate before a patient experiences discomfort.

Home Care

- Ensure that a patient is able and willing to self-administer IV therapy or that there is a reliable family caregiver to provide IV therapy care at home.
- Ensure that all sharps and equipment contaminated by blood are disposed of in puncture-resistant containers with lids. Some suppliers provide sharps containers for needle disposal. Teach patient and family to dispose of any open and sheathed needles into sharps container.
- Instruct patient and family caregiver about procedures of IV therapy, including hand hygiene and aseptic technique while handling syringes and other supplies.
- Ensure availability of 24-hour assistance with provider of home infusion therapy pharmaceuticals and equipment.
- Teach patient about activity restrictions (e.g., avoiding strenuous exercise of the arm with the IV).

SKILL 28-2 Regulating Intravenous Flow Rate

NSO Intravenous Fluid Therapy Management Module / Lesson 2

After initiating an infusion and ensuring that the line is patent, regulate the rate of infusion according to the health care provider's order. Accurate infusion rates are essential in the delivery of solutions and medications. Appropriate regulation of fluid rates reduces complications (e.g., phlebitis, infiltration, fluid overload,

or clotting of the VAD) associated with IV therapy (Policy and Procedures INS, 2011). Changes in patient position, flexion of the IV site extremity, and occlusion of the IV device influence infusion rates. Vasospasm of the vein, venous trauma, or manipulation of the device also affects infusion rates. A patient achieves

therapeutic outcomes and fewer complications when an IV system and flow rate are assessed systematically (Alexander et al., 2010).

There are a variety of methods for calculating infusion rates. Electronic infusion devices (EIDs) maintain correct flow rates and catheter patency and prevent an unexpected bolus of IV infusion. Many EIDs provide a record of the volume of fluid infused over a period of time.

An EID delivers a measured amount of fluid over a period of time (e.g., 100 mL/hr) using positive pressure. Infusion pumps are necessary for patients requiring low hourly rates, at risk for volume overload, with impaired renal clearance, or receiving solutions or medications that require a specific hourly volume (Alexander et al., 2010). EIDs use an electronic sensor and an alarm that signals if the pressure in the system changes and the desired flow rate alters. For example, when an infiltration occurs in the subcutaneous tissue or a patient's position obstructs IV flow, pressure builds up, and the alarm sounds. An infiltration is sometimes extensive before a positive-pressure EID alarm responds. The use of an EID does not absolve a nurse from checking to ensure that the pump is functioning and infusing at the prescribed rate (INS, 2011).

Non-EIDs such as a volume-control device deliver small fluid volumes with the aid of gravity. Patient and mechanical factors (e.g., height of the IV fluid container, IV tubing size, or fluid viscosity) affect an IV gravity controller. One example of a volume-control device is a calibrated chamber placed between the IV container and the insertion spike and drip chamber of an administration set (Fig. 28-3). You place a small volume of IV fluid in the chamber and regulate it for administration. The advantage of this system is that only the smaller volume of fluid infuses if the rate of the IV is inadvertently increased. Volume-control devices are beneficial when administering fluids to neonates, very young children, and older adults (Alexander et al., 2010). With either type of device, a patient requires consistent monitoring to verify the accurate infusion of the IV solution and detect and prevent complications.

The capabilities of EID have increased over the years, allowing for enhanced patient safety (Alexander et al., 2010). Multifunctional EIDs are designed to be a final step in preventing errors that

relate directly to administration of IV medications. These “smart pumps” have built-in software programmed from health care pharmacy databases with unit-specific profiles (Fig. 28-4). The pump has an audible and visual alert when its setting does not match the medication administration guidelines, helping to prevent infusion errors. Each pump has the potential to use add-on syringe pumps, permit multiple infusions, and administer patient-controlled analgesia. The potential reduction in serious medication errors and the improved patient outcomes have prompted many organizations to implement this technology (Alexander et al., 2010; INS, 2011). Know and follow your agency and manufacturer recommendations for selection and use of EIDs, alarm settings, pump controls, and features. Diligence is necessary on your part to assess and monitor patients since use of any EID or controller is not without the risk of malfunction, placing a patient at risk for harm or injury.

Patients in alternative care settings (e.g., home care, long-term care) can receive infusion therapy with ambulatory pumps, which promote independence and improved quality of life. Most pumps weigh less than 6 lbs and range from palm size to fitting in a backpack. Programming capabilities range from rate adjustments, remote site adjustments, and therapy-specific settings.

Delegation and Collaboration

The skill of regulating IV flow rate cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. The nurse instructs the NAP to:

- Inform the nurse when the EID alarm signals.
- Inform the nurse when the fluid container is empty.
- Report any patient complaints of discomfort related to infusion such as pain, burning, bleeding, or swelling.

Equipment

- ❑ Watch with second hand
- ❑ Calculator, paper, and pencil
- ❑ Tape
- ❑ Label
- ❑ IV administration set: EID (optional), volume-control device (optional)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| <p>1 Review accuracy and completeness of health care provider order in patient's medical record for patient name and correct solution: type, volume, additives, rate, and duration of IV therapy. Follow six rights of drug administration (see Chapter 20).</p> <p>2 Assess patient's knowledge of how positioning of IV site affects flow rate.</p> <p>3 Perform hand hygiene. Inspect IV site for signs and symptoms of IV-related complications such as pain, swelling, or redness.</p> <p>4 Observe for patency of IV tubing and VAD.</p> <p>5 Identify patient risk for fluid and electrolyte imbalance, given type of IV fluid (e.g., neonate, history of cardiac or renal disease).</p> | <p>Ensures that correct IV fluid is administered.</p> <p>Fosters patient participation in maintaining most effective position of arm with IV equipment. Nurse is responsible for positioning control clamp or setting infusion device rate.</p> <p>Observation or reports of any IV-related complications indicate need to reestablish patent IV access.</p> <p>IV line and VAD must be free of kinks, knots, and clots for fluid to infuse at proper rate.</p> <p>Helps prioritize assessments. Volume control needs to be strict. Guides choice of infusion device.</p> |
|--|---|

NURSING DIAGNOSES

- Deficient fluid volume
- Excess fluid volume
- Risk for injury
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Serum electrolyte levels remain within normal limits. • Patient receives prescribed volume of solution over desired time interval. • No signs or symptoms of IV-related complications (e.g., infiltration, infection). | <p>IV fluid helps to maintain fluid and electrolyte levels. Patient achieves therapeutic outcomes.</p> <p>Patient completes therapy without complications.</p> |
|---|--|

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> |
|---|---|

Clinical Decision Point *It is common for health care providers to write an abbreviated IV order such as: "D₅W with 20 mEq KCl 125 mL/hr continuous." This order implies that the IV should be maintained at this rate until order has been written for IV to be discontinued or changed to another order.*

- | | |
|---|--|
| <p>2 Have paper and pencil or calculator to calculate flow rate.</p> <p>3 Know calibration (drop factor) in drops per milliliter (gtt/mL) of infusion set used by agency:</p> <ul style="list-style-type: none"> a Microdrip: 60 gtt/mL: Used to deliver rates less than 100 mL/hr. b Macro drip: 10 to 15 gtt/mL (depending on manufacturer): Used to deliver rates greater than 100 mL/hr. <p>4 Determine how long each liter of fluid should run. Calculate milliliters per hour (hourly rate) by dividing volume by hours:</p> | <p>Use mathematic calculations to obtain correct rate.</p> <p>Microdrip tubing universally delivers 60 gtt/mL. Used when small or very precise volumes are to be infused.</p> <p>There are different commercial parenteral administration sets for macrodrip tubing. Used when large volumes or fast rates are necessary. Know drip factor for tubing being used.</p> <p>Basis of calculation to ensure infusion of fluid over prescribed hourly rate.</p> |
|---|--|

$$\text{mL/hr} = \frac{\text{Total infusion (mL)}}{\text{Hours of infusion}}$$

$$1000 \text{ mL} / 8 \text{ hr} = 125 \text{ mL/hr}$$

or if 3 L is ordered for 24 hours:

$$3000 \text{ mL} / 24 \text{ hr} = 125 \text{ mL/hr}$$

STEP

RATIONALE

5 Select one of the following formulas to calculate minute flow rate (drops per minute) based on drop factor of infusion set:

a $\text{mL/hr} / 60 \text{ min} = \text{mL/min}$

$\text{Drop factor} \times \text{mL/min} = \text{Drops/min}$

or

b $\text{mL/hr} \times \text{Drop factor} / 60 \text{ min} = \text{Drops/min}$

Calculate minute flow rate for a bag 1:1000 mL with 20 mEq KCl @ 125 mL/hr.

Microdrip:

$125 \text{ mL/hr} \times 60 \text{ gtt/mL} = 7500 \text{ gtt/hr}$

$7500 \text{ gtt} \div 60 \text{ minutes} = 125 \text{ gtt/min}$

Macrodrip:

$125 \text{ mL/hr} \times 15 \text{ gtt/mL} = 1875 \text{ gtt/hr}$

$1875 \text{ gtt} \div 60 \text{ minutes} = 31\text{--}32 \text{ gtt/min}$

6 For gravity infusions: Confirm hourly rate and minute rate based on drop factor of infusion set. Using formula (see Step 5), calculate flow rate.

a Ensure that IV container is 36 inches above the IV site for adults.

b Regulate flow rate by counting drops in drip chamber for 1 minute by watch; adjust roller clamp to increase or decrease rate of infusion.

7 For use of EID for infusion: Follow manufacturer guidelines for setup of EID.

a Insert IV tubing into chamber of control mechanism (see manufacturer directions) (see illustration).

b Turn on power button, select required drops per minute or volume per hour, close door to control chamber, and press start button (see illustration).

Once you determine hourly rate, these formulas compute correct flow rate.

When using microdrip, milliliters per hour (mL/hr) always equals drops per minute (gtt/min).

Multiply volume by drop factor and divide product by time (in minutes).

Calculates minute flow rate for regulation of infusion.

Pressure caused by gravity is necessary to overcome venous pressure and resistance from tubing and catheter (INS, 2011).

Regulates flow to prescribed rate.

Most electronic infusion pumps use positive pressure to infuse. Infusion pumps propel fluid through tubing by compressing and milking IV tubing.

Clinical Decision Point An anti-free flow safeguard (preventing bolus infusion in the event of machine malfunction or when tubing is removed from machine) is an important element of an EID and is required. Always check manufacturer recommendations for specific device features.

c Open drip regulator completely while EID is in use.

d Monitor infusion rate and IV site for complications according to agency policy. Use watch to verify rate of infusion, even when using EID.

Ensures that pump freely regulates infusion rate.

Infusion controllers or pumps are not perfect and do not replace frequent, accurate nursing evaluation. EIDs continue to infuse IV fluids after a complication has developed (INS, 2011).

STEP 7a Insert IV tubing into chamber of control mechanism.

STEP 7b Select rate and volume to be infused and press start button.

STEP	RATIONALE
e Assess patency of system when alarm signals.	Alarm indicates some blockage in system. Empty solution container, tubing kinks, closed clamp, infiltration, clotted catheter, air in the tubing, and/or low battery will all trigger EID alarm.
8 For volume-control device:	
a Place volume-control device between IV container and insertion spike of infusion set using aseptic technique.	Delivers small fluid volumes but needs refilling as volume becomes low. Reduces risk for sudden fluid infusion.
b Place no more than a 2-hour allotment of fluid into device by opening clamp between IV bag and device.	Allows for continuous infusion of fluid if you do not return in exactly 60 minutes to refill volume. If infusion rate accidentally increases, patient receives only a 2-hour allotment of fluid.
c Assess system at least hourly; add fluid to volume-control device. Regulate flow rate.	Maintains patency of system and patient monitoring.
9 Attach label to IV fluid container with date and time container changed (check agency policy).	Provides reference to determine next time for container change, especially with keep vein open (KVO) rate.
10 Instruct patient in purpose of alarms, to avoid raising hand or arm that affects flow rate, and to avoid touching control clamp.	Information allows patient to protect IV site and informs him or her about rationale for not altering control rate.

EVALUATION

1 Monitor IV infusion at least every hour, noting volume of IV fluid infused and rate.	Ensures that correct volume infuses over prescribed time period.
2 Observe patient for signs of fluid volume excess or deficit and signs of fluid and electrolyte imbalance.	Determines response to therapy. Signs and symptoms of dehydration, overhydration, or electrolyte imbalance warrant changing rate of fluid infused.
3 Evaluate for signs of IV-related complications (e.g., infiltration, phlebitis, occluded venous access device [VAD], kink or knot in infusion tubing).	Prevents complications that decrease or stop flow rate.

Unexpected Outcomes

- 1 Sudden infusion of large volume of solution occurs with patient having symptoms of dyspnea; crackles in lung; and increased urine output, indicating fluid overload.
- 2 IV fluid container empties with subsequent loss of IV line patency.
- 3 IV infusion is slower than ordered.

Related Interventions

- Slow infusion rate: KVO rates must have specific rate ordered by licensed independent practitioner (LIP) (Policy and Procedures INS, 2011).
- Notify health care provider immediately.
- Place patient in high-Fowler's position.
- Anticipate new IV orders.
- Administer diuretics if ordered.
- Discontinue present IV and restart new short peripheral catheter in new site.
- Check for positional change that affects rate, height of IV container, kinking of tubing or obstruction.
- Check VAD site for complications.
- Consult health care provider for new order to provide necessary fluid volume.

Recording and Reporting

- Record rate of infusion in drops per minute or milliliters per hour in nurses' notes and EHR or on parenteral administration form according to agency policy.
- Document use of any EID or control device and identification number on that device.
- At change of shift or when leaving on break, report rate of and volume left in infusion to nurse in charge or next nurse assigned to care for patient.

Special Considerations

Teaching

- Instruct patient to notify nurse if any signs or symptoms of IV complications are noted (e.g., swelling or pain).
- Patient using an EID should know the significance of alarms and when to notify nursing.
- Teach patient about factors affecting flow rate, to protect IV site, and importance of not altering rate control.

Pediatric

- Consider physiologic differences in children, particularly focusing on total body weight (85% to 90% water). Dehydration is a common cause of fluid and electrolyte imbalance; assessment of fluid needs includes meter square weight or caloric method (Alexander et al., 2010; Hockenberry and Wilson, 2011).
- Infusion pumps (especially syringe pumps) are almost always used in pediatrics because they infuse very small amounts of fluids and accurately provide the prescribed volume of IV solution.
- Use only small-volume containers for infusions (250 mL for children younger than 12 months, 500 mL for older children) (Alexander et al., 2010). Microdrip tubing is recommended for children.

Gerontologic

- Renal changes in older adults reduce the ability of the kidney to concentrate and dilute urine in response to water or salt excess. Combined with cardiac deficiencies and decreased blood flow to organs, an older patient balances between dehydration and fluid overload. Use an EID and microdrip tubing to administer fluids. Monitor electrolyte levels, blood urea nitrogen

(BUN), creatinine, urine output, and daily weight (Alexander et al., 2010).

- Some older patients easily develop cerebral edema from rapid dextrose infusions. Older patients with impaired renal function often develop hypernatremia from normal saline infusions.

Home Care

- Ensure that patient is able and willing to operate an infusion pump and administer IV therapy. If patient is unable to provide self-care, be sure that a reliable family caregiver is available in the home.
- Discuss proper EID function with patient. Consider use of an ambulatory-type device.
- Teach patient and family caregiver what EID alarms mean, methods to troubleshoot them, and how to disconnect the tubing from the EID pump in the event of a pump failure.
- Provide patient with a contact phone number that he or she can access 24 hours a day for problems.
- If using gravity infusion, teach patient and family caregiver to time drops per minute using watch with second hand.
- Ensure that patient’s electrical outlets are properly grounded.

SKILL 28-3 Changing Intravenous Solutions

NSO Intravenous Fluid Therapy Management Module / Lesson 3

Patients receiving intravenous (IV) therapy over time require periodic changes of IV solutions. IV containers include plastic bags and glass bottles. You change a container when there is an order for a new solution or when it becomes time to add a sequential container to avoid exceeding hang time (Alexander et al., 2010). It becomes clinically appropriate to change the type of solution depending on a patient’s fluid and electrolyte balance, response to therapy (e.g., therapeutic drug monitoring), and goals of therapy. The Infusion Nurses Society (INS) recommends changing a fluid container within 24 hours after adding a medication or an administration set (INS, 2011). The use of ambulatory infusion devices may remain longer than 24 hours if you use aseptic technique, if the system remains closed without injection ports or add-on tubing, and if the medication is stable for a longer time period. Organizational skills are necessary to complete this task in a manner that decreases the risk of infusion-related complications such as infusion

container becoming empty or clotting off of a venous access device (VAD).

Delegation and Collaboration

The skill of changing an IV solution cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. The nurse instructs the NAP to:

- Inform the nurse when an IV container is near completion.
- Report any cloudiness or precipitate in the IV solution.
- Report alarm sounding on electronic infusion device (EID).
- Report that insertion site appears with IV-related complications (e.g., red, swollen, or patient complaints of discomfort).

Equipment

- IV solution as ordered by health care provider

STEP **RATIONALE**

ASSESSMENT

- 1 Review accuracy and completeness of health care provider’s order in patient’s medical record for patient name and correct solution: type, volume, additives, rate, and duration of IV therapy. Follow six rights of drug administration (see Chapter 20).
- 2 Note date and time when IV tubing and solution were last changed.
- 3 Check the IV solution for integrity including, but not limited to, discoloration, cloudiness, leakage, expiration date. Determine compatibility of all IV fluids and additives by consulting approved online database, drug reference, or pharmacist.

Ensures that correct IV fluid is administered (Policy and Procedures INS, 2011).

Ensures correct change of tubing and dressings.

If there has been a break in the integrity of the solution container, a new bag is needed. Incompatibilities cause physical, chemical, and therapeutic changes with adverse patient outcomes (INS, 2011).

STEP	RATIONALE
4 Determine patient's understanding of need for continued IV therapy.	Indicates need for any patient education.
5 Assess patency of current venous access device (VAD) site, observing for any signs or symptoms of complications such as redness, swelling, complaints of discomfort.	New IV access site is necessary if IV is not patent.
6 Assess IV tubing for puncture, contamination, or occlusions.	Indicates need for tubing change.
7 Check laboratory data, such as potassium level.	Compare data with baseline to determine ongoing response to IV solution administration.

NURSING DIAGNOSES

- Deficient fluid volume
- Deficient knowledge regarding IV infusion
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • IV solution is correct. • VAD remains patent. • Patient and family caregiver can explain purpose of IV solution change. | Patient receives solution ordered for treatment of diagnosis.
Ensures infusion of fluid into intravascular space.
Demonstrates learning. |
|--|--|

IMPLEMENTATION

- | | |
|--|--|
| 1 Collect equipment. Have next solution prepared at least 1 hour before needed. If solution is prepared in pharmacy, ensure that it has been delivered to patient care unit. Allow solution to warm to room temperature if it has been refrigerated. Check that solution is correct and properly labeled. Check solution expiration date. Ensure that any light sensitivity restrictions are followed. | Adequate planning reduces risk for clot formation in vein caused by empty IV container. Checking that solution is correct prevents medication error. |
| 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). |
| 3 Change solution when fluid remains only in neck of container (about 50 mL) or when new type of solution has been ordered. | Prevents waste of solution. |
| 4 Prepare patient and family caregiver by explaining procedure, its purpose, and what is expected of patient. | Decreases anxiety and promotes cooperation. |
| 5 Perform hand hygiene. | Reduces transmission of microorganisms. |

STEP 8 A, Quickly remove spike from old solution container. B, Without touching tip, insert spike into new container.

STEP

- 6 Prepare new solution for changing. If using plastic bag, hang on IV pole and remove protective cover from IV tubing port. If using glass bottle, remove metal cap and metal and rubber disks.
- 7 Close roller clamp on existing solution to stop flow rate. Remove tubing from EID (if used). Then remove old IV fluid container from IV pole. Hold container with tubing port pointing upward.
- 8 Quickly remove spike from old solution container and, without touching tip, insert spike into new container (see illustration).

RATIONALE

- Permits quick, smooth, and organized change from old to new solution.
- Prevents solution remaining in drip chamber from emptying while changing solutions. Prevents solution in bag from spilling.
- Reduces risk for solution in drip chamber becoming empty and maintains sterility.

Clinical Decision Point *If spike is contaminated, you will need a new IV tubing set.*

- 9 Hang new container of solution on IV pole.
- 10 Check for air in tubing. If air bubbles have formed, remove them by closing roller clamp, stretching tubing downward, and tapping tubing with finger (bubbles rise in fluid to drip chamber) (see illustration).
- 11 Make sure drip chamber is one-third to one-half full. If drip chamber is too full, level can be decreased by removing bag from IV pole, pinching off tubing below drip chamber, inverting container, squeezing drip chamber (see illustration), releasing and turning solution container upright, and releasing pinch on tubing.
- 12 Regulate flow to ordered rate by using roller clamp on tubing or programming EID.
- 13 Place time label on side of container and label with time hung, time of completion, and appropriate intervals. If using plastic bags, mark only on label and not container.

- Gravity helps with delivery of fluid into drip chamber.
- Reduces risk for air entering tubing. Use of an air-eliminating filter also reduces risk.
- Reduces risk for air entering tubing. If chamber is completely filled, you cannot observe or regulate drip rate.
- Maintains measures to restore fluid balance and deliver IV fluid as ordered.
- Provides visual comparison of volume infused compared with prescribed rate of infusion. Ink on container sometimes leaks into plastic bags (INS, 2011).

STEP 10 Tap tubing to cause air bubbles to rise up to drip chamber.

STEP 11 Squeeze drip chamber to fill with fluid. Be sure to leave chamber one-third to one-half full.

STEP

RATIONALE

EVALUATION

- 1 Observe functioning, intactness, and patency of IV system and flow rate.
- 2 Observe patient for signs of fluid volume deficit (FVD) or fluid volume excess (FVE) to determine response to IV therapy.
- 3 Assess patient for signs and symptoms of IV-related complications. Palpate skin for temperature, edema, or tenderness.

Ensures proper fluid administration.

Provides ongoing evaluation of patient's fluid status.

Provides ongoing evaluation of VAD patency.

Unexpected Outcomes

- 1 Flow rate is incorrect; patient receives too little or too much fluid.

Related Interventions

- Notify health care provider if patient's anticipated infusion is 100 to 200 mL less than or greater than anticipated (follow agency policy).
- Evaluate patient for adverse effects of infusion.
- Determine and correct the cause of incorrect flow rate (e.g., change in position, tubing kink).
- Use EID when accurate flow rate is critical.

Recording and Reporting

- Record amount and type of solution infused, amount and type of solution started, and flow rate according to agency policy.
- Record solution and tubing change on patient's record. Use parenteral (IV) therapy flow sheet, if available.

Special Considerations

Teaching

- Inform patient of new solution, additives, flow rate, and potential side effects.

Home Care

- Teach patient and family caregiver how to perform an IV solution change. Observe them performing procedure.

SKILL 28-4 Changing Infusion Tubing

NSO Intravenous Fluid Therapy Management Module / Lesson 3

An important component of patient care is maintaining the integrity of the intravenous (IV) system through the conscientious use of infection-prevention principles. Administration sets are the primary method to carry a solution or medication to a patient. These administration sets are considered the primary set. In addition, patients may have add-on devices (e.g., filters, extension sets), which you connect to the primary set as indicated by the prescribed therapy. Secondary sets may be used as a method to administer additional medications in conjunction with the primary infusion (e.g., antibiotics). Depending on the solution or medication being infused and the method for administration (i.e., primary set with or without add-on device, secondary sets), adherence to infection-prevention principles must be followed to ensure positive patient outcomes. Luer-Lok connections should be used to prevent accidental disconnection and needle-stick injury (INS, 2011). When the short peripheral site is rotated, the administration set should be changed (INS, 2011). Follow agency policy and procedures for specific requirements (Table 28-5).

Administration sets used for parenteral nutrition (see Chapter 32) and blood or blood products (see Chapter 29) have specific criteria with which you need to be familiar when administering these advanced therapies (see agency policy). Whenever possible, schedule tubing changes when it is time to hang a new IV container (see Skill 28-1). To prevent entry of bacteria into the bloodstream, maintain sterility during tubing and solution changes. If the tubing becomes damaged, is leaking, or becomes contaminated, it must be changed, regardless of the tubing change schedule.

TABLE 28-5 Administration Set Changes

Primary and Secondary Continuous Infusions	Primary Intermittent Infusions	Use of Add-on Devices
<ul style="list-style-type: none"> • Every 96 hours for fluids <i>other</i> than lipid, blood, or blood products. • Extending to every 7 days may be considered if an antiinfective CVAD is being used and if fluids that enhance microbial growth are not administered (less than 10% dextrose solutions). • If the secondary set is removed from the primary set, the secondary set is now considered an intermittent set and should be changed every 24 hours. 	<ul style="list-style-type: none"> • Should be changed every 24 hours because of increased risk of infection with repeatedly disconnecting and reconnecting administration set. • Aseptically attach a covering device to the end of the administration set after each intermittent use. <i>Avoid</i> attaching the exposed end of the administration set to port on the same set (e.g., looping). 	<ul style="list-style-type: none"> • Should be minimized since each is a potential source of contamination and disconnection. • Use of administration sets with devices as part of the set is preferred. • Aseptically change with insertion of new short peripheral catheter or with each administration set replacement.

CVAD, Central vascular access device.

Modified from Infusion Nurses Society: Infusion nursing standards of practice, *J Intraven Nurs* 30(suppl 1):S1, 2011.

Delegation and Collaboration

The skill of changing infusion tubing cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. The nurse instructs the NAP to:

- Report to the nurse any leakage from or around the IV tubing.
- Report if tubing has become contaminated (lying on the floor).

Equipment

- Clean gloves
- Antiseptic wipes (alcohol wipes)
- Label

Continuous IV Infusion

- Microdrip or macrodrip administration set infusion tubing as appropriate
- Add-on device as necessary (e.g., filters, extension set, needleless connector)
- Tubing label

Intermittent Extension Set

- 3- to 5-mL syringe filled with preservative-free normal saline (NS) 0.9% normal saline solution (NSS)
- Short extension tubing (if necessary), injection cap

STEP**RATIONALE****ASSESSMENT**

- 1 Note date and time when IV tubing was last changed (see [Table 28-5](#) for recommendations on administration set changes).
- 2 Assess tubing for puncture, contamination, or occlusion that requires immediate change.
- 3 Determine patient's understanding of need for continued IV therapy.

Decreases risk of infection.

Compromised tubing results in fluid leakage and bacterial contamination.

Reinforces need for further instruction.

NURSING DIAGNOSIS

- Deficient knowledge regarding IV therapy
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient's IV site is free from signs and symptoms of IV-related complications (e.g., infection, redness, swelling, or pain).
 - Patient experiences no leakage of solution from or around IV tubing.
 - Patient's IV tubing is patent.
- Patient and family caregiver explain procedure, purpose, and patient expectations.

Adherence to administration set changes decreases risk of complications.

Intact system decreases risk for microbial contamination.

Brief interruption of IV infusion does not result in occlusion of venous access device (VAD).

Demonstrates learning.

IMPLEMENTATION

- 1 Identify patient using at least two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.
- 2 Prepare patient by explaining procedure, its purpose, and what is expected of him or her.
- 3 Coordinate tubing changes with solution changes when possible.
- 4 Perform hand hygiene.
- 5 Open new infusion set and connect add-on pieces (e.g., filters, extension tubing). Keep protective coverings over infusion spike and distal adapter. Secure all connections.
- 6 Apply clean gloves. If patient's IV cannula hub is not visible, remove IV dressing (see [Skill 28-5](#)). Do not remove tape securing cannula to skin.
- 7 Prepare infusion tubing with new bag. (See [Skill 28-1](#), Step 8.)

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

Decreases anxiety; promotes cooperation; and prevents sudden movement of extremity, which could dislodge IV catheter.

Decreases number of times system is open.

Reduces transmission of microorganisms.

Securing connections reduces risk later of air emboli and infection. Protective covers reduce entrance of microorganisms. All connections should be of Luer-Lok type (INS, 2011).

Cannula hub must be visible to provide smooth transition when removing old and inserting new tubing. Infections related to IV therapy are most often caused by catheter hub contamination (INS, 2011).

STEP

RATIONALE

- 8** Prepare infusion tubing with existing continuous IV infusion bag.
- Move roller clamp on new IV tubing to “off” position.
 - Slow rate of infusion through old tubing to KVO rate, using EID or roller clamp.
 - Compress and fill drip chamber of old tubing.
 - Invert container and remove old tubing. Keep spike sterile and upright. *Optional:* Tape old drip chamber to IV pole without contaminating spike.
 - Place insertion spike of new tubing into solution container. Hang solution bag on IV pole, compress and release drip chamber on new tubing, and fill drip chamber one-third to one-half full.
 - Slowly open roller clamp, remove protective cap from adapter (if necessary), and prime new tubing with solution. Stop infusion and replace cap. Place end of adapter near patient’s IV site.
 - Stop EID or turn roller clamp on old tubing to “off” position.
- 9** Prepare tubing with extension set or saline lock.
- If short extension tubing is needed, use sterile technique to connect new injection cap to new extension set or tubing.
 - Swab injection cap with antiseptic swab. Insert syringe with 3 to 5 mL of saline solution and inject through injection cap into extension set.
- 10** Reestablish infusion.
- Gently disconnect old tubing from extension tubing (or from IV catheter hub) and quickly insert adapter of new tubing or saline lock into extension tubing connection (or IV catheter hub) (see illustrations for example of connecting tubing to short extension set).

Prevents fluid spillage.
Prevents occlusion of VAD.

Ensures that fluid chamber remains full until new tubing is changed.
Fluid in drip chamber will continue to run and maintain catheter patency.

Permits drip chamber to fill and promotes rapid, smooth flow of solution through tubing.

Removes air from tubing and replaces it with IV solution.
Equipment is positioned for a quick connection of new tubing.

Prevents fluid spillage.

Prepares extension set for connecting with IV.

Maintains patency of catheter. Prevents introduction of microorganisms.

Allows smooth transition from old to new tubing, minimizing time system is open.

STEP 10a A, Disconnect old tubing. B, Insert adapter of new tubing.

STEP 10b Regulate flow of IV.

STEP	RATIONALE
<ul style="list-style-type: none"> b For continuous infusion, open roller clamp on new tubing and regulate drip rate using roller clamp (see illustration) or EID. c Attach piece of tape or preprinted label with date and time of tubing change onto tubing below drip chamber. d Form loop of tubing and secure it to patient's arm with strip of tape. 	<p>Ensures catheter patency and prevents occlusion.</p> <p>Provides reference to determine next time for tubing change.</p> <p>Avoids accidental pulling against site and stabilizes catheter.</p>
<p>11 Remove and discard old IV tubing. If necessary, apply new dressing (see Skill 28-5). Remove and dispose of gloves. Perform hand hygiene.</p>	<p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Evaluate flow rate hourly and observe connection site for leaking.</p>	<p>Ensures proper fluid administration.</p>
<p>2 Observe patient for signs of fluid volume deficit (FVD) or fluid volume excess (FVE) to determine response to IV therapy.</p>	<p>Provides ongoing evaluation of patient's fluid and electrolyte status.</p>
<p>3 Check entire IV system for patency, starting with solution bag hanging and working all the way down system to patient's IV access insertion site.</p>	<p>Prevents improper fluid infusion.</p>

Unexpected Outcomes

- 1 IV infusion is slower than ordered.

Related Interventions

- Check for positional change that affects rate, height of IV container, kinking of tubing, or obstruction.
- Check for patency by opening roller clamp.
- Check VAD site for complications.
- Consult health care provider for new order to provide necessary fluid volume.

Recording and Reporting

- Record tubing change, type of solution, volume, and rate of infusion on patient's record. Use a special IV therapy flow sheet for parenteral fluids per agency protocol.

Home Care

- Instruct patient or family caregiver in procedure for performing a sterile IV tubing change.
- Ensure that patient is able and willing to perform tubing change and maintain IV access site or that there is a reliable person at home to provide this IV therapy care.

Special Considerations

Teaching

- Instruct patient to notify nurse if fluid leaks from or around IV site or tubing or if tubing separates from catheter.

SKILL 28-5 Changing a Short Peripheral Intravenous Dressing

NSO *Intravenous Fluid Therapy Management Module / Lesson 4*

Administration of solutions via the parenteral route is not without complications, which can be either systemic or local (Alexander et al., 2010). Systemic complications occur within the vascular system and are usually remote to the infusion site (e.g., septicemia, circulatory overload, and embolism). Local complications result from trauma to the inner layer of the vein (tunica intima) as a direct result of many factors such as poor insertion technique, inappropriate size of short peripheral device (see Table 28-3), infusing a solution or medication with a pH or osmolarity not within required ranges (see Table 28-2), and poor assessment and incorrect

technique for short peripheral dressing changes (Alexander et al., 2010; Policy and Procedures INS, 2011). Short peripheral intravenous (IV) catheters require strict adherence to infection-prevention measures to avoid complications associated with these devices. The skin insertion site is the most common source of colonization and infection for IV catheters. Therefore you need to securely apply catheter dressings and change dressings when wet, soiled, or loosened. You may stabilize short peripheral IV catheters with a manufactured stabilization device, sterile tapes, or surgical strips and cover the site with a transparent semipermeable membrane (TSM) dressing or sterile gauze (INS, 2011). You change a transparent dressing during catheter site rotation of a short peripheral device and immediately if integrity of the dressing is compromised.

Change gauze dressings every 48 hours and immediately if integrity is compromised. When using gauze under a transparent dressing (although not recommended), it is considered a gauze dressing and should be changed every 48 hours (INS, 2011).

Delegation and Collaboration

The skill of changing a short peripheral IV dressing cannot be delegated to nursing assistive personnel (NAP). The nurse instructs the NAP to:

- Report to the nurse if a patient complains of moistness or loosening of an IV dressing.
- Protect the IV dressing during hygiene and activities of daily living (ADLs).

Equipment

- ❑ Antiseptic swabs (2% chlorhexidine preferred or 70% alcohol, povidone-iodine)
- ❑ Adhesive remover (*optional*)
- ❑ Skin protectant swab
- ❑ Clean gloves
- ❑ Strips of sterile, precut tape (or roll of sterile tape), or stabilization device
- ❑ Commercially available IV site protection (*optional*) (see Fig. 28-2)
- ❑ Sterile transparent semipermeable dressing
or
- ❑ Sterile 2 × 2- or 4 × 4-inch gauze pad

STEP

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <p>1 Determine when dressing was last changed. Dressing should be labeled to include date and time applied, size and type of venous access device (VAD), and date VAD was inserted.</p> <p>2 Perform hand hygiene. Observe present dressing for moisture and intactness. Determine if moisture is from site leakage or external source.</p> <p>3 Observe IV system for proper functioning or complications (e.g., current flow rate, tubing, or catheter kinks). Palpate catheter site through intact dressing for complaints of tenderness, pain, or burning. (NOTE: Apply clean gloves if gauze dressing is moist.)</p> <p>4 Monitor body temperature.</p> <p>5 Assess patient's understanding of need for continued IV infusion.</p> | <p>Provides information regarding length of time that present dressing has been in place. In addition, you are able to plan for dressing change (INS, 2011).</p> <p>Moisture is medium for bacterial growth and renders dressing contaminated. Nonadhering dressing increases risk for bacterial contamination to venipuncture site or displacement of IV catheter.</p> <p>Unexplained decrease in flow rate indicates problems with VAD placement and patency. Pain is associated with phlebitis and infiltration.</p> <p>Elevated temperature can be related to infection at VAD site or systemic complication.</p> <p>Reveals need for patient instruction.</p> |
|--|--|

NURSING DIAGNOSES

- Acute pain
- Deficient knowledge regarding IV therapy
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • IV insertion site remains free of IV-related complications (redness, swelling, tenderness, or exudate). • Patient and family caregiver can explain procedure and purpose of VAD dressing change. | <p>Proper care maintains IV site.</p> <p>Demonstrates learning.</p> |
|--|---|

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Explain procedure and purpose to patient and family caregiver. Explain that patient will need to hold affected extremity still. Explain how long procedure will take.</p> <p>2 Perform hand hygiene. Collect equipment. Apply clean gloves.</p> | <p>Decreases anxiety, promotes cooperation, and gives patient time frame around which to plan personal activities.</p> <p>Reduces transmission of microorganisms. Infections related to IV therapy are most often caused by catheter hub contamination; thus you need to use careful technique throughout dressing change (INS, 2011).</p> |
|--|--|

STEP

RATIONALE

- | | |
|--|---|
| <p>3 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>4 Remove dressing.
 <i>For transparent semipermeable dressing:</i> Remove by pulling up one corner and pulling side laterally while holding catheter hub with nondominant hand (see illustration). Repeat on other side. Leave tape or catheter stabilization device that secures IC catheter in place.
 <i>For gauze dressing:</i> Stabilize catheter hub while loosening tape and removing old dressing one layer at a time by pulling toward insertion site. Leave tape that secures VAD to skin intact. Be cautious if IV tubing becomes tangled between two layers of dressing.</p> <p>5 Observe insertion site for signs and symptoms of IV-related complications (tenderness, redness, swelling, exudate, or complaints of pain). If complication exists or if ordered by health care provider, discontinue infusion (see Procedural Guideline 28-1).</p> <p>6 Prepare new sterile tape strips for use. If IV is infusing properly, gently remove tape or stabilization device securing VAD. Stabilize VAD with one finger. Use adhesive remover to clean skin and remove adhesive residue if necessary.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Technique minimizes discomfort during removal. Use alcohol swab on transparent dressing next to patient's skin to loosen dressing.</p> <p>Presence of complication indicates need to remove VAD at current site.</p> <p>Exposes venipuncture site. Stabilization prevents accidental displacement of VAD. Adhesive residue decreases ability of new tape to adhere securely to skin.</p> |
|--|---|

Clinical Decision Point *Keep one finger over catheter at all times until tape or dressing secures placement. If patient is restless or uncooperative, it is helpful to have another staff member help with procedure.*

- | | |
|---|---|
| <p>7 While stabilizing IV, clean insertion site with chlorhexidine antiseptic swab, using friction vertically and horizontally and moving from insertion site outward with a third swab (see illustration). Allow antiseptic solution to dry completely.</p> <p>8 <i>Optional:</i> Apply skin protectant solution to area where you will apply tape or dressing. Allow to dry.</p> <p>9 While securing catheter, apply a sterile dressing over site (procedures differ; follow agency policy).
 a <i>Manufactured catheter stabilization device:</i> Apply catheter stabilization device as directed in Skill 28-1, Step 23a.</p> | <p>Allowing antiseptic solutions to air-dry completely effectively reduces microbial counts (INS, 2011). 2% Chlorhexidine takes 30 seconds to dry (INS, 2011).</p> <p>Coats skin with protective solution to maintain skin integrity, prevents irritation from adhesive, and promotes adhesion of dressing.</p> <p>Manufactured catheter stabilization device preserves integrity of VAD and minimizes catheter movement at hub (INS, 2011). Must be placed under transparent dressing and is a sterile device.</p> |
|---|---|

STEP 4 Remove transparent dressing by pulling side laterally.

STEP 7 Clean peripheral insertion site with antiseptic swab.

STEP	RATIONALE
b <i>Transparent dressing:</i> Apply transparent dressing as directed in Skill 28-1, Step 23b.	Prevents accidental dislodgement of catheter. Allows continuous inspection of insertion site (Alexander et al., 2010). Occlusive dressing protects site from bacterial contamination. Connection between administration set and hub needs to be uncovered to facilitate changing tubing if necessary.
c <i>Sterile gauze dressing:</i> Apply sterile gauze dressing as directed in Skill 28-1, Step 23c.	Only use sterile tape under sterile dressing to prevent site contamination. Gauze dressing obscures observation of insertion site and is changed every 48 hours (INS, 2011).
Clinical Decision Point Because Band-Aids are not occlusive and nonsterile tape increases the risk for insertion site infection, do not use either over catheter insertion points.	
10 Remove and discard gloves.	Prevents transmission of microorganisms.
11 <i>Optional:</i> Apply site protection device (e.g., I.V. House Ultra Protective Dressing®).	Reduces risk for phlebitis and infiltration from mechanical motion.
12 Anchor IV tubing with additional pieces of tape if necessary. When using transparent dressing, avoid placing tape over the dressing.	Prevents accidental displacement of VAD.
13 Label dressing per agency policy. Information on label includes date and time of IV insertion, VAD gauge size and length, and your initials.	Communicates type of device and time interval for dressing change and site rotation (INS, 2011).
14 Discard equipment and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Observe function, patency of IV system, and flow rate after changing dressing.	Validates that IV is patent and functioning correctly. Manipulation of catheter and tubing will affect rate of infusion.
2 Inspect condition of short peripheral site for signs and symptoms of IV-related complications (e.g., redness, complaints of pain, swelling, or exudate).	Complications such as phlebitis and infiltration require removal of short peripheral catheter and insertion of new catheter at new site above area of complication or other extremity.
3 Monitor patient's body temperature.	Elevated temperature indicates infection that can be associated with contamination of venipuncture site or septicemia.

Unexpected Outcomes

- 1 Short peripheral catheter is infiltrated, as evidenced by decreased flow rate or edema, pallor, or decreased temperature around insertion site.
- 2 Phlebitis is present (see Table 28-4).
- 3 Short peripheral catheter is accidentally removed or dislodged.
- 4 Patient has an elevated temperature.
- 5 Insertion site is red, edematous, and/or painful and/or has presence of exudate, indicating infection at venipuncture site.

Related Interventions

- Stop infusion and remove catheter (see Procedural Guideline 28-1).
- Restart new short peripheral catheter in other extremity or above previous insertion site if continued therapy is necessary.
- Stop infusion and remove short peripheral catheter (see Procedural Guideline 28-1).
- Restart new catheter in other extremity if continued therapy is necessary.
- Restart new short peripheral catheter if continued therapy needed.
- Notify health care provider.
- Prepare to obtain blood culture or culture of IV site to evaluate source of infection.
- Notify health care provider. Culture of catheter tip and/or exudate may be ordered (confirm before removal of IV).
- Remove short peripheral catheter (see Procedural Guideline 28-1).

Recording and Reporting

- Record time short peripheral dressing was changed, reason for change, type of dressing material used, patency of system, and description of venipuncture site.
- Report to nurse in charge or oncoming nursing shift that dressing was changed and any significant information about integrity of system.
- Report to health care provider and document any complications.

Special Considerations

Teaching

- Instruct patient to notify nurse if site appears red or swollen, has drainage, or is painful.

Pediatric

- Pediatric patients are not always able to fully understand explanations. Presence of parent or security toy during procedure helps to decrease fear and increase cooperation. Perform procedure on patient’s toy or doll first.
- Assistance is necessary to keep patient still and protect IV catheter from dislodgement.

- Use commercially available IV site protectors to cover and protect the IV site in young active children.
- Dried povidone-iodine should be removed with saline wipes or sterile water in infants under 2 months or pediatric patients with compromised skin integrity (INS, 2011).

Gerontologic

- Some older adults have fragile skin; thus prevent skin tears by minimizing the use of tape directly on the skin and applying skin protectant before applying tape.
- Infiltration may go unnoticed because of the decreased elasticity of skin and loose skinfolds. Because of decreased tactile sensation, a large amount of fluid may infiltrate before pain occurs.

Home Care

- Instruct patient and family caregiver about the signs and symptoms of IV-related complications.
- Have patient or family caregiver demonstrate hand hygiene.
- Teach patient to keep site dry during bath or shower by wrapping in plastic bag and taping occlusively.
- Teach patient and family caregiver what to do if dressing becomes compromised or if catheter comes out. If catheter comes out, apply gauze pressure dressing at site and notify home health agency nurse.

PROCEDURAL GUIDELINE 28-1 Discontinuing a Short Peripheral Intravenous Access

NSO Intravenous Fluid Administration Module / Lesson 4

You discontinue a short peripheral intravenous (IV) catheter when the prescribed length of therapy is completed or a complication occurs (e.g., phlebitis, infiltration, or catheter occlusion). The technique for discontinuing a short peripheral IV catheter follows infection-prevention guidelines to minimize the chance of the patient’s acquiring an infection. Care must also be taken because the risk of catheter emboli may occur if the catheter breaks off during removal.

Delegation and Collaboration

The skill of discontinuing a short peripheral intravenous line cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. The nurse instructs the NAP to:

- Report to the nurse any bleeding at the site after catheter has been removed.
- Report any complaints by patient of pain or observations of redness at the site.

Equipment

- Clean gloves
- Sterile 2 × 2- or 4 × 4-inch gauze sponge
- Antiseptic swab
- Tape

Procedural Steps

- 1 Observe existing IV site for signs and symptoms of IV-related complications (pain, infiltration, phlebitis, exudate).
- 2 Assess if patient is receiving an anticoagulant or has a history of a coagulopathy.
- 3 Review accuracy and completeness of health care provider’s order for discontinuation of IV therapy.
- 4 Assess patient’s understanding of the need for IV to be discontinued.

- 5 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient’s identification bracelet.
- 6 Explain procedure to patient before you remove catheter. Explain that patient needs to hold affected extremity still.
- 7 Turn IV tubing roller clamp to “off” position or turn electronic infusion device (EID) off and roller clamp to “off” position.
- 8 Perform hand hygiene and apply clean gloves.
- 9 Carefully remove IV site dressing and stabilize IV device (see Skill 28-5). Then remove tape securing catheter.

Clinical Decision Point *Never use scissors to remove the tape or dressing because you may accidentally cut the catheter.*

- 10 Place clean sterile gauze above insertion site and withdraw catheter, using slow, steady motion. Keep hub parallel to skin (see illustration).

STEP 10 IV catheter is removed slowly, keeping catheter parallel to vein.

PROCEDURAL GUIDELINE 28-1 Discontinuing a Short Peripheral Intravenous Access—cont'd

Clinical Decision Point Do not raise or lift catheter before it is completely out of the vein to avoid trauma or hematoma formation.

- 11 Apply pressure to site for a minimum of 30 seconds until bleeding has stopped.
NOTE: Apply pressure for at least 5 to 10 minutes if patient is on anticoagulants.
- 12 Inspect catheter for intactness after removal; note tip integrity and length.

- 13 Observe site for evidence of any complications such as bleeding, pain, exudate, or swelling.
- 14 Apply clean, folded gauze dressing over insertion site and secure with tape.
- 15 Discard used supplies, remove gloves, and perform hand hygiene.
- 16 Document procedure in patient's medical record.

SKILL 28-6 Caring for Central Vascular Access Devices

The need for safe and convenient intravenous (IV) therapy has led to the development of vascular access devices (VADs) designed for long-term access to the venous or arterial systems. Physicians or credentialed advanced practice nurses place these devices into the central vascular system. A central vascular access device (CVAD) differs from short peripheral or midline catheters related to the final catheter tip location. A CVAD has a final tip location in the lower third of the superior vena cava and the junction of the right atrium (Fig. 28-5) (INS, 2011). For CVADs placed in the femoral region the final tip placement should be in the inferior vena cava above the level of the diaphragm (INS, 2011). Many factors are considered before placement of a CVAD such as the pH and osmolarity of the solution or medication (pH less than 5.0 or greater than 9.0, osmolarity greater than 600 mOsm/L) to be administered, duration of therapy (greater than 7 days), status of veins for short peripheral access, and disease process (e.g., cancer, pain management). Your role is to help the health care provider place a CVAD, care for and maintain the device, administer solutions or medications, and assess for signs and symptoms of complications (Alexander et al., 2010). CVADs can be categorized as short- or long-term devices with various types within each category (Table 28-6).

Each of these devices has similarities and differences of which as a nurse you need to be aware because they will impact care and maintenance of each CVAD and patient education. These devices are composed of silicone or polyurethane and can be coated with heparin, antibiotics, or chlorhexidine (Alexander et al., 2010). Tip configuration can be either open ended or closed (valved) ended.

FIG 28-5 Catheter tip from CVAD lies in superior vena cava.

Open-ended devices are those in which the catheter tip is open like a “straw.” These devices carry a higher risk for complications (e.g., hemorrhage, air embolism, and occlusion from fibrin or clots) (Alexander et al., 2010). Valve-tipped devices are those in which the tip is configured with a three-way pressure-activated valve (e.g.,

TABLE 28-6 Central Vascular Access Devices

Short-Term Devices

Nontunneled Percutaneous

- Length of dwell: days to several weeks
- Insertion sites: subclavian, external/internal jugular, and femoral veins
- Insertion technique: Not surgically placed, can be done at bedside, direct puncture into intended vein without passing through subcutaneous tissue
- Held in place with sutures or manufactured securement device

Peripherally Inserted Central Catheters (PICCs) (Fig. 28-6)

- Length of dwell: as long as they function properly with no evidence of intravenous (IV)-related complications
- Insertion sites: Antecubital fossa or upper arm (basilic or cephalic vein) and advanced until catheter tip reaches superior vena cava (SVC)
- Insertion technique: Not surgically placed, can be done at bedside, in home setting, or in radiology setting
- Held in place with sutures or manufactured securement device

Long-Term Devices

External Tunneled (Hickman, Broviac, Groshong)

- Length of dwell: Considered permanent
- Insertion sites: Chest region through subclavian or jugular vein
- Insertion technique: Surgery required: Tunneling of the proximal end subcutaneously from insertion site and bringing it out through skin at an exit site (Fig. 28-7)
- Held in place by a Dacron cuff coated in antimicrobial solution; in approximately 2-3 weeks scar tissue forms around cuff, fixing catheter in place

Implanted Venous Ports

- Length of dwell: considered permanent
- Insertion sites: Chest, abdomen, or inner aspect of forearm
- Insertion techniques: Requires surgery; catheter placed via subclavian or jugular vein and attached to reservoir located within a subcutaneous pocket (Fig. 28-8)
- Held in place within reservoir pocket and accessed using a noncoring needle (Fig. 28-9)

FIG 28-6 Peripherally inserted central catheter (PICC). (Courtesy and copyright © Bard Access Systems.)

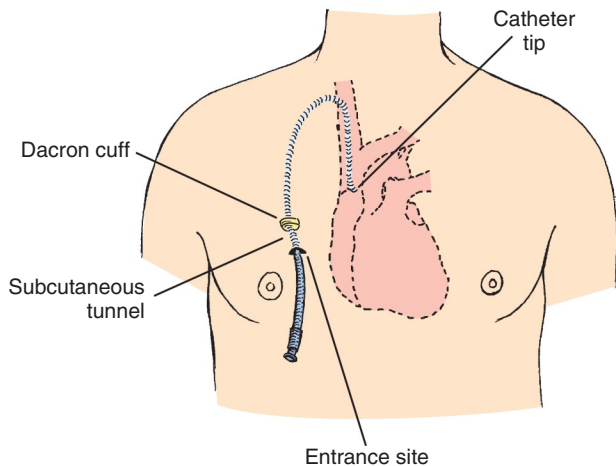

FIG 28-7 Tunneled catheter is in place, threaded into superior vena cava.

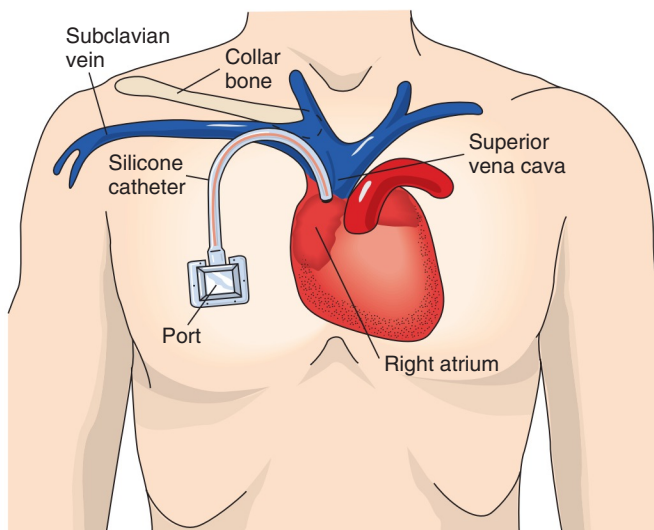

FIG 28-8 Implanted port and catheter.

FIG 28-9 Cross section of implantable port showing access of port with noncoring needle.

Groshong); or the hub of the device has a pressure-activated valve (e.g., PAS V), which reduces the risk of hemorrhage, air embolism, and occlusion. CVADs can have single or multiple lumens. The choice of the number of lumens depends on a patient's condition and prescribed therapy. Patients requiring numerous infusions and blood samplings may have a device placed with more than one lumen allowing simultaneous administration of solutions and medications. In addition, multilumens allow for administration of incompatible solutions or medications. With the exception of the implanted venous port, each of these devices is accessed using the hub of the device located on the end of each of the external lumen(s). Implanted venous ports are located within the reservoir pocket; therefore there are no external lumen(s) to which to attach administration sets or flush syringes. To use the implanted venous port the septum is palpated; and, using sterile technique, a special noncoring needle is inserted through the skin into a self-sealing injection port (see Fig. 28-9). When a port is not in use, no external catheter is present. According to the *INS Flushing Protocols*, implanted venous ports should be flushed monthly with 3 to 5 mL of heparin (100 units/mL) to maintain patency (INS, 2011).

Primary complications associated with CVADs are usually related to infection commonly referred to as *central line-associated bloodstream infections (CLABSIs)* caused by contamination of the catheter from the skin of the patient or poor infection-prevention practices during insertion or care and maintenance (Alexander et al., 2010). According to the National Quality Forum a list of serious reportable event (SRE) (Safe Practice 21) actions should be taken to prevent CLABSIs by implementing evidence-based intervention practices (NQF, 2011). The *Institute for Healthcare Improvement (2011)* recently introduced a CLABSI bundle. Care bundles are groupings of best practices with respect to a disease process or condition that individually improve care, but result in substantially greater improvement when applied together. The science supporting the bundle components is sufficiently established to be considered the standard of care. The IHI Central Line Bundle is a group of evidence-based interventions for patients with intravascular central catheters that, when implemented together, result in better outcomes than when implemented individually (IHI, 2011).

The key components of the IHI Central Line Bundle are:

- Hand hygiene
- Maximal barrier precautions on insertion
- Chlorhexidine skin antiseptics
- Optimal catheter site selection, with avoidance of the femoral vein for central venous access in adult patients
- Daily review of line necessity with prompt removal of unnecessary lines

Care of CVADs requires knowledge of the purpose and function of the devices and prevention of complications. Patients with CVADs require health education and teaching about infection-prevention practices and skin care.

Delegation and Collaboration

The skill of caring for a CVAD cannot be delegated to nursing assistive personnel (NAP). Delegation to licensed practical nurses (LPNs) varies by state Nurse Practice Act. The nurse instructs the NAP to:

- Report the following to the nurse immediately: patient's dressing becomes damp or soiled, catheter line appears to be pulled out farther than original insertion position, IV line becomes disconnected, patient has a fever, patient complains of pain at the site.
- Help with positioning patient during insertion and care.

Equipment

Insertion and Dressing Care

- Hair clippers
- Central vascular access insertion tray (Fig. 28-10)
- Caps
- Sterile gowns
- Sterile drapes
- Masks and protective eyewear
- Nonsterile gloves
- Sterile gloves (powder free)
- Gauze pads

FIG 28-10 CVAD insertion tray.

- Surgical towels
- Antimicrobial solutions: 2% chlorhexidine (IHI, 2011)
- 1% lidocaine (Xylocaine)
- Sterile drapes
- 10-mL syringe
- Transparent dressing (transparent semipermeable membrane [TSM]) or gauze 4 × 4 dressing for catheter insertion site
- Tape
- IV infusion pump
- Tincture of benzoin (*optional*)

Site Care and Dressing Change

- CVAD dressing change kit, which includes:
 - Sterile gloves
 - Mask
 - Antimicrobial swabs (e.g., 2% chlorhexidine [IHI, 2011] [see agency policy])
 - Transparent antimicrobial dressing (TSM)
 - 4 × 4 Gauze pads
 - Tape measure
 - Sterile tape
 - Label
- Catheter stabilization device (if not sutured) for peripherally inserted central catheter (PICC) or nontunneled catheters
- Needleless injection cap(s) for each lumen(s)
- Noncoring needle for implanted venous port

Blood Sampling

- Clean gloves
- Antimicrobial swabs (e.g., 2% chlorhexidine, alcohol)
- 5-mL Luer-Lok syringes
- 10-mL Luer-Lok syringes
- Vacutainer system or blood transfer device (see agency policy)
- Preservative-free saline flush 0.9% normal saline solution (NSS)
- Blood tubes, including waste tubes, labels
- Needleless injection cap
- Syringe (5 mL or 10 mL; see agency policy) for discarded blood
- 10-mL syringe with 5 to 10 mL saline flush
- 10-mL syringe with 3 mL heparin flush (100 units/mL)
- Clean gloves

Changing the Injection Cap

- Clean gloves
- Antimicrobial swabs (e.g., 2% chlorhexidine)
- Needleless injection cap(s)
- 10-mL syringe with 10 mL normal saline (NS) flush 0.9% NSS

Flushing a Positive-Pressure Device

- Clean gloves
- Alcohol swabs
- Positive-pressure injection cap
- 10-mL prefilled saline syringe

Discontinuation of a Nontunneled Catheter or PICC

- CVAD dressing change kit
- Tape
- Antimicrobial solution: 2% chlorhexidine (IHI, 2011)
- Suture removal kit (if sutures are in place)
- Goggles, gown, mask, and clean gloves

STEP

RATIONALE

ASSESSMENT

<p>1 Review accuracy and completeness of health care provider's order for insertion of CVAD for size and type. Assess treatment schedule: times for administration of IV solutions, medications, and blood sampling. Follow six rights of medication administration (see Chapter 20).</p> <p>2 Assess patient's hydration status: Skin turgor, dryness of mouth, skin texture, and fluid intake and output.</p> <p>3 Assess patient for any surgical procedures of upper chest or anatomic irregularities of proposed insertion site.</p> <p>4 Assess CVAD placement site for skin integrity (open lesions) and signs of infection (i.e., redness, swelling, tenderness, exudate).</p> <p>5 Assess patient for allergy to iodine, lidocaine (Xylocaine), latex, or chlorhexidine.</p> <p>6 Assess type of CVAD intended for placement. Review manufacturer directions concerning catheter and maintenance.</p> <p>7 Assess for proper function of existing CVAD before therapy: integrity of catheter, ability to flush or infuse fluid, ability to aspirate blood.</p> <p>8 Assess if any catheter lumens require flushing or if CVAD site needs dressing change by referring to medical record, nurses' notes, agency policies, and manufacturer-recommended guidelines for use.</p> <p>9 Assess patient's understanding of CVAD and knowledge of purpose, care, and maintenance. For long-term use ask patient to discuss steps in care and perform procedure (e.g., catheter site cleaning or dressing change).</p>	<p>Identifies patient's need for vascular access, evaluates response to therapy, and determines education needs. Insertion of central catheter requires informed consent (INS, 2011).</p> <p>Provides baseline. In addition, dehydration is depletion of fluid volume and makes insertion of central vascular catheter more difficult.</p> <p>Previous surgical procedures or central vascular catheterizations indicate that you should not use a particular site. Spinal deformities and contractions make positioning difficult.</p> <p>Compromised skin integrity contraindicates catheter insertion and can lead to secondary complications.</p> <p>Medications, solutions used during catheter insertion, and use of gloves and tape can cause serious allergic reactions.</p> <p>Care and management depends on type and size of catheter or port, number of lumens, purpose of therapy.</p> <p>Blood return should be obtained before infusion of solutions or medications (INS, 2011). If resistance is met and/or no blood return is noted, patency must be established before infusing solutions or medications (INS, 2011).</p> <p>Provides guidelines for maintaining catheter patency and preventing infection.</p> <p>Determines patient's level of understanding.</p> <p>Provides opportunity to educate patient for home care of CVAD.</p>
--	---

NURSING DIAGNOSES

- | | | |
|--|---------------------------|----------------------|
| • Deficient fluid volume | • Excess fluid volume | • Risk for infection |
| • Deficient knowledge regarding care of CVAD | • Impaired skin integrity | • Risk for injury |

Related factors are individualized based on patient's condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Insertion occurs without complication. • Placement of catheter tip is in superior vena cava near junction of right atrium or inferior vena cava above level of diaphragm (femoral approach). • CVAD site is intact, with no evidence of signs or symptoms of postinsertion complications (e.g., catheter migration, redness, swelling, aching or pain). • Prescribed solutions and medications infuse without difficulty. • Patient and family caregiver are able to explain purpose of CVAD therapy and perform required catheter care and infusion of solutions and medications. 	<p>Placement of CVAD carries risks such as pneumothorax, hematoma, air embolism, thrombosis, and infection.</p> <p>Confirmation of tip location is required before use of CVAD (INS, 2011).</p> <p>Catheter is patent, properly placed, and without evidence of complications.</p> <p>Catheter remains patent.</p> <p>Demonstrates that patient and family caregiver have understanding and competency in caring for CVAD.</p>
---	--

STEP

RATIONALE

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Explain procedure and purpose to patient and family caregiver. Explain to patient that he or she must not move during procedure. Offer opportunity at this time to toilet and offer pain medication (if needed).</p> <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.</p> <p>3 Catheter insertion: nontunneled device</p> <p>a Physician, with assistance of nurse, positions patient in Trendelenburg's or supine position for jugular or subclavian placement. Nurse places rolled towel or bath blanket between patient's shoulder blades, rotating them slightly to 10-degree angle. Turn patient's head away from insertion site.</p> <p>b Perform hand hygiene using antiseptic soap for 60 seconds.</p> <p>c If necessary, use scissors or electric clippers to remove any hair around insertion site. Explain rationale to patient.</p> <p>d Nurse positions drape underneath area to be cannulated.</p> <p>e Physician and nurse apply cap, mask, eyewear, surgical gown, and powder-free sterile gloves.</p> <p>f Physician opens central vascular access kit and adds any sterile equipment to kit for use during insertion (see Chapter 8).</p> <p>g Site preparation.
(1) Use 2% Chlorhexidine: Use scrubbing motion back and forth (vertically and horizontally) for 30 seconds and allow to air-dry for 30 seconds.</p> <p>h After cleansing site, physician and nurse remove gloves. Physician changes into second pair of sterile gloves and nurse performs hand hygiene. (Check agency policy because some agencies require strict precaution.)</p> <p>i Physician uses large sterile drape and sterile towels to create sterile field. Physician finds anatomic landmarks and places fenestrated drape appropriately over proposed insertion site.</p> <p>j Physician arranges equipment in kit in preparation for catheter insertion.</p> <p>k Nurse sets up IV bag, fills tubing, and covers end of tubing with sterile cap (see Skill 28-1).</p> | <p>Decreases anxiety, promotes cooperation, and prevents sudden movement during sterile procedure.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Opens angle between clavicle and first rib; dilates veins to facilitate eventual catheter insertion.</p> <p>Head down, below heart, promotes maximum filling and distention with increase in diameter of subclavicular vein (Phillips, 2010; Policy and Procedures, INS 2011); 10-degree tilt effectively achieves increase in diameter of vein.</p> <p>Transient microorganisms reside in body hair. Clippers do not cause microabrasions, which harbor microorganisms (INS, 2011).
Barrier protection to prevent infection.
Maximum barrier precautions needed when inserting central vascular catheter (INS, 2011).
Maintains sterile field.</p> <p>2% Chlorhexidine is preferred for skin antiseptis. Is not recommended for infants under 2 months of age (INS, 2011).</p> <p>Gloves become contaminated from surface bacteria picked up in solution.</p> <p>Provides sterile work space for catheter insertion (INS, 2011).</p> <p>Ensures smooth, orderly procedure.</p> <p>IV tubing is ready to be connected to IV catheter.</p> |
|---|---|

Clinical Decision Point Trendelenburg's position is contraindicated in patients with head injuries, increased intracranial pressure, certain respiratory conditions, and spinal cord injuries.

- | | |
|---|---|
| <p>l Nurse wipes off top of 1% lidocaine bottle with alcohol swabs and holds bottle upside down. <i>Optional:</i> Topical transdermal anesthetic agents can be applied before insertion.</p> <p>m Physician injects needle into bottle and withdraws approximately 3 to 4 mL lidocaine. He or she injects needle into site for subclavian puncture and anesthetizes venipuncture site, waiting 1 to 2 minutes for effect to take place.</p> | <p>Removes surface bacteria; allows physician to withdraw lidocaine while maintaining asepsis. Lidocaine has potential for creating allergic reaction and tissue damage.</p> <p>Minimizes discomfort patient feels during venipuncture.</p> |
|---|---|

Clinical Decision Point Just before time of insertion, ask patient to hold breath and strain. This is a Valsalva maneuver, which increases central venous pressure to prevent entry of air into the catheter. The Valsalva maneuver is the preferred method, although breath holding and humming may be a necessary option in uncooperative patients. In addition, if patient is unable to perform maneuvers, compress patient's abdomen gently.

STEP	RATIONALE
<p>n Physician inserts IV catheter into subclavian vein. Usually he or she does this by locating vein with large-bore cannula, removing needle from cannula, threading wire into cannula and vein, removing cannula over wire, and threading central vein catheter over wire to appropriate location (Seldinger technique) (Alexander et al., 2010).</p> <p>o Physician determines patency of line by withdrawing blood with 5-mL syringe, flushing with 0.9% sodium chloride solution, and placing caps on hubs.</p> <p>p Physician applies catheter securement device (e.g., manufactured stabilization device, sutures, sterile tape, or surgical Steri-Strips) to secure central vascular catheter in place. Cover with transparent dressing.</p> <p>q Physician removes sterile drapes and completes procedure.</p> <p>r Nurse adjusts IV infusion to prescribed rate and connects to electronic infusion pump once chest x-ray film study is obtained.</p>	<p>Large vein is selected because it will be less irritated by hypertonic solutions or medications.</p> <p>Determines patency of device.</p> <p>Suturing catheter to skin at insertion site increases risk for infection. Catheter securement devices are noninvasive and preferred for preventing catheter dislodgement (INS, 2011).</p> <p>Central line cannulations increase risk for pneumothorax (entrance of air into pleural space). Chest x-ray film examination verifies absence of pneumothorax and confirms location of IV catheter before solutions are administered at rapid flow (INS, 2011).</p>
4 Insertion site care and dressing change	
<p>a Position patient in comfortable position with head slightly elevated or, in the case of a PICC or midline device, have arm extended.</p> <p>b Prepare dressing materials. <i>Transparent dressing:</i> Provide insertion site care every 5 to 7 days and as needed. <i>Gauze dressing:</i> Provide insertion site care every 48 hours and as needed.</p> <p>c Perform hand hygiene and apply mask.</p> <p>d Apply clean gloves. Remove old dressing by lifting and removing either TSM or tape and gauze in direction of catheter insertion. Discard in appropriate biohazard container.</p> <p>e Remove catheter stabilization device if used. Must be removed with alcohol.</p>	<p>Provides access to patient.</p> <p>Transparent semipermeable membrane dressings have the advantage of being able to visualize the IV site. Gauze is preferable to TSM if the patient is diaphoretic or if the site is oozing or bleeding (INS, 2011).</p> <p>Reduces transfer of microorganisms; prevents spread of airborne microorganisms over CVAD insertion site. Stabilizes catheter as you remove dressing.</p> <p>Allows clear visualization of insertion site and surrounding skin (INS, 2011).</p>
<p>Clinical Decision Point <i>If sutures are used for initial catheter stabilization and become loosened or are no longer intact, alternative stabilization measures should be used (INS, 2011). Recent recommendations include use of a stabilization device because of the increased risk for infection when the catheter is sutured (Alexander et al., 2010).</i></p>	
<p>f Inspect catheter, insertion site, and surrounding skin. Measure mid-arm circumference above insertion site.</p> <p>g Remove and discard clean gloves, perform hand hygiene. Open CVAD dressing kit using sterile technique, and <i>apply sterile gloves</i>. Area to be cleaned should be same size as dressing.</p> <p>h Cleanse site: (1) 2% Chlorhexidine (preferred). Apply using back-and-forth motion vertically and horizontally for at least 30 seconds; allow to dry for 30 seconds. (2) Povidone-iodine may be used in some settings (see agency policy).</p> <p>i Apply skin protectant to entire area. Allow drying completely so skin is not tacky.</p> <p>j <i>Option:</i> Use chlorhexidine-impregnated dressing for short-term CVADs.</p>	<p>Insertion sites require regular inspection for early detection of signs and symptoms of IV-related complications (infection, pain, redness, swelling, drainage, or bleeding) (INS, 2011). Measurement of mid-arm circumference assesses for thrombosis. Sterile technique is required to apply new dressing.</p> <p>Allowing antiseptic solutions to air-dry completely effectively reduces microbial counts (INS, 2011). Drying allows time for maximum microbicidal activity of agents (Policy and Procedures INS, 2011).</p> <p>Protects irritated or fragile skin from dressing. It must be used if catheter stabilization device is used.</p> <p>These dressings should be considered for patients over 2 months of age to prevent catheter-related bloodstream infection (CRBSI) (INS, 2011).</p>

STEP	RATIONALE
k Apply new catheter stabilization device per manufacturer instructions if catheter is not sutured in place.	Provides catheter stability to minimize dislodgement or migration.
l Apply sterile, transparent semipermeable dressing, or gauze dressing over insertion site (see Skill 28-1).	Transparent dressing allows for clear visualization of catheter site between dressing changes (Policy and Procedures INS, 2011).
m Apply label to dressing with date, time, and your initials.	Provides information about next dressing change.
n Dispose of soiled supplies and used equipment. Remove gloves and perform hand hygiene.	Reduces transmission of microorganisms.
5 Blood sampling	
a Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
b Turn off all infusions for at least 1 minute before drawing blood. NOTE: If you cannot stop infusion, draw blood from peripheral vein.	Prevents transfer of body fluids.
c When drawing through multilumen catheters, the distal lumen (or one recommended by manufacturer) is preferred.	Prevents interruption of critical fluid therapy.
d Clean injection cap with antiseptic solution and allow to dry completely. Attach syringe and flush with 3 to 5 mL of preservative-free 0.9% sodium chloride.	Distal lumen typically is largest-gauge lumen (Alexander et al., 2010).
e Syringe Method	Maximizes bactericidal effectiveness of antiseptic swab.
NOTE: Check agency policy for use of Vacutainer with CVADs.	Determines catheter patency and clears IV (Policy and Procedures INS, 2010).
(1) Remove end of IV tubing or injection cap from catheter hub. Keep end of tubing sterile.	
(2) Disinfect catheter hub with antiseptic solution.	
(3) Attach an empty 10-mL syringe, unclamp catheter (if necessary) and withdraw blood 1.5 to 2 times fill volume (4 to 5 mL) of catheter for the discard sample.	Reduces risk of microorganisms.
(4) Reclamp catheter (if necessary); remove syringe with blood and discard in appropriate biohazard container.	Discard sample reduces risk of drug concentrations or diluted specimen (Alexander et al., 2010).
(5) Clean hub with another antiseptic solution.	
(6) Attach second syringe(s) to obtain required volume of blood needed for specimen ordered.	Open and valved CVADs differ in recommendations for clamping before removal of injection cap and syringe(s) (e.g., Hickman versus Groshong) (INS, 2011).
(7) Unclamp catheter(if necessary) to withdraw blood.	
(8) Once specimens are obtained, reclamp catheter (if necessary) and remove syringe.	Multiple syringes may be required, depending on specimens required and number of blood tubes needed.

STEP 5f Blood specimen transfer device. (Courtesy and ©Becton Dickinson & Co.)

STEP	RATIONALE
<p>(9) Clean catheter hub with antiseptic solution.</p> <p>(10) Attach prefilled injection cap attached to 10-mL syringe with 10 mL of 0.9% sodium chloride to catheter, unclamp (if necessary), and flush. Reclamp catheter (if necessary).</p> <p>(11) Remove syringe and discard into appropriate biohazard container.</p> <p>f Transfer blood using transfer vacuum device (see illustration).</p> <p>g Flush catheter with syringe containing heparin solution (check agency policy).</p>	<p>Flushing with 10 mL of 0.9% sodium chloride after blood draw is minimum volume of solution recommended (INS, 2011). Reduces risk for catheter clotting after procedure.</p> <p>Reduces transmission of microorganisms.</p> <p>Reduces risk of blood exposure.</p> <p>Heparin flush volume and concentration vary by agency and type of catheter. Flush Groshong catheters with 0.9% sodium chloride only.</p>
<p>Clinical Decision Point Always use a 10-mL syringe on central lines to minimize pressure during injection.</p>	
<p>h Remove syringe. Attach new sterile cap (see Step 6) or IV tubing to hub of catheter. Cleanse end of IV tubing with antiseptic swab before reconnecting. Resume infusion as ordered or clamp catheter (if necessary).</p> <p>i Dispose of soiled equipment and used supplies. Remove gloves and perform hand hygiene.</p>	<p>Decreases risk of contamination.</p> <p>Reduces transmission of microorganisms.</p>
<p>6 Changing injection cap</p>	
<p>a Determine if injection caps should be changed.</p> <p>b Prepare new injection cap(s):</p> <p>(1) Perform hand hygiene. Remove cap from package and clean septum with antiseptic solution using friction.</p> <p>(2) Keep protective cap on tip of injection cap.</p> <p>(3) Prime injection cap by attaching prefilled syringe and flushing with 0.9% normal saline through cap until fluid is seen in protective cap. Keep syringe attached.</p> <p>c If required based on device type, clamp catheter lumens one at a time by using slide or squeeze clamp.</p> <p>d Remove old injection caps using aseptic technique.</p> <p>e Apply clean gloves. Clean catheter hub with antiseptic swab. Connect new injection cap(s) on catheter hub.</p> <p>f Flush catheter with 10-mL syringe of 0.9% sodium chloride followed by heparin solution as required by manufacturer.</p> <p>g Dispose of all soiled supplies and used equipment. Remove gloves and perform hand hygiene.</p>	<p>Injection caps are usually changed with each administration set change, at least every 7 days for catheter maintenance, if residual blood is present, and when integrity is compromised (INS, 2011).</p> <p>Understanding of the types of injection caps available is imperative as the flushing technique will vary based on the type of device (e.g., positive or neutral displacement valves).</p> <p>Maintains sterility. Removes air from system.</p> <p>Prevents air from entering system when opened. Patient can also perform Valsalva maneuver during cap changes. Routine injection cap changes decrease catheter infections. Allowing antiseptic solutions to air-dry completely effectively reduces microbial counts (INS, 2011). Drying allows time for maximum antimicrobial activity of agents. Prevents clot formation.</p> <p>Reduces spread of microorganisms.</p>
<p>7 Flushing a positive-pressure device</p>	
<p>a Perform hand hygiene and apply clean gloves.</p> <p>b Prepare positive-pressure device by attaching prefilled saline syringe. Prime through device and leave syringe attached.</p> <p>c Clamp catheter (if necessary). Remove injection cap and discard.</p> <p>d Connect positive-pressure device, unclamp catheter, and flush through with saline as ordered.</p> <p>e Reclamp after syringe has been removed.</p> <p>f Dispose of all soiled supplies and used equipment. Remove gloves and perform hand hygiene.</p>	<p>Reduces transmission of microorganisms. Maintains sterility of device.</p> <p>Do not add extension tubing, which negates positive-pressure action of valve.</p> <p>If CVAD has a clamp, it needs to be engaged. If clamp is not engaged and device becomes loose and comes off, patient is exposed to possible air embolism or bleeding (INS, 2011). Reduces spread of microorganisms.</p>

STEP	RATIONALE
8 Discontinuing nontunneled catheters or PICCs	
a Verify health care provider's order to discontinue line. Check agency policy because most require physician to discontinue CVAD. In some settings advanced practice nurses or specially credentialed nurses can remove devices.	Verifies appropriateness of procedure. Only a competent health care professional can remove a CVAD.
b If IV fluids or medications are to continue, prepare to convert them to a short peripheral or midline before CVAD discontinuation. NOTE: Be aware of pH and osmolarity of solution or medication for appropriateness of conversion to short peripheral or midline catheter.	Prevents interruption of IV medication/fluid therapy.
c Position patient in 10-degree Trendelenburg's position.	Position promotes venous filling and prevents air embolus during catheter removal.
d Perform hand hygiene.	Prevents transmission of microorganisms.
e Turn off IV fluids infusing through central line.	Prevents fluid loss during CVAD removal.
f Place moisture-proof pad under site.	Minimizes soiling of bed linen. Provides clean environment.
g Apply gown, gloves, mask, and goggles.	Prevents transmission of microorganisms and exposure to bloodborne pathogens.
h Gently remove CVAD dressing. Discard in biohazard container. Inspect catheter and insertion site.	Prevents skin tears. Provides information about catheter and site before removal. Disposal prevents transmission of microorganisms.
i Remove gloves and perform hand hygiene; open CVAD dressing change kit and suture removal kit (if sutures in place). Add additional items to sterile field. Don sterile gloves.	Prevents transfer of organisms on soiled dressing to catheter insertion site.
j Clean CVAD site using combination antiseptic or chlorhexidine swabs (check agency policy). Begin at insertion site and move outward in circular motion or, with chlorhexidine only, use back-and-forth scrub method, vertical, horizontal and circular, for 30 seconds. Allow to dry completely.	Removes microorganisms from skin surrounding insertion site. Allowing antiseptic solutions to air-dry completely effectively reduces microbial counts (INS, 2011).
k If catheter securement device is present, carefully remove catheter from device and remove device with alcohol.	Alcohol aids in removal of securement device.
l To remove sutures with nondominant hand, grasp suture with forceps. Using dominant hand, carefully cut suture with sterile scissors; avoid damaging skin or catheter. Lift suture out and discard. Continue until all sutures are removed.	Technique prevents pulling contaminated end of suture through patient's skin.
Clinical Decision Point All CVADs require measurements of external catheter and total length of catheter removed. PICC lines also require measurement of the upper-arm circumference.	
m Using nondominant hand, apply sterile 4 × 4-inch gauze to site. Instruct patient to take deep breath and hold it as you withdraw catheter.	Valsalva maneuver reduces risk for air embolus by decreasing negative pressure in respiratory system.
n With dominant hand remove catheter in smooth, continuous motion an inch at a time. Note any resistance while removing catheter. Inspect catheter for intactness, especially along tip. Keeping fingers near insertion site, immediately apply pressure to site and continue until bleeding stops.	Gentle removal of catheter prevents stretching and breaking it. Damaged catheter may break off and leave a piece in patient's arm. Direct pressure reduces risk for bleeding and hematoma formation.
Clinical Decision Point It is often necessary to apply pressure longer if patient is receiving anticoagulation therapy or has prolonged clotting times.	
o Apply petroleum-based ointment to exit site (<i>optional</i> : see agency policy). Apply sterile occlusive dressing such as transparent dressing or sterile gauze to site. Change dressing every 24 hours until healed.	Reduces chance of air embolism and seals vein tract (INS, 2011). Inspect catheter removal site for bleeding and infection until it is healed (INS, 2011).
p Label dressing with date, time, and your initials.	Identifies date of catheter removal and need for dressing change.
q Inspect catheter integrity and discard in biohazard container. NOTE: Catheter cultures should be performed when catheter is removed for suspected CRBSIs. Catheter cultures should not be obtained routinely (INS, 2011; Mermel et al., 2009).	If catheter tip is broken or compromised, place in container and label for possible follow-up.

STEP	RATIONALE
r Return patient to comfortable position. Be sure that short peripheral IV or midline is infusing at correct rate.	Maintains IV fluid therapy.
s Dispose of soiled supplies; remove gloves and personal protective equipment. Perform hand hygiene.	Reduces transmission of microorganisms.
EVALUATION	
1 Determine daily, in consultation with physician, the continued need for the CVAD.	Daily review of line necessity with prompt removal of unnecessary lines is a practice recommended in the IHI CLABSI bundle (IHI, 2011).
2 Observe patient for shortness of breath or pain in chest or shoulder after CVAD insertion. Auscultate for breath sounds.	Pain, shortness of breath, and absent breath sounds indicate complication of pneumothorax.
3 Observe patient for bleeding or swelling at insertion site or neck and occlusiveness of dressing.	Symptoms indicate infiltration of IV fluids into subcutaneous tissues or damage to vessel lumen. Dressing must remain occlusive to protect against entrance of microorganisms.
4 Monitor intake and output as directed by agency policy for fluid balance and monitor laboratory values for electrolyte balance as indicated.	Assesses patient's circulatory system and indicates fluid volume excess or deficit.
5 Routinely assess vital signs of patient, noting changes symptomatic of infection.	Catheter-related sepsis causes fever, chills, flushed skin, tachycardia.
6 Observe catheter insertion site and exit for erythema, warmth, tenderness, edema, or drainage.	Continual monitoring for signs of inflammation or infection is essential.
7 Observe all catheter connection points, being sure they are secure (see agency policy).	An intact system prevents accidental blood loss or entrance of air.
8 Inspect condition of catheter and connection tubing as directed by agency policy for leaks or tears, kinks or obstructions, or cracked hubs.	Break in integrity of system predisposes patient to hemorrhage, infection or air embolus.
9 Observe for clot formation in catheter, air embolism, infiltration/extravasation during infusions, and catheter migration.	Early detection of complications improves patient outcomes.
10 Consult x-ray film examination reports for catheter placement.	A routine chest x-ray film examination will confirm position of catheter tip.
11 Evaluate ability of patient and family caregiver to provide care and maintain catheter or infusion port through discussion and return demonstrations of dressing changes and skin care. Determine need for restrictions on daily activities.	Measures patient's ability to care for self and any additional learning needs.

Unexpected Outcomes

- 1 For catheter complications, see Table 28-7.
- 2 Patient or family caregiver is unable to explain or perform CVAD care.

Related Interventions

- See Table 28-7.
- Indicates need for home care referral or additional instruction.

Recording and Reporting

- Immediately notify health care provider of signs and symptoms of any complications.
- Document catheter site care in nurses' notes and EHR: size of catheter, change of injection caps, appearance of site, condition and type of securement device, date and time of dressing change.
- Document in nurses' notes and EHR the condition of exit site or port insertion site, including skin integrity, signs of complications, placement, integrity, external catheter length, mid-arm circumference, and functionality of catheter.
- Document in nurses' notes and EHR catheter removal: patient position, appearance of site, length of catheter removed, integrity of catheter after removal, dressing applied, patient's tolerance of procedure, presence/absence of bleeding from site every 15 minutes for 1 hour, and any problems with removal.
- Document in nurses' notes and EHR blood draw: date, time, sample drawn.

- Document in nurses' notes and EHR unexpected outcomes, health care provider notification, interventions, and patient response to treatment.

Special Considerations

Teaching

- Instruct patient to report discomfort around the site; discomfort in arms, shoulders, or side of the neck; or any shortness of breath.
- Discuss and provide written emergency measures and telephone numbers of health care personnel to be used in case of catheter damage, displacement, swelling, redness, or leakage at insertion site; occlusion of port or catheter; temperature above 100.4° F (38° C) (see agency policy); and shaking chills.
- Provide written instruction for dressing changes, inspection of insertion site, flushing, and tubing changes.
- Arrange for instruction and return demonstration of skills by patient or family caregiver.

TABLE 28-7 Complications of Vascular Access Devices

Complication	Assessment	Prevention	Intervention
Catheter damage, breakage	Every shift observe for pinholes, leaks, tears. Assess for drainage from site after flushing.	Follow proper clamping procedure. Avoid sharp objects near catheter. Use needleless system device. Use only 10-mL syringe for flushing. Never flush against resistance.	Clamp catheter near insertion site and place sterile gauze over break or hole until repaired. Use only repair kit that is recommended by manufacturer. Remove catheter.
Occlusion: Thrombus, fibrin sheath, fibrin tail, precipitation, malposition	Assess insertion site and sutures. Assess for blood return. Assess for ability to infuse fluid. Assess equipment. If port is in place, reaccess and verify noncoring needle placement. Assess with syringe directly on catheter. Assess for discomfort or pain in shoulder, neck, ear, or arm at insertion site. Assess for neck or shoulder edema.	Follow routine flushing with positive pressure and/or use positive-pressure valve injection cap. Secure with catheter stabilization device to prevent tension on CVAD. Do not flush against resistance. Flush between medications. Flush vigorously after viscous solutions. Avoid mixing incompatible drugs. Avoid kinking catheter.	Reposition patient. Have patient cough and deep breathe. Raise patient's arm overhead. Obtain venogram if ordered. Administer thrombolytics if ordered. Remove catheter (CVAD requires order). Obtain x-ray film as ordered. Do not use a 1-mL syringe to instill saline because pressure exceeds 200 psi.
Infection and sepsis: Exit site, tunnel, thrombus, port pocket (CLABSI)	Assess exit site for redness, drainage, edema, or tenderness. Assess for signs of systemic infection. Monitor laboratory findings.	Use aseptic technique. Prevent contamination of catheter hub. Adhere to dressing change technique. Apply transparent semipermeable dressing over exit site.	Obtain blood cultures first from peripheral and CVAD if ordered. Remove catheter (CVAD requires order). Replace catheter.
Dislodgement	Assess length of catheter daily. Inform patient of possible catheter dislodgement. Identify edema at exit site or drainage. Palpate exit site and tunnel for coiling (catheter can feel cordlike underneath the skin). Assess for distended neck veins.	Loop and tape catheter securely. Use catheter stabilization device and transparent semipermeable dressing. Avoid pulling on CVAD. Avoid manipulating catheter by hand.	Insert new catheter. Secure with catheter stabilization device. Teach patient not to manipulate catheter.
Catheter migration (e.g., length of catheter moved from original position), pinch-off syndrome (e.g., compression of catheter between clavicle and first rib), port separation or catheter fracture (e.g., internal fracture or separation of catheter)	Assess for patient complaints of gurgling sounds. Assess for change in patency of catheter by evaluating change in flow rate, local irritation, swelling, occlusion, tenderness, pain, inability to aspirate fluid and/or blood. Pain at site when flushed or symptoms of embolus. Obtain x-ray film examination. Assess edema of arm and hand on side of insertion. Assess for distended neck veins. Assess for inability to infuse fluids. Assess length of catheter daily.	Avoid trauma. Avoid placement near site of local infection, scarring, or skin disorder.	Reposition under fluoroscopy as ordered. Remove catheter as ordered. Stop all fluid administration.
Skin erosion (e.g., mechanical loss of skin tissue), hematomas (e.g., local collection of blood), cuff extrusion (e.g., tissue at edges of insertion site separate), scar tissue formation over port	Assess for loss of viable tissue over septum site. Assess for separation of exit site edges. Assess for drainage at exit site. Assess for redness. Assess for edema, contusions. Note if tunneled catheter is exposed (Dacron cuff is visible).	Maintain nutritional status. Avoid pressure or trauma. Rotate with each port access. Do not reinsert a noncoring needle in the same "hole" of a previous insertion. This creates a permanent hole in the septum. Do not use standard needle to access port.	Remove CVAD as ordered. Improve nutrition. Provide appropriate skin care.

TABLE 28-7 Complications of Vascular Access Devices—cont'd

Complication	Assessment	Prevention	Intervention
Infiltration, extravasation	<p>Assess for erythema.</p> <p>Assess for edema.</p> <p>Assess for spongy feeling.</p> <p>Assess for swelling around IV site and at termination of catheter tip.</p> <p>Assess for labored breathing.</p> <p>Assess for aspiration of fluid and/or blood.</p> <p>Assess for complaints of pain with infusion of solutions or medications (e.g., burning).</p> <p>Assess for no free-flow IV drip.</p>	<p>Immediately stop vesicant administration.</p> <p>Administer antidote or therapeutic medications to maintain tissue integrity according to protocol.</p>	<p>Apply cold/warm compresses according to specific vesicant protocol.</p> <p>Provide emotional support.</p> <p>Obtain x-ray film if ordered.</p> <p>Use antidotes per protocol.</p> <p>Discontinue IV fluids.</p>
Pneumothorax, hemothorax, air emboli, hydrothorax	<p>Assess for subcutaneous emphysema by inspecting and palpating skin around insertion site and along arm. Inspection may reveal edema where air is located, and air may travel if skin is loose.</p> <p>Palpation reveals a crackling sensation such as popping plastic bubble wrap.</p> <p>Assess for chest pain.</p> <p>Assess for dyspnea, apnea, hypoxia, tachycardia, hypotension, nausea, confusion.</p>	<p>Use injection cap on distal end when not in use.</p> <p>Do not leave catheter open to air. If appropriate for device, be sure that clamps are engaged.</p>	<p>Administer oxygen as ordered.</p> <p>Elevate feet. Aspirate air, fluid.</p> <p>If air emboli suspected, place patient on left side with head down. Remove catheter as ordered.</p> <p>Help with insertion of chest tubes as ordered.</p>
Incorrect placement	<p>Assess for cardiac dysrhythmias.</p> <p>Assess for hypotension.</p> <p>Assess for neck distention.</p> <p>Assess for narrow pulse pressure.</p> <p>Assess for inadequate blood withdrawal.</p> <p>Assess for retrograde flow of blood (flow of blood back into tubing usually caused by decreased pressure gradient between venous system and access device unit [e.g., IV infusion, heparin lock]).</p>	<p>Obtain x-ray film examination after placement.</p> <p>Reposition catheter as warranted.</p>	<p>Stop all fluid administration until placement is confirmed.</p> <p>Discontinue catheter (requires order).</p> <p>Obtain x-ray film and electrocardiogram (for PICC and CVAD). Administer support medications as ordered.</p>

CLABSI, Central line–associated bloodstream infection; CVAD, central vascular access device; CVC, central venous catheter; IV, intravenous; PICC, peripherally inserted central catheter.

- Have patient or family caregiver maintain a list of caregivers and telephone numbers (e.g., physician, nurse, social worker, pharmacist, dietitian).

Pediatric

- Central vein catheters that are of a smaller diameter and shorter length are available for children and infants.
- Take care to secure infant catheters in a manner that does not allow them to twist. Small-diameter catheters are fragile, and twisting them causes them to tear.
- Amount and dosage of flush solution (heparin/saline) vary with age and size. Record volume of blood draws on intake and output record.

Gerontologic

- Some older adults have difficulty with lying flat in bed, and a modification of the totally supine position during CVAD insertion is often necessary.
- PICC insertion may provide an alternative route of administration and reduce the risk of complications associated with subclavian or jugular insertion.

Home Care

- Initiate early referral for discharge planning to social service, counselor, or home care coordinator for assessment of resources.
- Provide patient with written list of providers for supplies and equipment.
- Instruct patient or family caregiver in flushing technique, site care and dressing change, and emergency interventions.
- Instruct patient and family caregiver in adaptations of hospital procedures that they can make at home (e.g., good hand hygiene instead of sterile gloves).
- Ongoing assessment by the home care provider is essential in the early detection of complications and preservation of CVADs.
- Assess home environment and determine suitable area for dressing changes, avoiding areas where contaminants are potential hazards.
- Provide appropriate information about home disposal of soiled dressings and equipment (see Chapter 42).

Critical Thinking Exercises

A patient is admitted to the medical unit from the emergency department with a diagnosis of pneumonia and dehydration. The health care provider has ordered 1000 mL D₅ ½ NS at 100 mL/hr to be started on admission. The patient has an intravenous (IV) infusion running in her left antecubital fossa that shows evidence of inadequate flow rate, and the patient complains of discomfort at the site.

- Using microdrip tubing, what would be the correct drip rate for this IV? Using a 15 gtt/mL macrodrip tubing, what would be the correct drip rate for this IV?
- When you obtain the IV fluids for the patient, which assessment steps are necessary before you change the solution?
- Which assessments and interventions are required for the existing IV in the left arm?
- Discuss the information to document after discontinuing the left antecubital IV.

REVIEW QUESTIONS

- A patient is receiving 1 L of D₅ lactated Ringer's (LR) every 12 hours using an administration set with a drop factor of 15 gtt/mL. At what rate should the nurse set this infusion?
 - 10 gtt/min
 - 21 gtt/min
 - 33 gtt/min
 - 83 gtt/min
- A patient had an intravenous (IV) catheter inserted 48 hours ago to receive antibiotic therapy. During assessment of the IV site the nurse observes redness and tenderness on palpation. The nurse documents that the IV was discontinued and restarted because of which complication of IV therapy?
 - Clotting of the IV catheter
 - Infiltration
 - Phlebitis
 - Puncturing of the opposite side of the vein
- Considerations for selecting an intravenous (IV) catheter for a patient include which of the following?
 - Selecting the longest catheter with the largest gauge
 - Selecting the longest catheter with the smallest gauge
 - Selecting the shortest catheter with the smallest gauge
 - Selecting the shortest catheter with the largest gauge
- Place in correct order the following steps for changing a dressing over a short peripheral IV device:
 - Clean insertion site with antiseptic swab.
 - After removing tape, remove transparent dressing (transparent semipermeable membrane [TSM]).
 - Apply new transparent dressing (TSM).
 - Observe site for signs and symptoms of intravenous (IV)-related complications.
- A midline catheter is considered a central vascular access device.
 - True
 - False
- An obese patient who had a right mastectomy several years ago has better veins in her right hand but is left handed. Where should the nurse place the intravenous (IV) catheter?
 - In her right hand
 - In her left lower arm
 - Wherever the patient wants
 - In her right antecubital site

- The health care provider discontinued a patient's anticoagulant therapy. Which nursing intervention is most appropriate after the nurse removes the intravenous (IV) catheter from his hand?
 - Apply pressure to the IV site until the bleeding stops.
 - Convert the catheter to an intermittent heparin lock for 24 hours.
 - Encourage the patient to keep his hand elevated for 10 minutes.
 - Use a warm compress at the site for several minutes.
- A patient just had a peripherally inserted central catheter (PICC) placed in the right antecubital site. When reading the x-ray film report verifying correct placement of the catheter, the nurse knows that the tip of the PICC is located correctly if it is in which vessel?
 - The inferior vena cava
 - The basilic vein
 - The cephalic vein
 - The superior vena cava
- Which of the following is a key component of the Central Line Bundle?
 - Chlorhexidine skin antisepsis
 - Soap and water skin preparation
 - Alcohol skin antisepsis
 - Hydrogen peroxide skin preparation
- An order is received to provide a solution with an osmolarity greater than 600 mOsm/L to a patient. Which of the following intravenous (IV) devices is appropriate?
 - Short peripheral in cephalic vein
 - Midline in basilic vein
 - Peripherally inserted central catheter (PICC) in subclavian vein
 - Implanted venous port in superior vena cava (SVC)

KEY TERMS

Agglutinate	Blood transfusion	Human leukocyte antigen (HLA)	Transfusion reaction
Allogeneic	Blood type	Immune-mediated platelet refractoriness	Transfusion-related acute lung injury (TRALI)
Anemia	Febrile nonhemolytic reaction (FNH)	Reinfusion	Transfusion-associated graft-versus-host disease (TA-GVHD)
Autologous transfusion	Hemochromatosis	Thrombocytopenia	
Autotransfusion	Hemolysis		
Blood group			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss indications for blood therapy.
- Describe various transfusion reactions.
- Demonstrate the following skills on selected patients: initiating blood therapy, implementing autotransfusion, and monitoring for adverse reactions to transfusion.

Since the first blood transfusion over 200 years ago, transfusion therapy has evolved to a much more complex process with many different blood components. A competent nurse must know not only the complexities of the ABO and Rh system, but also the numerous components of blood that can be transfused and the serious negative outcomes that can occur.

Transfusion therapy or blood replacement is the intravenous (IV) administration of whole blood (Fig. 29-1), its components (Fig. 29-2, A and B), or a plasma-derived product (Fig. 29-3) for therapeutic purposes (Alexander et al., 2010). Transfusions restore intravascular volume with whole blood or albumin, restore the oxygen-carrying capacity of blood with red blood cells, and provide clotting factors and/or platelets. The most common method of blood transfusion is allogeneic blood (blood donated from someone else). Despite precautions, transfusion therapy carries risks. Compatibility of the patient and donor is essential. Human-related errors (e.g., improper labeling, poor hand-off between nurses and the person transporting blood, or the method used to complete a blood requisition) that may lead to the administration of incompatible transfusions can occur in every step of the

process. In addition, disease transmission is also a possibility (Alexander et al., 2010; Busch, 2008; Gabriel, 2008). Comprehensive screening and testing reduce these occurrences considerably; however, the administration of blood and blood products cannot be taken lightly since a majority of the complications result from human error during transfusion (Alexander et al., 2010). Complications resulting from immunologic response to blood or blood products can be reduced by modifications such as washed or irradiated red blood cells or leukocyte-reduced blood.

Autologous transfusion or autotransfusion is a method in which a patient's own blood is collected and reinfused for the purpose of intravascular volume replacement (Alexander et al., 2010; AABB, 2011). Patients who have a concern about transfusion-related reactions or transmission of disease find positive advantages to autologous transfusion. It is ideal for preoperative blood donation, intraoperative cell salvage, and postoperative blood salvage. Preoperative blood donation is the most commonly used type of autologous donation. In this process patients donate their own blood approximately 4 to 6 weeks before therapy via phlebotomy, which is performed weekly. The last donation must occur more than 72 hours

FIG 29-1 Unit of blood. (Image courtesy American Red Cross.)

FIG 29-2 Bag of Cryo (A) and bag of platelets (B). (Images courtesy American Red Cross.)

TABLE 29-1 Types of Blood Preservatives

Anticoagulant Preservative	Composition	Shelf Life Provided (Days)
CPD	Citrate, phosphate, and dextrose	21
CPDA-1	CPD plus adenine	35
CPDA-1 additive system	CPD plus various preservative combinations	35-42

before surgery. The donated blood is stored at 1° to 6° C (33.8° to 42.8° F) for 35 to 42 days (Alexander et al., 2010; AABB, 2011).

To decrease transfusion-related adverse events, blood and its components are treated and stored in controlled environments. Blood is a living tissue; and, once obtained via the donor, it must remain healthy before transfusion (Alexander et al., 2010). Various anticoagulants and preservatives are used to maintain the shelf life of donated blood. Citrate-phosphate-dextrose (CPD) and citrate-phosphate-dextrose-adenine (CPDA-1) are two commonly used anticoagulant preservatives (Table 29-1) (Alexander et al., 2010; AABB, 2011). Caution is needed when infusing an older unit of blood. When blood is stored, there is continual destruction of red blood cells, which releases potassium (K) from the cells into the plasma. Often a laboratory test of a patient's K level is ordered before administering a unit of blood.

As a nurse your role during a blood transfusion is to carry out the health care provider's order by safely administering the blood/blood products and assessing a patient before, during, and after the transfusion.

ABO SYSTEM

There are three blood-typing systems: ABO, Rh, and human leukocyte antigen (HLA). These systems ensure a close match between transfused products and a recipient's blood. The ABO system uses the presence or absence of specific antigens on the surface of red

blood cells to identify blood groups. When the type A antigen is present, the blood group is type A. When the type B antigen is present, the blood group is type B. When both A and B antigens are present, the blood group is type AB, and when neither A nor B antigens are present, the blood group is type O (Alexander et al., 2010; AABB, 2011) (Table 29-2).

Antibodies that react against the A and B antigens are naturally present in the plasma of people whose red blood cells do not carry the antigen. These antibodies (agglutinins) react against the foreign antigens (agglutinogens). Incompatible red blood cells agglutinate (clump together) and result in a life-threatening hemolytic transfusion reaction. People with type A blood have anti-B antibodies; people with type B blood have anti-A antibodies. People with type AB blood have neither antibody and can receive all blood types. People with type O blood have both A and B antibodies and can receive only type O blood (Alexander et al., 2010; AABB, 2011; Snyder et al., 2008).

TABLE 29-2 ABO System

Patient Blood Type (Rh Factor)	Red Blood Cell Antigen	Transfuse with Type A	Transfuse with Type B	Transfuse with Type AB	Transfuse with Type O	Transfusion Options
A (+)	A	Yes	No	No	Yes	A+, A- O+, O-
A (-)	A	Yes	No	No	Yes	A-, O-
B (+)	B	No	Yes	No	Yes	B+, B- O+, O-
B (-)	B	No	Yes	No	Yes	B-, O-
AB (+)	AB	Yes	Yes	Yes	Yes	A+, A- B+, B- O+, O- Universal recipient
AB (-)	AB	Yes	Yes	Yes	Yes	A- B- O-
O (+)	None	No	No	No	Yes	O+, O-
O (-)	None	No	No	No	Yes	O- Universal donor

**FIG 29-3** Bag of plasma. (Image courtesy American Red Cross.)

RH SYSTEM

Although nearly 50 types of Rh antigen may be present on the surface of red blood cells, the type D antigen is widely prevalent and is most likely to elicit an immune response. It is the presence or absence of the D antigen that determines a person's Rh type. A person with the D antigen is Rh positive, and a person without the D antigen is Rh negative (Alexander et al., 2010, AABB, 2011, Gabriel, 2008). Unlike the ABO antigens, there are not naturally occurring antibodies to the Rh(D) antigen. A person with Rh-negative blood must first be exposed to Rh-positive blood before any Rh antibodies are formed. A person with Rh-negative blood who is exposed to a large volume (200 mL or more) of Rh-positive blood will develop enough antibodies to cause a severe

transfusion reaction with repeat exposure. These antibodies take up to 2 weeks to form. Therefore, in the case of massive transfusion as used in trauma situations, Rh-positive blood may be used for a person with Rh-negative blood without adverse effect, provided that the person has not been previously exposed to Rh-positive blood (Alexander et al., 2010; AABB, 2011).

An Rh-negative mother previously exposed to Rh antigen can transfer Rh antibodies across the placenta to an Rh-positive fetus. This can result in severe fetal hemolysis (i.e., the breakdown of red blood cells, with resultant anemia and jaundice) and is often fatal to the infant. To prevent current or future fetal hemolysis, Rh(D) immune globulin (RhoGam) is given by intramuscular injection to the mother. RhoGam can suppress or destroy the fetal Rh-positive blood cells that have passed from the fetal to the maternal circulation.

HUMAN LEUKOCYTE ANTIGEN SYSTEM

Although most commonly linked to transplant rejection, human leukocyte antigens (HLA)s are highly immunogenic antigens that can cause serious transfusion complications. HLA antibodies are located on the cell surface of leukocytes. They may also be found on lymphocytes, granulocytes, monocytes, and platelets (Alexander et al., 2010; AABB, 2011; Gabriel, 2008). HLA complications most commonly seen are:

- Febrile nonhemolytic reaction (FNH).
- Immune-mediated platelet refractoriness.
- Transfusion-related acute lung injury (TRALI).
- Transfusion-associated graft-versus-host disease (TA-GVHD).

EVIDENCE-BASED PRACTICE

Compliance with standards and policies and ongoing education are essential to maintain patient safety and reduce potential errors. Safety and risk management are key factors in transfusion therapy. ABO incompatibilities are one of the most serious errors with transfusions and usually have fatal outcomes (Alexander et al., 2010; AABB, 2011; Gabriel, 2008). A human error most often

involves misidentification of the patient or the unit of blood or mislabeling the pretransfusion blood sample. Advances in technology help to decrease transfusion-related errors:

- Bar-code technology helps prevent errors in the identification process between a patient and the compatible blood unit.
- Radiofrequency transponder microchips are used to standardize and document key steps in the blood collection and confirm the recipient–blood unit matching at a patient's bedside.

Advanced technologic laboratory screening procedures also help to ensure safe transfusions with regard to bloodborne pathogens:

- Screening identifies and thereby reduces pathogen transmission.
- Better assessment of blood and plasma cell integrity is available to avoid loss of blood component function.
- Blood alternative therapies with pharmacologic developments such as colloids, crystalloids, erythropoietin, antifibrinolytics, and hematinics reduce the risks associated with transfusing human blood.

PATIENT-CENTERED CARE

When administering blood products, you need to consider a patient's values and cultural beliefs about blood therapy. A person's perception of his or her disease or health condition affects how receptive he or she is to receiving blood. Blood transfusion is often equated to severity of illness. Allay patient anxieties when possible. Some religions do not allow blood transfusions. For example,

members of Jehovah's Witness do not allow blood transfusions or organ donation if it involves blood exchange (Snyder et al., 2008). It is helpful to consult a religious leader when caring for patients in need of blood therapy. Be familiar with agency policies and procedures to follow when patients refuse blood transfusion and inform the health care provider of a patient's decision.

Another aspect of patient-centered care is safety, specifically the prevention of transfusion-related complications. Transfusion-related reactions occur most commonly from clerical error. To ensure safe patient outcomes, the National Quality Forum (NQF) endorses a list of serious reportable events (SREs), which outlines 28 events that are preventable. Regarding transfusion therapy, any "patient death or serious disability associated with a hemolytic reaction due to the administration of ABO/HLA-incompatible blood or blood products" is considered a Care Management Event and must be reported (NQF, 2011).

Safety Guidelines

- 1 Administration of blood and blood components requires meticulous attention to detail (e.g., preparation, administration, and monitoring) to prevent life-threatening transfusion reactions (Table 29-3).
- 2 Ensure that each blood unit is correctly labeled; check against patient's identification.
- 3 Review agency policy and procedure regarding administration of blood or blood products.
- 4 Two nurses should verify correct unit and correct patient before administration.

TABLE 29-3 Transfusion Reactions

Reaction	Mechanism	Onset	Signs and Symptoms	Prevention	Nursing Intervention
Febrile, nonhemolytic (most common)	Accompanies less than 1% of transfusions; possible sensitivity of recipient to leukocytes or platelets in donor's blood	30 min after initiation to 6 hrs after completion of transfusion	Fever greater than 1°C above baseline, flushing, chills, headache, muscle pain; occurs most frequently in immunosuppressed patients	Use leukocyte-reduced blood products in patients who have experienced febrile nonhemolytic reactions in the past.	Stop transfusion. Administer antipyretics as ordered. Monitor temperature every 4 hrs.
Acute hemolytic transfusion reaction	ABO, Rh incompatibility; causes intravascular destruction of transfused RBCs as antibodies in recipient's plasma attach to antigens on donor RBCs.	Within 15 minutes of transfusion initiation	Severe pain in kidney area and chest; increased temperature (up to 41°C or 105°F), increased heart rate; sensation of heat and pain along vein receiving blood; chills, low back pain, headache, nausea, chest or back pain, chest tightness, dyspnea, bronchospasm, anxiety, hypotension, vascular collapse, disseminated intravascular coagulation, possibly death	Carefully identify patient and blood sample obtained for blood typing and compatibility screening. When blood is released from blood bank, match with patient information. Follow agency verification procedures at bedside before transfusion.	Stop transfusion. Remove blood product and tubing. Maintain IV access. Notify health care provider. Monitor vital signs at least every 15 min. Administer ordered therapy to correct arterial blood pressure and coagulopathy. Insert Foley catheter. Monitor intake and output hourly. Assess for shock. Dialysis may be required. Obtain blood and urine samples and send to laboratory with unused portion of unit of blood. Document reaction according to agency policy.

TABLE 29-3 Transfusion Reactions—cont'd

Reaction	Mechanism	Onset	Signs and Symptoms	Prevention	Nursing Intervention
Delayed hemolytic transfusion reaction	Immune response mounted by recipient against non-ABO donor antigens; usually the result of destruction of transfused RBCs by alloantibodies not detected during cross-match	2-14 days	Unexplained fever, unexplained decrease in Hgb/Hct, increased bilirubin levels, jaundice	Careful cross-matching of donor and recipient blood. Has potential to be missed because it may occur several days after transfusion.	Monitor laboratory values for anemia. (Recognition is important because subsequent transfusions may cause an acute hemolytic reaction.) If detected, notify health care provider and blood bank. Most delayed hemolytic reactions require no treatment.
Allergic reaction (mild-to-moderate)	Caused by recipient allergy to a plasma protein in donor's blood	During transfusion to 1 hr after transfusion	Local erythema, hives, and urticaria, itching or pruritus	May administer antihistamines before transfusion if prescribed.	Stop transfusion. Notify health care provider and blood bank. Administer antihistamines as ordered. Monitor and document vital signs every 15 min. Transfusion may be restarted if fever, dyspnea, and wheezing are not present.
Allergic reaction (severe)	Caused by recipient allergy to a donor antigen (usually IgA) Agglutination of RBCs obstructing capillaries and blocking blood flow, causing symptoms to all major organ systems	Within 5-15 min of initiation of transfusion	Coughing, nausea, vomiting, respiratory distress, wheezing, hypotension, loss of consciousness, possible cardiac arrest	Transfusion of saline-washed or leukocyte-depleted RBCs.	This is a life-threatening reaction. Stop transfusion. Maintain IV access. Notify health care provider and blood bank. Administer antihistamines, corticosteroids, epinephrine, and antipyretics as ordered. Measure and document vital signs until stable. Initiate cardiopulmonary resuscitation if necessary.
Graft-versus-host disease	Donor lymphocytes are destroyed by recipient's immune system. In immunocompromised patients the donor lymphocytes are identified as foreign; however, patient's immune system is not capable of destroying, and in turn patient's lymphocytes are destroyed.	Days to weeks	Skin rash, fever, jaundice caused by liver dysfunction, bone marrow suppression	Administer irradiated blood and/or leukocyte-depleted RBC products as prescribed.	Administer methotrexate and corticosteroids as ordered.

Continued

TABLE 29-3 Transfusion Reactions—cont'd

Reaction	Mechanism	Onset	Signs and Symptoms	Prevention	Nursing Intervention
Circulatory overload	Occurs with transfusion of excessive volume or excessively rapid rate; can lead to pulmonary edema.	Anytime during or within 1-2 hrs after transfusion	Dyspnea, cough, crackles at lung bases, tachypnea, headache, hypertension, tachycardia, increased central venous pressure, distended neck veins	Administer blood or component at prescribed rate, usually no greater than 2-4 mL/kg/hr; pay particular attention to rate and volume in older adults, young children, and patients with cardiac and renal disorders. Administer PRBCs instead of whole blood. Minimize amount of saline infused with transfusion.	Slow or stop transfusion as ordered. Elevate patient's head. Notify health care provider. Administer diuretics as ordered.
Infectious disease transmission	Microorganism contamination of infused product	During transfusion to 2 hrs after transfusion Complete transfusion within 4 hrs	High fever, chills, abdominal cramping, vomiting, diarrhea, profound hypotension, flushed skin, back pain	Proper care of blood or blood product from time of procurement through end of administration.	Stop transfusion. Remove blood product and tubing. Maintain IV access. Notify health care provider. Monitor and document vital signs. Obtain samples for blood culture and Gram stain from recipient. Administer IV fluids, broad-spectrum antimicrobials, vasopressors, and steroids as ordered.
Iron overload	Iron from donated blood binds to protein and is not eliminated	May occur with multiple transfusions or chronic transfusion therapy	Cardiac dysfunction, SOB, arrhythmias, heart failure, increased serum transferrin, increased liver enzymes, jaundice	Chelation, phlebotomy, monitor serum iron levels.	Monitor patient for heart failure, cardiac disorder, liver disorder, serum transferrin.

Data modified from Alexander M, et al.: *Infusion nursing: an evidence-based approach*, ed 3, St Louis, 2010, Mosby; and American Association of Blood Banks: *Standards for blood banks and transfusion services*, ed 27, Bethesda, Md, 2011, The Association.

HF, Heart failure; Hct, hematocrit; Hgb, hemoglobin; IV, intravenous; PRBCs, packed red blood cells; RBC, red blood cell; SOB, shortness of breath.

SKILL 29-1 Initiating Blood Therapy

NSO Blood Therapy Module / Lessons 1 & 2

Blood is administered for different clinical indications (Table 29-4). A patient's medical condition determines which blood component is indicated. A health care provider's order is required for the administration of a blood product. A nurse is responsible for understanding which components are appropriate in various situations. In addition, a nurse must ensure that a blood sample has been collected and sent to the laboratory within 72 hours for typing and compatibility screening. The blood sample collector must be meticulous when labeling the patient's identification information on the blood tube. This is the first step in the prevention of error (Alexander et al., 2010; Gabriel, 2008).

Blood is stored in a refrigerated environment. In emergency situations rapid transfusion of cold blood may lead to dysrhythmias and a reduction of core temperature. Sometimes a blood-warmer machine is used for large transfusions of greater than 50 mL/kg/hr or patients with cold agglutinins (Ackley et al., 2008) (Fig. 29-4).

Video Clip

Do not heat blood products in a microwave or with hot water because this is dangerous and may destroy blood cells.

Delegation and Collaboration

The skill of initiating transfusion therapy cannot be delegated to nursing assistive personnel (NAP). The skill of initiating transfusion therapy by a licensed practical nurse (LPN) varies by state Practice Acts. After the transfusion has been started and the patient is stable, monitoring of a patient by NAP does not relieve a registered nurse (RN) of the responsibility to continue to assess the patient during the transfusion. The nurse instructs the NAP about:

- Frequency of vital sign monitoring needed.
- What to observe such as complaints of shortness of breath, hives, and/or chills and reporting this information to the nurse.

TABLE 29-4 Blood and Blood Component Products*

Blood Product and Source	Volume and Infusion Time	Able to Transmit HIV/HBV	ABO/RH Testing Needed	Actions/Uses
Whole blood—Single donor: allogeneic or autologous	300-550 mL Within 4 hrs	Yes	Yes—Must be ABO identical; Rh—Yes	Replaces red cell mass and plasma volume; expected to raise Hgb 1 g/100 mL and Hct by 3% in nonhemorrhaging adult.
Packed RBCs—Single donor: allogeneic or autologous	250-350 mL Within 4 hrs	Yes	Yes/Yes	Preferred method of replacing red blood cell mass; expected to raise Hgb/Hct level same as whole blood.
Leukocyte-poor RBCs—Single donor: allogeneic or directed	200-250 mL Within 4 hrs	Yes	Yes/Yes	Replaces RBCs while preventing febrile, nonhemolytic transfusion reactions; reduces risk for CMV transmission.
Irradiated RBCs—Single donor: allogeneic or directed	250-350 mL Within 4 hrs	Yes	Yes/Yes	Replaces RBCs while preventing transfusion-associated graft-versus-host disease; used in immunodeficient patients (any blood component can be irradiated).
Fresh frozen plasma—Single donor	200-250 mL Infuse within 24 hrs of thawing Within 4 hrs	Yes	Yes/No	Replaces plasma without RBCs or platelets; contains most coagulation factors and complement; used in control of bleeding when replacement of coagulation factors is needed (e.g., DIC, TTP).
Cryoprecipitate—Multiple donors, pooled	5-20 mL/unit; 1 unit/10 kg body weight 1-2 mL/min Infuse within 6 hrs of thawing or 4 hrs of pooling	Yes	No/No	Replaces factors VIII, XIII, von Willebrand's factor, and fibrinogen.
Platelets—Multiple/random donor, pooled	40-70 mL/unit; 1 unit/10 kg body weight Within 6 hrs of pooling	Yes	Yes/Yes	Used in patients with thrombocytopenia. Certain microaggregate filters are not to be used with platelets—check manufacturer instructions.
Platelets—Single donor	200-500 mL Within 4 hrs	Yes	Yes/Yes	Single-donor platelets are most useful in immunologically refractory patients when given as HLA matched with recipient. Each unit expected to raise platelet count by 5000-10,000/mL in a 70-kg patient.
Colloid components—Albumin 5% pooled	250-500 mL 1-10 mL/min	No	No/No	Oncotically equivalent to plasma; used to treat hypoproteinemia in burns and hypoalbuminemia in shock and ARDs; used to support blood pressure in dialysis and acute liver failure.
Colloid components—Albumin 25% pooled	50-100 mL 0.2-0.4 mL/min	No	No/No	Increases circulating blood volume by increasing intravascular oncotic pressure.

Data modified from Alexander M et al.: *Infusion nursing: an evidence-based approach*, ed 3, St Louis, 2010, Mosby; American Association of Blood Banks (AABB): *Standards for blood banks and transfusion services*, ed 27, Bethesda, Md, 2011, The Association.

*Other less commonly used blood components include factors VIII and IX concentrates, granulocytes, immunoglobulin, and saline-washed RBCs.

ARD, Acute respiratory disease; CMV, cytomegalovirus; DIC, disseminated intravascular coagulation; HBV, hepatitis B virus; Hct, hematocrit; Hgb, hemoglobin; HIV, human immunodeficiency virus; HLA, human leukocyte antigen; RBC, red blood cell; TTP, thrombotic thrombocytopenic purpura.

FIG 29-4 Blood-warming system. (Used with permission of Estill Medical Technologies, Inc. All rights reserved.)

- Obtaining blood components from the blood bank (check agency policy).

Equipment

- ❑ Y-type blood administration set (in-line filter) (NOTE: Depending on blood product, special tubing and filter are necessary.)
- ❑ Prescribed blood product
- ❑ 250-mL bag 0.9% NaCl (normal saline) intravenous (IV) solution
- ❑ Antiseptic wipes (chlorhexidine based)
- ❑ Clean gloves
- ❑ Tape
- ❑ Vital sign equipment: Thermometer, blood pressure cuff, and stethoscope
- ❑ Signed transfusion consent form

Optional Equipment

- ❑ Rapid infusion pump
- ❑ Electronic infusion device (EID) (Verify that pump can be used to deliver blood and blood products)
- ❑ Leukocyte-depleting filter
- ❑ Blood warmer
- ❑ Pressure bag
- ❑ Pulse oximeter

STEP

RATIONALE

ASSESSMENT

- 1 Verify health care provider's order for specific blood or blood product, date, time to begin transfusion, duration, and any pretransfusion or posttransfusion medications to administer.
- 2 Obtain patient's transfusion history and note known allergies and previous transfusion reactions. Verify that type and cross-match have been completed within 72 hours of transfusion.
- 3 Verify that IV cannula is patent and without complications such as infiltration or phlebitis.
 - a Administer blood or blood components to an adult, using a 14- to 24-gauge short peripheral catheter.
 - b Transfuse a neonate or pediatric patient using a 22- to 24-gauge device (INS, 2011a).
 - c A 1.9 Fr is the smallest central venous access device (CVAD) that can be used (INS, 2011a).
- 4 Assess laboratory values such as hematocrit, coagulation values, platelet count.
- 5 Check that patient has properly completed and signed transfusion consent before retrieving blood.
- 6 Know indications or reasons for transfusion (e.g., packed red blood cells [PRBCs] for patient with low hematocrit level from gastrointestinal bleeding or surgery blood loss).
- 7 Obtain and record pretransfusion baseline vital signs (temperature, respirations, and blood pressure). If patient is febrile (temperature greater than 37.8°C [100°F]), notify health care provider before initiating transfusion.

A health care provider's order must be present before transfusing a blood product. Verifying order helps to ensure that appropriate blood component will be administered (Alexander et al., 2010; INS, 2011a). Premedications such as an antihistamine or antipyretic may be ordered, especially if patient demonstrated previous transfusion sensitivity.

Identifies patient's prior response(s) to transfusion of blood components. If patient has experienced reaction in the past, anticipate similar reaction and be prepared to rapidly intervene.

Patent IV ensures that transfusion will be infused within established time guidelines.

The gauge of the IV cannula should be appropriate for accommodating the infusion of blood and/or blood components (INS, 2011a). Large-gauge cannulas promote rapid flow of blood components.

Use of smaller cannula gauges such as 24 gauge often requires blood bank to divide the unit so each half can be infused within allotted time or pressure-assisted devices.

Provides baseline for later evaluation of patient response to transfusion.

Agencies require patients to sign consent forms before receiving blood component therapy because of inherent risks (INS, 2011a).

Allows you to anticipate patient's response to therapy.

Change from baseline vital signs during infusion alerts nurse to potential transfusion reaction or adverse effect of therapy (INS, 2011a).

STEP	RATIONALE
8 Assess patient's need for IV fluids or medications while transfusion is infusing.	If IV medications need to be administered during transfusion, second IV site is necessary. No other infusions are to be administered through same IV site as blood transfusion. Administer blood or blood components only with 0.9% normal saline solution (INS, 2011a).
9 Assess patient's understanding of procedure and rationale.	Alleviates some of the anxiety patient may have.

NURSING DIAGNOSES

- | | | |
|--|---|--|
| <ul style="list-style-type: none"> • Activity intolerance • Decreased cardiac output • Deficient fluid volume | <ul style="list-style-type: none"> • Deficient knowledge regarding transfusion | <ul style="list-style-type: none"> • Excess fluid volume • Ineffective peripheral tissue perfusion |
|--|---|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of the procedure:</p> <ul style="list-style-type: none"> • Patient verbalizes understanding of rationale for therapy. • Patient experiences improved activity tolerance. • Mucous membranes are pink and patient has brisk capillary refill. • Patient's cardiac output returns to baseline. • Patient's systolic blood pressure improves, and urine output is 0.5 to 1 mL/kg/hr. • Patient's laboratory values improve in targeted areas (e.g., hematocrit, coagulation values, platelet count). <p>2 Explain procedure to patient and family caregiver.</p> | <p>Indicates patient's understanding and ability to make an informed decision for consent.</p> <p>Oxygenation is improved.</p> <p>Tissue perfusion is improved.</p> <p>Intravascular volume is restored.</p> <p>Parameters reflect optimal fluid status and adequate renal blood flow.</p> <p>Indicates that patient responds appropriately to blood or blood component infusion.</p> <p>Promotes patient's cooperation and ability to report complications.</p> |
|---|--|

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Preadministration protocol:</p> <p>a Obtain blood component from blood bank following agency protocol (see illustration). Blood transfusion must be initiated within 30 minutes after release from laboratory or blood bank (INS, 2011a).</p> <p>b Check blood bag for any signs of contamination (i.e., clumping/clots, gas bubbles, purplish color) and presence of leaks.</p> | <p>Timely acquisition ensures that product is safe to administer. Agency protocol usually encompasses safeguards to ensure quality control throughout transfusion process.</p> <p>Do not transfuse blood if integrity is compromised. Air bubbles, clots, and discoloration indicate bacterial contamination or inadequate anticoagulation of stored component and are contraindications for transfusion of that product (Alexander et al., 2010; AABB, 2011; Gabriel, 2008).</p> <p>Blood serves as medium for bacterial growth.</p> |
|---|---|

STEP 1a Unit of blood with label.

STEP

RATIONALE

c Verbally compare and correctly verify patient, blood product, and type with another person considered qualified by your agency (e.g., RN or LPN) before initiating transfusion. Check the following:

- (1) Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- (2) Transfusion record number and patient's identification number match.

Strict adherence to verification procedures before administration of blood or blood components reduces risk for administering wrong blood to patient. Misidentification of patient is one of the most important factors in transfusion errors (INS, 2011a).

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

Prevents accidental administration of wrong component.

Clinical Decision Point *If you notice a discrepancy during verification procedure, do not administer the product. Notify blood bank and appropriate personnel as indicated by agency policy. Return blood to blood bank until discrepancy is resolved (INS, 2011a).*

(3) Patient's name is correct on all documents. Check identification number and date of birth on identification band and patient record.

(4) Check unit number on blood bag with blood bank form to ensure that they are the same.

(5) Blood type matches on transfusion record and blood bag. Verify that component received from blood bank is same component that health care provider ordered (e.g., packed red cells, platelets) (see illustration).

(6) Check that patient's blood type and Rh type are compatible with donor blood type and Rh type (e.g., Patient A+: Donor A+ or O+).

(7) Check expiration date and time on unit of blood.

Ensures that patient receives correct therapy. One of most common causes of patient receiving incorrect transfusion is obtaining wrong blood component from blood bank (Alexander et al., 2010; Gabriel, 2008; INS, 2011a).

Verifies accurate donor blood type and compatibility.

(8) Just before initiating transfusion, check patient identification information with blood unit label information (see illustration). Do not administer blood to patient without an identification bracelet.

(9) Both individuals verify patient and unit identification record process as directed by agency policy.

Never use expired blood because cell components deteriorate and may contain excess citrate ions (Alexander et al., 2010; AABB, 2011; INS, 2011a).

Serves as last point of patient and blood confirmation and is most important step in verification process (Alexander et al., 2010; INS, 2011a; INS, 2011b).

Documentation is the legal medical record.

d Review purpose of transfusion and ask patient to report any changes that he or she may feel during the transfusion.

Signs and symptoms of transfusion reactions include chills, low back pain, shortness of breath, rash, hives, or itching (Alexander et al., 2010). Prompt notification aids in early intervention.

e Empty urine drainage collection container or have patient void.

If transfusion reaction occurs, urine specimen containing urine produced after initiation of transfusion will be sent to the laboratory (Alexander et al., 2010).

Clinical Decision Point *Initiate the blood transfusion within 30 minutes from time of release from blood bank. If this cannot be completed because of factors such as an elevated temperature, immediately return the blood to the blood bank and retrieve it when you can administer it.*

STEP 1c(5) Two clinicians verifying blood type with health care provider order.

STEP 1c(8) Two clinicians verifying identification of patient and blood product.

STEP

RATIONALE

2 Administration:

- a** Perform hand hygiene. Apply clean gloves.
- b** Open Y-tubing blood administration set for single unit. Use multiset if multiple units are to be transfused.
- c** Set all clamp(s) to “off” position.
- d** Spike 0.9% normal saline IV bag with one of Y-tubing spikes. Hang bag on IV pole and prime tubing. Open upper clamp on normal saline side of tubing and squeeze drip chamber until fluid covers filter and one third to one half of drip chamber (see illustration).
- e** Maintain clamp on blood product side of Y-tubing in “off” position. Open common tubing clamp to finish priming tubing to distal end of tubing connector. Close tubing clamp when tubing is filled with saline. All three tubing clamps should be closed. Maintain protective sterile cap on tubing connector.
- f** Prepare blood component for administration. Gently agitate blood unit bag, turning back and forth, upside down. Remove protective covering from access port. Spike blood component unit with other Y connection. Close normal saline clamp above filter, open clamp above filter to blood unit, and prime tubing with blood. Blood will flow into drip chamber (see illustration). Tap filter chamber to ensure that residual air is removed.

Using standard precautions reduces risk for transmission of microorganisms.

Y-tubing facilitates maintenance of IV access with normal saline in case patient will need more than 1 unit of blood.

Setting clamps to “off” position prevents accidentally spilling and wasting product.

Primes tubing with fluid to eliminate air in Y-tubing. Closing clamp prevents spillage and waste of fluid.

This will completely prime tubing with saline, and IV line is ready to be connected to the patient’s vascular access device (VAD).

Gentle agitation suspends red blood cells in anticoagulant. Protective barrier drape may be used to catch any potential blood spillage. Tubing is primed with blood unit and ready for transfusion into patient.

Clinical Decision Point Normal saline is compatible with blood products, unlike solutions that contain dextrose, which cause coagulation of blood. Only use 0.9% normal saline solution to administer blood. No other solutions are to be administered with blood (piggybacked) (INS, 2011a).

- g** Maintaining asepsis, attach primed tubing to patient’s VAD. Open common tubing clamp and regulate blood infusion to allow only 2 mL/min to infuse in initial 15 minutes.

This initiates infusion of blood product into patient’s vein.

STEP 2d Blood administration set primed with normal saline.

STEP 2f Unit of blood connected to Y-tubing setup.

STEP

RATIONALE

- h** Remain with patient during first 15 minutes of transfusion. Initial flow rate during this time should be 2 mL/min or 20 gtt/min (using macrodrip of 10 gtt/mL).

Most transfusion reactions occur within first 15 minutes of a transfusion (Snyder et al., 2008). Infusing small amount of blood component initially minimizes volume of blood to which patient is exposed, thereby minimizing severity of reaction.

Clinical Decision Point *If signs of a transfusion reaction occur, stop the transfusion, start normal saline with a new primed tubing directly to the VAD, and notify the health care provider immediately (see Skill 29-2). Do not infuse saline through existing tubing because it will cause blood in tubing to enter patient.*

- i** Monitor patient's vital signs at 5 minutes, 15 minutes, and every 30 minutes until 1 hr after transfusion (AABB, 2011) or per agency policy.
- j** If there is no transfusion reaction, regulate rate of transfusion according to health care provider's orders. Check drop factor for blood tubing.

Frequently monitoring vital signs helps to quickly alert you to transfusion reaction (Alexander et al., 2010; Gabriel, 2008; INS, 2011a).

Maintaining prescribed rate of flow decreases risk for fluid volume excess while restoring vascular volume. Drop factor for most blood tubing is 10 gtt/mL.

Clinical Decision Point *Do not let a unit of blood hang for more than 4 hours because of danger of bacterial growth. Administration sets should be changed at the completion of each unit or every 4 hours to reduce bacterial contamination (INS, 2011a). Never store blood in an agency refrigerator.*

Clinical Decision Point *Never inject medication into the same IV line with a blood component because of the risk for contaminating the blood product with pathogens and the possibility of incompatibility. Maintain a separate IV access if patient requires IV solutions or medications (INS, 2011a).*

- k** After blood has infused, clear IV line with 0.9% normal saline and discard blood bag according to agency policy. When consecutive units are ordered, maintain IV patency with 0.9% normal saline at keep vein open (KVO) rate and retrieve subsequent unit for administration.
- l** Appropriately dispose of all supplies. Remove gloves and perform hand hygiene.

Infusing IV saline solution infuses remainder of blood in IV tubing and keeps IV line patent for supportive measures in case of transfusion reaction (INS, 2011a).

Standard precautions during transfusion reduce transmission of microorganisms.

EVALUATION

- 1 Observe IV site and status of infusion each time vital signs are taken.
- 2 Observe for any changes in vital signs and any signs of transfusion reactions such as chills, flushing, itching, dyspnea, or rash.
- 3 Observe patient and assess laboratory values to determine response to administration of blood component.

Detects presence of IV-related complications (e.g., infiltration, phlebitis) and verifies continuous and safe infusion of blood product.

Compare presenting signs and symptoms to baseline assessment of patient before transfusion. These are early signs of transfusion reaction (see Table 29-3).

Aids in determining whether goals of therapy have been reached or if further blood component therapy will be required. Laboratory results may not reflect transfusion reaction for several hours.

Unexpected Outcomes

- 1 Patient displays signs and symptoms of transfusion reaction.
- 2 Patient develops infiltration or phlebitis at venipuncture site.
- 3 Rate of infusion slows in absence of infiltration.
- 4 Fluid overload occurs and/or patient exhibits difficulty breathing or has crackles on auscultation.

Related Interventions

- Stop transfusion immediately.
- Disconnect blood tubing at VAD hub and cap distal end with sterile connector to maintain sterile system.
- Connect normal saline-primed tubing at VAD hub to prevent any subsequent blood from infusing from tubing.
- Keep vein open with slow infusion of normal saline at 10 to 12 gtt/min to ensure venous patency and maintain venous access for medication or to resume transfusion.
- Notify health care provider.
- See [Table 29-3](#) for interventions.
- Remove IV line and insert new VAD (above compromised site or in opposite extremity). Restart product if remainder can be infused within 4 hours of initiation of transfusion.
- Institute nursing measures to reduce discomfort at infiltrated or phlebotic area.
- Verify that IV catheter is patent and all clamps are open.
- Gently flush IV line with normal saline or use pressure bag or EID that permits blood transfusion.
- Slow or stop transfusion, elevate head of bed, and inform health care provider of physical findings.
- Administer diuretics, morphine, and/or oxygen as ordered by health care provider.
- Continue frequent assessments and closely monitor vital signs and intake and output.

Recording and Reporting

- Record pretransfusion medications, vital signs, location and condition of IV site, and patient education.
- Record the type and volume of blood component, blood unit/donor/recipient identification, compatibility, and expiration date according to agency policy, along with patient's response to therapy. Document on the transfusion record, nurses' notes, electronic health record (EHR), medication administration record, flow sheet, and/or intake and output sheet, depending on agency policy.
- Record volume of normal saline and blood component infused.
- Report signs and symptoms of a transfusion reaction immediately to the health care provider.
- Record amount of blood received by autotransfusion and patient's response to therapy.
- Report to health care provider any intratransfusion/posttransfusion deterioration in cardiac, pulmonary, and/or renal status.
- Record vital signs before, during, and after transfusion.

Special Considerations

Teaching

- Instruct patient regarding rationale for transfusion and anticipated amount of time for completion of transfusion.
- Discuss with patient and family caregiver the rationale for frequent vital sign monitoring throughout transfusion.
- Inform patient and family caregiver to notify nurse if patient experiences itching, swelling, dizziness, dyspnea, low back pain, and/or chest pain because these may indicate a transfusion reaction.
- Instruct patient to inform nurse if pain, swelling, or redness occurs at IV site because these indicate infiltration.

Pediatric

- Infuse the first 50 mL or 20% of volume (whichever is smaller) of a blood transfusion very slowly in a pediatric patient. Nurse should stay with the child during this time frame ([Hockenberry and Wilson, 2011](#)).

- Smaller portions of blood are often available for use with pediatric patients ([AABB, 2011](#)).
- A 27-, 26-, or 24-gauge cannula can be used to infuse PRBCs without significant hemolysis ([Alexander et al., 2010](#); [Hockenberry and Wilson, 2011](#)).
- Umbilical catheters or catheters placed in the small saphenous veins are commonly used in infants and/or pediatric patients ([Alexander et al., 2010](#)).

Gerontologic

- Some older adults have decreased cardiac function, thus requiring a slower infusion time. Half units may be obtained if a patient is unable to tolerate the volume in a whole unit of blood or blood component.
- In older adults at risk for circulatory overload, regulate flow rate at 1 mL/kg/hr.

Home Care

- Patients who have had prior transfusion reactions, acute angina, or heart failure are not good candidates for home transfusion.
- Initiate the transfusion as soon as possible after component is obtained from blood bank. Transport blood in an insulated container with coolant to maintain temperature.
- Nursing personnel must be present during the entire transfusion process and for 30 to 60 minutes after transfusion.
- When blood sample is obtained for blood typing and cross-matching, attach identification band to patient with full name and identification number used by laboratory. This provides clear identification of patient when blood component transfusion is initiated.
- Instruct patient and family caregiver regarding signs and symptoms of a delayed hemolytic transfusion reaction (i.e., unexplained fever, decrease in hemoglobin and hematocrit levels 2 to 14 days after transfusion) so they can report them and receive treatment if necessary.
- Return the container, empty bags, and tubing to the home care agency after completion of the transfusion.

SKILL 29-2 Monitoring for Adverse Transfusion Reactions

NSO Blood Therapy Module / Lesson 3

Adverse transfusion reactions may occur any time during a transfusion of blood products. Life-threatening reactions usually occur within the first 15 minutes of transfusion. Remain with a patient during this time to monitor physiologic responses.

Several types of adverse reactions may result from a blood transfusion (see Table 29-3). A hemolytic reaction is a systemic response to the administration of a blood product that is incompatible with that of the recipient. The product contains allergens to which the recipient is sensitive or allergic, or it is contaminated with pathogens. Some patients who have a history of frequent transfusion may receive premedication with diphenhydramine (Benadryl) to combat acquired sensitivities.

Before a transfusion each blood unit undergoes extensive serologic testing to reduce the risk for patients acquiring a bloodborne disease. Symptoms that indicate an adverse reaction range from fever, chills, and skin rash to hypotension and cardiac arrest. Some patients also experience a delayed transfusion reaction, which sometimes does not occur for days or weeks after the transfusion (Alexander et al., 2010; AABB, 2011). Other possible adverse

outcomes that result from transfusion therapy include transmission of diseases, circulatory overload, and transfusion-related acute lung injury (TRALI), characterized by noncardiogenic pulmonary edema with an onset within 6 hours of transfusion (Alexander et al., 2010; Busch, 2008). The most fatal risk for transfusion-associated death is the erroneous transfusion of ABO-incompatible allogeneic units (AABB, 2011; King, 2008). Agencies must report fatalities that occur as the result of a transfusion reaction to the Food and Drug Administration (NQF, 2011).

Delegation and Collaboration

The skill of monitoring for adverse blood transfusion reactions by a licensed practical nurse (LPN) varies by state Nurse Practice acts. After the transfusion has been started and the patient is stable, monitoring of a patient by nursing assistive personnel (NAP) does not relieve a registered nurse (RN) of the responsibility to continue to assess the patient during the transfusion. The nurse instructs the NAP about:

- Frequency of vital sign monitoring needed.
- The signs and symptoms of a transfusion reaction that patient may exhibit and to immediately report these to the nurse.

STEP

RATIONALE

ASSESSMENT

- 1 With initiation of a transfusion, observe patient for fever with or without chills.
- 2 Assess patient for tachycardia and/or tachypnea and dyspnea.
- 3 Observe patient for drop in blood pressure.
- 4 Observe patient for hives or skin rash, including assessment of trunk and back.
- 5 Observe patient for flushing.
- 6 Observe patient for gastrointestinal symptoms.

Fever indicates onset of an acute hemolytic reaction, febrile nonhemolytic reaction, or bacterial sepsis.
Indicates acute hemolytic reaction or circulatory overload. In the case of circulatory overload, a cough may accompany these symptoms.
Hypotension indicates infectious disease transmission, an acute hemolytic reaction, and anaphylaxis.
These are early indications of an allergic reaction, anaphylaxis, or graft-versus-host disease, which occurs after transfusion.
These are early indications of an acute hemolytic reaction or a febrile nonhemolytic reaction. Sometimes localized flushing presents with an allergic reaction.
Nausea and vomiting are present in acute hemolytic transfusion reactions, anaphylactic reactions, or infectious disease transmission.

Clinical Decision Point Report sepsis and other infections caused by a transfusion to the blood bank and an agency infection control department, which will communicate the information to the state health department and the Centers for Disease Control and Prevention (NQF, 2011).

- 7 Observe patient for wheezing, chest pain, and possible cardiac arrest.
- 8 Be alert to patient complaints of headache or muscle pain in presence of fever.
- 9 Monitor patient for disseminated intravascular coagulation (DIC), renal failure, anemia, and hemoglobinemia/hemoglobinuria by reviewing laboratory test results (complete blood count [CBC] with differential, hemoglobin [Hgb], hematocrit [Hct]).
- 10 Auscultate patient's lungs and monitor central venous pressure (CVP) if possible.
- 11 Observe patient for jaundice and increased liver enzyme levels, indicating liver damage; and decreased red blood cells (RBCs), white blood cells (WBCs), and platelets, indicating bone marrow suppression.

These are all indications of an anaphylactic reaction.

Both indicate febrile nonhemolytic reaction.

All are late signs of an acute hemolytic reaction.

Crackles in bases of lungs and rising CVP are indications of circulatory overload.

These indicate graft-versus-host disease and would occur following transfusion.

STEP	RATIONALE
------	-----------

<p>12 In patients receiving massive transfusions, observe for mild hypothermia, cardiac dysrhythmias, hypotension, hypocalcemia, and hemochromatosis (iron overload).</p>	<p>Cold blood products affect cardiac conduction system, resulting in ventricular dysrhythmias. Other cardiac dysrhythmias, hypotension, and tingling indicate hypocalcemia, which occurs when citrate (used as a preservative for some blood products) combines with patient's calcium. Iron overload may occur after 10 transfusions (see Table 29-3). It usually occurs in patients who require chronic transfusions.</p>
--	--

NURSING DIAGNOSES

<ul style="list-style-type: none"> • Acute pain • Anxiety • Decreased cardiac output 	<ul style="list-style-type: none"> • Excess fluid volume • Hyperthermia • Hypothermia 	<ul style="list-style-type: none"> • Impaired gas exchange • Risk for infection
<p><i>Related factors are individualized based on patient's condition or needs.</i></p>		

PLANNING

<p>1 Expected outcomes following completion of the procedure:</p> <ul style="list-style-type: none"> • Patient's cardiac parameters (heart rate, blood pressure, CVP) return to baseline. • Patient maintains core body temperature of 36° to 37.2°C (97° to 99° F). • Patient has urine output of 0.5 to 1 mL/kg/hr. • Patient maintains oxygen saturation of greater than 95%. • Patient is comfortable and calm. 	<p>Intravascular volume is restored, reaction reversed.</p> <p>Helps to confirm absence of transfusion reaction, infection, and sepsis.</p> <p>Reflects optimal fluid status.</p> <p>Improved tissue perfusion.</p> <p>Absence of transfusion reaction. Appropriate nursing measures keeps patient at ease.</p>
<p>2 Explain treatment of reaction to patient and family caregiver.</p>	<p>Calms anxiety and helps patient/family caregiver anticipate nurse's actions.</p>

IMPLEMENTATION

<p>1 If you suspect transfusion reaction:</p> <p>a Immediately stop transfusion.</p> <p>b Remove blood component and tubing containing blood product. Replace them with new bag of 0.9% normal saline and tubing (see Chapter 28). Connect tubing to hub of intravenous (IV) catheter. <i>Exception:</i> If patient symptoms suggest mild allergic reaction, stop transfusion, administer antihistamine, and restart or discontinue transfusion per health care provider's order.</p> <p>c Maintain patent IV line using 0.9% normal saline.</p> <p>d Obtain vital signs. Remain with patient for continuous monitoring and assessment. Do not leave patient alone.</p> <p>e Notify health care provider.</p> <p>f Notify blood bank.</p> <p>g Obtain blood samples (if needed) from extremity opposite extremity receiving transfusion. Check agency policy regarding number and type of tubes to be used.</p> <p>h Return remainder of blood component and attached blood tubing to blood bank according to agency policy.</p>	<p>Severity of reaction is related to amount of blood component infused and cause of reaction. It is critical to prevent any more blood from infusing into patient.</p> <p>Prevents additional blood in tubing from being infused.</p> <p>Normal saline keeps patent IV and provides route for emergency medications and fluids.</p> <p>Vital signs are objective measure of patient's condition, which can deteriorate rapidly.</p> <p>Transfusion reactions require immediate medical intervention. Follow protocol for emergency interventions for anaphylactic reactions.</p> <p>Blood bank has procedure to follow when notified of transfusion reaction.</p> <p>Typically one tube of blood will be cross-matched to pretransfusion sample to ensure that correct blood was given to recipient. Blood will be checked for antibodies to determine type of reaction. A second sample will be checked for free hemoglobin in serum, indicating hemolysis, and bilirubin level should be obtained.</p> <p>A sample of this blood will be cross-matched to patient's pretransfusion and posttransfusion samples to determine if error in cross-matching occurred.</p>
---	---

STEP	RATIONALE
<p>i Monitor patient's vital signs every 15 minutes or more frequently if needed.</p> <p>j Administer prescribed medications according to type and severity of transfusion reaction.</p> <ol style="list-style-type: none"> (1) Epinephrine (2) Antihistamine (3) Antibiotics (4) Antipyretics/analgesics (5) Diuretics/morphine (6) Corticosteroids (7) IV fluids <p>k In the event of cardiac arrest, initiate cardiopulmonary resuscitation (see Chapter 27).</p> <p>l Obtain first voided urine sample and send to laboratory. You may need to insert a Foley catheter to obtain the urine (see Chapter 33).</p>	<p>Maintains ongoing assessment of patient's cardiopulmonary status and response to treatment.</p> <p>Follow medical protocol or health care provider's orders.</p> <p>Stimulates sympathetic nervous system to relieve respiratory distress and combat vasodilation in anaphylaxis.</p> <p>Diminishes some aspects of allergic response by blocking histamine receptors.</p> <p>Administered when bacterial contamination/sepsis is suspected.</p> <p>Administered to relieve fever and discomfort in acute hemolytic reactions, febrile nonhemolytic reactions, graft-versus-host disease, and bacterial sepsis.</p> <p>Treats circulatory overload by reducing intravascular volume (diuresis) and decreasing vascular tone (opioid effect).</p> <p>Stabilizes cell membranes, decreasing histamine release.</p> <p>Administered in severe allergic reactions.</p> <p>Rapid administration of IV fluids counteracts some symptoms of anaphylactic shock.</p> <p>Anaphylaxis can quickly lead to cardio-pulmonary arrest. Prompt resuscitation may prevent further complications.</p> <p>Hemoglobinuria occurs with acute hemolytic reactions. Degree of damage to kidneys is influenced by pH of urine and rate of urinary excretion. Attempts will be made to initiate diuresis and alkalize urine. If kidney damage is severe, dialysis may be required.</p>

EVALUATION

- | | |
|--|---|
| <p>1 Continue monitoring patient for signs and symptoms of transfusion reactions.</p> | <p>Continued monitoring of patient's cardiopulmonary status and physiologic response will indicate if reaction has been reversed.</p> |
|--|---|

Unexpected Outcomes

- 1 Patient's physiologic status worsens.

Related Interventions

- Appropriate interventions depend on type of transfusion reaction. [Table 29-3](#) provides general guidelines.

Recording and Reporting

- Document the exact time transfusion reaction was first noted, all vital signs and other physiologic assessments, treatments instituted, and patient response in medical record. Complete transfusion reaction report (see agency policy).
- Immediately report presence of transfusion reaction and patient's physical assessment findings to nurse in charge and health care provider.

Special Considerations

Teaching

- Teach patients and family caregiver signs and symptoms of transfusion reactions and steps to take if they occur.

Pediatric

- Irradiated RBCs and platelets are preferable in children under 6 years of age because of their immature immune systems and to avoid graft-versus-host disease.

Gerontologic

- Administer blood components cautiously to older adults, considering both rate and amount of infusion, because they are at risk for developing circulatory overload.

Home Care

- Certain adverse outcomes (development of hepatitis) or transfusion reactions (delayed hemolysis) occur days to weeks after patient has received transfusion and may become evident in the home setting. It is important that patient, family caregiver, and home care workers be aware of signs and symptoms of these adverse occurrences and steps to be taken should they occur.

Critical Thinking Exercises

Catherine Cooper is a 68-year-old woman scheduled for a right total knee replacement in 6 weeks. She has a history of previous injury from years of playing tennis and basketball. She states that she is concerned about the possibility of receiving a blood transfusion. She has read stories of people contracting diseases and viruses, and her friends have told her about someone who became very ill from a transfusion.

- 1 You are conducting Ms. Cooper's preoperative planning. How should you respond to her concerns?
- 2 Ms. Cooper decided to donate a unit of blood before her operation in the event that she needed transfusion therapy after surgery. She comments to you that she is so glad that she doesn't have to worry about any problems since she is receiving her own blood. What can you tell her about what to expect about her blood donation?
- 3 Following type and cross, it is determined that Mrs. Cooper has AB+ blood. Which type of blood can she receive? Which type of antigens does she carry on her red blood cells?
- 4 Describe your responsibilities associated with initiating and monitoring the transfusion.
- 5 The health care provider orders another transfusion of red blood cells. Because Ms. Cooper had only 1 unit of autologous blood, she consents to a unit of allogeneic blood. Within 15 minutes of the blood initiation, Ms. Cooper complains of itching. Which actions should you take?

REVIEW QUESTIONS

- 1 The nurse is preparing a blood transfusion infusion set. Which solution should be used to prime the tubing?
 - 1 0.45% sodium chloride ($\frac{1}{2}$ NS)
 - 2 Dextrose 5% in 0.45% sodium chloride ($D_5\frac{1}{2}$ NS)
 - 3 0.9% sodium chloride (normal saline [NS])
 - 4 Dextrose 5% in 0.9% sodium chloride (D_5 NS)
- 2 A patient with A- blood type needs a blood transfusion. Which blood types are appropriate for the patient to receive?
 - 1 A+ or A-
 - 2 A- or O+
 - 3 A- or O-
 - 4 A+ or AB-
- 3 A patient is to receive blood that has been stored for a long period of time. Which recent laboratory value should the nurse check before administering the unit?
 - 1 Sodium
 - 2 Hematocrit
 - 3 Hemoglobin
 - 4 Potassium
- 4 A patient is to receive a blood transfusion. Which nursing action has the greatest impact on preventing a potential transfusion reaction?
 - 1 Administering an antihistamine 15 minutes before the transfusion
 - 2 Comparing the patient's identification bracelet with the blood bag label number
 - 3 Ensuring that the patient knows his or her blood type
 - 4 Obtaining the patient's previous transfusion history
- 5 A patient receiving a blood transfusion begins having signs and symptoms of a transfusion reaction. In addition to stopping the transfusion and assessing vital signs, what else should the nurse do?
 - 1 Hang a new infusion setup with D_5W to maintain an access for medications
 - 2 Finish infusing the blood remaining in the tubing and flush the tubing with the normal saline hanging on the Y-tubing
 - 3 Keep the existing tubing patent with a dextrose solution in case diphenhydramine is needed
 - 4 Hang a new infusion setup with normal saline to maintain an intravenous (IV) access

- 6 Place the following steps for the administration of a unit of packed red blood cells (PRBCs) in the correct order.
 - 1 Verbally compare and correctly verify patient and blood product
 - 2 Check appearance of blood for leaks, bubbles, clots, or purplish color
 - 3 Prepare Y-tubing administration set with 0.9% normal saline solution (NSS)
 - 4 Obtain baseline vital signs
- 7 Anticoagulant preservative citrate-phosphate-dextrose-adenine (CPDA-1) maintains the shelf life for donated blood by how many days?
 - 1 21
 - 2 14
 - 3 35
 - 4 42
- 8 Human leukocyte antigen (HLA) complications include:
 - 1 Fetal hemolysis.
 - 2 Transfusion-related acute lung injury (TRALI).
 - 3 Rh incompatibility.
 - 4 No reaction.
- 9 During the administration of blood the health care provider orders intravenous (IV) antibiotics to be infused. The most appropriate intervention is to:
 - 1 Stop the transfusion.
 - 2 Piggyback into the transfusion.
 - 3 Question the order.
 - 4 Start a new IV site.
- 10 Administration of blood and blood products can be delegated to the nursing assistive personnel (NAP).
 - 1 True
 - 2 False

KEY TERMS

Albumin	Bolus	MyPlate Food Guidance system	Nutritional risk
Anthropometrics	Dysphagia	National Dysphagia Diet	Nutritional screening
Aspiration	Gag reflex		Prealbumin
Body mass index (BMI)	Malnutrition		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Perform accurate nutritional screening.
- Identify and refer patients for nutritional assessment to a registered dietitian.
- Assess a patient's ability to swallow.
- Identify risk factors for aspiration related to dysphagia.
- Evaluate a patient's tolerance of oral nutrition.
- Identify appropriate meals for a patient to receive.
- Demonstrate how to properly feed a patient who cannot self-feed.

Nutrition is a basic component of health that affects a patient's rate of recovery from short-term and chronic illness, surgery, and injury. Lack of attention to a patient's nutritional status leads to malnutrition. Malnutrition develops as a result of decreased intake of nutrients, increased nutrient requirements, or complications associated with a disease process such as poor nutrient absorption (Adams et al., 2008). Complications such as muscle wasting, delayed wound healing, increased susceptibility to skin breakdown, and infection result from malnutrition. Complications lead to prolonged hospitalization, increased cost, and possibly increased mortality rates (Adams et al., 2008; Fletcher, 2009; Grodner et al., 2012). **Box 30-1** provides a list of risk factors for nutritional problems.

Nurses have a key role in assessing, planning, and initiating interventions to ensure that patients receive the support required to maintain optimal nutritional status (Jefferies et al., 2011). You collaborate with a variety of health care professionals regarding the nutritional health of patients and participate in nutritional screenings and assessments. You also assess and help patients with feeding and identify

patients at risk for difficulty swallowing and aspiration during feeding.

SCREENING FOR NUTRITIONAL RISK

Nutrition screening, assessment, and intervention are key components of nutrition care (Mueller et al., 2011). Nutritional screening identifies individuals who are either malnourished or are at risk for malnutrition and can determine if a detailed nutritional assessment is indicated (Hammond and Litchford, 2012; Mueller et al., 2011). The Joint Commission (TJC) (2012) standards require the identification of patients who are nutritionally at risk by means of an initial screening mechanism. Nutritional screening must be completed within 24 hours of admission to a hospital, within 14 days of admission to a long-term care facility, or within a facility-defined period of time in ambulatory and home care settings (TJC, 2012). In addition, TJC also requires education and training of patients regarding nutritional intervention and modified diets.

BOX 30-1 Risk Factors for Potential Nutritional Problems

- Clear- or full-liquid diets for more than 3 days without nutrient supplementation or with inappropriate or insufficient nutrient supplementation
- Intravenous feeding (dextrose or saline) or NPO for more than 3 days without supplementation
- Low intakes of prescribed diet or tube feedings
- Weight 20% above or 10% below desirable body weight (accounting for edema)
- Pregnancy weight gain deviating from normal patterns
- Diagnoses that increase nutritional needs or decrease nutrient intake (or both): Cancer, malabsorption, diarrhea, hyperthyroidism, excessive inflammation, postoperative status, hemorrhage, infected or draining wounds, burns, infection, major trauma
- Chronic use of drugs, especially alcohol, which affects nutritional intake
- Alterations in chewing, swallowing, appetite, taste, and smell
- Body temperature consistently above 37° C (98.6° F) for more than 2 days
- Hematocrit: <43% in men, <37% in women; hemoglobin <14 g/dL in men, <12 g/dL in women
- Absolute decrease in lymphocyte count (<1500 cells/mm³)
- Elevated (>250 mg/dL) or decreased (<130 mg/dL) total plasma cholesterol
- Serum albumin <3 g/dL in patients without renal or liver disease, generalized dermatitis, overhydration

Modified from Grodner M et al: *Foundations and clinical applications of nutrition: a nursing approach*, ed 5, St Louis, 2012, Mosby.
NPO, Nothing by mouth.

Nurses screen for actual and potential nutritional alterations by focusing on the effects of an illness or disease on a patient's nutritional status such as recent weight loss and decreased oral intake (Jefferies et al., 2011). Assessment determines presence of physical limitations and psychosocial factors that might affect a patient's nutritional intake (Fletcher, 2009). Findings will determine the need for consultation with a registered dietitian (RD) to complete a more in-depth assessment of a patient's current nutritional status. In addition, assessment findings can lead to a medical referral for a speech-language pathologist (SLP) if the patient has swallowing difficulties. Recommendations for improving nutritional status such as change in diet, alternative feeding methods, or further medical assessment and intervention stem from nutritional assessments (Mueller et al., 2011).

NUTRITION SCREENING AND ASSESSMENT TOOLS

A variety of screening tools standardize the nutrition assessment process, including the Subjective Global Assessment (SGA), which is commonly used to evaluate the presence of malnutrition in patients with different disease conditions. In contrast, The Malnutrition Universal Screening Tool (MUST) was developed to assess older adults in various clinical settings, including acute care, long-term care, and the community (Fig. 30-1). It is a five-step screening tool that identifies adults who are malnourished, at risk for malnutrition, or obese. MUST also provides management guidelines if an individual is found to be malnourished (Raymond, 2010).

The Mini Nutritional Assessment (MNA) (Fig. 30-2) is a nutritional screening tool also used with the elderly (Bauer et al., 2010).

It is a simple, well-validated nutrition screening and assessment tool designed as a first step in providing comprehensive, coordinated nutritional services for persons 65 years and older residing in the assisted-living community long-term care facilities (Skates and Anthony, 2009). It quickly identifies those who are at risk for malnutrition or are malnourished at an early stage so treatment can be initiated early (Skates and Anthony, 2009). The screening includes questions related to change in oral intake, weight loss, mobility, stress, and body mass index (BMI). The assessment component includes arm and calf circumference, specific questions related to eating habits, and questions related to medical history. After a screening, refer any patients at risk so their nutritional status can be improved (Phillips et al., 2010).

Nutritional Assessment by a Registered Dietitian

Nurses and dietitians work closely together to provide comprehensive nutritional care to patients. Dietitians use a problem-solving method, the nutrition care process (NCP), to think critically and make decisions regarding nutrition therapy (Charney and Escott-Stump, 2012). The process is similar to the nursing process. There are four interrelated steps: nutrition assessment, nutrition diagnosis, nutrition intervention, and nutrition monitoring and evaluation (ADA, 2008; Charney and Escott-Stump, 2012). The dietitian first performs a comprehensive assessment of a patient's nutritional status, including medical, social, nutritional, and medication history; physical examination; anthropometric measurements; and laboratory data. The goal of the assessment is to develop an effective nutritional plan of care that addresses patients' nutritional problems. The RD then makes a nutritional diagnosis that describes alterations in a patient's nutritional status that a dietitian can treat independently (ADA, 2008). The nutritional intervention is a purposely planned activity with the intent to resolve the nutrition diagnosis (i.e., to change a nutrition-related alteration). Nutrition monitoring and evaluation identifies patient progress, including patient understanding and adherence.

FOUNDATIONS OF NUTRITION

Dietary guidelines are reviewed regularly and modified based on the most current evidence related to nutrition, physical activity, and health. *Dietary Guidelines for Americans* was released in January 2011 and targets individuals 2 years and older (USDA and US DHHS, 2010). The intent is to promote health, reduce the risk of chronic diseases, and prevent and reverse obesity through improved nutrition and physical activity. The 2010 guidelines stress maintaining calorie balance over time, staying within a personal calorie limit, and choosing physical activities that fit within an individual's lifestyle.

In addition, the guidelines focus on consumption of nutrient-dense foods and sugar-free beverages that include vegetables, fruits, whole grains, seafood, eggs, beans, unsalted nuts and seeds, lean meats, poultry, and fat-free and low-fat milk products (Kennedy et al., 2011; USDA and USDHHS, 2010). The guidelines accommodate food preferences, cultural traditions, and customs of diverse individuals (USDA, 2010b).

The MyPlate Food Guidance System (Fig. 30-3) replaces MyPyramid (USDA, 2010a). The new symbol was developed in an effort to promote healthy eating by reminding individuals to make healthy food choices. It illustrates the five food groups using a familiar visual of a plate and includes only the five food groups in an effort to help individuals prioritize their choices and focus on the entire meal (Center for Nutrition Policy, 2011). The names of the five food groups have been modified to grains, vegetables, fruit,

Alternative measurements and considerations

Step 1: BMI (body mass index)

If height cannot be measured

- Use recently documented or self-reported height (if reliable and realistic).
- If the subject does not know or is unable to report their height, use one of the alternative measurements to estimate height (ulna, knee height, or demispan).

If height and weight cannot be obtained

- Use mid-upper arm circumference (MUAC) measurement to estimate BMI category.

Step 2: Recent unplanned weight loss

If recent weight loss cannot be calculated, use self-reported weight loss (if reliable and realistic).

Subjective criteria

If height, weight, or BMI cannot be obtained, the following criteria that relate to them can assist your professional judgment of the subject's nutritional risk.

1. BMI

- Clinical impression: thin, acceptable weight, overweight. Obvious wasting (very thin) and obesity (very overweight) can also be noted.

2. Unplanned weight loss

- Clothes and/or jewelry have become loose fitting (weight loss).
- History of decreased food intake, reduced appetite, or swallowing problems over 3-6 months and underlying disease or psychosocial/physical disabilities likely to cause weight loss.

3. Acute disease effect

- No nutritional intake or likelihood of no intake for more than 5 days.

FIG 30-1, cont'd

dairy, and protein food groups. Each group contains a variety of foods with similar nutrient content and reflects the way food is used by consumers (Center for Nutrition Policy and Promotion, 2011). Recommendations for building a healthy plate include making half of the plate fruits and vegetables; adding lean protein, including seafood twice a week and whole grain; and including dairy such as a cup of fat-free or low-fat milk. Soy milk or fat-free or low-fat yogurt can be used alternatively in the meal.

EVIDENCE-BASED PRACTICE

Malnutrition is a serious and debilitating condition that is prevalent yet not fully identified. Consequently it may remain untreated in hospitals, the community, and long-term care (Adams et al., 2008; Gout et al., 2009). It is important that all health care workers understand factors associated with inadequate nutritional intake. Patients have identified barriers to adequate nutritional intake, including pain, decreased appetite, nausea, and side effects of medications (Adams et al., 2008; Holst et al., 2010).

As a primary caregiver you are in the ideal position to monitor a patient's nutritional status. Barriers to effective nutritional care by nurses include lack of interest and inadequate nutritional knowledge, resulting in inconsistencies in nutritional screening and documentation (Holst et al., 2010; Mowe et al., 2008). After screening and assessment, you need to collaborate with other health team members to design and implement actions that optimize patients' nutritional health (Fletcher and Carey, 2011):

- Nutritional care of patients is a primary responsibility of registered nurses and is essential to prevent complications associated with malnutrition.
- Regular and ongoing nutritional screening and assessment are imperative for early detection and improvement of outcomes for high-risk and malnourished patients (Gout et al., 2009).
- Failure of nurses to identify and refer malnourished patients for evaluation can result in adverse clinical outcomes (Gout et al., 2009).

Mini Nutritional Assessment MNA [®]			
Last name:	First name:	Sex:	Date:
Age:	Weight, kg:	Height, cm:	I.D. number:
<p>Complete the screen by filling in the boxes with the appropriate numbers. Add the numbers for the screen. If score is 11 or less, continue with the assessment to gain a Malnutrition Indicator Score.</p>			
Screening			
A Has food intake declined over the past 3 months due to loss of appetite, digestive problems, chewing or swallowing difficulties? 0 = Severe loss of appetite 1 = Moderate loss of appetite 2 = No loss of appetite	<input type="checkbox"/>	J How many full meals does the patient eat daily? 0 = 1 meal 1 = 2 meals 2 = 3 meals	
B Weight loss during the last 3 months 0 = Weight loss greater than 3 kg (6.6 lb) 1 = Does not know 2 = Weight loss between 1 and 3 kg (2.2 and 6.6 lb) 3 = No weight loss	<input type="checkbox"/>	K Selected consumption markers for protein intake • At least one serving of dairy products (e.g., milk, cheese, yogurt) per day? Yes <input type="checkbox"/> No <input type="checkbox"/> • Two or more servings of legumes or eggs per week? Yes <input type="checkbox"/> No <input type="checkbox"/> • Meat, fish, or poultry every day Yes <input type="checkbox"/> No <input type="checkbox"/> 0.0 = If 0 or 1 yes 0.5 = If 2 yes 1.0 = If 3 yes	
C Mobility 0 = Bed or chair bound 1 = Able to get out of bed/chair but does not go out 2 = Goes out	<input type="checkbox"/>	L Consumes two or more servings of fruits or vegetables per day? 0 = No 1 = Yes	
D Has suffered psychological stress or acute disease in the past 3 months 0 = Yes 2 = No	<input type="checkbox"/>	M How much fluid (e.g., water, juice, coffee, tea, milk) is consumed per day? 0.0 = Less than 3 cups 0.5 = 3 to 5 cups 1.0 = More than 5 cups	
E Neuropsychological problems 0 = Severe dementia or depression 1 = Mild dementia 2 = No psychological problems	<input type="checkbox"/>	N Mode of feeding 0 = Unable to eat without assistance 1 = Self-fed with some difficulty 2 = Self-fed without any problem

PATIENT-CENTERED CARE

Culture as related to nutrition is the shared knowledge, beliefs, values, and customs of a group around food and eating (Burns, 2009) (Box 30-2). Using a patient-centered approach to nutrition ensures a relevant and individualized nutritional plan for your patients. Make every attempt to provide patients with nutritional food that is familiar and congruent with their beliefs (O'Regan, 2009). Food preferences are a major factor in patient adherence to modifications of safe oral intake. A patient must be a part of the decision-making process when dietary modifications are required. Assess his or her willingness to accept diet modifications and be aware that patient and family members might have difficulty accepting dietary modifications that clash with personal meaning and values towards food (Burns, 2009). Alterations in the ability to safely self-feed and/or needing to consume an altered diet and fluids may impact a patient's perception of quality of life. Psychological reactions may include altered body image, embarrassment, depression, and feelings of social isolation (DeFabrizio and Rajappa, 2010).

Mealtime in a health care setting is the ideal time to interact with patients. During the meal continue your patient assessment, encourage decision making, and provide education. Use the time to teach patient, family, and significant others rationales for dietary modifications, including positioning during and after meals. Risk for aspiration increases if modifications are not followed (Garcia and Chambers, 2010). Maintain a patient's dignity as you implement individualized actions to correct, promote, or maintain nutritional health.

Safety Guidelines

1 Assess for signs and symptoms of malnutrition and identify patients at risk.

BOX 30-2 Cultural Considerations To Enhance Patient Nutrition

Understand the meaning of food and food preferences for patient and family. Avoid making value judgments about their food preferences and practices.

Food is often associated not only with caring and love but also with health promotion, maintenance, and restoration.

Assess religious and cultural influences on nutritional practices:

- African-Americans and Mexicans have large extended family networks. Eating food prepared by family members or loved ones can meet nutritional needs and serve as an expression of love.
- Buddhists and Hindus are generally vegetarians because of their respect for life and belief in transmigration of the soul.
- Vegetarians and vegans prefer meat substitutes.
- Hindus generally avoid eating beef, but some eat chicken and lamb, whereas some fast to obtain blessing from their gods.
- Muslims eat *halal* foods and avoid those that are classified such as *haram* (pork, alcohol).
- Orthodox Jews generally eat kosher foods and avoid serving meat and dairy at the same time. They eat fish with fins and scales (e.g., tuna), animals that chew their cud (e.g., cows), and nonpredatory birds (e.g., chicken). Shellfish cannot be eaten.
- Muslims fast all day, including from food and water, during the month of Ramadan. They eat before dawn and during evenings.

Collect information on the types of foods that are generally given for different types of conditions:

- Some African-Americans believe that certain foods build blood, thereby preventing anemia.
- Some pregnant Hispanic and African-American women have specific cravings and believe that they need to eat starch or red clay to promote a baby's health.
- Asians, Hispanics, Eastern Europeans, and Africans believe in the hot-and-cold theory of health and illness. Foods are classified as cold or hot based on their characteristics, independent of the temperature at which they are served. There is no universal agreement across cultures about which foods are hot or cold.

Understand food practice, and collaborate to develop healthy alternatives. Use cultural food guides developed for specific populations:

- Assess which ingredient or food content you need to reduce.
- A Chinese patient on a low-sodium diet needs to use low-sodium soy sauce and avoid shrimp paste and oyster sauce.

- 2 Identify patients at risk for dysphagia and collaborate with other members of the health care team to minimize complications such as aspiration pneumonia (NQF, 2010).
- 3 Ensure that patients receive the correct therapeutic diets.
- 4 Assess level of consciousness before feeding.

SKILL 30-1 Performing a Nutritional Assessment

Assessment of nutritional status is an essential part of patient care and is the foundation for diagnosing nutritional problems (Bauer et al., 2010; Mueller et al., 2011). It may lead to recommendations such as change in diet, need for alternative mode of nutrition intake, or improvement in a patient's nutritional status (Ukleja et al., 2010). There are four basic components of a holistic nutritional assessment: (1) patient history (psychological and social); (2) dietary history; (3) physical examination and anthropometric measurements; and (4) biochemical indices (Grodner et al., 2012).

History

Elements of a patient history such as appetite, psychosocial factors affecting intake, economics, and cultural issues provide a background for factors influencing current nutritional status (Burns, 2009). Collect the history by reviewing a patient's medical record and by direct interview. The medical history indicates medications, surgery, and coexisting medical conditions compromising nutrition. The psychological history includes screening for depression, alcohol abuse, or abnormal psychiatric behavior leading to decreased food intake. A social history provides important insight into poverty, avoidance of specific food groups, and food customs influencing nutritional education.

Physical Examination

A nutrition-focused physical examination can identify some nutritional deficiencies that may not be identified by other assessment approaches (Table 30-1) (Hammond and Litchford, 2012; Litchford, 2012). Conduct the examination in an organized manner and tailor it to each patient to ensure efficiency and thoroughness (see Chapter 6) (Hammond and Litchford, 2012).

Anthropometrics

Anthropometric measurements are commonly used to describe nutritional status because they reflect body composition (Kahn et al., 2009). Anthropometry involves taking body measurements using simple techniques that measure height and weight, skinfold

thickness, and waist and muscle circumferences. Muscle circumferences include measuring the mid-arm and calf. Calf circumference is a sensitive indicator of nutritional status in the elderly because it indicates lean muscle changes (Portero-McLellan, 2010). Evaluation of results involves comparison of the data collected with predetermined reference points that determine if the patient falls into a nutritional risk category such as severity of malnutrition (Grodner et al., 2012). Registered dietitians typically measure circumferences and skinfold thickness.

Nurses are responsible for taking height and weight measurements. Height and weight are useful in determining the nutritional status of both children and adults. Length is important in evaluating growth in children. The use of length alone as an indicator of nutritional status is usually only used in children (Fletcher, 2009). The length and weight of a child are plotted on a growth chart and evaluated against standards based on the normal U.S. population. This information is essential to tracking the growth of children over time, which reflects nutritional adequacy.

Height is needed to assess weight and body size and calculate body mass index (BMI) in adults (Fletcher, 2009; Grodner et al., 2012; Perry, 2009). Direct measurement of height is done using a movable measuring arm on a clinical platform scale. In this case the individual must be able to stand erect. When a patient cannot stand, it is possible to obtain an accurate indirect height by measuring knee height in the lying position using special equipment.

Body weight is a simple, gross estimate of body composition. As a nutritional screening tool, weight is used to recognize changes that may suggest altered nutritional status, for predicting energy expenditure, and to calculate BMI (CDC, 2011; Grodner et al., 2012; Perry, 2009). When weight loss is expected, an assessment requires the collection of usual body weight (UBW) and actual body weight (ABW) to determine percent of weight change.

$$\% \text{ Weight change} = \frac{(\text{Usual weight} - \text{Actual weight})}{\text{Usual weight}}$$

TABLE 30-1 Clinical Signs of Nutritional Status

Body Area	Signs and Symptoms of Nutritional Risk	Nutritional Implications
Hair	Dull, shedding, easily pluckable	Generalized protein calorie malnutrition
Face	Malar pigmentation (dark skin over cheeks and under eyes) Bitemporal wasting Nasolabial seborrhea Edematous Moon face Pallor	Niacin, B vitamins Malnutrition Niacin, riboflavin, vitamin B ₆ deficiency Protein deficiency Corticosteroid impact Inadequate Fe ⁺⁺ , undernutrition
Eyes	Pale eye membranes	Inadequate Fe ⁺⁺
Lips	Cheilosis (red/swelling) Angular fissures	Inadequate niacin, vitamin B ₆ , riboflavin, Fe ⁺⁺
Gingiva	Spongy, bleeding, abnormal redness	Inadequate vitamin C
Tongue	Glossitis (red, raw, fissured) Pale, atrophic, smooth/slick (filiform papillary atrophy), magenta	Inadequate folate, niacin, riboflavin, Fe ⁺⁺ , vitamin B ₆ , vitamin B ₁₂ Inadequate Fe ⁺⁺ , vitamin B ₁₂ , niacin, folate Inadequate riboflavin
Nails	Spoon shaped, brittle, ridged	Inadequate Fe ⁺⁺
Back	Bony prominences along shoulder girdle	Malnutrition

Modified from Seidel H et al: *Mosby's guide to physical examination*, ed7, St Louis, 2011, Mosby.

Percent of weight change is a useful nutrition index. Table 30-2 summarizes weight changes as indicators of nutritional status. The magnitude and direction of weight change are more meaningful than standard weight references when dealing with sick or debilitated patients (Grodner et al., 2012). When evaluating fluctuations in weight, determine the period of time over which it occurred. Assess whether a patient has been dieting recently or following an exercise program. Also assess for signs of fluid volume deficit or excess, which can cause weight fluctuations (see Chapter 33). Fluid may be the cause if more than 1 pound (0.45 kg) is gained in a day (Grodner et al., 2012).

Measure an ambulatory patient’s weight by using beam scales with movable but detachable weights or electronic scales (Grodner et al., 2012). Some agencies have hospital beds that have the capability to obtain weights on nonambulatory patients. Previously determined weight of the bed is deducted so the patient’s precise weight is measured. Another alternative to weighing nonambulatory patients is a wheelchair scale. Platform scales are specifically designed to be installed on the floor so a wheelchair/ chair or walker can be used. The weight of the wheelchair needs to be weighed

separately if different wheel chairs are used. This type of scale ensures that a patient can remain safely in his or her wheelchair as an accurate weight is obtained.

BMI is a ratio of weight to height and is associated with overall mortality and nutritional risk (Nelms, 2010). The use of BMI allows people to compare their own weight status to that of the general population (Centers for Disease Control and Prevention, 2011) and is one of the best methods for assessing degree of underweight, excess weight, and obesity. Calculation requires only height and weight and is most easily done by referring to a standard BMI chart (Fig. 30-4).

However, BMI alone is not a perfect predictor of overweight or obesity because it is calculated from an individual’s weight, which includes both muscle and fat. For example, highly trained athletes may have a high BMI because of increased muscularity rather than increased body fat (Centers for Disease Control and Prevention, 2011; Kravitz, 2010). As a result, some individuals may have a high BMI but not a high percentage of body fat. In addition, BMI may underestimate body fat in the elderly and in those who have lost muscle mass (National Heart, Lung and Blood Institute, 2008). It is a weak indicator of weight-related problems among certain ethnic groups, such as African-Americans and Hispanic-American women (National Institute of Diabetes, Digestive and Kidney Diseases, 2008). Box 30-3 lists BMI by degree of body adiposity.

BMI and waist circumference provide useful estimates of body fat distribution (Kravitz, 2010). The location of excess fat on the body is important. If it is distributed around the waist, it is more likely that health problems will develop than if it is mainly in the hips and thighs. Abdominal fat (visceral or intraabdominal fat) is related to coronary heart disease, hypertension, diabetes, and sleep apnea (Kravitz, 2010). A circumference greater than 16 cm (40 inches) for men and greater than 14 cm (35 inches) in women corresponds with an increased cardiovascular risk (Kravitz, 2010).

Weight Change (%)	Time Period	Nutritional Status
1-2	1 week	Moderate weight loss
>2	1 week	Severe weight loss
5	1 month	Moderate weight loss
>5	1 month	Severe weight loss

	Obese (30+)
	Overweight (25.0-29.9)
	Normal (18.5-24.9)
	Underweight (below 18.5)

FIG 30-4 Body mass index grid. Data from Centers for Disease Control and Prevention (CDC): *Healthy weight—it’s not a diet, it’s a lifestyle*, August 16, 2011, available at <http://www.cdc.gov/healthyweight/index.html>, accessed May 5, 2012.

BOX 30-3 Body Mass Index

To calculate body mass index (BMI):

$$\text{BMI} = \text{Weight (kg)} / \text{Height (m)}^2$$

or

$$\text{BMI} = \frac{\text{Weight (lb)}}{\text{Height (inches)} \times \text{Height (inches)}} \times 703$$

Classification of BMI in Adults

Degree of Adiposity	BMI
Underweight	<18.5 kg/m ²
Normal weight	18.5-24.9 kg/m ²
Overweight	25-29.9 kg/m ²
Obesity (class 1)	30-34.9 kg/m ²
Obesity (class 2)	35-39.9 kg/m ²
Extreme obesity (class 3)	≥40 kg/m ²

From Expert Panel on the Identification, Evaluation, and Treatment of Overweight and Obesity in Adults: *The practical guide: identification, evaluation, and treatment of overweight and obesity in adults*, Bethesda, Md, 2000, National Institutes of Health.

BMI, Body mass index.

Biochemical Markers of Nutritional Status

Laboratory-based nutritional testing provides objective data along with nutritional-based physical assessment, dietary intake assessment, and anthropometric data to determine nutrition-related health conditions (Grodner et al., 2012; Litchford, 2012). Laboratory data show variations in nutritional status before clinical or anthropometric changes are detected (Litchford, 2012). Results can be influenced by inflammation, diseases, medication trauma, or stress (Portero-McLellan et al., 2010) and fluid balance alterations (Prins, 2010). There is lack of consensus about which biochemical marker clearly assesses nutritional status (Beghetto et al., 2009). Traditionally serum albumin and prealbumin levels are used

because they measure visceral proteins (proteins other than muscle tissue). Normal serum albumin values are within 3.5 to 5.0 g/dL. For nutritional analysis values between 2.8 and 3.5 g/dL may indicate compromised protein status (Grodner et al., 2012). Prealbumin also provides a measure of visceral protein status and normally ranges from 20 to 50 mg/dL. The test is useful in monitoring short-term changes in visceral protein (Grodner et al., 2012). It often is used to monitor nutritional interventions (Barbosa-Silva, 2008). A patient has compromised protein status when levels are between 10 and 15 g/dL. Red blood cells should be assessed for nutritional-based anemias. Assess iron, vitamin B₁₂, and folate levels to confirm a nutritional anemia diagnosis (Prins, 2010).

It is important to remember that no one component of the nutritional assessment directly measures nutritional status or determines nutritional problems or needs. Each part of the process must be used to interpret the patient's nutritional health. Once the nutritional assessment is complete, analysis of all data is completed. Interpreting the data in a meaningful and relevant way allows nutritional nursing diagnoses to be identified and goals to be determined followed by appropriate and individualized interventions.

Delegation and Collaboration

The skill of performing and interpreting a nutritional assessment cannot be delegated to nursing assistive personnel (NAP). However, measurement of a patient's height and weight can be delegated. The nurse directs the NAP to:

- Measure patient's weight after voiding, at the same time of day and wearing same clothing.
- Use the internal bed scale according to guidelines (if applicable).
- Report inability to measure height if patient is nonambulatory.

Equipment

- Scale (beam, electronic, bed with scale, wheelchair/chair)
- Assessment sheet and pen or computerized assessment form

STEP**RATIONALE****ASSESSMENT**

- 1 Assess patient's knowledge of procedure.
- 2 Ask patient to report usual body weight (UBW), noting recent changes in weight. Ask if weight loss was intentional or unintentional.
- 3 Obtain complete and thorough nursing history (see Chapter 6), including social, economic, and psychological factors affecting nutrition. Determine patients' current nutritional habits.
- 4 Perform physical assessment (see Chapter 6), including condition of skin, hair, nails, oral mucosa, muscle mass, and strength. Note any mental changes.
- 5 Review results of relevant laboratory tests (e.g., albumin, prealbumin).
- 6 Determine medications and other dietary supplements that patient is taking (over-the-counter and prescribed). Be aware of common drug-drug and drug-nutrient interactions.

Encourages cooperation, minimizes risks and anxiety. Identifies teaching needs.

In adults weight is usually stable. A loss of 10 lbs (4.5 kg) during a 6-month period whether intentional or unintentional, is a critical indicator for further assessment, especially in the older adult (Dimaria-Ghalili, 2008).

Identifies patients who are at nutritional risk (Burns, 2009). Determines teaching needs related to nutritional health.

The most obvious signs of malnutrition on physical examination are apparent in the skin, mouth, muscles, and central nervous system (Lewis et al., 2011).

Test data provide clues about nutritional status.

Certain medications inhibit or increase action of other medications. Some nutrients interact with medications. For example, vitamin K-rich foods (green leafy vegetables) interfere with action of warfarin (Coumadin) (anticoagulant).

Medications such as mineral oil laxatives impair nutrient use.

STEP	RATIONALE
<p>7 Measure ABW.</p> <p>a Have patient void. Be sure that he or she is wearing underwear or hospital gown. Make sure that patient is weighed either barefoot or with same shoes. Weigh at same time of day.</p> <p>b Make sure that beam scale has been calibrated. If ambulatory, help patient to stand still on scale with weight evenly distributed on both feet.</p> <p>c If patient is unable to stand, use wheelchair or bed scale.</p> <p>d Record weight to the nearest 0.25 lb (0.1 kg).</p>	<p>Women tend to underestimate their weight more than men, and for both sexes extent of underreporting increases as actual weight increases (Grodner et al., 2012).</p> <p>Improves accuracy of actual weight for comparison over time.</p>
<p>8 Measure actual height.</p> <p>a Help patient to standing position; have him or her stand erect with weight equally distributed on both feet.</p> <p>b Instruct patient to let arms hang free at sides with palms facing thighs.</p> <p>c Have patient look straight ahead, take a deep breath, and hold position while bringing horizontal bar firmly on top of head. Measure to nearest 0.1 cm ($\frac{1}{8}$ inch). Make sure that your eyes are level with bar to read measurement.</p>	<p>Accurate measurement requires regularly calibrated and maintained scales (Perry, 2009). Standing still with equal weight distribution aids in obtaining accurate weight (Grodner et al., 2012).</p> <p>Ensures accurate measurement of weight while maintaining patient's safety.</p> <p>Provides precise measurement of weight used to calculate BMI.</p> <p>On average, when asked, people report being slightly taller than they actually are (Grodner et al., 2012).</p> <p>Ensures accurate height (Grodner et al., 2012).</p>
<p>9 Calculate IBW.</p> <p>a Calculate via standard height and weight chart. IBW range for normal is 10% above and 10% below IBW.</p> <p>b Use the following formulas: <i>Male:</i> 106 lbs (48.1 kg) for first 5 feet, then add 6 lbs (2.7 kg) per additional 2.5 cm (inch). <i>Female:</i> 100 lbs (45.4 kg) for the first 5 feet, then add 5 lbs (2.25 kg) per additional 2.5 cm (inch).</p>	<p>Prevents movement of shoulders, which will result in inaccurate measurement.</p> <p>Steady position ensures accurate measurement.</p> <p>Provides precise measurement of height used to calculate BMI.</p>
<p>10 Calculate BMI:</p> $\text{BMI} = \frac{\text{Weight (kg)}}{\text{Height}^2 (\text{m}^2)}$ <p>a Divide weight in pounds by 2.2.</p> <p>b Convert height to inches. Multiply inches by 2.54.</p> <p>c Divide height in centimeters by 100.</p> <p>d Divide weight in kilograms by the square of height in meters (m²).</p>	<p>Use IBW to compare with patient's actual weight to determine if he or she is at risk for nutritional alteration.</p>
<p>11 Assess patient's diet history, including current diet, food choices/preferences, appetite, explanations for any restrictions, food allergies, and food intolerances.</p>	<p>Assesses patient's adiposity (obesity) against national standards (Centers for Disease Control and Prevention, 2011).</p>
<p>12 Have patient provide 24-hour diet recall. Ask him or her to report all food and beverages consumed over past 24 hours.</p>	<p>Converts pounds into kilograms.</p> <p>Converts height in inches to centimeters.</p> <p>Converts height to meters.</p> <p>Computes BMI.</p>
<p>13 Determine patient's ability to manipulate eating utensils and self-feed.</p>	<p>Assesses factors affecting diet adequacy and appetite (Burns, 2009).</p>
<p>14 Explain to patient that nutritional assessment is complete.</p>	<p>Estimated or measured food records can provide a more realistic picture of patient's intake (Grodner et al., 2012).</p>
<p>15 Report diet restrictions and preferences to food and nutrition department.</p>	<p>Difficulty in self-feeding creates significant risk for malnutrition (Meiner, 2011).</p> <p>Allows time for patient to ask questions about assessment.</p> <p>Ensures that an inpatient or resident will receive appropriate diet.</p>

NURSING DIAGNOSES

- Deficient knowledge regarding nutritional recommendations
- Imbalanced nutrition: more than body requirements
- Imbalanced nutrition less than body requirements

Related factors are individualized based on patient's condition or needs.

EVALUATION

- | | |
|---|--|
| <p>1 Review history and physical findings. Note abnormal findings or areas of concern.</p> | <p>Permits prompt identification of risk for malnutrition and need for nutritional interventions.</p> |
| <p>2 Compare patient's weight for height with IBW. Compare BMI with recommended BMI for height/weight.</p> | <p>Determines nutritional risk factors and health-related conditions (National Heart, Lung and Blood Institute, 2008).</p> |

STEP

3 Compare normal laboratory test levels with patient's levels.

Unexpected Outcomes

1 Body weight is below or above UBW and/or IBW.

Recording and Reporting

- Record assessment finding results on nutritional screening form. Notify health care provider of abnormal findings.
- Make referral to the RD.

Special Considerations

Gerontologic

- The “normal” anthropometric standards are based on a healthy middle-age population. However, there are methods of comparing anthropometric measurements over time for older adults (Meiner, 2011).

RATIONALE

When considered with other nutritional parameters, abnormal values can indicate malnutrition (Grodner et al., 2012; Litchford, 2012).

Related Interventions

- Ensure that patient is receiving correct diet.
- Identify trends in weight loss/gain.
- Check that patient is being weighed on same scale, with same type of clothing/shoes, and at same time of day.
- Report changes to registered dietitian (RD) or health care provider so RD can conduct a nutritional assessment, calculate patient's caloric needs (calories per kilogram), and determine amount of protein that patient requires and route of nutrition (enteral versus parenteral) (see Chapters 31 and 32).

Pediatric

- Anthropometric data include measurement of length, weight, and head circumference in children. Compare these measurements with standard growth charts to determine percentiles. The most commonly used growth charts are from the National Center for Health Statistics (Hockenberry and Wilson, 2011). These charts now include BMI for age and weight for stature percentiles.

SKILL 30-2 Assisting an Adult Patient with Oral Nutrition

Hospitalized patients receive a number of different oral diets that require a health care provider's order. A therapeutic diet treats many illness and disease states (Table 30-3). For specific information about special diets see the agency dietary manual or contact a registered dietitian (RD). You can modify a regular diet in two ways: quantitatively or qualitatively (Grodner et al., 2012). Qualitative diets include modifications in consistency, texture, or nutrients such as clear or full liquid. Quantitative diets include modifications in number or size of meals served or amounts of specific nutrients such as six small feedings or calorie diets. You can supplement any diet with oral nutrition supplements. You prepare a patient so he or she can be comfortable and not interrupted during a meal. You may be asked to maintain a calorie count. Usually the percentage of each food that a patient eats is recorded next to the food choice directly on the menu for each meal. The RD is able to determine caloric intake and need for nutrition supplements or dietary change. Liquid supplements with or between meals can significantly increase protein and calorie intake (O'Regan, 2009).

Helping adults with oral nutrition requires time, patience, knowledge, and understanding. Most people eat without assistance. However, the older adult commonly loses some fine-motor skills required to get food from the plate and into the mouth. When they are ill, many patients require assistance either to feed themselves or, if necessary, to be fed by another person if unable to eat independently (Webster and Healy, 2009; Wright et al., 2008). Altered dentition, improperly fitted dentures, oral lesions or infections, or diseases causing impaired digestion limit the types and consistencies of foods tolerated. Hemiplegia, fractured arm, quadriplegia,

debilitating illness, or generalized weakness limits self-feeding ability and appetite. The presence of intravenous (IV) catheters or tubing, dressings, and bandages also limits mobility needed for self-feeding. Consult an occupational therapist (OT) for collaboration on assessing patients' ability to self-feed and for recommendations for adaptive equipment and supplies for self-feeding. An adult who needs help to eat needs compassion and understanding. Use common sense when feeding an adult and provide a socially meaningful mealtime experience.

Delegation and Collaboration

The skill of assisting a patient with oral nutrition can be delegated to nursing assistive personnel (NAP). However, the nurse is responsible to determine if a patient is able to receive oral nutrition, including swallowing ability and restrictions. The nurse directs the NAP by:

- Explaining any specific swallowing strategies/techniques unique to the patient.
- Reviewing when to stop feeding and report immediately to the nurse incidences of coughing, gagging, or difficulty swallowing.

Equipment

- Stethoscope and tongue blade for assessment
- Washcloths and towels
- Tongue blade
- Adaptive utensils as necessary for self-feeding
- Oral hygiene supplies

TABLE 30-3 Progressive and Therapeutic Diets

Diet	Description
Clear-liquid	Foods that are clear and liquid at room or body temperature (e.g., water, apple or cranberry juice, gelatin, Popsicles), that leave little residue, and are easily absorbed; commonly ordered for short-term use (24 to 48 hours) after surgery, before diagnostic tests, and after episodes of diarrhea and vomiting
Full-liquid	Includes foods on clear-liquid diet plus addition of smooth-textured dairy products (e.g., milk and ice cream), strained soups and custard, refined cooked cereals, vegetable juice, and pureed vegetables; commonly ordered before or after surgery for patients who are acutely ill from infection or for patients who cannot chew or tolerate solid foods; must verify that patients are able to tolerate lactose before providing dairy products
Pureed	Includes foods on clear- and full-liquid diet plus easily swallowed foods that do not require chewing (e.g., scrambled eggs, pureed meats, vegetables, and fruits; mashed potatoes); ordered for patients with head and neck abnormalities or who have had oral surgery; can be modified for low sodium, fat, or calorie count
Mechanical or dental-soft	Consists of all previous diets plus addition of lightly seasoned ground or finely diced meats, flaked fish, cottage cheese, cheese, rice, potatoes, pancakes, light breads, cooked vegetables, cooked or canned fruit, bananas, and peanut butter; avoid tough meats, nuts, bacon, and fruits with tough skins or membranes; ordered for patients who have chewing problems or mild GI problems; used as a transition diet from liquids to regular
Soft/low-residue	Addition of low-fiber, easily digested foods such as pastas, casseroles, moist tender meats, and canned cooked fruits and vegetables; includes foods that are easy to chew and simply cooked; does not permit fatty, rich, and fried foods; is sometimes referred to as <i>low fiber</i>
High-fiber	Addition of fresh uncooked fruits, steamed vegetables, bran, oatmeal and dried fruits; includes sufficient amounts of indigestible carbohydrates to relieve constipation, increase GI motility, and increase stool weight
Regular or diet as tolerated	No restrictions; permits patient preferences and allows for postoperative diet progression
Sample Therapeutic Diets	
Restricted fluids	Required in severe heart failure or kidney failure
Sodium-restricted	Allows low levels of sodium and may include a 4-g (no added salt), 2-g (moderate), 1-g (strict), or 500-mg (very strict) diet; may be ordered for patients with heart failure, renal failure, cirrhosis, or hypertension
Fat-modified	Low total and saturated fat and low cholesterol intake limited to less than 300 mg daily, and fat intake 30% to 35%; eliminates or reduces fatty foods for hypercholesterolemia, malabsorption disorders, and diarrhea
Diabetic	Essential treatment for patients with diabetes mellitus; provide patient with a diet recommended by the American Diabetes Association, which allows for patients to select set amount of food from basic food groups.

Grodner M et al: *Foundations and clinical applications of nutrition: a nursing approach*, ed 4, St Louis, 2012, Mosby. GI, Gastrointestinal.

STEP**RATIONALE****ASSESSMENT**

- | | |
|---|--|
| 1 Assess patient's knowledge of procedure. | Encourages cooperation, minimizes risks and anxiety. Identifies teaching needs. |
| 2 Assess if patient passes flatus and is without nausea. Auscultate bowel sounds. | Determines if gastrointestinal tract is functioning normally (see Chapter 6). |
| 3 Review health care provider's diet order. | Awareness of specific diet order ensures that patient gets appropriate meal tray. |
| 4 Assess presence and condition of teeth. Determine if dentures are poorly fitted. | Absence of teeth and ill-fitting dentures inhibit normal chewing and preparation of food for safe swallowing. This places patient at risk for dysphagia (Kyle, 2011) (see Skill 30-3). |
| 5 Assess a neurologic patient's cranial nerve function. Assess cranial nerves V, VII, IX, and X (see Chapter 6). | Intact cranial nerves are necessary for safe swallowing. As a chronic neurologic disease progresses, cranial nerves become damaged, leading to dysphagia (Remig and Weeden, 2012). |
| 6 Determine to what extent patient is able to self-feed. Assess physical motor skills (e.g., ability to grasp utensils, hold cup and move to mouth). Evaluate level of consciousness, visual acuity and peripheral vision, and mood. | Patients with any level of independence should be encouraged to feed self as much as possible. Thorough understanding of patient's physical and cognitive limitations alerts you to type of assistance patient needs. Visual impairments make it difficult to see food and utensils (Chang and Roberts, 2011). |
| 7 Assess patient's appetite, tolerance of foods, recent fluid intake, cultural and religious preferences, and food likes and dislikes. | Determines type of foods and size of meals that can potentially improve oral intake. |
| 8 Assess patient's ability to swallow (see Skill 30-3). | Determines aspiration risk, influencing food selection. |

STEP

RATIONALE

NURSING DIAGNOSES

- Feeding self-care deficit
- Impaired swallowing
- Risk for aspiration
- Risk for deficient fluid volume
- Risk for imbalanced nutrition less than body requirements

Related factors are individualized based on patient's condition or needs.

PLANNING

- Expected outcomes following completion of procedure:
 - Patient's weight is maintained or trends toward desired level.
 - Patient's nutrition-related laboratory values trend toward normal.
 - Patient demonstrates increased ability to self-feed or open items on tray as appropriate.
 - Patient coughs appropriately with no indication of respiratory compromise.

Nutritional intake meets daily needs.
 Biochemical markers along with nutritional assessment indicate nutritional status.
 Indicates increased strength, improved mental status, and increased well-being.
 Ineffective cough and respiratory compromise are indicators of dysphagia and aspiration.

IMPLEMENTATION

- Prepare patient's room for mealtime.
 - Perform hand hygiene. Clear over-bed table.
 - Help patient to comfortable sitting position in chair or place bed in high-Fowler's position. If patient is unable to sit, turn him or her on side with head of bed elevated.
- Prepare patient for meal.
 - Help patient with pain relief and elimination needs and help him or her perform hand hygiene before meals.
 - Help patient put in dentures and put on eyeglasses or insert contact lenses if used.
- Ask in which order patient would like to eat his or her meal. Ask about desired seasonings. Help patient to cut food in bite size pieces if unable to do independently.
- Use adaptive eating and drinking aids as needed according to your assessment (e.g., two-handed cup with lid, plate with plate guard, utensils with splints, utensils with enlarged handles) (see illustration).
- Identify food placement for disoriented, visually impaired, or easily fatigued patients by locating on plate as if plate were a clock (see illustration).

Reduces transmission of microorganisms and prepares room for food tray.
 Upright position facilitates swallowing, reducing aspiration risk. Conditions such as pressure ulcer, traction, or spinal surgery prevent positioning with head elevated.

Increases patient's comfort and enjoyment of meal, which helps increase patient's nutritional intake.
 Enhances patient's ability to see, bite, chew, and swallow food.

Allows patient more independence and control. Small pieces are easier to chew and minimize risk for aspiration.

Eating and drinking aids help to place, direct, and control food bolus (saliva-softened mass of chewed food) and liquid and to maintain proper head posture while eating (Ney et al., 2009).

Helps patient locate food items; may be able to feed self if given adequate information about food placement on tray.

STEP 4 Mealtime equipment. *Clockwise from upper left:* Two-handed cup with lid, plate with plate guard, utensils with splints, and utensils with enlarged handles.

STEP 5 Clock setup to prepare food on a plate for the visually impaired patient.

STEP

RATIONALE

<p>6 Feed patient in manner that facilitates chewing and swallowing.</p> <p>a <i>Older adult:</i> Feed small amounts at a time, observing biting, chewing, swallowing, and fatigue between bites; be sure that patient has swallowed food.</p>	<p>Chewing and sitting up for feeding accelerates onset of fatigue (Ebersole et al., 2008).</p>
<p>Clinical Decision Point <i>If you suspect that patient is aspirating, stop feeding immediately and suction airway (see Skill 30-3).</i></p>	
<p>b <i>Neurologically impaired patient:</i> Feed small amounts at a time and assess for ability to chew, manipulate tongue to form bolus, and swallow. Check for food left inside cheeks (pocketing).</p> <p>7 Provide fluids as requested. Encourage patients not to drink all liquid at beginning of meal.</p> <p>8 Talk with patient during meal.</p> <p>9 Use meal as opportunity to educate patient (e.g., topics related to nutrition, postoperative exercises, discharge plans).</p> <p>10 Help patient with hand hygiene and performing mouth care.</p> <p>11 Help patient to resting position, leave head elevated 30-45 degrees for 30-60 minutes after meal.</p> <p>12 Return patient's tray to appropriate place and perform hand hygiene.</p>	<p>Some patients with limited tongue strength and control are unable to move food to back of mouth for swallowing. Checking for "pocketed" food in mouth prevents aspiration (Remig and Weeden, 2012).</p> <p>Helps with swallowing. Prevents patient from filling up on liquids.</p> <p>Meal should be a pleasant event. Conversation promotes socialization. Involve family if possible.</p> <p>Education can occur whenever nurse and patient are together.</p> <p>Maintains comfort.</p> <p>Patient may feel tired after full meal. Elevation of head reduces risk for aspiration.</p> <p>Reduces spread of microorganisms.</p>

EVALUATION

<p>1 Monitor body weight daily or weekly.</p> <p>2 Monitor laboratory values as indicated.</p> <p>3 Monitor intake and output (I&O) (see Chapter 6) and percentage of food on tray after meal.</p> <p>4 Observe patient's ability to self-feed, including ability to feed certain items, part, or all of meal.</p> <p>5 Observe patient for choking, coughing, gagging, or food left in mouth during eating.</p>	<p>Determines nutritional status.</p> <p>Biochemical markers such as albumin and prealbumin aid in identifying changes in nutritional status.</p> <p>Helps to determine what assistance patient needs with feeding.</p> <p>Indicates dysphagia and possible aspiration.</p>
---	---

Unexpected Outcomes

- 1 Patient is unable to eat entire meal or refuses to eat.
- 2 Patient chokes on food.

Related Interventions

- Determine why patient is unable to finish meal (e.g., inadequate personnel for feeding assistance, ingestion of large volume of liquids immediately before meal). Also clarify if patient has food preferences, culture influences, or religious restrictions.
- Determine if patient is in pain or nauseated or if he or she has constipation.
- Perform oral assessment; provide oral care as needed.
- If inability to eat meal is a repeated problem, collaborate with health care provider and RD.
- Stop feeding immediately; place on side with head pointing down, suction food and secretions from mouth and airway.
- Contact health care provider if choking occurs repeatedly.
- Suggest appropriate referrals (e.g., speech-language pathologist, RD) (see Skill 30-3).

Recording and Reporting

- Document in patient's chart tolerance of diet and amount eaten. Record percentage of the meal eaten by the patient (e.g., 25% of food consumed at breakfast).
- If patient is on calorie counts, record caloric intake on appropriate form; if evaluating I&O, record fluid intake on appropriate form.
- If patient is receiving oral nutritional supplements (e.g., Ensure, Boost), record the amount taken and communicate patient

tolerance (likes or dislikes, supplements to fill or replace meals) to the health care team.

- Report any swallowing difficulties, food dislikes, refusal to eat.

Special Considerations

Teaching

- Discuss dietary concerns of patient's illness. Explain why specific foods are not included in a meal or why only limited amounts are allowed (Grodner et al., 2012).

- Instruct patient and family to maintain a balanced diet and monitor intake of fluids and percent or amount of meals and snacks consumed. If intake falls below 75% for any length of time, refer patient to an RD for medical nutrition therapy.
- Teach family caregivers techniques to safely help patient in feeding. Have family encourage patient to do as much as possible to feed self.

Pediatric

- Human milk is the most desirable complete diet for infants during the first 6 months. Infants who are breastfed or bottle-fed do not require additional fluids, especially water or juice, during the first 4 months of life. Excessive intake of water causes water intoxication, failure to thrive, and hyponatremia. Typically infants do not consume solid foods until 6 months of age. Iron-fortified infant cereal is usually the first solid food to offer. A common sequence for introducing solid food is one new food every 5 to 7 days. Strained fruits followed by vegetables and

finally meats is the usual pattern (Hockenberry and Wilson, 2011).

- Do not mix solid foods in a bottle and feed through a nipple with a larger hole (Hockenberry and Wilson, 2011).

Gerontologic

- Some older adults have diminished appetite because of loss of taste and smell and decreased number of taste buds (Chang and Roberts, 2011).
- Interactions between nutrients and medications affect taste of foods or metabolism, absorption, digestion, or excretion of drugs.

Home Care

- Assess financial resources of patient and family to determine if they are able to purchase nutritionally complete foods for patient.
- Help patient and family identify ways to make meals in the home pleasant and enjoyable experiences.

SKILL 30-3 Aspiration Precautions

Video Clip

The ability to swallow effectively and safely is a basic human need. Safe transport of food and fluid through the mouth, pharynx, and esophagus to the stomach requires a complex and fine coordination of cranial nerves and the muscles of the tongue, pharynx, larynx, and jaw. Any alteration or delay in the swallowing process causes dysphagia (difficulty swallowing). People with dysphagia have difficulty holding food and fluid in their mouths or experience difficulty in the movement of food and fluids into the esophagus (Nazarko, 2009). Dysphagia can occur at any age, but is most common in the elderly because the likelihood of diseases associated with swallowing alterations increases with age (Garcia and Chambers, 2010; Palmer and Metheny, 2008). Approximately 40% of individuals older than age 60 experience dysphagia (Ney et al., 2009).

Almost any condition that produces general muscle weakness or any condition associated with neurologic impairment of the swallowing mechanism and altered mental status places patients at risk for dysphagia (e.g., brain injury, stroke) (Leder et al., 2011; Thomas, 2008) (Box 30-4). These patients may also have altered swallowing reflexes such as difficulty knowing what to do when food is placed in the mouth and holding food in the mouth for prolonged periods (Brady, 2008).

Be aware that patients without primary neurologic diagnoses such as myocardial infarction (heart attack), pneumonia, and chronic obstructive pulmonary disease are also at risk for dysphagia (DeFabrizio and Rajappa, 2010; Garon, et al., 2009). Structural obstructions and medication side effects cause difficulty swallowing (DeFabrizio and Rajappa, 2010; Ney et al., 2009). Symptoms of dysphagia vary, depending on the swallowing alteration (Garcia and Chambers, 2010). You should suspect dysphagia if a patient has frequent drooling, loss of food from the mouth during eating, pocketing food (holding food in the cheek), and spitting pieces of food out. In addition, a patient might experience choking or coughing during or following meals and a gurgling or wet-sounding voice quality (Brady, 2008; Kyle, 2011). He or she may complain about the sensation of food sticking in his or her throat or make multiple attempts to swallow.

Inability to coordinate the complex, sequential swallowing mechanism slows eating, results in food being left in the mouth, and may lead to failure to adequately protect the airway (Thomas, 2008). Gastric material and secretions in the mouth and pharynx and pathogenic bacteria enter the trachea and lungs (Eisenstadt, 2010). The aspirated material may be food, water, vomitus, or oral contents. Aspiration pneumonia can be a fatal complication of dysphagia, especially in older adults (Garcia and Chambers, 2010;

BOX 30-4 Causes of Dysphagia

Neurogenic

Stroke
Cerebral palsy
Guillain-Barré syndrome
Multiple sclerosis
Amyotrophic lateral sclerosis (Lou Gehrig's disease)
Diabetic neuropathy
Parkinson's disease

Myogenic

Myasthenia gravis
Aging
Muscular dystrophy
Polymyositis

Obstructive

Benign peptic stricture
Lower esophageal ring
Candidiasis
Head and neck cancer
Inflammatory masses
Trauma/surgical resection
Anterior mediastinal masses
Cervical spondylosis

Other

Gastrointestinal or esophageal resection
Rheumatologic disorders
Connective tissue disorders
Vagotomy

Lewis et al., 2011). Tachypnea (respirations above 26) is an early clue of aspiration (Eisenstadt, 2010). Other signs include cough; dyspnea (trouble breathing); decreased breath sounds; and abnormal breath sounds such as wheezing, rales, and rhonchi (see Chapter 6). A wet-sounding vocal quality is a clinical indicator that the patient may be silently aspirating saliva (Brady, 2008).

Silent or asymptomatic aspiration refers to passage of foods or liquids into the trachea and lungs without producing a productive cough or other signs consistent with aspiration (Garon et al., 2009). The condition often results from sensory damage to the pharynx and muscle weakness in the throat and mouth that produces a lack of protective cough reflex (Garon et al., 2009). Lack of outward signs such as coughing reduces awareness by the patient, family, and health team members that aspiration is occurring. This can result in longer periods of ingestion of food and liquids into the lungs and places the patient in a higher-risk group for the development of pneumonia (Garon et al., 2009). The more subtle signs associated with silent aspiration are easy to miss and include lack of speech, depressed alertness, wet quality to voice, drooling, difficulty controlling secretions, and absence of gag reflex.

Dysphagia Evaluation

The goal of dysphagia evaluation and management is to ensure that a patient will be able to swallow oral fluids and food safely (Brady, 2008). You are in close contact with patients and are in a key position to identify swallowing difficulties and make referrals to appropriate health care professionals as needed. When your assessment shows that a patient is at risk for dysphagia and aspiration, referral for a more comprehensive examination is necessary (Box 30-5). At-risk patients must be assumed to have difficulty swallowing and

be at risk for choking and aspiration. (Hollin, 2011; Tanner, 2010). The single most important measure to prevent aspiration is to place the patient on NPO until a swallowing evaluation determines that dysphagia poses no substantial risk (Tanner, 2010). Any patient who is at risk for aspiration needs to be formally referred for a dysphagia evaluation by a speech-language pathologist (SLP). Early screening and intervention are crucial in the prevention of aspiration and pneumonia (Hines et al., 2011). The Joint Commission mandates that patients admitted with a stroke diagnosis be screened before they can ingest an oral diet (TJC, 2012). Use simple orientation questions and single-step commands to determine the potential for both aspiration and safe oral intake before dysphagia screening (Leder et al., 2009). Dysphagia screening is a minimally invasive evaluation procedure that initially documents the likelihood that dysphagia is present, the need for further swallowing assessment, and the safety of patient intake.

Bedside screening for dysphagia includes giving patient water or foods with different textures and observing for coughing, gagging, choking, and voice alteration. Individuals who have a weak spontaneous cough are not able to ingest water without clinical signs of aspiration (Garon et al., 2009; Marques et al., 2008). However, bedside assessment is not sufficient for evaluating the frequency of silent aspiration because it does not have specific symptoms (Garon et al., 2009; Nam-Jong Paik, 2011; Thomas, 2008). Recommendations include accompanying fluid administration with pulse oximetry measurement. Normal oxygen saturation (SpO₂) is greater than 95%. A drop in oxygen saturation greater than or equal to 2% is used to determine aspiration (Bours et al., 2009; Marques et al., 2008; Weinhardt, 2008).

Dysphagia Management

Dysphagia management includes dietary modification by altering the consistency of foods and liquids and is most effective when implemented using a multidisciplinary approach (Garcia and Chambers, 2010). The SLP and registered dietitian (RD) are central to dysphagia management. An SLP specializes in swallowing disorders and makes treatment recommendations to the health care provider that may include texture modifications for food and liquids. The RD ensures that recommendations are balanced with the nutritional and caloric needs of patients. Appropriate food choices and consistency of liquids are individualized and based on which phase of swallowing is dysfunctional (Bottino-Bravo and Thomas, 2008). Changes in food and/or liquid consistencies, elimination of oral intake, and initiation of tube feedings are common diet modifications.

In October 2002 the American Dietetic Association published the National Dysphagia Diet. The diet standards provide guidelines and standard terminology for food and texture modifications. The diet comprises four levels: dysphagia puree, dysphagia mechanically altered, dysphagia advanced, and regular (Table 30-4). There are also four levels of liquid consistencies used simultaneously with diet modification. These include thin liquids (low viscosity) such as water, coffee, tea and anything that liquefies in the mouth at room temperature. Swallowing thin liquids requires the most coordination and control (Remig and Weeden, 2012). Thin liquids create safety risks in swallowing because of their speed and decreased texture for patients with impaired oral motor control (Garcia et al., 2010).

Thickened liquids are commonly prescribed to prevent aspiration pneumonia (Frey and Ramsberger, 2011). Nectarlike liquids (medium viscosity) are liquids such as peach or apricot nectar that are thickened but drip off a spoon at a slower rate than thin liquids. Honeylike liquids (high viscosity) are thickened so the liquid drips

BOX 30-5 Criteria for Dysphagia Referral

Before Referral:

If the answer is yes to either of the following two questions, referral at this time is not appropriate.

- Is patient unconscious or drowsy?
- Is patient unable to sit in an upright position for a reasonable length of time?

Please Consider the Next Two Questions Before Making the Referral:

- Is the patient near the end of life?
- Does the patient have an esophageal problem that will require surgical intervention?

When Observing the Patient or Giving Mouth Care, Look for the Following:

- Open mouth (weak lip closure)
- Drooling liquids or solids
- Poor oral hygiene/thrush
- Facial weakness
- Tongue weakness
- Difficulty with secretions
- Slurred, indistinct speech
- Change in voice quality
- Poor posture or head control
- Weak involuntary cough
- Delayed cough (up to 2 minutes after swallow)
- General frailty
- Confusion/dementia
- No spontaneous swallowing movements

If any of the above is present, the patient may have swallowing problems and need referral to a speech-language pathologist.

TABLE 30-4 National Dysphagia Diet Stages

Stage	Description	Examples
NDD 1: Dysphagia pureed	Uniform, pureed, cohesive, pudding-like texture	Smooth hot cereals cooked to a “pudding” consistency; mashed potatoes; pureed meat and vegetables; pureed pasta on rice; yogurt
NDD 2: Dysphagia mechanically altered	Moist, soft textured. Easily forms a bolus	Cooked cereals; dry cereals moistened with milk; canned fruit (except pineapple); moist ground meat; well-cooked noodles in sauce/gravy; well cooked, diced vegetables
NDD 3: Dysphagia advanced	Regular foods (except very hard, sticky, or crunchy foods)	Moist breads (e.g., butter, jelly); well-moistened cereals, peeled soft fruits (peach, plum, kiwi); tender, thin-sliced meats; baked potato (without skin); tender, cooked vegetables
Regular	All foods	No restrictions

Modified from National Dysphagia Task Force (NDDTF): *National dysphagia diet: standardization for optimal care*, Chicago, 2002, American Dietetic Association.

off a spoon at a much slower rate. A thickening agent alters flavor and texture qualities (Garcia et al., 2010). There are often complaints about their taste and thickness, which increase nonadherence (Brady, 2008; Frey and Ramsberger, 2011). There are spoon-thick viscosity liquids that include foods that do not easily drip off a spoon. It is important to remember that the desired thickness of a liquid depends on the patient’s swallowing deficit. Always read the label directions when modifying liquids to prepare the desired thickness (Garcia et al., 2010). If a patient’s diagnostic tests reveal aspiration with all food and liquid consistencies, intravenous fluids (parenteral nutrition) (see Chapter 32) may be initiated short term to maintain hydration (see Chapter 28) until alternatives for oral nutrition are discussed and accepted by the patient for nutritional support. Enteral nutrition (tube feeding) is used for long-term nutritional support (see Chapter 31).

Consequences Of Dysphagia

Physiologic consequences of dysphagia include decreased appetite, weight loss, dehydration, malnutrition, and pneumonia (DeFrabrizio and Rajappa, 2010; Garcia and Chambers, 2010). Dietary intake may be affected for long periods of time; and the malnutrition that occurs is secondary to insufficient protein, calorie, and micronutrient intake (Meiner, 2011). Dysphagia may affect a patient’s quality of life. Understand the emotional impact of losing the ability to eat and drink safely. A patient’s normal nutritional intake is altered because he or she either is unable to consume oral nutrition or has to make diet modifications to swallow without risk of aspiration. Emotional responses may include altered body image,

embarrassment, social isolation, and depression (DeFrabrizio and Rajappa, 2010). In addition, a patient may feel as though he or she is a burden to family members or caregivers (DeFrabrizio and Rajappa, 2010).

Delegation and Collaboration

The assessment of a patient’s risk for aspiration and determination of positioning cannot be delegated to nursing assistive personnel (NAP). However, NAP may feed patients after receiving instruction on aspiration precautions. The nurse directs the NAP to:

- Position patient upright or according to medical restrictions during and after feeding.
- Use aspiration precautions while feeding patients who need assistance.
- Immediately report any onset of coughing, gagging, or a wet voice or pocketing of food.

Equipment

- Upright chair or bed in high-Fowler’s position
- Thickening agents as designated by SLP (rice, cereal, yogurt, gelatin, commercial thickener)
- Tongue blade
- Penlight
- Oral hygiene supplies (see Chapter 17)
- Pulse oximeter
- Suction equipment (see Chapter 25)
- Clean gloves

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient’s knowledge of aspiration risks.
- 2 Perform a nutritional assessment (see Skill 30-1).
- 3 Assess mental status, including alertness, orientation, and ability to follow simple commands (e.g., open your mouth; stick out your tongue).
- 4 Determine if patient has an increased risk for aspiration and assess for signs and symptoms of dysphagia (see Box 30-4). Use dysphagia screening tool if available.
- 5 Assess patient’s oral health. Check level of dental hygiene, missing teeth or poorly fitting dentures (apply clean gloves if needed).

Encourages cooperation, minimizes anxiety. Identifies teaching needs.

Patients with dysphagia alter their eating patterns or choose foods that do not provide adequate nutrition (White et al., 2008).

If orientation and command-following are impaired, there is a higher risk of aspiration than with patients who are oriented and can follow commands (Leder et al., 2009).

Performing an assessment before feeding determines when referral to SLP is necessary. Interventions to minimize aspiration and possible pneumonia can be implemented.

Poor oral hygiene can result in decayed teeth, plaque, and periodontal disease and cause growth of bacteria in the mouth, which can be aspirated (Eisenstadt, 2010).

STEP	RATIONALE
6 Observe patient during mealtime for signs of dysphagia such as coughing, dyspnea, or drooling. Note during and at end of meal if patient tires.	Indicates swallowing impairment and possible aspiration. Chewing and sitting up for feeding accelerate onset of fatigue (Meiner, 2011). Fatigue increases risk for aspiration (White et al., 2008).

NURSING DIAGNOSES

- Impaired swallowing
- Risk for aspiration

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient does not exhibit signs or symptoms of aspiration. • Patient maintains stable weight. | Interventions for preventing aspiration are successful. Patient is able to maintain adequate oral nutrition. |
|--|--|

IMPLEMENTATION

- | | |
|---|--|
| 1 Perform hand hygiene. | Prevents transmission of microorganisms. |
| 2 Indicate on patient's chart and Kardex that dysphagia/aspiration risk is present. <i>Option:</i> Some agencies use different-colored meal trays to signify patients at risk for aspiration. | Identifying patient as dysphagic reduces risk that he or she will receive oral nutrition without supervision. |
| 3 Apply pulse oximeter to patient's finger during feeding. | A decrease in oxygen saturation may indicate aspiration (Weinhardt, 2008). |
| 4 Position patient in an upright (90 degrees) or highest position allowed by medical condition during mealtimes. | Uses gravity to facilitate safe swallowing and enhances esophageal motility (Grodner et al., 2012; Ney et al., 2009). Side-lying position is an option if patient cannot have head elevated. |
| 5 Using penlight and tongue blade, gently inspect mouth for pockets of food. | Pockets of food found inside cheeks occur when patient has difficulty moving food from mouth into pharynx; may lead to aspiration (Remig and Weeden, 2012). Patient is usually unaware of pocketing (Chang and Roberts, 2011). |
| 6 Have patient assume chin-tuck position. | Chin-tuck or chin-down position helps reduce aspiration by positioning epiglottis in more forward position, allowing for airway protection during swallowing (Brady, 2008). Position also slows movement of food and liquid through mouth and pharynx, minimizing risk of aspiration (Ney et al., 2009). |
| a Have patient swallow twice or repeatedly and monitor swallowing and for any respiratory difficulty. | Double- or repeat-swallowing requires patient to use additional swallows to help clear any remaining food from an unprotected airway (Garcia and Chambers, 2010). |
| 7 Add thickener to thin liquids to create desired consistency per SLP evaluation. | Increasing viscosity or thickness of liquid slows movement through mouth and pharynx and protects airway (Brady, 2008). |
| 8 Encourage patient to feed himself or herself. | Promotes independence and may help patient to initiate more natural swallow (Brady, 2008). |
| 9 Tell patient not to tilt head backward when eating or while drinking out of a glass or cup. | Backward head tilt extends neck; thus food and liquid are more likely to be misdirected into airway (Ney et al., 2009). |
| 10 If patient is unable to feed self, place ½ to 1 teaspoon of food on unaffected side of mouth, allowing utensils to touch mouth or tongue. | Small bites help patient's ability to swallow (Grodner et al., 2012). Provides tactile cue to begin eating; avoids pocketing of food on weaker side, which may increase risk of aspiration (Brady, 2008). |
| 11 Provide verbal cues while feeding. Remind patient to chew and think about swallowing. | Helps to elicit normal swallow and prevent aspiration (Brady, 2008). |
| 12 Avoid mixing food of different textures in same mouthful. Alternate liquids and bites of food. | Single textures are easier to swallow than multiple textures. Alternating solids with liquids helps to remove food residue in mouth (Ney et al., 2009). |
| 13 Minimize distractions and do not rush patient. Allow time for adequate chewing and swallowing. | Environmental distractions and conversations during mealtime increase risk for aspiration (Chang and Roberts, 2011). |
| 14 Use sauces, condiments, and gravies to facilitate cohesive food bolus formation. | Cohesive food bolus helps to prevent pocketing or small food particles from entering the airway (Ney et al., 2009). |
| 15 Report signs and symptoms of dysphagia or aspiration to health care provider. | Communication with members of health care team regarding high-risk patients may prevent adverse outcomes in dysphagic patients (Tanner, 2010). |
| | Identifies need to have an assessment performed by radiologist or SLP (White et al., 2008). |

STEP	RATIONALE
16 Ask patient to remain sitting upright for at least 30 to 60 minutes after meals.	Remaining upright after meals or snack reduces chance of aspiration by allowing food particles remaining in pharynx to clear (Frey and Ramsberger, 2011).
17 Provide thorough oral hygiene after meals (see Chapter 17).	Oral hygiene reduces plaque and secretions containing bacteria that can cause pneumonia, especially in patients with decreased immunity (Eisenstadt, 2010; Frey and Ramsberger, 2011).
18 Perform hand hygiene.	Reduces spread of microorganisms

EVALUATION

1 Continually evaluate at-risk patient's ability to cough and manage oral secretions. Also monitor ability to swallow food and fluids of different textures and viscosities without choking.	Indicates improvement with swallowing and absence of signs related to aspiration (DeFabrizio and Rajappa, 2010). Ability to swallow can improve or deteriorate (Nazarko, 2009).
2 Weigh patient daily or weekly.	Determines if weight is stable and reflects nutritional status.
3 Monitor patient's intake and output (I&O), calorie count, and food intake.	Aids in detection of malnutrition and dehydration resulting from dysphagia.
4 Monitor pulse oximetry readings for high-risk patients when eating.	Deteriorating oxygen saturation levels indicate aspiration.

Unexpected Outcomes

- 1 Patient coughs, gags, complains of food "stuck in throat," and has wet quality to voice when eating.
- 2 Patient experiences weight loss.

Related Interventions

- Stop feeding immediately and place patient on NPO. Notify health care provider and suction as needed.
- Anticipate consultation with SLP for swallowing exercises and techniques to improve swallowing.
- Consult with health care provider and RD about increasing frequency of meals or providing oral nutritional supplements or alternative feeding methods such as tube feedings.

Recording and Reporting

- Document in patient's medical record assessment findings, patient's tolerance of liquids and food textures, amount of assistance required, position during meal, absence or presence of any symptoms of dysphagia during feeding fluid intake, and amount eaten.
- Report any coughing, gagging, choking, or swallowing difficulties to health care provider.

Special Considerations

Pediatric

- Monitor growth, hydration, and nutritional status in children with dysphagia (Hollin, 2011).
- Families and caregivers caring for children with dysphagia require support, information, reassurance, and appreciation for their efforts (Hollin, 2011).
- Be aware that silent aspiration has been reported in children with dysphagia before, during, and after swallowing (Hollin, 2011).

Gerontologic

- The risk for aspiration pneumonia is higher in older adults because of an increased incidence of dysphagia and gastroesophageal reflux (Meiner, 2011; White et al., 2008).
- Malnutrition occurs rapidly in older adults with dysphagia. Enteral feedings are sometimes necessary, but there is still a risk for aspiration (Meiner, 2011).

Home Care

- Educate patient and family caregivers about aspiration precautions used to prevent pneumonia (Bottino-Bravo and Thomas, 2008).
- Determine patient's and family caregiver's knowledge of appropriate food choices, strategies to increase caloric intake, and food and liquid texture modifications.
- Dysphagia in home care is best managed with a multidisciplinary approach that includes patient, family caregivers, health care provider, nurse occupational therapist, and speech therapist (Bottino-Bravo and Thomas, 2008).

Critical Thinking Exercises

Mr. Jasper is a 73-year-old patient with Alzheimer's disease. He is receiving medication that leaves him with a dry mouth. Results of a nutritional screening indicate difficulty swallowing. Symptoms include frequent coughing during the meal. The speech-language pathologist (SLP) recommended a dysphagia mechanically altered diet with thickened liquids. He currently weighs 138 lbs (62.7 kg) and is 180 cm (6 feet) tall. His daughter visits frequently. Although he can feed himself, she usually feeds him during scheduled mealtimes in the busy dining room. She frequently gives him sips of her coffee and bites of his favorite oatmeal cookies. The daughter encourages him to bend his head backward to make sure that he drinks all of the liquids in a cup or glass.

- 1 Determine Mr. Jasper's body mass index (BMI) and rate his nutritional status.
- 2 Develop a teaching plan related to decreasing Mr. Jasper's aspiration risk. Include rationales for your actions.
- 3 The SLP recommends a soft/low-residue diet. Identify three foods to include.

REVIEW QUESTIONS

- 1 An older adult is admitted to the hospital, where the Mini Nutritional Assessment (MNA) is done and a score of 19 is obtained. Which priority measure should be included in this patient's care?
 - 1 Evaluation of potential interactions between drugs and foods consumed
 - 2 Having the registered dietitian talk with the patient about which foods could be eaten more easily
 - 3 Obtaining a weight every day at the same time and on the same scale
 - 4 Assessing what the patient understands related to nutritional health
- 2 The nurse is feeding a patient at risk for aspiration. The patient's oxygenation status is being monitored by pulse oximetry. Before feeding, oxygenation level is 95%. The nurse suspects that the patient may be silently aspirating. The pulse oximetry reading would be: _____. (Fill in the blank.)
- 3 Which of the following should not be delegated by the nurse to nursing assistive personnel (NAP)?
 - 1 Nutritional screening
 - 2 Aspiration precautions
 - 3 Feeding
 - 4 Pulse oximetry
- 4 Which statement made by a patient during a nutritional assessment requires follow-up by the nurse?
 - 1 "My weight changed from 195 to 185 in 1 month."
 - 2 "I've increased my intake of fruits and vegetables."
 - 3 "I'm trying to exercise, but I don't have the time."
 - 4 "I try to eat 3 meals a day."
- 5 A patient is unable to eat more than 25% of any meal because of pain and nausea. Which of the following interventions would be most important for the nurse to perform?
 - 1 Encourage the patient to eat small amounts several times during the day
 - 2 Ask the patient which foods and beverages cause the least amount of nausea
 - 3 Record a chronology of what the patient has been eating for the past 2 days
 - 4 Determine strategies to decrease the pain and nausea
- 6 The nurse performs a physical assessment on a newly admitted patient and notes a diminished gag reflex. The health care provider has written an order for the patient to have a full liquid diet ordered. What is the most appropriate nursing action?
 - 1 Place the patient on NPO status
 - 2 Observe the patient while eating
 - 3 Elevate the head of patient's bed to prepare him or her for the meal
 - 4 Change the diet order to clear liquids to see how the patient tolerates the fluids
- 7 Which of the following foods is the safest for the patient with dysphagia?
 - 1 Applesauce
 - 2 Shredded wheat and milk
 - 3 Jell-O
 - 4 Orange sherbet
- 8 Which finding assessed on physical examination of an adult patient is a potential indicator of malnutrition?
 - 1 Pink, spongy gums
 - 2 Soft and toned muscles
 - 3 Shiny, sparse hair
 - 4 Smooth and swollen tongue
- 9 Which statement made by a patient receiving a clear liquid diet indicates a need for further teaching?
 - 1 "I'll order ice tea for lunch."
 - 2 "I drank my coffee with cream and sweetener."
 - 3 "I really want grape popsicles with each meal."
 - 4 "I really like beef bouillon with lunch."
- 10 The nurse is caring for a patient who is of the Orthodox Jewish faith. In keeping with their religious practices, the patient will not eat:
 - 1 Duck.
 - 2 Shrimp.
 - 3 Ham.
 - 4 Hamburger.

KEY TERMS

Enteral nutrition	Jejunostomy feeding tube	Nasogastric (NG) feeding tube	Pulmonary aspiration
Gastrostomy feeding tube			Residual volume

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Assess patients who are to receive enteral tube feedings.
- Demonstrate the ability to correctly insert a small-bore feeding tube.
- Discuss the rationale for methods to determine nasogastric or nasoenteric feeding tube placement.
- Discuss the reasons for risks for pulmonary complications during the insertion and maintenance of a feeding tube.
- Demonstrate the appropriate technique for irrigating a feeding tube.
- Demonstrate three appropriate techniques for administering enteral formulas.
- Evaluate a patient's tolerance of enteral feeding.

Enteral nutrition, commonly called *tube feeding*, refers to the delivery of nutritional formulas through a tube that has been placed into the gastrointestinal (GI) tract. Candidates for tube feeding include patients who have adequate digestion and absorption but cannot ingest, chew, or swallow food safely or in adequate amounts. A tube feeding is administered into the stomach or small intestine. The selection of the type of tube and placement method depends on the anticipated duration of feeding and other patient-related factors such as gastric emptying and risk for pulmonary aspiration, the most serious complication of tube feeding. For short-term feeding nasal or oral feeding tubes are appropriate. Terms used to describe these types of tubes include *nasogastric (NG)*, *orogastric (OG)*, and *nasoenteric*. When the duration of tube feeding extends beyond 4 weeks or in situations in which access to the GI tract through the nose or mouth is contraindicated, direct enteral access through the abdominal wall is the optimal choice. The

stomach (gastrostomy tube) and jejunum (jejunostomy tube) are the usual sites for long-term feeding tubes.

Besides inserting a tube, nursing responsibilities include verifying and maintaining proper position of a tube, keeping it patent, administering the nutrient formula, and preventing complications. A nurse, dietitian, and health care provider collaborate to select an enteral feeding formula based on a patient's protein and calorie requirements and digestive ability. Liquid formulas in the United States are sterile and lactose free. Disease-specific formulas are available, but research does not always support their efficacy (Chen and Peterson, 2009).

EVIDENCE-BASED PRACTICE

Safe and effective enteral nutrition depends on knowledgeable nurses and high-quality nursing care. A multidisciplinary approach with adherence to evidence-based protocols or

algorithms enhances the quality and safety of enteral nutrition (Bankhead et al., 2009; Kenny and Goodman, 2010). Follow these evidence-based guidelines to ensure correct placement of enteral feeding tubes:

- NG feeding tubes are often inserted at the bedside, without technologic assistance, in a procedure commonly referred to as *blind* placement. More sophisticated aids such as fluoroscopy or electromagnetic tracking may be required to successfully direct a tube into the small bowel (Bankhead et al., 2009).
- The most serious complication of NG tube insertion is inadvertent pulmonary intubation. Researchers estimate that 1% to 2% of NG tubes placed blindly enter the airway undetected, which can lead to serious pulmonary injury (Krenitsky, 2011).
- Feeding tubes are positioned into the small bowel to reduce the incidence of pulmonary aspiration of stomach contents. Research has not consistently demonstrated this benefit, but newer techniques for detecting aspiration provide some evidence that small intestine feeding does reduce the incidence of pulmonary aspiration (Metheny et al., 2011).
- Variation in the color and pH of fluid withdrawn from feeding tubes can help to differentiate tubes positioned in the stomach from those that rest in the small intestine. However, these indicators are not consistently reliable for distinguishing between placement in the GI tract and tracheobronchial system. X-ray film confirmation of correct tube placement is mandatory before enteral feeding or medication is administered through a blindly placed feeding tube (Bankhead et al., 2009).
- Carbon dioxide (CO₂) detectors can help locate the position of tubes during insertion and potentially reduce insertion-related pulmonary injury. A sensor attached to the end of the feeding tube changes color in the presence of CO₂, thus indicating that the tube may have entered the airway. However, capnography cannot accurately identify tubes that terminate in the esophagus, a situation that can lead to reflux and pulmonary aspiration of enteral formula (Bankhead et al., 2009; Munera-Seeley et al., 2008).
- Maintaining and monitoring tube location during feeding and keeping the head-of-bed elevation at a minimum of 30 degrees (preferably 45 degrees) effectively reduces aspiration and subsequent pneumonia (Kenny and Goodman, 2010).
- Measurement of gastric residual volumes (GRVs) is done routinely during tube feeding to identify risk for regurgitation and pulmonary aspiration of gastric contents. This technique involves withdrawing and measuring the contents of the stomach at regular intervals during tube feeding. Feeding is stopped when GRVs exceed a specified level; however, studies have failed to demonstrate a consistent relationship between GRV and risk of pulmonary aspiration (DeLegge, 2011; Metheny et al., 2008). Recommendations for stopping tube feeding for elevated GRVs range from 250 to 500 mL (Bankhead et al., 2009; DeLegge, 2011; Metheny et al., 2008). Researchers agree that decisions to stop tube feeding must not rely solely on GRV but should also include an assessment of a patient's clinical condition (Metheny et al., 2008).

PATIENT-CENTERED CARE

The insertion and use of a feeding tube often raises emotional and psychological concerns. A patient and family caregiver need

reassurance and encouragement throughout the insertion procedure and once the tube feeding is underway. Nursing interventions such as oral hygiene and care of the nasal passage or tube insertion site promote patient comfort during tube feeding and can reduce complications.

Although tube feeding may offer life-sustaining treatment, artificial nutrition can never replace the social and symbolic benefits of sharing meals. Many social, religious, and cultural events involve food; and patients requiring long-term tube feeding may feel a sense of loss regarding their ability to participate in life activities. Studies show that many patients associate tube feeding with low quality of life (Bozetti, 2008). In these cases a multidisciplinary team, including a speech pathologist (to evaluate the ability to swallow safely), can help patients and family caregivers use strategies to preserve or enhance quality of life. If oral intake is not contraindicated, encourage tube-fed patients to partake of food for the pleasurable sensations associated with eating. Support groups such as the Oley Foundation can serve as valuable sources of information and practical advice for patients who require long-term tube feeding.

Enteral nutrition therapy is not obligatory in cases of futile care or end-of-life situations. However, some clinical circumstances, as in cases of advanced dementia or degenerative neurologic disease, can raise ethical concerns about the role of enteral nutrition. Although a convincing body of evidence demonstrates a link between poor clinical outcomes and tube feeding in patients with progressive neurologic disease, not all patients or their family caregivers are willing to forgo nutritional support in this situation. Patients with a living will or other advance directive may specifically refuse the use of artificial feeding by tube. Decisions about whether tube feeding should be started or continued demand a multidisciplinary approach that considers cultural, spiritual, and psychological dimensions of the issue. Situations such as this require effective communication with the patients and their family caregiver, realistic goals, and respect for patient autonomy (Barocas et al., 2010).

Safety Guidelines

- 1 Be aware of factors that increase risk for complications related to feeding tube insertion: altered level of consciousness, abnormal clotting, impaired gag or cough reflex.
- 2 Know the purpose of the feeding and the intended location of the tip of the feeding tube.
- 3 Take precautions to prevent microbial contamination of enteral formulas.
- 4 Be aware of safety measures to prevent pulmonary aspiration of gastric contents and accidental tube displacement by patients.
- 5 Consult with a pharmacist regarding a patient's medications and their route of delivery to determine if administration via feeding tube is appropriate.
- 6 Be vigilant when manipulating components of enteral feeding systems for procedures such as medication administration or tube irrigation to avoid tubing misconnections with intravenous systems or other medical devices (NQF, 2011).

SKILL 31-1 Inserting and Removing a Small-Bore Nasogastric or Nasoenteric Feeding Tube

NSO Enteral Nutrition Module / Lessons 1 and 2

Throughout this chapter nasally placed feeding tubes (8 to 12 Fr) are referred to as *nasogastric (NG) tubes*; but some types of NG tubes, which are larger and more rigid, are used for gastric decompression instead of feeding (see [Chapter 34](#)). Because feeding tubes are soft and flexible, many use a removable guidewire or stylet to provide stiffness during tube insertion. Although these wires facilitate placement of a tube, they also add to the risk of pulmonary or esophageal injury during insertion. Nurses can also pass feeding tubes through the mouth, especially in critical care when the patient is also intubated or when contraindications to nasal placement such as a basilar skull fracture or facial trauma exist.

Placement of a feeding tube requires a health care provider's order. All candidates for NG or nasoenteric tube placement require an assessment of their coagulation status. Because anticoagulation and bleeding disorders pose a risk for epistaxis during nasal tube placement, the health care provider may order platelet transfusion or other corrective measures before tube insertion.

Delegation and Collaboration

The skill of feeding tube insertion cannot be delegated to nursing assistive personnel (NAP). However, NAP may help with patient positioning and comfort measures during tube insertion.

Equipment

- ❑ Small-bore NG or nasoenteric tube with or without stylet (select the smallest diameter possible to enhance patient comfort) ([Fig. 31-1](#))
- ❑ 60-mL Luer-Lok or catheter-tip syringe

- ❑ Stethoscope and pulse oximeter
- ❑ Hypoallergenic tape, semipermeable (transparent) dressing, or tube fixation device
- ❑ Tincture of benzoin or other skin barrier protectant
- ❑ pH indicator strip (scale 0.0 to 11.0)
- ❑ Cup of water and straw or ice chips (for patients able to swallow)
- ❑ Emesis basin
- ❑ Towel or disposable pad
- ❑ Facial tissues
- ❑ Clean gloves
- ❑ Suction equipment in case of aspiration
- ❑ Penlight to check placement in nasopharynx
- ❑ Tongue blade

FIG 31-1 Small-bore feeding tube. (Courtesy Kendall Brands, Mansfield, Mass.)

STEP

RATIONALE

ASSESSMENT

- 1 Verify health care provider's order for type of tube and enteric feeding schedule.
- 2 Assess patient's knowledge of procedure.
- 3 Have patient close each nostril alternately and breathe. Examine each naris for patency and skin breakdown.
- 4 Review patient's medical history (e.g., for basilar skull fracture, nasal problems, nosebleeds, facial trauma, nasal-facial surgery, deviated septum, anticoagulant therapy, coagulopathy).

Health care provider's order is needed to intubate patient with feeding tube.
 Encourages cooperation, reduces anxiety, and minimizes risks. Identifies teaching needs.
 Sometimes nares are obstructed or irritated, or a septal defect or facial fractures are present. Place tube in most patent nostril.
 History of these problems may require you to consult with health care provider to change route of nutritional support. Passage of tube intracranially can cause neurologic injury.

Clinical Decision Point *If a patient is at risk for intracranial passage of the tube, avoid the nasal route. Oral placement or placement under medical supervision using direct visualization is preferable. Insertion of a gastrostomy or jejunostomy tube is another alternative.*

- 5 Assess patient's mental status (ability to cooperate with procedure, sedation), presence of cough and gag reflex, ability to swallow, critical illness, and presence of an artificial airway.

These are risk factors for inadvertent tube placement into tracheobronchial tree ([Krenitsky, 2011](#)).

Clinical Decision Point *Recognize situations in which blind placement of a feeding tube poses an unacceptable risk for placement. Devices designed to detect pulmonary intubation such as CO₂ sensors or electromagnetic tracking devices enhance patient safety. Alternatively, to avoid insertion complications from blind placement in high-risk situations, clinicians trained in the use of visualization or imaging techniques should place tubes ([AACN, 2010](#); [Krenitsky, 2011](#)).*

- 6 Perform physical assessment of abdomen (see [Chapter 6](#)).

Absent bowel sounds, abdominal pain, tenderness, or distention may indicate medical problem contraindicating feedings.

STEP

RATIONALE

NURSING DIAGNOSES

- Imbalanced nutrition: less than body requirements
- Readiness for enhanced nutrition
- Risk for aspiration

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Tube is verified as placed in stomach or intestine. • Feeding tube remains patent. • Patient has no respiratory distress (e.g., increased respiratory rate, coughing, poor color) or signs of discomfort or nasal trauma. | <p>Correct technique ensures placement in intended location (Bourgault and Halm, 2009).
Proper irrigation clears tube of formula residue (Bankhead et al., 2009).
Correctly placed tube causes no interference with airway.</p> |
| <p>2 Explain procedure to patient, including sensations that will be felt during insertion.</p> | <p>Increases patient's cooperation with intubation procedure and helps lessen anxiety.</p> |
| <p>3 Explain to patient how to communicate during intubation by raising index finger to indicate gagging or discomfort.</p> | <p>Patient must have way of communicating to alleviate stress and enhance cooperation.</p> |

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
Some agencies are now using a bar-code system to help with patient identification.</p> |
| <p>2 Perform hand hygiene.</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>3 Position patient upright in high Fowler's position unless contraindicated. If patient is comatose, raise head of bed as tolerated in semi-Fowler's position with head tipped forward, chin to chest. If necessary have an assistant help with positioning of confused or comatose patients. If patient is forced to lie supine, place in reverse Trendelenburg's position.</p> | <p>Reduces risk for pulmonary aspiration in event patient should vomit. Forward head position assists with closure of airway and passage of tube into esophagus.</p> |
| <p>4 Apply pulse oximeter and measure vital signs.</p> | <p>Permits objective assessment of respiratory status during tube insertion.</p> |
| <p>5 Determine length of tube to be inserted and mark location with tape or indelible ink.</p> <p>a Measure distance from tip of nose to earlobe to xyphoid process of sternum (see illustration).</p> | <p>Length approximates distance from nose to stomach.</p> |

STEP 5a Determine length of tube to be inserted.

STEP

RATIONALE

Clinical Decision Point *Tip of tube must reach stomach to avoid the risk for pulmonary aspiration, which occurs when tubes terminate in the esophagus.*

- | | |
|--|---|
| <p>6 Prepare NG or nasoenteric tube for intubation.</p> <p>a Inject 10 mL of water from 30- to 60-mL Luer-Lok or catheter-tip syringe into the tube.</p> <p>b If using stylet, make certain that it is positioned securely within tube.</p> <p>7 Cut hypoallergenic tape 10 cm (4 inches) long or prepare membrane dressing or other tube fixation device.</p> <p>8 Apply clean gloves.</p> <p>9 Dip tube with surface lubricant into glass of room-temperature water or apply water-soluble lubricant (see manufacturer directions).</p> <p>10 Explain the step and gently insert tube through nostril to back of throat (posterior nasopharynx). This may cause patient to gag. Aim back and down toward ear (see illustration).</p> <p>11 Have patient flex head toward chest after tube has passed through nasopharynx.</p> <p>12 Encourage patient to swallow by giving small sips of water or ice chips. Advance tube as patient swallows.</p> <p>13 Reemphasize need to mouth breathe and swallow during procedure.</p> <p>14 When tip of tube reaches carina (approximately 25 to 30 cm [10 to 12 inches] in an adult), stop and listen for air exchange from distal portion of tube.</p> <p>15 Advance tube each time patient swallows until desired length has been passed (see illustration).</p> | <p>Ensures that tube is patent. Avoid using non-Luer-Lok syringes and connectors to reduce risk of tubing misconnection (Simmons et al., 2011).</p> <p>Promotes smooth passage of tube into gastrointestinal (GI) tract. Improperly positioned stylet can cause tube to kink or injure patient.</p> <p>Used to secure tubing after insertion.</p> <p>Reduces transmission of microorganisms.</p> <p>Activates lubricant to facilitate passage of tube into naris and GI tract.</p> <p>Natural contours facilitate passage of tube into GI tract.</p> <p>Closes off glottis and reduces risk for tube entering trachea.</p> <p>Swallowing facilitates passage of tube past oropharynx. Distinct tug may be felt as patient swallows, indicating that tube is following expected path.</p> <p>Helps facilitate passage of tube and alleviates patient's fears during procedure.</p> <p>Audible breath sounds may indicate that tube is in respiratory tract; remove and start over.</p> <p>Some agency policies require radiograph at 30 to 35 cm (12 to 14 inches) to rule out airway position before proceeding with tube insertion (Krenitsky, 2011).</p> <p>Reduces discomfort and trauma to patient.</p> |
|--|---|

STEP 10 Insert tube through nostril to back of throat.

STEP 15 NG feeding tube inserted through nose and esophagus into stomach.

STEP

RATIONALE

Clinical Decision Point Do not force the tube or push against resistance. If patient starts to cough, experiences a drop in oxygen saturation, or shows other signs of respiratory distress, withdraw the tube into the posterior nasopharynx until normal breathing resumes.

- | | |
|--|---|
| 16 Check for position of tube in back of throat with penlight and tongue blade. | Tube may be coiled, kinked, or entering trachea. |
| 17 Temporarily anchor tube to nose with small piece of tape. | Movement of tube stimulates gagging. Assesses general position before anchoring tube more securely. |
| 18 Keep tube secure and check placement of tube by aspirating stomach contents to measure gastric pH (see Skill 31-2). | Proper tube position is essential before initiating feeding. |

Clinical Decision Point Insufflation of air into tube while auscultating abdomen is not a reliable means to determine position of feeding tube tip (AACN, 2010; Bourgault and Halm, 2009; Kenny and Goodman, 2010).

- | | |
|--|--|
| 19 Anchor tube to patient's nose, avoiding pressure on nares. Mark exit site on tube with indelible ink. Select one of the following options for anchoring:
a Apply tape:

(1) Apply tincture of benzoin or other skin adhesive on tip of patient's nose and allow it to become "tacky."
(2) Remove gloves and split one end of tape lengthwise 5 cm (2 inches).
(3) Place intact end of tape over bridge of patient's nose. Wrap each of the 5-cm strips in opposite directions around tube as it exits nose (see illustration).
b Apply membrane dressing or tube fixation device:
(1) Membrane dressing:
(a) Apply tincture of benzoin or other skin protector to patient's cheek and area of tube to be secured.
(b) Place tube against patient's cheek and secure tube with membrane dressing, out of patient's line of vision.
(2) Tube fixation device:
(a) Apply wide end of patch to bridge of nose (see illustration).
(b) Slip connector around feeding tube as it exits nose (see illustration). | Properly secured tube allows patient more mobility and prevents trauma to nasal mucosa.

Prevents pulling of tube. May require frequent change if tape becomes soiled.
Helps tape adhere better. Protects skin.

Secures tube firmly.

Permits longer securement without need to change dressing.

Decreases risk for patient's inadvertent extubation. |
| 20 Fasten end of NG tube to patient's gown using clip (see illustration) or piece of tape. Do not use safety pins to secure tube to gown. | Reduces traction on naris if tube moves.
Safety pins become unfastened and cause injury to patients. |
| 21 Assist patient to comfortable position. Remove gloves and perform hand hygiene. | |

STEP 19a(3) Wrap first strip of tape down length of feeding tube. Bring second strip down around length of tube, wrapping in opposite direction.

STEP 19b(2)(a) Apply tube fixation patch to bridge of nose.

STEP

RATIONALE

Clinical Decision Point Leave stylet in place until correct position is verified by x-ray film. Never try to reinsert a partially or fully removed stylet while feeding tube is in place. This can cause perforation of tube and injure patient.

- | | |
|--|---|
| <p>22 Obtain x-ray film of chest/abdomen.</p> <p>23 Apply clean gloves and administer oral hygiene (see Chapter 17). Clean tubing at nostril with washcloth dampened in mild soap and water.</p> <p>24 Remove gloves, dispose of equipment, and perform hand hygiene.</p> | <p>X-ray film examination is most accurate method to determine feeding tube placement (Bankhead et al., 2009).</p> <p>Promotes patient comfort and integrity of oral mucous membranes.</p> <p>Reduces transmission of microorganisms.</p> |
|--|---|

STEP 19b(2)(b) Slip connector around feeding tube.

STEP 20 Fastening feeding tube to patient's gown.

Tube Removal

- | | |
|--|--|
| <p>1 Verify health care provider's order for type of tube and enteric feeding schedule.</p> <p>2 Gather equipment: Disposable pad, tissues, clean gloves, disposable plastic bag or receptacle.</p> <p>3 Explain procedure to patient.</p> <p>4 Perform hand hygiene. Apply clean gloves.</p> <p>5 Position patient in high Fowler's position unless contraindicated.</p> <p>6 Place disposable pad or towel over patient's chest.</p> <p>7 Disconnect tube from feeding administration set if present.</p> <p>8 Remove tape or tube fixation device from patient's nose. Unclip tube from patient's gown.</p> <p>9 Instruct patient to take deep breath and hold it.</p> <p>10 Kink end of tube securely by folding it over on itself.</p> <p>11 Completely withdraw tube by pulling it out steadily and smoothly. Dispose of it into appropriate receptacle.</p> <p>12 Offer tissues to patient to blow nose.</p> <p>13 Offer mouth care.</p> <p>14 Remove gloves; perform hand hygiene.</p> | <p>Health care provider's order is needed to remove feeding tube.</p> <p>Encourages cooperation, reduces anxiety, and minimizes risks. Identifies teaching needs.</p> <p>Reduces transmission of microorganisms.</p> <p>Reduces risk for pulmonary aspiration in event patient should vomit.</p> <p>Prevents mucus and gastric secretions from soiling patient's clothing.</p> <p>Prevents formula from spilling from tube as it is removed. Allows tube to be removed easily.</p> <p>Prevents inadvertent aspiration of gastric contents while tube is removed.</p> <p>Keeps any residual fluid in tube from flowing out.</p> <p>Prevents transmission of microorganisms.</p> <p>Clears nasal passages of remaining secretions.</p> <p>Promotes patient's comfort.</p> <p>Reduces transmission of microorganisms.</p> |
|--|--|

EVALUATION

- | | |
|--|--|
| <p>1 Observe patient's response to intubation. Have patient speak. Check vital signs. <i>Option:</i> You may use capnography in critical care settings to determine if tip of tube is in trachea or lung.</p> <p>2 Confirm x-ray results with health care provider</p> <p>3 Remove the stylet (if used) after x-ray film verification of correct placement.</p> | <p>Abnormal lung sounds may indicate aspiration. Assists with confirmation of tube placement.</p> <p>Verifies position of tube before initiating enteral feeding. If placement needs adjustment, stylet is still in place.</p> |
|--|--|

STEP

- 4 Routinely check location of external exit site marking on the tube and color and pH of fluid aspirated from tube.
- 5 After removal, assess patient's level of comfort.

RATIONALE

Routine evaluation ensures correct placement of tube and reduces the risk of aspiration.
Provides for continued comfort of the patient.

Unexpected Outcomes

- 1 Aspiration of stomach contents into respiratory tract (delayed response or small-volume aspiration), evidenced by auscultation of crackles or wheezes, dyspnea, or fever.
- 2 Displacement of feeding tube to another site (e.g., from duodenum to stomach) possibly occurs when patient coughs or vomits.

Related Interventions

- Report change in patient condition to health care provider; if there has not been a recent chest x-ray film, suggest ordering one.
- Position patient on side.
- Suction nasotracheally and orotracheally
- Prepare for possible initiation of antibiotics.
- Aspirate GI contents and measure pH.
- Remove displaced tube and insert and verify placement of new tube.
- If there is a question of aspiration, obtain chest x-ray film.

Recording and Reporting

- Record and report type and size of tube placed, location of distal tip of tube, patient's tolerance of procedure, and confirmation of tube position by x-ray film examination.
- Record removal of tube and patient's tolerance.
- Report any type of unexpected outcome and the interventions performed.
- Tube removal: record patient's level of comfort.

Special Considerations

Teaching

- Instruct patient or family caregiver to offer oral hygiene frequently and keep patient's lips lubricated.
- Teach patient or family caregiver to report tension on feeding tube or displacement of tape or tube fixation device; instruct patient or caregiver to stabilize the tube and call for help.

Pediatric

- The distance from nose-to-ear-to-mid-umbilicus better predicts insertion length for gastric tube placement in neonates and children than traditional nose-to-ear-to-xyphoid measurements (Cirgin Ellett et al., 2011).

- X-ray film confirmation of tube position is not routinely performed because of the radiation risk.
- Routine flushing of tubes is not recommended in pediatric patients.
- When inserting a feeding tube in an infant, observe for vagal stimulation evidenced by a decreased heart rate.

Gerontologic

- Ensure adequate lubrication of tube to decrease discomfort for the older adult because of the potential for decreased oral or nasopharyngeal secretions.

Home Care

- Assess patient or primary caregiver's ability to maintain a tube for a feeding program.
- Assess the environmental safety and sanitation of patient's home to determine potential for infection or injury.
- Teach patient or primary caregiver how to assess tube placement (see Skill 31-2).
- Teach the family caregiver correct method for securing a feeding tube.

SKILL 31-2 Verifying Feeding Tube Placement

NSO Enteral Nutrition Module / Lesson 3

Nurses insert small-bore feeding tubes nasally for intermittent or continuous feeding. It is possible for the tip of a feeding tube to move or migrate into a different location (e.g., from the stomach into the intestine or esophagus, from the intestine into the stomach). Although all tubes should be marked to document correct position, tube dislocation can sometimes occur without any external evidence that the tube has moved. The risk of aspiration of regurgitated gastric contents into the respiratory tract increases when the tip of the tube accidentally dislocates upward into the esophagus.

Following initial x-ray film verification of correct feeding tube position, you must monitor the tube to ensure that the tube tip remains in the intended site. Based on a patient's clinical condition and agency policies, you check feeding tube position at regular intervals (often every 4 to 6 hours) and before administering formula or medications through the tube. Radiographic verification is impractical every 4 to 6 hours, but the reports of routine chest

and abdominal films should be monitored for reference to the feeding tube location. Because no single bedside method of monitoring tube position during feeding is completely reliable, there are a number of techniques to use in combination to detect feeding tube dislocation:

- Monitor the external length of the tube and observe the appearance, volume, and pH of fluid aspirated through it. The color of the fluid can help differentiate gastric from intestinal placement. Because most intestinal aspirates are stained by bile to a distinct yellow color and most gastric aspirates are not, the difference in color can often distinguish the sites (Fig. 31-2).
- Testing the pH of an aspirate at the bedside using pH paper offers some information regarding the position of a feeding tube, but results are not reliable during continuous feeding and should be used in combination with other indicators with careful assessment of a patient in the clinical setting (AACN, 2010; Bankhead et al., 2009; Renner, 2010).
- Obtain repeat x-ray film confirmation if bedside methods create any doubt regarding the location of the tube.

FIG 31-2 Typical color of aspirates from stomach, intestine, and airway. (Used with permission from Metheny NA, et al: *pH, color, and feeding tubes*, RN 61:25, 1998.)

Delegation and Collaboration

The verification of tube placement is the responsibility of the nurse and cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Immediately inform the nurse if patient’s respirations change or patient complains of shortness of breath, coughing, or choking.
- Immediately inform the nurse if the patient vomits or the NAP notices vomitus in patient’s mouth during oral hygiene.
- Immediately inform the nurse if nasal skin irritation is present.

- Immediately inform the nurse if a change in the external length of the tube occurs, which could indicate displacement of the tube.

Equipment

- 60-mL catheter-tip syringe
- Stethoscope
- Clean gloves
- pH indicator strip (scale of 0.0 to 11.0)
- Small medication cup

STEP

RATIONALE

ASSESSMENT

- 1 Review agency policy and procedures for frequency and method of checking tube placement. Do not insufflate air into tube to check placement.
- 2 Observe for signs and symptoms of respiratory distress during feeding: coughing, choking, or reduced oxygen saturation.
- 3 Identify conditions that increase risk for spontaneous tube migration or dislocation:
 - a Altered level of consciousness, agitation.
 - b Retching/vomiting/coughing.
 - c Nasotracheal suction.

Maintains quality of patient care. Listening for air instilled through tube is unreliable (AACN, 2010; Bankhead et al., 2009).

Once the tube has been correctly placed into gastrointestinal (GI) tract, movement into pulmonary system is unlikely. However, a tube that has been pulled back into esophagus can lead to regurgitation and aspiration of formula.

Feeding tubes may become dislocated by increases in intraabdominal pressure or coughing, but most frequently they are displaced when patient moves or during pulls on tube.

STEP	RATIONALE
4 Observe external portion of tube for movement of ink mark away from mouth or naris (see Skill 31-1).	Increased external length of tube indicates that distal tip is no longer in correct position.
5 Review patient's medication record for orders for continuous feeding or a gastric acid inhibitor (e.g., cimetidine [Tagamet], ranitidine [Zantag], famotidine [Pepcid AC], nizatidine [Axid]) or a proton pump inhibitor (e.g., omeprazole [Prilosec]).	The presence of enteral formula in aspirated secretions diminishes usefulness of pH measurements by buffering pH of stomach. Similarly, H ₂ receptor antagonists reduce acid content of secretions, also raising pH value (Bankhead et al., 2009; Renner, 2010).
6 Review patient's record for history of prior tube displacement.	Patients are at increased risk for repeated tube displacement.

NURSING DIAGNOSES

- Impaired gas exchange
- Risk for aspiration

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Color, pH, and appearance of gastric aspirate are consistent with initial tube placement. 	Indicates that tube has likely remained in correct location, initially confirmed by x-ray film (AACN, 2010).
2 Explain procedure to patient.	Patient has right to be informed regarding all procedures. Relieves anxiety.

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). Some agencies are now using a bar-code system to help with patient identification.
2 Prepare equipment at patient's bedside, perform hand hygiene, and apply clean gloves.	Reduces transmission of microorganisms.
3 Verify tube placement at the following times: <ol style="list-style-type: none"> For intermittently tube-fed patients, test placement immediately before each feeding and before medications. Follow agency policy regarding pH testing for patients receiving continuous tube feeding. AACN (2010) recommends that continuous feedings be stopped for several hours to obtain reliable pH readings. Wait to verify placement at least 1 hour after medication administration by tube or mouth. 	Each administration of feeding/medication can lead to pulmonary aspiration if tube is displaced. pH testing is of minimal value during continuous tube feeding. Feedings should not be stopped for purpose of pH testing, but pH testing may be helpful when feedings are interrupted for procedures or diagnostic studies (AACN, 2010). Premature withdrawal of contents will remove unabsorbed medication, reducing dose delivered to patient.
4 Draw up 30 mL of air into a 60-mL syringe and attach to end of feeding tube. Flush tube with 30 mL of air before attempting to aspirate fluid. Repositioning patient from side to side is helpful. In some cases more than one bolus of air is necessary.	Burst of air aids in aspirating fluid more easily. Smaller syringes generate unnecessarily high pressures inside tube. It is often more difficult to aspirate fluid from small intestine than from stomach or smaller-size tube (AACN, 2010).
5 Draw back on syringe slowly and obtain 5 to 10 mL of gastric aspirate (see illustration). Observe appearance of aspirate (see Fig. 31-2).	Drawing back quickly or with a smaller syringe may cause tube to collapse. Quantity is sufficient for pH testing. Appearance of aspirate helps to assess position of tube. Aspirates from nasogastric (NG) tubes of continuously tube-fed patients often look like curdled enteral formula. Gastric aspirates from intermittently tube-fed patients are not typically bile stained (unless intestinal fluid has refluxed into stomach) (AACN, 2010).
6 Gently mix aspirate in syringe. Expel few drops into clean medicine cup. Measure pH of aspirated GI contents by dipping pH strip into fluid or by applying a few drops of fluid to strip. Compare color of strip with color on chart (see illustration) provided by manufacturer. <ol style="list-style-type: none"> Gastric fluid from patient who has fasted for at least 4 hours usually has pH range of 5.0 or less. Fluid from tube in small intestine of fasting patient usually has pH greater than 6.0 (AACN, 2010; Bankhead et al., 2009). 	Mixing ensures equal distribution of contents for testing. Most-accurate readings of gastric pH levels are provided by pH paper covering a minimal range of from 0 to 11.0. A pH reading of 5.0 or less is reliable indicator of stomach placement, especially when gastric acid inhibitor is not being used (AACN, 2010; Bankhead et al., 2009). Intestinal contents are more basic than stomach contents.

STEP

RATIONALE

- c Patient with continuous tube feeding may have pH of 5.0 or higher (AACN, 2010; Bankhead et al., 2009).
- d pH of pleural fluid from tracheobronchial tree is generally greater than 6.0 (AACN, 2010).
- 7 If after repeated attempts it is not possible to aspirate fluid from a tube that was confirmed by x-ray film to be in desired position and if there are no risk factors for tube dislocation, monitor external length of tube and observe patient for evidence of respiratory distress (AACN, 2010; Bankhead et al., 2009).
- 8 Irrigate tube (see Skill 31-3).
- 9 Remove and dispose of gloves and supplies in appropriate receptacle. Perform hand hygiene.

Formulas contain solutions that are basic.

Reports of routine chest or abdominal x-ray films can be used to monitor tube location. Repeat radiographic confirmation of tube position is indicated if external length of tube changes, tape holding tube comes loose, or patient coughs forcefully or vomits (Bankhead et al., 2009).

Keeps tube patent.

Reduces transmission of microorganisms.

STEP 5 Obtaining gastric aspirate.

STEP 6 Compare color on test strip with color on pH chart.

EVALUATION

- 1 Observe patient for respiratory distress: persistent gagging, paroxysms of coughing, drop in O₂ saturation, respiratory patterns (e.g., rate and depth) that are inconsistent with baseline measures.
- 2 Verify that external length of tube, pH, and appearance of aspirate are consistent with initial tube placement.

Feeding enters airways.

Indicates that tip of tube is likely to be positioned in same place as it was following x-ray film confirmation.

Unexpected Outcomes

- 1 Red or brown coloring (coffee grounds appearance) of fluid aspirated from feeding tube indicates new or old blood, respectively, in GI tract.
- 2 Patient develops severe respiratory distress (e.g., dyspnea, decreased oxygen saturation, increased pulse rate) as a result of aspiration or tube displacement into lung.
- 3 Abdomen becomes distended.

Related Interventions

- If color is not related to medications recently administered, notify health care provider.
- Stop any enteral feedings.
- Notify health care provider.
- Obtain chest x-ray film as ordered.
- Notify health care provider.
- Stop enteral feedings.

Recording and Reporting

- Record and report pH and appearance of aspirate.

Pediatric

- Decrease the amount of air insufflated according to the size of patient (e.g., an infant may only need 1 mL of air, a small child 5 mL) before withdrawal of gastric secretions.

Special Considerations

Teaching

- Instruct patient to not pull or alter position of enteral tube.

Home Care

- Instruct patient or primary caregiver not to proceed with feedings or medication administration via the tube if there is any doubt as to its proper placement.

SKILL 31-3 Irrigating a Feeding Tube

Feeding tubes must remain patent to ensure that liquid nutritional formulas can pass through easily. All types of feeding tubes require routine irrigation to keep a tube patent. Inability to instill air or fluid suggests that a tube is occluded. Curdled enteral formula and improperly crushed medications are the most common causes of feeding tube occlusion.

Delegation and Collaboration

The skill of irrigating a feeding tube cannot be delegated to nursing assistive personnel (NAP).

The nurse directs the NAP to:

- Report when a continuous tube feeding stops infusing.

Equipment

- 60-mL catheter-tip syringe
- Water (tap water or sterile [see agency policy], dated and initialed container at patient's bedside)
- Towel
- Clean gloves
- Stethoscope

STEP**RATIONALE****ASSESSMENT**

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Inspect volume, color, and character of gastric aspirates (if obtainable). 2 Assess bowel sounds. 3 Note ease with which tube feeding infuses through tubing. 4 Monitor volume of enteral formula administered during a shift and compare with ordered amount. 5 Refer to agency policies regarding routine irrigation, usually every 4 to 12 hours (Bankhead et al., 2009). | <p>Excess volume of secretions (more than 250 mL) may indicate delayed gastric emptying.</p> <p>Determines if peristalsis is present.</p> <p>Failure of formula to infuse as desired may indicate developing obstruction.</p> <p>Indicates whether sufficient volume of feeding is infusing.</p> <p>Determines frequency of irrigations.</p> |
|--|--|

NURSING DIAGNOSES

- Deficient fluid volume
- Excess fluid volume
- Imbalanced nutrition: less than body requirements

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <ol style="list-style-type: none"> 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Feeding tube remains patent. • Patient receives prescribed caloric intake. 2 Explain procedure to patient. 3 Position patient in high-Fowler's (if tolerated) or semi-Fowler's position. | <p>Irrigation fluid clears inner lumen of feeding tube of solids and secretions.</p> <p>Feeding infuses without interruption.</p> <p>Decreases patient anxiety.</p> <p>Reduces reflux and risk for pulmonary aspiration during irrigation.</p> |
|---|--|

IMPLEMENTATION

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. 2 Perform hand hygiene, prepare equipment at patient's bedside, and apply clean gloves. 3 Verify tube placement (see Skill 31-2) if fluid can be aspirated for pH testing. 4 Irrigate routinely before, between, and after final medication (before feedings are reinstated); and before an intermittent feeding is administered. 5 Draw up 30 mL of water in syringe (see illustration). Do not use irrigation fluids from bottles that are used on other patients. Patient should have an individual bottle of solution. | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Some agencies are now using a bar-code system to help with patient identification.</p> <p>Reduces transmission of microorganisms. Ensures an organized approach to irrigation.</p> <p>With tip of tube correctly placed in stomach, irrigation will not increase risk for pulmonary aspiration.</p> <p>Certain formulas have properties that predispose to tube clogging. Irrigation prevents mixing of medications in tube, which may cause clogging.</p> <p>This amount of solution will flush length of tube. Water is most effective agent for preventing tube clogging. Alternative flushing solutions such as cola and fruit juices increase clogging of tubes because of acidity of these fluids (Bankhead et al., 2009; Dandeles and Lodolce, 2011).</p> |
|---|---|

STEP

- 6 Change irrigation bottle every 24 hours. Irrigation trays, which hold both irrigation fluid and syringe, are considered open systems and may be more easily contaminated than sterile water bottles.
- 7 Kink feeding tube while disconnecting it from administration tubing or while removing plug at end of tube (see illustration).
- 8 Insert tip of syringe into end of feeding tube. Release kink and slowly instill irrigation solution (see illustration).

RATIONALE

Ensures sterile solution. Sterile water is required for neonates and patients who are immune suppressed or critically ill (Bankhead et al., 2009).
 Tap water may be appropriate in some clinical settings and in home care if municipal water supply is safe (Bankhead et al., 2009).
 Prevents leakage of gastric secretions.
 Infusion of fluid clears tubing.

STEP 5 Draw up 30 mL of water into syringe.

STEP 7 Kink tubing while unplugging feeding tube.

STEP 8 Irrigate feeding tube.

STEP	RATIONALE
9 If unable to instill fluid, reposition patient on left side and try again.	Tip of tube may be against stomach wall.
10 When water has been instilled, remove syringe. Reinstigate tube feeding or administer medication as ordered. Flush each medication completely through tube (see Skill 21-2).	Changing patient's position may move tip away from stomach wall. Tubing is clear and patent.
11 Remove and discard gloves; dispose of supplies in appropriate receptacle. Perform hand hygiene.	Ensures that full dose reaches stomach and medications do not mix with formula. Reduces transmission of microorganisms.

EVALUATION

1 Observe ease with which tube feeding instills through tubing.	A successfully irrigated tube is patent, allowing for free flow of solution.
2 Monitor patient's caloric intake.	Total enteral nutrition infuses without difficulty.

Unexpected Outcomes

- 1 Tube cannot be irrigated and remains obstructed.
- 2 Fluid and electrolyte imbalances occur. Insufficient irrigation can cause water deficiency; excessive irrigations can cause fluid volume excess.

Related Interventions

- Repeat irrigation; if unsuccessful, notify health care provider. Tube may need to be removed, and a new tube placed.
- Notify health care provider of abnormal electrolyte levels or imbalanced intake and output.

Recording and Reporting

- Record time of irrigation, amount and type of fluid instilled.
- Report if tubing has become clogged.

Special Considerations

Pediatric

- Irrigation of a tube requires a smaller volume of solution in children: 1 to 3 mL for neonates and 3 to 5 mL for pediatric patients (Bankhead et al., 2009).

SKILL 31-4 Administering Enteral Nutrition: Nasoenteric, Gastrostomy, or Jejunostomy Tube

NSO Enteral Nutrition Module / Lesson 4

Enteral nutrition, or tube feeding, is a method for providing nutrients to patients who are not able to meet their nutritional requirements orally. As a rule, candidates for enteral nutrition must have a sufficiently functional gastrointestinal (GI) tract to absorb nutrients. Examples of indications for enteral feeding include the following:

- 1 Situations in which normal eating is not safe because of high risk for aspiration: Altered mental status, swallowing disorders, impaired gag reflex, dependence on mechanical ventilation, certain esophageal conditions (strictures, or dysmotility), and delayed gastric emptying.
- 2 Clinical conditions that interfere with normal ingestion or absorption of nutrients or create hypermetabolic states: Surgical resection of oropharynx, proximal intestinal obstruction or fistula, pancreatitis, burns, and severe pressure ulcers.
- 3 Conditions in which disease or treatment-related symptoms reduce oral intake: Anorexia, nausea, pain, fatigue, shortness of breath, or depression.

Gastric feedings are the most common type of enteral nutrition, allowing tube-feeding formulas to enter the stomach and then pass gradually through the intestinal tract to ensure absorption. In contrast, small bowel feeding occurs beyond the pyloric sphincter of the stomach, which theoretically reduces the risk for pulmonary aspiration, provided that feedings do not reflux back into the stomach (Metheny et al., 2011). To avoid bloating, cramping, and diarrhea, an enteral infusion pump is used to control the

administration rate of small bowel feedings and many continuous gastric feedings. Inadequate delivery of nutrients, potentially leading to caloric deficit or electrolyte disturbances, sometimes occurs because of frequent interruptions in feeding.

Delegation and Collaboration

The skill of administration of nasoenteric tube feeding can be delegated to nursing assistive personnel (NAP). (Refer to agency policy.) However, a registered nurse (RN) or licensed practical nurse (LPN) must first verify tube placement and patency. The nurse directs the NAP to:

- Elevate head of bed to a minimum of 30 degrees (preferably 45 degrees) or sit patient up in bed or a chair.
- Not adjust feeding rate; infuse the feeding as ordered.
- Report any difficulty infusing the feeding or any discomfort voiced by patient.
- Report any gagging, paroxysms of coughing, or choking.
- Provide frequent oral hygiene.

Equipment

- Disposable feeding bag, tubing, or ready-to-hang system
- 60-mL or larger catheter-tip syringe
- Stethoscope
- Enteral infusion pump for continuous feedings
- pH indicator strip (scale 0.0 to 11.0)
- Prescribed enteral formula
- Clean gloves

STEP

RATIONALE

ASSESSMENT

<p>1 Assess patient’s clinical status to determine potential need for tube feedings: Decreased level of consciousness, nutritional deficits, head or neck surgery, facial trauma, or impaired swallow. Consult with nutrition support team or health care provider.</p> <p>2 Assess patient for food allergies.</p> <p>3 Perform physical assessment of abdomen, including auscultation for bowel sounds before feeding (see Chapter 6).</p> <p>4 Obtain baseline weight and review serum electrolytes and blood glucose measurement. Assess patient for fluid volume excess or deficit, electrolyte abnormalities, and metabolic abnormalities (e.g., hyperglycemia).</p> <p>5 Verify health care provider’s order for type of formula, rate, route, and frequency.</p>	<p>Identify candidates for enteral nutrition before they become nutritionally depleted.</p> <p>Prevents patient from developing localized or systemic allergic responses to feeding.</p> <p>Absent bowel sounds are not a contraindication to feeding; but a change from baseline in abdominal examination, particularly if tenderness or distention is present, should be reported to ordering health care provider to determine if tube feeding can proceed safely (Bankhead et al., 2009; McClave et al., 2009).</p> <p>Enteral feedings should restore or maintain patient’s nutritional status. Measures provide objective data and baseline to determine selection of formula and measure effectiveness of feedings.</p> <p>Ensures that correct formula will be administered in appropriate volume. Enteral formulas are not interchangeable.</p>
---	--

NURSING DIAGNOSES

- Imbalanced nutrition: less than body requirements
- Impaired swallowing
- Risk for aspiration
- Readiness for enhanced nutrition

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient achieves established target for body weight over time. • Patient has no sign of respiratory distress. • Patient remains or returns to fluid/electrolyte balance. • Patient is free of abdominal cramping. <p>2 Explain procedure to patient.</p>	<p>Indicates that patient’s nutritional status is maintained or improved.</p> <p>Feeding tube does not enter airway, and patient does not aspirate feeding.</p> <p>Scheduled feedings are administered as ordered.</p> <p>Feeding administered without abdominal distention.</p> <p>Decreases patient anxiety.</p>
---	--

IMPLEMENTATION

<p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient’s identification bracelet.</p> <p>2 Perform hand hygiene. Apply clean gloves (Bankhead et al., 2009).</p> <p>3 Obtain formula to administer:</p> <ul style="list-style-type: none"> a Verify correct formula and check expiration date; note condition of container. b Provide formula at room temperature. <p>4 Prepare formula for administration:</p> <ul style="list-style-type: none"> a Use aseptic technique when manipulating components of feeding system (e.g., formula, administration set, connections). b Shake formula container well. Clean top of canned formula with alcohol swab before opening it (Bankhead et al., 2009). c For closed systems, connect administration tubing to container. If using open system, pour formula from brick pack or can into administration bag (see illustration). 	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Some agencies are now using a bar-code system to help with patient identification.</p> <p>Reduces transmission of microorganisms and potential contamination of enteral formula.</p> <p>Ensures that correct therapy is to be administered and checks integrity of formula.</p> <p>Cold formula causes gastric cramping and discomfort because liquid is not warmed by mouth and esophagus.</p> <p>Bag, connections, and tubing must be free of contamination to prevent bacterial growth (Bankhead et al., 2009).</p> <p>Ensures integrity of formula; prevents transmission of microorganisms.</p> <p>Formulas are available in closed-system containers that contain a 24- to 48-hour supply of formula or in an open system, in which formula must be transferred from brick packs or cans to a bag before administration.</p>
--	---

STEP

- 5 Open roller clamp and allow administration tubing to fill. Clamp off tubing with roller clamp. Hang container on intravenous (IV) pole.
- 6 Place patient in high-Fowler's position or elevate head of bed at least 30 degrees (preferably 45 degrees). For patient forced to remain supine, place in reverse Trendelenburg's position.
- 7 Verify tube placement (see Skill 31-2). Observe appearance of aspirate and note pH measure.
- 8 Check gastric residual volume (GRV) before each feeding (for bolus and intermittent feedings) and every 4 to 6 hours (for continuous feedings) (Metheny et al., 2008; Bankhead et al., 2009).
 - a Draw up 10 to 30 mL air into syringe and connect to end of feeding tube.
 - b Inject air into tube. Pull back slowly and aspirate total amount of gastric contents (see illustration).
 - c Return aspirated contents to stomach unless volume exceeds 250 mL (see agency policy) (Metheny, 2010).
 - d Do not administer feeding when a single GRV measurement exceeds 500 mL or when two measurements taken 1 hour apart each exceed 250 mL (Bankhead et al., 2009) (check agency policy).
 - e Flush feeding tube with 30 mL water (see Skill 31-3).
- 9 Before attaching feeding administration set to feeding tube, trace tube to its point of origin. Label administration set, "Tube Feeding Only."
- 10 Intermittent gravity drip:
 - a Pinch proximal end of feeding tube and remove cap. Connect distal end of administration set tubing to feeding tube and release tubing.
 - b Set rate by adjusting roller clamp on tubing or attach tubing to feeding pump. Allow bag to empty gradually over 30 to 45 minutes (see illustration). Label bag with tube-feeding type, strength, and amount. Include date, time, and initials.

STEP 4c Pour formula into open feeding container.

RATIONALE

- Prevents introduction of air into stomach once feeding begins.
- Elevated head helps prevent pulmonary aspiration.
- Verifies if tip of tube is in stomach or intestine based on pH value.
- GRV determines if gastric emptying is delayed. Intestinal residual is usually very small. If residual volume is greater than 10 mL, displacement of tube into stomach may have occurred.
- Prevents loss of nutrients and electrolytes in discarded fluid. Some questions exist regarding safety of returning high volumes of fluid into stomach (Metheny, 2010).
- Some controversy exists regarding ability of elevated GRVs to identify risk for pulmonary aspiration. However, frequent interruptions of feeding based on GRV levels is a well-recognized reason for failure to meet nutritional goals (Bankhead et al., 2009; DeLegge, 2011; Metheny et al., 2008).
- Prevents clogging of tubing.
- Avoids misconnections between feeding set and IV systems or other medical tubing or devices (Bankhead et al., 2009; Simmons et al., 2011).
- Prevents excessive air from entering patient's stomach and leakage of gastric contents.
- Gradual emptying of tube feeding reduces risk for abdominal discomfort, vomiting, or diarrhea induced by bolus or too-rapid infusion of tube feedings.

STEP 8b Check for GRV.

STEP

RATIONALE

Clinical Decision Point Use pumps designated for tube feeding, not IV fluids.

- c Change bag every 24 hours.
- 11 Continuous drip method:
 - a Connect distal end of administration set tubing to feeding tube as in Step 10a.
 - b Thread tubing through feeding pump; set rate on pump and turn on (see illustration).

Decreases risk for bacterial colonization.
 Continuous feeding method is designed to deliver prescribed hourly rate of feeding and reduce risk for abdominal discomfort.

Delivers continuous feeding at steady rate and pressure. Feeding pump alarms for increased resistance.

Clinical Decision Point Maximum hang time for formula is 12 hours in an open system; 24 to 48 hours in closed, ready-to-hang system (if it remains closed). Refer to manufacturer guidelines.

- 12 Advance rate of tube feeding gradually, as ordered.
- 13 Flush tubing with 30 mL water every 4 hours during continuous feeding (see agency policy), before and after an intermittent feeding. Have registered dietitian recommend total free water requirement per day and obtain health care provider's order (see Skill 31-3).
- 14 When patient is receiving intermittent tube feeding, cap or clamp end of feeding tube when not being used.
- 15 Rinse bag and tubing with warm water whenever feedings are interrupted. Use new administration set every 24 hours.
- 16 Dispose of supplies and perform hand hygiene.

Tube feeding can usually begin with full-strength formula. Gradual advancement to goal rates helps to prevent diarrhea and gastric intolerance to formula (Bankhead et al., 2009).

Provides patient with source of water to help maintain fluid and electrolyte balance. Clears tubing of formula.

Prevents air from entering stomach between feedings and limits microbial contamination of system.

Rinsing bag and tubing with warm water clears old tube feedings and reduces bacterial growth.

Reduces transmission of microorganisms.

STEP 10b Administer intermittent feeding.

STEP 11b Connect tubing through infusion pump. (Image used with permission Covidien. All rights reserved.)

STEP

RATIONALE

EVALUATION

- 1 Measure GRV per policy, usually every 4 to 6 hours, and ask if nausea or abdominal cramping is present.
- 2 Monitor intake and output at least every 8 hours and calculate daily totals every 24 hours.
- 3 Weigh patient daily until maximum administration rate is reached and maintained for 24 hours; then weigh patient 3 times per week.
- 4 Monitor laboratory values.
- 5 Observe patient's respiratory status.
- 6 Auscultate bowel sounds.
- 7 For tubes placed through abdominal wall, inspect site for signs of impaired skin integrity.

- GI tolerance of tube feedings must be closely monitored to avoid complications.
- Intake and output are indications of balance or fluid volume excess or deficit.
- Slow weight gain is indicator of improved nutritional status; however, sudden gain of more than 2 lbs (0.9 kg) in 24 hours usually indicates fluid retention.
- Determines correct administration of formula rate and strength.
- Change in respiratory status indicates aspiration of tube feeding into respiratory tract.
- Evaluates status of gastric peristalsis.
- Enteral tubes often cause pressure and excoriation at insertion site.

Unexpected Outcomes

- 1 Feeding tube becomes clogged.
- 2 GRV exceeds 250 mL or cutoff per agency policy.
- 3 Patient aspirates formula.
- 4 Patient develops large amount of diarrhea (more than three loose stools in 24 hours).
- 5 Patient develops nausea and vomiting, which may indicate paralytic ileus.
- 6 Fluid withdrawn through tube has foul odor or unusual appearance.
- 7 Skin around gastrostomy or jejunostomy site breaks down.

Related Interventions

- Attempt to flush tube with water.
- Special products are available for unclogging feeding tubes; do not use soda and juice.
- Hold feeding and notify health care provider.
- Maintain patient in semi-Fowler's position.
- Recheck residual in 1 hour (see agency policy).
- Notify health care provider if GRV remains high (typically hold feeding if residual >250 mL two consecutive checks).
- See Related Interventions for Skill 31-1.
- Notify health care provider. Consult dietitian about need to change formula.
- Consider other causes such as *Clostridium difficile* infection or bacterial contamination of feeding (Bankhead et al., 2009).
- Provide perianal skin care after each stool.
- Determine if patient is receiving medications (e.g., containing sorbitol) that induce diarrhea (Btaiche et al., 2010).
- Withhold tube feeding and notify health care provider.
- Be sure that tube is patent; aspirate for residual.
- Notify health care provider.
- Do not return aspirated material of unusual odor or appearance without first consulting health care provider.
- See Procedural Guideline 31-1. Institute skin care (see Chapter 38).

Recording and Reporting

- Record and report amount and type of feeding, method of infusion, patient's response to tube feeding (e.g., GRV, cramping), patency of tube, condition of skin at tube site.
- Record volume of formula and any additional water on intake and output form.
- Report type of feeding, status of feeding tube, patient's tolerance, and adverse outcomes.

Special Considerations

Teaching

- Instruct patients and family caregivers not to reconnect lines that have separated but to seek clinical assistance.
- Teach patient and caregiver that, if tolerated, patient should remain upright for 1 hour after feedings.
- Instruct patient or caregiver that patient may express feelings of fullness, increased gas, belching, or diarrhea.

- Teach patient or caregiver how to determine correct placement of feeding tube.

Pediatric

- Preterm infants who are at risk for necrotizing enterocolitis frequently receive minimal enteral feeding (MEF) to limit stress on the GI tract. Breast milk is the preferred "formula" in this situation. MEF is usually administered slowly with a pump and supplemented with IV nutrition (Bankhead et al., 2009).
- Temporary small-bore nasogastric tubes are often placed in infants just before each feeding and removed afterward.
- Measurement of GRV is not a standard practice in pediatric patients.

Gerontologic

- Some older adults have decreased gastric emptying so formula remains in the stomach longer than for younger patients. GRV checks are especially important in patients with impaired cognition to decrease the risk for pulmonary aspiration.

Home Care

- Ask patient or family caregiver about any symptoms or discomfort during enteral feedings. Reinforce instruction to contact nurse if symptoms of discomfort occur.
- Teach patient or caregiver how to perform skin care around the gastrostomy or jejunostomy tube and signs and symptoms of infection at insertion site (see [Procedural Guideline 31-1](#)).

PROCEDURAL GUIDELINE 31-1 Care of a Gastrostomy or Jejunostomy Tube

Feeding tubes can be placed directly into the gastrointestinal (GI) tract through the abdominal wall in patients who cannot tolerate nasoenteric feeding tubes or require long-term enteral nutrition. The stomach (gastrostomy tube) and jejunum (jejunostomy tube) are the most common sites for long-term feeding tubes. Long-term tubes require endoscopic, radiologic, or surgical placement. The insertion method used to place tubes may call for specific nursing interventions in the postinsertion period, but otherwise these tubes are used in a similar way to other feeding tubes. Feedings delivered via a gastrostomy tube are relatively safe to administer, provided the patient has normal gastric emptying. Gastrostomy tubes are often called *G tubes*; but they are also commonly referred to as percutaneous endoscopic gastrostomy (*PEG tubes*), a term used to describe tubes placed endoscopically. Gastrostomy tubes range in size from 16 Fr to 28 Fr and exit through an incision in the upper left quadrant of the abdomen, where an internal bumper or balloon and an external bumper or disk hold the tube in place (Fig. 31-3).

Jejunostomy tubes are indicated when the risk of regurgitation and aspiration is especially high, as in cases of severely delayed gastric emptying or conditions such as pancreatitis that limit the use of the stomach for feeding. Jejunostomy tubes can be placed directly into the small intestine in a surgical procedure or threaded through the stomach into the jejunum under fluoroscopy. Some jejunal tubes inserted through this transgastric approach are dual-channel devices that have openings in both the stomach and the small intestine portion of the tube. These *combination tubes*, as they are called, allow simultaneous gastric decompression and intestinal feeding for patients with impaired gastric emptying or upper-GI cancers. Each lumen of a combination tube is clearly labeled to distinguish between the gastric and the jejunal ports (Fig. 31-4). Sometimes a jejunostomy tube may be placed through an existing PEG tube. The percutaneous endoscopic jejunostomy

(PEJ) tube is passed through the PEG and advanced into the jejunum (Fig. 31-5). Because the PEJ tube occupies the lumen of the PEG tube, this tube-through-a-tube design does not allow drainage of the stomach during small-intestine feeding. In the case of both combination tubes and PEJ tubes, you must know whether

FIG 31-4 Dual lumen “combination tube” to allow jejunal feeding and gastric decompression. (Image used with permission Kimberly-Clark Health Care. All rights reserved.)

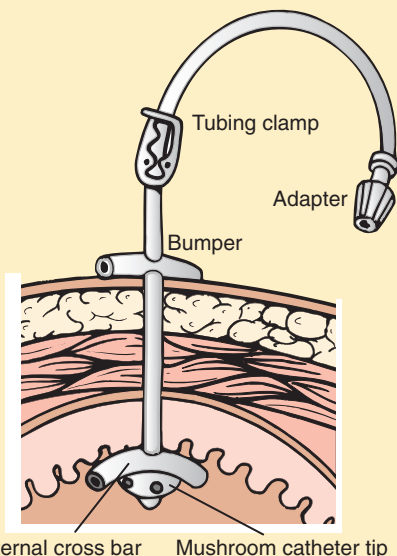

FIG 31-3 Placement of PEG tube into stomach.

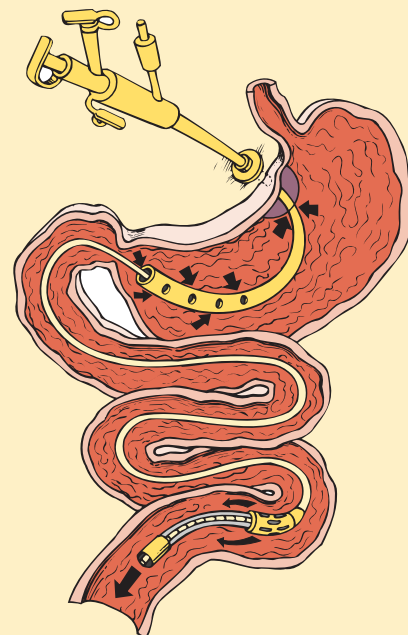

FIG 31-5 Endoscopic insertion of jejunostomy tube.

PROCEDURAL GUIDELINE 31-1 Care of a Gastrostomy or Jejunostomy Tube—cont'd

the intended site for formula delivery is gastric or jejunal to ensure safe and effective nutritional care.

Delegation and Collaboration

Care of a PEG or PEJ tube cannot be delegated to nursing assistive personnel (NAP). However, there may be some exceptions (refer to nurse practice acts and agency policy). The nurse directs the NAP to:

- Inform the nurse of any patient complaints of discomfort at the insertion site.
- Inform the nurse of any drainage on the insertion site dressing.

Equipment

- Normal saline, dated and initialed container at patient's bedside
- 4 × 4-inch gauze
- Prepared drain-gauze dressing
- Tape
- Clean gloves

Procedural Steps

- 1 Determine whether exit site is left open to air or if a dressing is indicated. Check health care provider's order or verify agency policy.
- 2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy.

- 3 Compare identifiers with information on patient's identification bracelet.
- 3 Perform hand hygiene and apply clean gloves.
- 4 Remove old dressing. Fold dressing with drainage contained inside; remove gloves inside out over dressing. Discard in appropriate container.
- 5 Assess exit site for evidence of excoriation, drainage, infection, or bleeding.
- 6 Clean skin around site with warm water and mild soap or saline (according to agency policy) using 4 × 4-inch gauze. (If drainage is present, apply clean gloves.)
- 7 Dry site completely.
- 8 Apply thin layer of protective skin barrier to exit site if indicated (e.g., site excoriated).
- 9 If dressing is ordered, place a drain-gauze dressing over external bar or disc. **NOTE:** Do not place dressing under external bar; this can cause gastric tissue erosion or internal abdominal wall pressure.
- 10 Secure dressing with tape.
- 11 Place date, time, and initials on new dressing.
- 12 Remove gloves and dispose of supplies in appropriate receptacle. Perform hand hygiene.
- 13 Document in nurse's notes and electronic health record (EHR) appearance of exit site, drainage noted, and dressing application.
- 14 Report to health care provider any exit site complications.

Critical Thinking Exercises

A 72-year-old male patient is admitted to the acute stroke unit following a cerebral hemorrhage. As a result of his stroke, he has left-sided paralysis and is sometimes not responsive to verbal commands. He recognizes his family and at times has spoken a few words. The nutrition support team has recommended that he have a small-bore feeding tube inserted for nutritional support. A continuous tube-feeding formula has been ordered.

- 1 Before inserting the feeding tube, which assessments would be appropriate to determine the patient's risk for inadvertent tracheo-pulmonary placement of the tube?
- 2 As you prepare to insert the feeding tube, which steps of the procedure do you anticipate will be difficult for the patient, and how can you adapt as a result?
- 3 Twenty-four hours after the patient's feeding tube was inserted, the nurse has difficulty withdrawing any stomach contents from the tube. What is a common cause of tube clogging, and what could be done to avoid this problem?
- 4 The patient has been receiving enteral nutrition for 3 days. Which measures does the nurse use to ensure that the tip of the feeding tube has remained in his stomach?

- 2 A nurse caring for a neutropenic patient prepares to irrigate the feeding tube. Which of the following steps are included in this procedure? (Select all that apply.)
 - 1 Identify correct patient by checking name and room number
 - 2 Position patient flat in bed
 - 3 Perform hand hygiene and apply clean gloves
 - 4 Use 30 mL sterile water as a flushing agent
 - 5 Insert tip of syringe into end of feeding tube and slowly instill irrigation solution
 - 6 Flush tube every 4 hours and before and after medication administration
- 3 A patient's oxygenation saturation level has gone from 97% to 90% during a coughing spell even though the small-bore feeding tube seems to be in place. Which action should the nurse take initially?
 - 1 Stop the continuous tube feeding
 - 2 Elevate the head of the bed
 - 3 Auscultate the patient's lungs
 - 4 Notify the health care provider
- 4 A patient receiving enteral feedings develops abdominal cramping and diarrhea. Which additional information should the nurse check before notifying the health care provider?
 - 1 The patency of the enteral feeding tube
 - 2 If the formula or medications contain sorbitol
 - 3 If the patient has a history of a latex allergy
 - 4 A complete assessment of the gastrointestinal system
- 5 A patient on enteral nutrition has gained 4 lbs (1.8 kg) over the past 48 hours. Which action should the nurse take initially?
 - 1 Check the current laboratory values
 - 2 Check for signs of fluid retention
 - 3 Slow the rate of the tube feeding by 20%
 - 4 Ask the patient how he feels

REVIEW QUESTIONS

- 1 A patient receiving continuous gastric feeding has a gastric residual volume of 150 mL. What is the correct nursing action?
 - 1 Decrease rate of tube feeding by 50%
 - 2 Stop the feeding immediately
 - 3 Continue tube feeding as ordered
 - 4 Discard the fluid withdrawn through the tube

- 6 Which of the following is the most reliable method of verifying the location of blindly inserted feeding tubes?
 - 1 pH testing of fluid withdrawn through the tube
 - 2 Auscultating over the epigastrium while instilling air through the tube
 - 3 Observing the color and appearance of fluid aspirated through the tube
 - 4 An x-ray film image of the entire course of the tube
- 7 As a result of a motor vehicle accident, a patient has had multiple facial fractures and suffered a stroke. Based on these facts, which route is the safest and most likely for feeding tube placement?
 - 1 Nasoenteric
 - 2 Gastrostomy tube
 - 3 Jejunostomy tube
 - 4 Percutaneous endoscopic gastrostomy (PEG)
- 8 What is the most important intervention that a nurse can perform to prevent health care–associated infections related to enteral nutrition?
 - 1 Inserting nasogastric tubes using sterile technique
 - 2 Keeping formula cold at all times
 - 3 Using aseptic technique when handling the feeding system
 - 4 Changing the feeding bags and liquid on time
- 9 The nurse is checking placement of a feeding tube of a patient who is receiving enteral medications. Which of the following techniques is correct in this situation?
 - 1 The nurse attaches a 20-mL syringe to the tube and pulls back quickly while watching for facial grimacing.
 - 2 The nurse places the patient flat in bed 30 minutes before checking for gastric residual volume.
 - 3 The nurse attaches syringe and pulls the plunger slowly to obtain 10 mL of gastric juice at least an hour after medications were given.
 - 4 The nurse flushes the tube with 60 mL of air through the syringe while watching for abdominal distention.
- 10 In assessing an elderly patient who is receiving a nasogastric (NG) tube feeding, it is noted that the patient has a history of constipation. The nurse notes that bowel sounds are diminished. What is the most appropriate nursing action?
 - 1 Assess for nausea, abdominal pain, tenderness, or distention
 - 2 Consult with health care provider to obtain an order for cathartic medications
 - 3 Weigh the patient
 - 4 Stop the feeding immediately

catheter (PICC)

Glucose monitoring

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe the purpose and components of parenteral nutrition (PN).
- Identify patients who are candidates for PN.
- Discuss risks associated with PN.
- List the monitoring procedures used for patients receiving PN.
- Identify measures used to prevent complications of PN.
- Demonstrate appropriate nursing care and use of safe precautions when caring for a patient receiving PN.

Parenteral nutrition (PN) is a specialized form of nutritional support that is given intravenously by an infusion pump to patients who have significant gastrointestinal (GI) dysfunction. PN is intended to meet the nutritional needs of patients until their GI function has improved enough to allow adequate intake using the oral or tube feeding route. In addition, PN meets long-term nutritional needs with infusions at home if GI dysfunction is expected to be long term (months to years) (Box 32-1). PN is an adjunctive therapy to enteral tube feeding in critically ill patients with larger nutrient requirements than can be provided with tube feeding because of limited GI function. Clinically stable, well-nourished adults can be maintained on peripheral IV therapy for up to 2 weeks without difficulty (Worthington and Gilbert, 2012). The goal for patients with short-term GI dysfunction is to provide nutritional requirements while minimizing PN-related complications until patients can resume full oral diets or meet their needs with enteral tube feedings (ASPEN, 2007; Worthington and Gilbert, 2012). Long-term nutritional management goals include ensuring that nutrient requirements are met while avoiding toxicity and minimizing complications.

RISKS ASSOCIATED WITH PARENTERAL NUTRITION

Although the use of PN has been an important technologic advance that allowed improved care for patients with GI

disorders, a number of complications have been associated with the therapy, the most frequent of which is catheter-related bloodstream infection (CRBSI), a risk that is found in both hospitalized patients and those with PN at home (Table 32-1). Hospitalized patients who are allowed nothing by mouth (NPO) and have PN have a risk of sludge accumulating in the gallbladder; and some cases result in acute cholecystitis, a problem that most often resolves once patients are able to eat again and PN is stopped. PN has also been associated with liver disease, particularly in patients with multiple bloodstream infections, very severe GI disease, and longer PN duration (Worthington and Gilbert, 2012). In-home PN patients with severe GI disease and long-term PN have been reported to develop metabolic bone disease (Worthington and Gilbert, 2012). There is also a risk of allergic reaction when PN is administered, although the incidence of allergy is low.

VENOUS ACCESS FOR ADMINISTRATION OF PARENTERAL NUTRITION

The type of catheter to use for administration of PN depends on patient factors and the expected length of PN therapy. The location of the catheter is defined based on where the distal tip of the catheter lies. Concentrated PN solutions are quickly diluted when infused into a large-diameter central vein (Fig. 32-1). PN should not be infused into a peripheral intravenous (IV) or midline catheter because of the increased risk for phlebitis. If only peripheral lines are available, the orders

BOX 32-1 Indications for Parenteral Nutrition**Short-term (Less Than 1 month) Gastrointestinal Dysfunction**

- Small intestinal surgery
- Intestinal obstruction
- Intolerance to adequate rates of enteral tube feeding
- Severe mucositis or gastrointestinal (GI) tract pain after cancer therapy
- High-output GI fistula
- Severe acute pancreatitis and inability to tolerate enteral tube feeding
- Anastomotic leak or severe GI bleed after obesity surgery
- Severe malnutrition before surgery

Long-term Gastrointestinal Dysfunction

- Short-bowel syndrome
- Dysmotility syndromes
- Radiation enteritis
- Permanent bowel obstruction caused by tumor

FIG 32-1 Placement of central venous catheter inserted into subclavian vein. IV, Intravenous. (Courtesy Rolin Graphics.)

should state clearly that the administration route will be a peripheral IV line so the compounding pharmacy will prepare the PN with a lower osmolarity (Table 32-2), which will require added fluid volume. Patients who cannot tolerate larger volumes of fluid intake such as those with renal, cardiac, or hepatic failure or those with severe malnutrition should be considered candidates for central lines if PN is needed. Many hospitals use peripherally inserted central catheters, termed *PICC lines* (Fig. 32-2), that are placed by specially trained nurses or radiologists. The catheter is threaded through a peripheral vein (such as the antecubital vein) until the tip reaches a central vein. These catheters may be inserted at the patient's bedside. Following central venous catheter insertion, do not initiate PN until placement of venous catheter tip is confirmed by a radiograph. Lipid emulsions may be administered through a separate peripheral line, through a central line by a Y-connector tubing (see Chapter 22), or as an admixture to the PN solution. Patients who will self-administer their PN solutions at home will require a central catheter, most typically a tunneled device (Fig. 32-3; see Chapter 28). They may also require special tubing to enable them to access the catheter without assistance. Patients who require IV access have a risk of CRBSI. The risk of CRBSI is increased with multilumen catheters, use of PN, multiple

FIG 32-2 Peripherally inserted central catheter.

FIG 32-3 Tunneled catheter used for home central parenteral nutrition. (From Morgan SL, Weinsier RL: Fundamentals of clinical nutrition, ed 2, St Louis, 1998, Mosby.)

IV therapies, and central venous access handling by multiple caregivers. Careful handling of the central line, dressings, tubing, and PN port is essential (see Skill 28-6).

COMPONENTS OF A PARENTERAL NUTRITION SOLUTION

A PN solution is produced using sterile technique in a laminar airflow hood in a pharmacy to reduce the risk of microbial and pyrogen contamination. The components of the PN solution are amino acids, glucose, and lipid as energy sources, with the addition of electrolytes, minerals, trace elements, vitamins, and water. The addition of lipid emulsion to the PN solution results in a preparation called a *3:1*, *3-in-1*, or *total nutrition admixture (TNA)*. The advantage to a 3:1 mixture is that it allows lipid infusion over 24 hours, decreasing the risk of hypertriglyceridemia from more rapid lipid infusion. Although PN without lipid can be infused using tubing with a 0.22- μ m filter, a larger 1.2- μ m filter is needed when

TABLE 32-1 Complications of Parenteral Nutrition

Problem	Cause	Symptoms	Immediate Action	Prevention
Pneumothorax	Tip of catheter enters pleural space during insertion, causing lung to collapse	Sudden chest pain, difficulty breathing, decreased breath sounds, cessation of normal chest movement on affected side, tachycardia	Per health care provider's order, the proper professional (CRNP, PA-C, or MD) may remove the central catheter. Administer oxygen via nasal cannula. Insert chest tube to remove air under water seal drainage or dry one-way valve system	Medical personnel should be properly trained to insert central catheters. Researchers suggest use of ultrasound when placing CVCs (Lamperti et al., 2012). Catheter should be secured properly to prevent migration, movement.
Air embolism	IV tubing disconnected; part of catheter system open or removed without being clamped	Sudden respiratory distress; decreased oxygen saturation levels, shortness of breath, coughing, chest pain, decreased blood pressure	Clamp catheter; position patient in left Trendelenburg's position; call health care provider; administer oxygen as needed	Make sure that all catheter connections are secure; clamp catheter when not in use. Never use a stopcock with a CVC. Instruct patient in Valsalva maneuver for tubing changes.
Localized infection (exit site or tunnel)	Poor aseptic technique in removal of skin flora during site preparation and dressing care	<i>Exit site:</i> Erythema, tenderness, induration, or purulence within 2 cm (0.8 inches) of skin at exit site <i>Tunnel:</i> Same as above but extends beyond 2 cm from exit site	Call health care provider <i>Exit:</i> Warm compress, daily site care, oral antibiotics <i>Tunnel:</i> Remove catheter	Provide catheter site care using aseptic technique; include cleaning of site, application of new stabilization device, and application of sterile dressing (INS, 2011). Change transparent dressings every 7 days, gauze dressings every 48 hours (INS, 2011). Change dressing if damp, loosened, or soiled or when inspection of site is necessary (INS, 2011). Clean site with chlorhexidine, tincture of iodine, iodophor, or 70% alcohol solution for a minimum of 3 to 5 min. Routine use of antibiotic ointment not recommended (INS, 2011).
Catheter-related sepsis or bacteremia (In 2009 U.S. incidence in ICU patients is down more than 50% from 2001 levels, but 41,000 patients have CRBSI each year [CDC, 2011].)	Catheter hub contamination; contamination of infusate; spread of bacteria through bloodstream from distant site	<i>Systemic:</i> Isolation of same microorganism from blood culture and catheter segment, with patient showing fever, chills, malaise, elevated white blood cell count	<i>Systemic:</i> Antibiotics intravenously, removal of catheter by proper professional (CRNP, PA-C, or MD).	Use full sterile-barrier precautions during catheter insertion and dressing change. Use antibiotic-impregnated catheters. Do not disconnect tubing unnecessarily. Replace IV tubing and filter every 72 hours for standard PN (INS, 2011).
Hyperglycemia	Possible blood-draw error, confirm with bedside glucose device; patient receiving too little insulin in PN solution	Excessive thirst, urination, blood glucose >160 mg/100 dL, confusion	Call health care provider; may need to slow infusion rate (health care provider order)	Review medical history for blood drawn through central line with PN infusing (repeat peripheral blood draw), glucose intolerance or diabetes, new infection, new medication such as steroids; keep rate as ordered; never increase PN to "catch up." Maintain blood glucose in range of 90-130 mg/100 dL or within range ordered by health care provider. Use aseptic technique and routine blood glucose monitoring.

TABLE 32-1 Complications of Parenteral Nutrition—cont'd

Problem	Cause	Symptoms	Immediate Action	Prevention
Hypoglycemia	PN abruptly discontinued; too much insulin	Patient shaky, dizzy, nervous, anxious, hungry, blood glucose level <80 mg/100 dL	Call health care provider; if PN discontinued abruptly, may need to restart D ₁₀ W at previous PN rate. If patient has oral intake, give ½ cup fruit juice. Perform blood glucose monitoring; retest in 15 to 30 min.	Decrease PN, “tapering” gradually until discontinued; blood glucose monitoring is used to ensure adequate insulin.

CRBSI, Catheter-related bloodstream infection; CVC, central venous catheter; PN, Central parenteral nutrition; CRNP, certified registered nurse practitioner; ICU, intensive care unit; IV, intravenous; MD, medical doctor; PA-C, physician’s assistant-certified.

TABLE 32-2 Comparison of Central versus Peripheral Parenteral Nutrition Orders

	Central Parenteral Nutrition	Peripheral Parenteral Nutrition
Osmolality	>600 mOsm	<600 mOsm
Route of administration	Central venous catheter	Small peripheral vein
Usual daily caloric intake	20-35 kcal/kg/day	5-10 kcal/kg/day
Usual daily volume (mL)	1000-2000	2000-3000
Fat emulsion	Minor caloric source	Major caloric source

lipid is infused. A filter is necessary because it prevents particulate matter or large droplets of lipid from reaching a patient, which could potentially result in a pulmonary embolism.

Patients who receive PN solutions containing glucose and amino acids but no lipids are at risk for essential fatty acid deficiency (EFAD). EFAD can appear within 3 weeks of fat-free PN administration when no oral or enteral fat intake is provided (Worthington and Gilbert, 2012). EFAD is characterized by scaly dermatitis, hair loss, impaired wound healing, decreased resistance to stress, increased susceptibility to respiratory tract infections, anemia, thrombocytopenia, and liver function abnormalities.

MEDICATIONS

In some patients regular insulin is added to a PN admixture to maintain blood glucose control. In addition, some hospital policies also permit the addition of medications that reduce gastric acidity. However, the routine addition of any medications is discouraged when the compatibility and stability of the components are not known. Bedside addition of any medication is prohibited by most hospital policies because of the risk of solution contamination.

ADMINISTRATION OF PARENTERAL NUTRITION

Nurses collaborate with nutrition support teams and health care providers in administering PN and monitoring patients’ response

to PN therapy. Although practice patterns vary across hospitals, typically dietitians or pharmacists provide advice on nutrition support goals and/or write PN orders. Nurses at the bedside administer the ordered PN with care regarding accuracy of PN label versus orders, with attention to obtaining blood glucose, laboratory panels, intake/output measures, body weight, vital signs, and food intake if the patient has a diet order.

LABORATORY MONITORING

Because hyperglycemia has been linked with increased infection rates, monitoring blood glucose levels during a PN infusion is an important procedure (see Skill 43-9). Typical orders may be to monitor blood glucose levels every 6 hours (4 times daily) until it is within optimal limits (i.e., 70 to 180 mg/dL) or as defined by unit protocols for 48 hours. Then you monitor blood glucose daily for the duration of PN therapy. When the goal is to prepare a patient for home infusion of PN, it is very important to monitor glucose levels approximately 2 hours after an infusion begins (peak level) and 2 hours after it ends (trough level) to evaluate the need for adding regular human insulin to the infusion bag.

Patients who require PN infusions do so for medical or surgical conditions that are often associated with electrolyte instability. Thus a typical laboratory panel relative to PN infusions would include a baseline assessment of electrolytes, serum proteins, and complete blood count (Box 32-2). Nutrients in a PN infusion may alter serum levels. In very malnourished patients, during a process termed *refeeding syndrome*, some electrolytes (e.g., potassium [K], magnesium [Mg] and phosphorus) may shift intracellularly with glucose provided in the PN, potentially resulting in low serum levels with risk for arrhythmias and muscle weakness. If refeeding syndrome is predicted based on the degree of malnutrition or if it occurs, electrolyte panels may be ordered 2 or 3 times daily to permit adequate electrolyte repletion.

MONITORING PATIENT STATUS AND OUTCOMES

Since a PN solution is typically provided in response to GI dysfunction and to support nutritional needs, it is important for you to monitor data that describes patient progress. Measurement of intake and output is very important to document when a patient’s GI function is changing and to provide information regarding the adequacy of fluid intake from the PN solution. The patient’s body

BOX 32-2 Typical Monitoring and Laboratory Orders for Patients with Parenteral Nutrition**Monitor**

- Fluid intake, urine and gastrointestinal output every 8 hours
- Vital signs every 4 hours
- Body weight at least 3 times weekly

Initial and Repeated Weekly

- Complete metabolic panel with sodium (Na), potassium (K), chloride (Cl), carbon dioxide (CO₂), glucose, calcium (Ca), phosphate (PO₄), magnesium (Mg), triglycerides, transaminases
- Complete blood count (CBC) with hemoglobin, hematocrit, white blood count (WBC), red blood cells (RBC), lymphocyte count
- Serum proteins, often including albumin, transferrin, and/or prealbumin

Daily Until Stable

- Electrolyte panel daily until stable; then weekly
- Glucose every 6 hours until within normal limits for 48 hours; then daily
- Glucose in preparation for cyclic home parenteral nutrition (PN); monitor 2 hours after PN begins and 2 hours after PN ends; adjust insulin per orders

weight is a second sign of whether hydration needs are being met and, over a longer term, whether energy needs are adequate. Since there is a risk of bloodstream infection in patients with catheters, monitoring temperature regularly is important. Most typically intake and output are measured every 8 hours, vital signs every 4 hours, and body weight at least 3 times weekly (see *Box 32-2*).

EVIDENCE-BASED PRACTICE

When critically ill patients cannot tolerate enteral nutrition, PN alone provides beneficial effects and decreases patient infection rates when it is initiated early versus later in their care (*Kutsogiannis et al., 2011; Thibault and Pichard, 2010*). Patterns of practice regarding blood glucose control in hospitalized patients who receive PN are controversial and may change over time. In some instances there is lower mortality when critically ill patients receive insulin to maintain tight blood glucose control (*Pasquel et al., 2010*). A clinical trial documented 10% higher mortality in patients who were not overfed but were treated with insulin to achieve tight blood glucose control (*NICE-SUGAR, 2009*). Because of concern about the risks of hypoglycemia, several professional organizations recommend more relaxed goals for glycemic control (*Worthington and Gilbert, 2012*).

- Early nutritional assessment is crucial to determine a patient's need for PN as a single or adjunct nutritional therapy (*Worthington and Gilbert, 2012*).
- When PN is the only nutritional therapy for critically ill patients, a patient who was healthy and well-nourished before the illness can wait 7 days for its initiation (*Worthington and Gilbert, 2012*).
- Patients with preexisting nutritional deficits and catabolic illnesses require earlier PN intervention.

- Blood glucose should be maintained in a range of 70 to 180 mg/dL (*Moghissi et al., 2009*).
 - Hypoglycemia with blood glucose level <70 mg/dL should be avoided (*Moghissi et al., 2009*).
- The ideal method for delivering PN is through a central venous catheter, which allows for a higher concentration of nutrients (*Kutsogiannis et al., 2011; Worthington and Gilbert, 2012*).

PATIENT-CENTERED CARE

Patients needing PN are usually quite ill and at times require a lengthy stay in a health care agency. In addition, some patients receive PN in their home setting. Regardless of the reason or duration for PN, each patient has individual care needs that extend beyond the nutritional support that PN offers. Remember that your patients have individual preferences related to their hygiene practices; these preferences should never be overlooked because a patient requires PN. Include patient and family in decisions to maintain patient control, activity level, personal decision making, and socialization with friends and family.

PN may pose concerns for members of ethnic groups or people with philosophic beliefs that include restriction of animal products. Consider the following guidelines:

- Accommodate religious and cultural beliefs that require avoidance of animal products.
 - The components of PN are largely synthetic and do not contain pork.
 - The lipid emulsion contains egg phospholipid, a product that may be objectionable to vegan patients.
- Even though people who are ill are exempt from expectations of fasting during Ramadan, some devout Muslim patients may prefer to fast from dawn to dusk.
 - If this is the case, the patient's PN may be gradually cycled to begin the infusion at dusk and take it down at dawn the next morning.
- The use of mechanical devices such as infusion pumps may be objectionable for Orthodox Jews on the Sabbath.
 - If this is the case, discuss the possibility of running the pump with a fully charged battery rather than having it plugged in to an electrical outlet.

Safety Guidelines

- 1 Know the complications associated with PN, including metabolic disturbances, fluid imbalance, technical management of catheter system, and infections.
- 2 Monitor a patient's vital signs, electrolyte levels, glucose levels, triglyceride levels, weight, and fluid intake and output and compare baseline with treatment values. Some patients who receive PN have rapid changes in these values.
- 3 Know the patient's recent temperature range. Patients with peripheral or central IV lines are susceptible to CRBSIs; an elevated temperature is an early indicator of a bacterial infection.
- 4 Routinely assess the site of a central venous access device for signs of infection.
- 5 Use strict aseptic technique in the care and maintenance of central venous catheters and PICC lines.

SKILL 32-1 Administering Parenteral Nutrition Through a Central Line

Administration of parenteral nutrition through a central line (CPN) requires the use of strict aseptic technique and application of critical thinking. Because of the composition of CPN fluids, patients can experience metabolic and fluid balance changes quickly. In addition, the clinical condition of patients receiving CPN is usually poor, especially when they have alterations in host defenses, severe underlying illnesses, and extremes of age. You will need to anticipate changes in a patient’s condition that signal developing complications. Similarly, you need to use good judgment to maintain the intravenous (IV) system and ensure that it is functioning properly.

Delegation and Collaboration

The skill of administering CPN cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report when the pump alarms, catheter dressings are wet, temperature is elevated, or a patient has any complaints.
- Perform fingerstick blood glucose monitoring as directed and report any abnormal results to the nurse.

- Report vital signs that are out of range to nurse.
- Weigh patient as directed.

Equipment

- IV infusion tubing with Luer-Lok tip
- Parenteral (PN) solution
- IV filter (1.2-µm filter for three-in-one solutions or lipids containing a membrane that is particulate retentive and air eliminating; 0.22-µm filter for solutions that do not contain lipids) (INS, 2011)
- IV infusion pump
- Bedside glucose monitoring kit
- Adhesive tape or tubing label
- Clean gloves
- Stethoscope
- Medication administration record (MAR) or computer printout

STEP

RATIONALE

ASSESSMENT

- 1 Assess indications of and risks for protein/calorie malnutrition: weight loss from baseline or ideal, muscle atrophy/weakness, edema, lethargy, failure to wean from ventilatory support, chronic illness, and nothing by mouth for more than 6 days. Confer with nutritional support team.
- 2 Inspect condition of central vein access site for presence of inflammation, edema, and tenderness. Inspect tubing of access device for patency and kinking.
- 3 Assess levels of serum albumin, total protein, transferrin, prealbumin, and triglycerides and check blood glucose level by fingerstick (see Chapter 43).
- 4 Assess patient’s medical history for factors influenced by PCN administration: electrolyte levels; renal, cardiac, and hepatic function. Assess for history of allergies.
- 5 Assess vital signs, auscultate patient’s lung sounds, and measure weight.
- 6 Consult with health care provider and dietitian on calculation of calorie, protein, and fluid requirements for patient.
- 7 Verify order for nutrients, minerals, vitamins, trace elements, electrolytes, added medications, and flow rate. Check for compatibility of added medications.

- Clinical indications for PN. These baseline details provide a baseline from which change can be noted.
- Identifies early signs of infection, infiltration, or disruption in system integrity. Development of complication contraindicates infusion of fluids and indicates need to establish new IV site.
- Provides baseline for measuring patient’s nutritional status. In addition, nutritional baseline identifies patient’s unique requirements, and PN admixture is tailored to patient’s specific needs (Worthington and Gilbert, 2012).
- Serum glucose determines patient’s baseline and tolerance to high levels of glucose in CPN solution.
- Some patients require that CPN therapy be adapted by composition or volume (requires health care provider order) based on medical history. CPN includes constituents (e.g., medications) to which patient may be allergic.
- Provides baseline for monitoring patient’s response to fluid infusion and nutrients. Crackles in lungs are early indication of fluid volume excess.
- Provides multidisciplinary plan for patient’s nutritional support.
- CPN is often ordered daily in hospital setting after review of laboratory values. In home setting orders may be obtained less frequently (e.g., weekly). Pharmacies that prepare parenteral solutions will check medication compatibility.

NURSING DIAGNOSES

- Deficient fluid volume
- Excess fluid volume
- Imbalanced nutrition: less than body requirements
- Risk for infection
- Risk for unstable blood glucose level

Related factors are individualized based on patient’s condition or needs.

STEP

RATIONALE

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient's ideal weight gain is between 1 and 2 lbs (0.5 to 1 kg) per week.
 - Serum glucose levels are less than 180 mg/dL or maintained between 70 and 140 mg/dL. Check health care provider's order for desired glucose range.
 - Central venous access device is patent; and site is free of pain, swelling, redness, or inflammation.
 - Patient is afebrile.
- 2 Explain purposes of CPN to patient.
- 3 If CPN solution is refrigerated, remove from refrigeration 1 hour before infusion.

Weight is an indicator of patient's nutritional status and determines fluid volume. Weight gain greater than 1 lb (0.5 kg)/day indicates fluid retention.

The benefits of tight glucose control have not been determined; thus a glucose range should be individualized to a patient's specific health care need (Worthington and Gilbert, 2012). Both high and low blood glucose levels have been associated with morbidity and complications (Moghissi et al., 2009).

Ensures that CPN is infusing into vein rather than into surrounding tissues and that there are no signs of an access device infection.

Absence of systemic infection.

Promotes understanding and reduces anxiety.

Solution should be at room temperature for administration (INS, 2011).

IMPLEMENTATION

- 1 Perform hand hygiene.
- 2 Review transcriber's order against MAR and ensure that solution is correct and properly labeled.
- 3 Compare label of CPN bag with MAR or computer printout; check for correct additives and solution expiration date. Also check patient's name against label of CPN bag.
- 4 Inspect 2:1 CPN solution for particulate matter; inspect 3:1 CPN solution for separation of solution.

Reduces transmission of microorganisms.

Prevents medication error. *This is the first check for accuracy.*

This is the second check for accuracy.

Deterioration of three-in-one solution results in breakdown of emulsion.

Clinical Decision Point Do not use CPN solution if it has coalesced (thick, dense layer of fat droplets at surface, appearing 10 cm [4 inches] in thickness) or oiled out (fat droplets separate from solution that appear as a clear layer at surface) or appears abnormal in any way. Notify the pharmacy and request a new solution (Hardy and Puzovic, 2009).

- 5 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.
- 6 Apply clean gloves. Attach appropriate filter to IV tubing. Prime tubing with CPN solution, making sure that no air bubbles remain, and turn off flow with roller clamp (see Chapter 28). Connect end of tubing to appropriate port of central catheter and label port. Open roller clamp to rate that maintains patency of line.
- 7 Place IV tubing into IV infusion pump, open roller clamp completely, and regulate flow rate on pump as ordered (see Chapter 28) (see illustration). In some agencies, infusion rate is immediately set at the ordered rate. In other agencies an initial rate of 40 to 60 mL/hr is established, and the rate is gradually increased until patient's nutritional needs are supplied (refer to agency policy).

Ensures correct patient. Complies with The Joint Commission requirements and improves patient safety (TJC, 2012). *This is the third check for accuracy.*

Air introduced into central circulation can result in an air embolus, a fatal complication. Labeling of high-risk catheters prevents connection with inappropriate tube or catheter (TJC, 2012).

PN flow rates are ordered to meet patient's metabolic and electrolyte needs. Maintaining rates prevents electrolyte imbalances.

Critical Decision Point Increase rate of infusion gradually to prevent metabolic and electrolyte abnormalities because central PN is hyperosmolar and patients usually tolerate it when it is increased incrementally. If PN must be discontinued suddenly, hang infusion of 5% dextrose in water at same infusion rate to prevent hypoglycemia. PN solution, including lipids, should be infused within 24 hours (INS, 2011).

- 8 Infuse all IV medications or blood through an alternative IV line. Do not obtain blood samples or central venous pressure readings through same lumen or port used for CPN.

Prevents drug incompatibility. Prevents occlusion of central line and reduces risk for transmission of infection.

STEP

RATIONALE

STEP 7 Parenteral nutrition solution infusing via infusion pump.

- | | |
|--|---|
| <p>9 Do not interrupt PN infusion (e.g., during showers, transport to procedure, blood transfusion) and be sure that rate does not exceed ordered rate.</p> <p>10 Change infusing tubing and filter using strict aseptic technique. Change IV administration sets for CPN every 24 hours and immediately on suspected contamination (INS, 2011).</p> <p>11 Discard used supplies and perform hand hygiene.</p> | <p>Maintains continuous infusion of nutrients; prevents hypoglycemic reaction. Never attempt to catch up on a delayed infusion.</p> <p>Prevents development of catheter-related bacteremia (Worthington and Gilbert, 2012).</p> <p>Reduces transmission of infection.</p> |
|--|---|

EVALUATION

- | | |
|---|--|
| <p>1 Monitor flow rate routinely, at least hourly.</p> <p>2 Monitor fluid intake and urine and gastrointestinal fluid output every 8 hours.</p> <p>3 Obtain daily weights or weights as ordered.</p> <p>4 Assess for fluid retention; palpate skin of extremities; auscultate lung sounds.</p> <p>5 Monitor patient's glucose level every 6 hours or as ordered and other laboratory parameters daily or as ordered.</p> <p>6 Inspect central venous access site.</p> <p>7 Monitor for temperature, elevated white blood cell count, and malaise.</p> | <p>Too-rapid or too-slow infusion could result in metabolic disturbances such as hyperglycemia and fluid overload.</p> <p>Prevents fluid imbalance from too-slow or too-rapid infusion.</p> <p>Routine measurement of weights will reflect a gain/loss resulting either from caloric intake or fluid retention. Gradual weight gain, if weight gain is the goal, indicates adequate tolerance.</p> <p>Weight gain in excess of 1 lb (0.5 kg)/day, dependent edema, lung crackles, and intake greater than output per each 24-hour period indicate fluid retention.</p> <p>Maintenance of normal electrolyte levels, satisfactory fluid balance, acceptable serum glucose levels, and improvement in serum proteins indicate adequate tolerance to PN.</p> <p>Determines IV patency and absence of infection, infiltration, or phlebitis.</p> <p>Signs of systemic infection.</p> |
|---|--|

Unexpected Outcomes

- 1 There is redness, swelling, and tenderness around venous access site, indicating possible exit site infection.
- 2 Patient develops fever, malaise, and chills, indicating systemic infection.
- 3 Infusion stops flowing or flows at rate slower than ordered.
- 4 Patient experiences weight gain greater than 1 lb (0.5 kg)/day. Taut skin turgor is also present. Crackles auscultated over lung fields.
- 5 Serum glucose level is greater than 180 mg/dL or target set by health care provider.
- 6 Serum electrolyte levels are out of normal range.

Related Interventions

- Notify health care provider.
- Apply warm compress and initiate daily site care as ordered.
- Systemic antibiotic therapy may begin.
- Check exit site for signs of infection.
- Notify health care provider and consult about need to obtain cultures of exit site or blood.
- Systemic antibiotic therapy may begin.
- Venous access device is possibly occluded with fibrin or particulate matter. Report occlusion to health care provider.
- If device is a surgically placed device or peripherally inserted central catheter (PICC), thrombolytic agent may be ordered.
- Notify health care provider.
- Anticipate need to reduce IV infusion rate.
- Notify health care provider.
- Indicates intolerance to glucose load in CPN solution.
- Possible need for addition of insulin to CPN, modification of CPN solution, or sliding-scale insulin coverage.
- Indicates movement of electrolytes in response to infusion of fluids and glucose or excess requirements caused by medications or gastrointestinal losses. May need to adjust electrolyte levels in solution.

Recording and Reporting

- Record condition of central venous access device, rate and type of infusion, catheter lumen used for infusion, intake and output (I&O) every 8 hours, blood glucose levels, vital signs, and weights.
- If signs of infection, occlusion, fluid retention, or infiltration occur, notify the health care provider.

Special Considerations

Teaching

- Instruct patient and family in the purpose and goals of CPN. Keep them informed about daily care of central line.

Pediatric

- Consider children's developmental needs when they are on long-term CPN. Perform regular assessments of development to determine child's progress. Implement interventions to encourage expected milestones (Hockenberry and Wilson, 2011).

Gerontological

- Some older adults have impaired ability to tolerate higher fluid volumes because of cardiac or renal impairment.

Home Care

- Patients requiring long-term CPN benefit from a referral to a home nutrition therapy team.

- Patients receiving home CPN usually have a tunneled or implanted catheter inserted into the subclavian vein (see Fig. 32-3) to reduce the possibility of infection. Patients or family members need to learn to perform catheter site care, dressing changes, and techniques for connecting and disconnecting PN solutions.
- Some patients receive home CPN at night during sleep (cyclic CPN) to allow the freedom to leave home or work during the day. Most patients also take oral diet as tolerated, although their impaired gastrointestinal function limits nutrient absorption.
- Teach patient and family caregiver to monitor patient's weight, oral intake, I&O, and serum glucose level.
- Teach patient and family caregiver about actions to take in case of emergency or unexpected outcomes such as telephoning the health care provider or going to the hospital, depending on the circumstances.
- If home CPN patients require insulin in their CPN, they will need a home glucose monitoring device and instruction in its use.
- Patient teaching for home CPN administration will be given by home infusion nurses after discharge or may be initiated in the hospital and continued at home.

SKILL 32-2 Administering Parenteral Nutrition Through a Peripheral Line

Video Clip

The administration of parenteral nutrition (PN) via peripheral veins (PPN) requires a lower nutrient content and is more appropriate for preventing malnutrition than for correcting nutritional deficits. Patients with elevated nutritional requirements from hypermetabolic illnesses or conditions and patients with fluid restrictions are not suitable candidates (Worthington and Gilbert, 2012). This therapy is for short-term use, usually for 2 weeks or less. The PPN solution uses lower concentrations

of dextrose and amino acids to reduce the osmolality (see Table 32-2 on p. 799) and decrease the risk for phlebitis. Adding lipid emulsion adds a source of calories with minimal impact on the osmolality. A lipid emulsion must be administered through vented intravenous (IV) tubing as a primary IV or as a piggyback.

This skill describes a piggyback administration of PN. Administration sets (including piggybacks) used for fat emulsions are changed every 24 hours and immediately on suspected contamination (INS, 2011). The administration set must have a Luer-Lok design. Indications for PPN include the following:

- 1 *Adequate peripheral access:* Despite its lower osmolality, PPN tends to cause phlebitis and often requires frequent changes in the access location.
- 2 *Ability to tolerate larger volumes of fluid:* Because of the lower concentration of dextrose in PPN, a larger volume of fluid is required to attain adequate calories. Some patients with impaired renal or cardiac function do not tolerate PPN.
- 3 *Ability to tolerate lipid emulsions:* Lipid is the most calorically dense nutrient. One liter of 10% dextrose without lipid provides only 340 kcal. A 250-mL amount of 20% lipid solution provides 500 kcal.

Delegation and Collaboration

The skill of administering PPN through a peripheral IV line cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report patient complaint of burning, pain, or redness at peripheral IV site.

- Report to nurse infusion pump alarms or moist IV site dressing.
- Report to nurse patient complaints of shortness of breath and change in vital signs.

Equipment

- PPN solution
- Lipid emulsion in glass container or in a separate chamber of the PN bag
- IV tubing for PPN with 0.22-µm filter for amino acid/dextrose solution
- Nonphthalate vented IV tubing infusion set for fat emulsion
- Needleless cannula
- Bedside glucose monitoring kit
- Antimicrobial swab
- Infusion pump
- Clean gloves
- Medication administration record (MAR) or computer printout

STEP **RATIONALE**

ASSESSMENT

- 1 Assess patient for hypertriglyceridemia. Obtain orders for serum triglyceride level before initiation of PPN and weekly.
- 2 Select or initiate appropriate functional IV site (18-gauge catheter) to administer PPN and lipid emulsion. Assess its patency and function (see [Chapter 28](#)).
- 3 Check health care provider’s order against MAR for volume of fat emulsion, PPN solution, and administration time for fat emulsion.
- 4 Read label of fat emulsion solution.
- 5 Assess blood glucose level by fingerstick (see [Skill 43-9](#)).
- 6 Assess patient’s fluid status by monitoring for edema, shortness of breath, or fluid intake greater than fluid output.
- 7 Obtain patient’s weight and vital signs before beginning infusion.

- Determines patient’s ability to metabolize lipid.
- Large-gauge catheter ensures more efficient flow of infusion.
- Health care provider must order fat emulsions and PPN. Fat emulsions may cause adverse symptoms if infused too rapidly as separate infusion. Infusion time is normally at least 8 hours. Fat emulsions should hang no longer than 12 hours as separate infusion from original container. *This is the first check for accuracy.*
- Lipid emulsions are white and opaque; thus make sure to avoid confusing enteral tube feeding formula with parenteral lipids.
- Provides baseline to determine tolerance to glucose infusion.
- The fluid intake that is given with PPN may cause fluid overload in patients who are elderly or have impaired renal or cardiac function ([Worthington and Gilbert, 2012](#)).
- Provides baseline information to determine effectiveness and tolerance to PPN solution.

NURSING DIAGNOSES

- Excess fluid volume
- Imbalanced nutrition: less than body requirements
- Risk for infection
- Risk for unstable blood glucose level

Related factors are individualized based on patient’s condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Triglyceride level is <250 mg/dL in most patients.
 - Venipuncture site is free of phlebitis, pain, swelling, redness, and inflammation.
 - Patient does not show signs of systemic infection (e.g., elevated temperature).
 - Patient does not show signs of allergy to lipids.
- 2 Explain purposes of PPN and fat emulsion.

- Indicates adequate clearance of lipid.
- Ensures proper administration and monitoring of PPN with lipids.
- Temperature is indication of possible systemic infection related to PN.
- Monitoring of infusion requires observation for allergic response to infusion.
- Promotes understanding and reduces anxiety.

STEP	RATIONALE
3 Place patient in comfortable position for IV insertion or initiation of infusion.	When patients are comfortable, they tolerate procedures more readily.
4 If PPN solution is refrigerated, remove from refrigeration 1 hour before infusion.	Solution should be at room temperature for administration (INS, 2011).

IMPLEMENTATION

1 Perform hand hygiene.	Reduces transmission of microorganisms. Prevents medication error. <i>This is the second check for accuracy.</i>
2 Compare label of PPN bag and lipid emulsion bottle with MAR or computer printout; check for correct additives and solution expiration date. Also check patient's name.	Do not administer if these elements appear.
3 Examine lipid solution for separation of emulsion into layers or fat globules or presence of froth.	Ensures patient identity. Complies with The Joint Commission requirements and improves patient safety (TJC, 2012). <i>This is the third check for accuracy.</i>
4 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in patient's MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.	Provides baseline assessment. Immediate allergic reaction can develop once infusion begins.
5 Measure patient's vital signs.	To prevent air from entering vascular system, clear all tubing.
6 Apply clean gloves. Prepare IV tubing for PPN solution (see Skill 28-3); run solution through tubing to remove excess air. Turn roller clamp to "off" position. Add sterile capped needle or place sterile cap on end of tubing. Follow same procedure with separate infusion set for lipid infusion.	Prevents disruption of existing IV and ensures patent infusion. Pump will deliver infusion at prescribed rate.
7 Connect PPN solution to patient's functional peripheral IV (see Skill 22-6). Gently disconnect old PPN tubing from IV site and insert adapter of new PPN infusion tubing. Open roller clamp on new tubing. Allow solution to run to ensure that tubing is patent; then regulate IV drip rate using electronic infusion pump.	Removes surface organisms at injection site and prevents organisms from entering blood system.
8 Clean needleless peripheral line tubing injection port with antimicrobial swab.	Fat emulsions cannot infuse through a 0.22- μ m IV filter. Refer to agency policy; if larger, 1.2- μ m filter is used, lipids may be infused above filter (INS, 2011). Labeling of high-risk catheters prevents connection with an inappropriate tube or catheter (TJC, 2012). Height of solution prevents backup into main infusion tubing.
9 Insert needleless valve at end of fat emulsion infusion tubing into injection port of main IV, closest to patient but below infusion filter on main parenteral nutrition line. Label tubing.	Initial slow infusion allows you to observe for allergic response.
10 Open roller clamp completely on fat emulsion infusion and check flow rate on infusion pump.	Up to 2.5 g fat/kg per day may be infused, but current practice is generally to give <1 g fat/kg body weight per day in adults.
11 Infuse lipids initially at 1 mL/min for adults and 0.1 mL/min for child for first 15 to 30 minutes; increase rate as ordered.	The rate of PPN administration does not need to be increased gradually. The lower concentration of dextrose allows most patients to tolerate the full administration rate without difficulty.
12 Begin PPN at ordered rate. 20% fats are infused over at least 8 hours. All lipids can hang for 12 hours as a separate infusion.	Reduces transmission of microorganisms.
13 Discard supplies and perform hand hygiene.	

EVALUATION

1 Monitor flow rate routinely hourly or more frequently if necessary.	Too-rapid or too-slow infusion could result in metabolic disturbances such as hyperglycemia.
2 Measure vital signs and patient's general comfort level every 10 minutes for first 30 minutes.	Monitors patient for lipid allergy.

STEP

RATIONALE

- 3 Monitor patient's laboratory values (e.g., triglycerides, liver function tests) daily and perform blood glucose monitoring as ordered. Measure serum lipids 4 hours after discontinuing infusion.
- 4 Monitor temperature every 4 hours and regularly inspect venipuncture site for signs of phlebitis or infiltration.
- 5 Assess patient's weight, intake and output (I&O), condition of peripheral extremities (for edema), and breath sounds.

Provides objective data to measure response to therapy (e.g., ability of liver to metabolize lipids). Measurement of lipids too soon after an infusion will yield incorrect blood values.

Determines onset of fever, a complication of intolerance to fat emulsion or sepsis. Determines integrity of IV system.

Weight gain, I&O imbalance, peripheral edema, and crackles in lungs indicate fluid retention.

Unexpected Outcomes

- 1 There is intolerance to fat emulsion, as evidenced by increased triglyceride levels, increased temperature (3° to 4° F), chills, flushing, headache, nausea and vomiting, diaphoresis, muscle ache, chest and back pain, dyspnea, pressure over the eyes, vertigo.
- 2 See Unexpected Outcomes and Related Interventions for Skill 32-1.

Related Interventions

- Turn PN infusion off.
- Inform health care provider.
- Prepare to treat anaphylactic reaction according to health care provider's orders.
- Record lipid allergy in patient's medical record.

Recording and Reporting

- Record condition of IV site, type of solutions, rate and status of infusion, catheter lumen used for infusion, I&O every 8 hours, blood glucose levels, vital signs, weights, and other assessment findings in nurses' notes and electronic health record (EHR) or appropriate flow sheets.
- Record any adverse reactions in nurses' notes and EHR.
- If signs of fat intolerance, infection, occlusion, fluid retention, or infiltration occur, notify the health care provider.

Special Considerations

Teaching

- PPN administration does not occur in the home.

Pediatric

- See Skill 32-1.

Gerontologic

- Some older adults may have fragile peripheral veins or poor fluid tolerance because of cardiac or renal dysfunction, making PPN undesirable.

Home Care

- See Skill 32-1.

Critical Thinking Exercises

Mr. Giles is a 43-year-old patient admitted to the hospital with a severe exacerbation of Crohn's disease. He lost 4.5 kg (10 lbs) in the last 3 weeks and suffers recurrent abdominal pain, cramping, and loose stools. He is unable to tolerate food orally, becoming easily nauseated. He is to receive bowel rest and nutritional support with parenteral nutrition (PN). The health care provider inserted a central line for 3:1 PN therapy.

- 1 Identify four physical parameters that can change quickly and should be part of your baseline assessment before initiating PN.
- 2 Explain why it is necessary to assess blood glucose measurement before a patient receives PN.
- 3 On the third day after central line insertion, the patient develops a fever and fatigue, preferring to stay in bed. What might the fever indicate, and what could be its source?
- 4 Two days after beginning PN infusion, Mr. Giles experiences a 2-kg (5-lb) weight gain. He comments, "This stuff is great. I'm gaining back some of the weight I lost." What would be your response? What would you include in a nursing assessment?

REVIEW QUESTIONS

- 1 A patient is being switched from a standard intravenous (IV) solution to PN. What should the nurse tell the patient about why a large-diameter vein needs to be used for the infusion? (Select all that apply.)
 - 1 The fluid is very hyperosmolar.
 - 2 The fluid cannot flow through smaller veins.
 - 3 Peripheral veins become very irritated because of the content of the fluid.
 - 4 The patient will have the infusion for a long time; he will have use of both of his hands without an IV in them.
- 2 A patient is receiving an infusion of lipids through his central line. What symptoms might suggest that he or she is experiencing a lipid allergy?
 - 1 Elevated temperature, chills, nausea, and chest pain
 - 2 Respiratory distress, shortness of breath, chest pain, and decreased blood pressure
 - 3 Increased temperature, chills, malaise, and elevated white blood cell count
 - 4 Nausea and vomiting and bleeding and swelling at the insertion site
- 3 A patient is receiving a 3:1 PN infusion. How often should the IV infusion tubing be changed?
 - 1 Once a week
 - 2 Every 24 hours
 - 3 Every 72 hours
 - 4 After each solution is administered

- 4 What is the main purpose of PN?
 - 1 To provide full nutrient requirements while oral intake is precluded
 - 2 To replace enteral tube feedings
 - 3 To cure metabolic alterations from cancer
 - 4 To obtain additional caloric intake during hospitalization
- 5 What are the components of PN?
 - 1 Trace elements and electrolytes
 - 2 Vitamins
 - 3 Glucose, amino acids, lipids, and water
 - 4 All of the above
- 6 Which size filter should be used with a lipid-containing PN infusion?
 - 1 No filter required
 - 2 0.22- μ m filter
 - 3 1.2- μ m filter
 - 4 2- μ m filter
- 7 Which of the following is the most frequent risk associated with PN?
 - 1 Bowel obstruction
 - 2 Pneumonia
 - 3 High albumin levels
 - 4 Catheter-related bloodstream infections
- 8 Which of the following risks is more common with long-term use of PN than short-term PN?
 - 1 Hyperglycemia
 - 2 Hypercholesterolemia
 - 3 Hepatic disease
 - 4 Renal disease
- 9 A patient with which of the following is a good candidate for short-term PN?
 - 1 Anastomotic leak
 - 2 Intestinal obstruction
 - 3 Severe mucositis
 - 4 Severe malnutrition before surgery
 - 5 All of the above
- 10 Which of the following patients is a good candidate for long-term PN in the home?
 - 1 Short-bowel syndrome or dysmotility
 - 2 Inadequate food intake
 - 3 Personal preference
 - 4 Limited use of upper extremities because of disease process

KEY TERMS

Catheterization

Urinary retention

Micturition

Urinary tract infection

Postvoid residual (PVR)

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss nursing interventions that promote normal micturition when toilet access is compromised or after a catheter is removed.
- Discuss the relationship between fluid balance and urinary elimination.
- Identify factors that increase risk for catheter-associated urinary tract infection (CAUTI).

- Perform the following skills: place and remove urinal, insert urinary catheter, care for an indwelling urinary catheter, measure postvoid residual (PVR) with catheterization and bladder scan, irrigate a catheter, remove an indwelling catheter, apply a condom catheter, and care for a suprapubic catheter.

A key nursing responsibility is to support patients as they respond to threats to their health. A basic human function is urinary elimination, a function that can be compromised by a wide variety of illnesses and conditions. It is the role of a nurse to support bladder emptying as needed by helping a patient to a toilet or bedside commode, assist with a urinal, or perform catheterization. During acute illness a patient may require urinary catheterization for close monitoring of urine output or to facilitate bladder emptying when bladder function is compromised. Some patients require long-term indwelling catheters, urethral or suprapubic, when the bladder fails to empty effectively. The nurse also implements

measures to minimize risk for infection when bladder function is impaired or urinary drainage tubes are required.

EVIDENCE-BASED PRACTICE

In 2009 the Centers for Medicare and Medicaid Services (CMS) enacted policies that addressed expensive and potentially preventable conditions. One of those conditions included the use of indwelling urinary catheters in the acute care setting (CMS, 2009). The CMS policies included a major focus on preventing complications such as catheter-associated urinary tract infection (CAUTI). Soon after, the Centers for Disease

Control and Prevention (CDC) published its revised evidence-based guidelines for the prevention of CAUTI (Gould et al., 2009). Other major organizations such as Shearman and Sterling (S&S) and Infectious Disease Society of America (Lo et al., 2008); Association for Professionals in Infection Control and Epidemiology (APIC) (Green et al., 2008); International Consultation on Continence (Cottenden et al., 2009); and the Wound Ostomy Continence Nursing Society (WOCN) (Parker et al., 2009; Willson, 2009) have all published evidenced-based documents related to catheterization and catheter care. The Joint Commission (TJC) has included in its 2012 National Patient Safety Goals (2012) those that require the implementation of evidenced-based practices related to urinary catheterization to reduce CAUTI. All of these evidenced-based guidelines/goals contain common practices that nurses should incorporate when performing urinary catheterization and/or caring for patients with indwelling catheters. The practices for preventing CAUTI include:

- Aseptic insertion of urinary catheters (Gould et al., 2009; Green et al., 2008; Lo et al., 2008).
- Limiting the use of indwelling catheters to essential conditions and removing them as soon as medically indicated (Gould et al., 2009; Green et al., 2008; Nazarko, 2008). Examples of appropriate indications for catheterization include acute urinary retention, accurate intake and output measurement in critically ill patients, perioperative preparation for select surgeries, healing of open sacral or perineal wounds in incontinent patients, patients requiring prolonged bedrest, and comfort for end-of-life care (Gould et al., 2009).
- Using the smallest catheter possible (Gould et al., 2009; Lo et al., 2008; Parker et al., 2009).
- Daily cleansing of the urethral meatus with soap and water or perineal cleanser (Gould et al., 2009).
- Maintaining a closed urinary drainage system (Gould et al., 2009; Green et al., 2008; Lo et al., 2008).
- Maintaining a free flow of urine through the catheter (Gould et al., 2009; Green et al., 2008; Lo et al., 2008).
- Avoiding urethral trauma by securing a catheter (Gould et al., 2009; Green et al., 2008; Lo et al., 2008).
- Antiseptics applied to the urinary meatus are not effective and should not be applied (Willson et al., 2009).
- Antiseptic solutions placed in drainage bags and complex urinary drainage systems have not been found to be effective (Gould et al., 2009).

PATIENT-CENTERED CARE

The personal level of touch required when you assist patients with problems in urinary elimination requires you to understand their values and preferences. Determine how patients feel about having to undergo procedures such as catheterization. Try to adapt procedures to minimize the invasive nature of catheterization and maintain a patient's dignity and respect.

When caring for patients from divergent cultures, it is important to incorporate into the plan of care sensitivity and awareness of factors that may impact how you deal with urinary elimination problems. Variations within a cultural group are common. Assess each patient and care for him or her as an individual. Many cultures have specific beliefs and practices related to elimination, privacy, and gender-specific care. For example:

- Provide for a same-gender caregiver for cultures that emphasize female modesty and prohibit nonrelated males and females from touching, such as Iranian, Jewish Orthodox, Korean, Hindu, and Vietnamese (Purnell, 2009).

- Hispanic families tend to emphasize interdependence over independence; thus family presence at the bedside for important decision making is common (D'Avanzo, 2008).
- Privacy is important in many cultures; thus careful attention to draping is important.
- Some cultures continue to practice female genital circumcision, which can include removal of all or part of the clitoris; complete removal of the clitoris; part or complete removal of the labia minora; or in its most severe form the total removal of the clitoris and labia and sewing together the labia majora, leaving only a small opening for urine and menses (AAP, 2010).

Safety Guidelines

- 1 Regularly assess and determine patients' functional status, such as their ability to safely stand and/or transfer to a toilet or commode, their ability to follow and understand directions, and their motivation to help in self-care activities, such as using a toilet, commode, or urinal.
- 2 Evaluate a patient's normal pattern of micturition. Patients taking diuretic medications should have a toilet, commode, and/or urinal close to their bed or chair. Respond to any request for toileting assistance in a prompt manner to lessen the chance of patients falling as they try to reach a toilet.
- 3 Consider a patient's age when assessing voiding habits. Toilet training and enuresis are concerns for toddlers and preschoolers. Frail older adults are at higher risk for incontinence because of multiple health care problems and associated physiologic changes.
- 4 Patients who need assistance with elimination should have a call bell within easy reach and the offer for assistance at regular

TABLE 33-1 Signs of Fluid Volume Deficit and Fluid Volume Excess

Eyes	<i>FVD</i> : Sunken eyes, dry conjunctivae, decreased or absence of tearing <i>FVE</i> : Periorbital edema, blurred vision, papilledema
Mouth	<i>FVD</i> : Sticky, dry mucous membrane; dry, cracked lips; decreased saliva; increased viscosity of saliva; furrowed, shrunken tongue <i>FVE</i> : Excessive salivation
Skin	<i>FVD</i> : Increased skin temperature; dry, scaly skin; poor turgor <i>FVE</i> : Edema, anasarca
Cardiovascular	<i>FVD</i> : Increased pulse rate, weak pulse, hypotension, decreased pulse volume/pressure, decreased capillary filling, increased hematocrit, flat neck veins <i>FVE</i> : Bounding pulse rate, blood pressure normal with or without orthostatic changes, third heart sound (S ₃), distended neck veins
Gastrointestinal	<i>FVD</i> : Sunken abdomen <i>FVD</i> or <i>FVE</i> : Vomiting, diarrhea, abdominal cramps
Renal	<i>FVD</i> : Oliguria or anuria, urine specific gravity increased (normal, 1.010 to 1.030) <i>FVE</i> : Decreased urine specific gravity, diuresis (if kidneys are normal)

FVD, Fluid volume deficit; *FVE*, fluid volume excess.

- intervals, especially in the morning after awakening, after meals, and before bedtime.
- 5 Adequate oral intake is essential for bladder health, especially if a patient has an indwelling urinary catheter. Some patients with urinary problems limit fluid intake in fear of incontinence and/or increased urinary frequency. Explain the importance of fluid intake in maintaining urinary health.
 - 6 Evaluate urinary output.
 - a Know the average output range for a patient. Adult urinary output averages 2200 to 2700 mL in 24 hours. An hourly output of less than 30 mL/hr for 2 hours identifies the need for further evaluation.
 - b Know the signs of dehydration and fluid overload (Table 33-1). Start measurement of intake and output (I&O) when there is an actual or anticipated change in fluid balance.
 - c Assess a patient's most recent serum electrolyte measurements. Abnormal values reflect alterations in fluid balance that can lead to deterioration in patients' health.
 - d Weigh a patient to determine fluid status. Ask him or her to empty the bladder. Weigh with the same scale; at the same time of day; and with comparable articles of clothing, including bed linen if bed weights are necessary.
 - 7 Maintain aseptic technique when catheterizing a patient to prevent CAUTI (NQF, 2011).

PROCEDURAL GUIDELINE 33-1 Assisting with Use of a Urinal

Video Clip

A urinal is a container used to hold urine when access to a toilet is restricted. Patients who may need a urinal include those who have compromised mobility, severe dyspnea, or other illnesses that make walking to a bathroom impossible or excessively painful. In some instances a male patient may be able to stand at the bedside and use a urinal. Most urinals are used by men, but there are specially designed urinals for women (Fig. 33-1). The female urinal has a larger opening at the top with a defined rim, which helps position the urinal closely against the genitalia.

Delegation and Collaboration

The skill of assisting a patient in using a urinal can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Adjust for any special needs or adaptations such as a need to hold a urinal for a patient.
- Provide personal hygiene as necessary after urination.
- Report immediately any changes in urine color, clarity, and odor; development of incontinence (involuntary loss of urine); patient reports of dysuria, which could indicate an infection; and any changes in the frequency and amount of urine.
- Explain the procedure to patient and family to promote understanding and participation in care.

Equipment

- Urinal
- Clean gloves

- Graduated cylinder (used for measuring volume if urinal is not marked)
- Supplies for diagnostic urine tests and specimen collection (see Chapter 43)
- Washbasin, washcloths, towels, and soap
- Toilet tissue

Procedural Steps

- 1 Assess patient's normal urinary elimination habits, including any episodes of incontinence.
- 2 Determine how much assistance is needed to place and remove the urinal.
- 3 Determine if a urine specimen is to be collected.
- 4 Explain procedure to patient.
- 5 Provide privacy by closing bedside curtain and room door.
- 6 Assess for a distended bladder by inspecting the lower one third of the abdomen or palpating gently above symphysis pubis.
- 7 Perform hand hygiene and apply clean gloves.
- 8 Help patient into appropriate position: *for a male patient*: on side, back, sitting with head of bed elevated, or in standing position; *for a female patient*: lying supine. If needed, place an absorbent pad under patient's buttocks to protect bed linens from accidental spills.

Clinical Decision Point Before having a patient stand to void, assess lower-extremity strength and mobility and for orthostatic hypotension, especially if he has been on prolonged bed rest.

FIG 33-1 A, Male. B, Female urinals. (B Courtesy Briggs Medical Service Co.)

PROCEDURAL GUIDELINE 33-1 Assisting with Use of a Urinal—cont'd

- 9 If possible, a male patient should hold urinal and position penis in urinal. If needed, help patient by positioning penis completely in urinal and holding urinal in place or by helping him hold urinal. Ensure that the urinal is placed dependent of the flow of urine.
- 10 Help a female patient by positioning the urinal against the genitalia and stabilizing it to keep it in position and dependent of urine flow.
- 11 Cover patient with bed linens and place the call bell within reach. If possible, give patient further privacy by leaving the bedside after ensuring that he or she is in a safe and comfortable position.
- 12 After patient has finished voiding, remove urinal and assess characteristics of the urine for color, clarity, odor, and amount. Help him or her wash and dry penis or genitalia.
- 13 Measure urine and record output on intake and output (I&O) record, if needed (see [Chapter 6](#)).
- 14 Empty and clean urinal. Return urinal to patient for future use.
- 15 Help patient perform hand hygiene as needed.
- 16 Remove and dispose of gloves; perform hand hygiene.

**SKILL 33-1** Insertion of a Straight or an Indwelling Urinary Catheter**NSO** *Urinary Catheterization Module / Lessons 1 and 2*

Urinary catheterization is the placement of a tube through the urethra into the bladder to drain urine. This is an invasive procedure that requires a medical order and aseptic technique in institutional settings (Gould et al., 2009; Lo et al., 2008). Urinary catheterization may be short term (2 weeks or less) or long term (more than 1 month) (Parker et al., 2009). There are a limited number of conditions in which the use of a short- or long-term urinary catheter is appropriate (see [Evidence-Based Practice](#)). Excessive accumulation of urine in the bladder is painful for a patient; increases the risk for urinary tract infection (UTI); and can cause backward flow of urine up the ureters to the kidneys, causing kidney damage. Urinary incontinence, an involuntary leakage of urine, may require indwelling catheterization if the leaking urine interferes with wound healing (Cottenden et al., 2009). Intermittent catheterization is used to measure postvoid residual (PVR) when a bladder scanner is not available or as a way to manage chronic urinary retention.

The steps for inserting an indwelling and a single-use straight/intermittent catheter are the same. The difference lies in the inflation of a balloon to keep the indwelling catheter in place and the presence of a closed drainage system. Urinary catheters are made with one to three lumens (Fig. 33-2). Single-lumen catheters (see Fig. 33-2, A) are used for intermittent catheterization (i.e., the insertion of a catheter for one-time bladder emptying). Double-lumen catheters, designed for indwelling catheters, provide one lumen for urinary drainage and a second lumen to inflate a balloon that keeps the catheter in place (see Fig. 33-2, B). Triple-lumen catheters (see Fig. 33-2, C) are used for continuous bladder irrigation or when it becomes necessary to instill medications into the bladder. One lumen drains the bladder, a second lumen is used to inflate the balloon, and a third lumen delivers irrigation fluid into the bladder.

A health care provider chooses a catheter on the basis of factors such as latex allergy, history of catheter encrustation, and susceptibility to infection. Indwelling catheters are made of latex or silicone. Latex catheters with special coatings reduce urethral irritation (Cottenden et al., 2009). All silicone catheters have a larger internal diameter and may be helpful in patients who require frequent

catheter changes because of encrustation (Newman and Wein, 2009). Antimicrobial catheters are coated with silver or an antibiotic. These coated catheters have been shown to reduce the incidence of catheter-associated urinary tract infection (CAUTI) for short-term use, but to date there are insufficient data to support their use in long-term catheter users (Drekonja et al. 2008; Parker et al. 2009; Schumm and Lam, 2008). Straight or intermittent catheters are made of rubber (softer and more flexible) or polyvinylchloride (PVC). Patients who self-catheterize have a large selection of catheters, some with special coatings that do not require lubrication and some that are self-contained systems consisting of a catheter prelubricated and packaged with a preconnected drainage bag.

The size of a urinary catheter is based on the French (Fr) scale, which reflects the internal diameter of the catheter. Most adults with an indwelling catheter should have a size 14 to 16 Fr to minimize trauma and risk for infection. Larger catheter diameters increase the risk for urethral trauma (Parker et al., 2009). However, larger sizes are used in special circumstances such as after urologic surgery or in the presence of gross hematuria. Smaller sizes are needed for children (i.e., 5-6 Fr for infants, 8-10 Fr for children, and 12 Fr for young girls).

Indwelling catheters come in a variety of balloon sizes from 3 mL (for a child) to 30 mL for continuous bladder irrigation (CBI). The size of the balloon is usually printed on the catheter port (Fig. 33-3). The recommended balloon size for an adult is a 5-mL balloon (filled with 10 mL). Long-term use of larger balloons (30 mL) has been associated with increased patient discomfort, irritation, and trauma; increased risk of catheter expulsion; and incomplete emptying of the bladder because of urine that pools below the level of the catheter drainage lumen (Cottenden et al., 2009; Newman and Wein, 2009).

For patients with urinary retention or critical illness and who require long-term catheterization, catheter changes should be individualized, not routine (Gould et al., 2009; Green et al., 2008; Willson et al., 2009). They should be changed for leaking, for blockage, and before obtaining a sterile specimen for urine culture (Smith et al., 2008). Long-term catheterization should be avoided because of its association with UTI (Green, et al., 2008). Make every attempt to remove catheters as soon as a patient can void.

SKILL 33-1 Insertion of a Straight or an Indwelling Urinary Catheter

FIG 33-2 A, Single-lumen or straight catheter (cross section). B, Double-lumen or indwelling retention catheter (cross section). C, Triple-lumen catheter for continuous closed irrigation (cross section).

FIG 33-3 Size of catheter and balloon printed on catheter inflation valve.

An indwelling catheter is attached to a urinary drainage bag to collect the continuous flow of urine. Always hang the bag below the level of the bladder on the bed frame or a chair so urine drains down, out of the bladder. The bag should never touch the floor. When a patient ambulates, carry the bag below the level of his or her bladder. The only exception to this rule is when a catheter is attached to a specially designed drainage bag (belly bag) that is worn across the abdomen. A one-way valve prevents the back flow of urine into the bladder.

Delegation and Collaboration

The skill of inserting a straight or indwelling urinary catheter cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Help with patient positioning, focus lighting for the procedure, maintain privacy, empty urine from collection bag, and help with perineal care.
- Report postprocedure patient discomfort or fever to the nurse.
- Report abnormal color, odor, amount of urine in drainage bag, and if the catheter is leaking or causes pain.

Equipment

- ❑ Catheter kit (Fig. 33-4) containing the following sterile items: (Catheter kits vary; thus it is important to check the list of contents on the package.)
 - Catheter of correct size and type for procedure or patient condition (i.e., indwelling [double lumen 14 or 16 Fr] or intermittent [usually 12 to 14 Fr]). Some kits contain a catheter with attached drainage bag; others contain only a catheter; others have no catheter.
 - Drapes (one fenestrated—has an opening in the center)
 - Sterile gloves
 - Lubricant
 - Antiseptic cleaning solution such as chlorhexidine or povidone-iodine incorporated in an applicator or to be added to cotton balls (forceps to pick up cotton balls)
 - Specimen container
 - Prefilled syringe with sterile water for balloon inflation of an indwelling catheter

FIG 33-4 Indwelling catheterization kit includes drainage device, specimen cup, sterile drapes, sterile gloves, indwelling catheter, cleaning solution, sterile saline, sterile cotton balls, forceps, and lubricant. (Image used with permission Medline Industries. All rights reserved.)

- Sterile drainage tubing and collection bag (Some kits come preconnected; others do not, and a separate package is required.)
- Sterile drainage tubing and bag (if not included in the kit)
- Device to secure catheter (i.e., strap)
- Extra sterile gloves and catheter (optional)
- Bath blanket
- Waterproof absorbent pad
- Clean gloves; basin with warm water, soap or perineal cleaner, washcloth; and towel for perineal care
- Additional lighting as needed (such as a flashlight or procedure light)
- Measuring container for urine

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| <p>1 Review patient's medical record, including health care provider's order and nurses' notes. Note previous catheterization, including catheter size, response of patient, and time of catheterization.</p> | <p>Identifies purpose of inserting catheter (such as for measurement of PVR, preparation for surgery, or specimen collection) and potential difficulty with catheter insertion.</p> |
| <p>2 Review medical record for any pathologic condition that may impair passage of catheter (e.g., enlarged prostate gland in men, urethral strictures).</p> | <p>Obstruction of urethra may prevent passage of catheter into bladder.</p> |
| <p>3 Ask patient and check chart for allergies.</p> | <p>Identifies allergy to antiseptic, tape, latex, and lubricant.</p> |
| <p>4 Assess patient's weight, level of consciousness, developmental level, ability to cooperate, and mobility.</p> | <p>Determines positioning for catheterization; indicates how much assistance is needed to properly position patient, ability of patient to cooperate during procedure, and level of explanation needed.</p> |
| <p>5 Assess patient's gender and age.</p> | <p>Determines catheter size.</p> |
| <p>6 Assess patient's knowledge, prior experience with catheterization, and feelings about the procedure.</p> | <p>Reveals need for patient instruction and/or support.</p> |

Clinical Decision Point Large catheters can damage the urethra and urinary meatus, increase bladder irritability, and cause urine to leak around the catheter because of spasm (Cottenden et al., 2009). Use the smallest-size catheter possible to minimize trauma and patient discomfort (Gould et al., 2009; Lo et al., 2008).

- | | |
|---|--|
| <p>7 Assess for pain and bladder fullness. Palpate bladder over symphysis pubis or use bladder scanner (if available) (see Procedural Guideline 33-2).</p> | <p>Palpation of full bladder causes pain and/or urge to void, indicating full or overfull bladder.</p> |
| <p>8 Perform hand hygiene and apply clean gloves. Inspect perineal region, observing for perineal anatomic landmarks, erythema, drainage or discharge, and odor. Remove gloves and perform hand hygiene.</p> | <p>Assessment of female perineal landmarks improves accuracy and speed of catheter insertion.</p> |

NURSING DIAGNOSES

- | | | |
|---|---|---|
| <ul style="list-style-type: none"> • Acute pain • Anxiety | <ul style="list-style-type: none"> • Deficient knowledge regarding catheterization • Impaired urinary elimination | <ul style="list-style-type: none"> • Risk for infection • Urinary retention |
|---|---|---|

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient's bladder is not palpable. • Patient verbalizes absence of abdominal discomfort or bladder pressure/fullness. • Patient has urine output of at least 30 mL/hr as measured in urinary drainage bag. • Patient verbalizes purpose and expectations about procedure. <p>2 Explain procedure to patient.</p> <p>3 Arrange for extra personnel to help as necessary.</p> | <p>Bladder successfully emptied.</p> <p>Catheterization and free flow of urine through catheter relieve bladder distention and discomfort.</p> <p>Verifies presence of catheter in bladder, catheter patency, and adequate kidney function.</p> <p>Reflects patient understanding of procedure.</p> <p>Promotes cooperation.</p> <p>Some patients are unable to assume positioning independently for procedure.</p> |
|---|---|

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Check patient's plan of care for size and type of catheter (if this is a reinsertion). Use smallest-size catheter possible. Collect all required equipment.</p> <p>3 Perform hand hygiene.</p> <p>4 Provide privacy by closing room door and bedside curtain.</p> <p>5 Raise bed to appropriate working height. If side rails in use, raise side rail on opposite side of bed and lower side rail on working side.</p> <p>6 Place waterproof pad under patient.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Ensures that patient receives correct size and type of catheter. Larger catheter diameters increase the risk for urethral trauma (Parker et al., 2009). Small catheter allows for adequate drainage of periurethral glands.</p> <p>Reduces transmission of microorganisms.</p> <p>Promotes comfort and protects patient confidentiality.</p> <p>Promotes good body mechanics. Use of side rails in this manner promotes patient safety.</p> <p>Prevents soiling of bed linen.</p> |
|--|--|

Clinical Decision Point Obtain assistance to position and support weak, frail, obese, or confused patients from a co-worker.

- | | |
|---|--|
| <p>7 Position patient:</p> <p>a Female patient:</p> <p>(1) Help to dorsal recumbent position (on back with knees flexed). Ask patient to relax thighs so you can rotate hips.</p> <p>(2) Alternate female position: Position side-lying (Sims') position with upper leg flexed at knee and hip. Support patient with pillows if necessary to maintain position.</p> <p>b Male patient:</p> <p>(1) Position supine with legs extended and thighs slightly abducted.</p> <p>8 Drape patient.</p> <p>a Female patient</p> <p>(1) Drape with bath blanket. Place blanket diamond fashion over patient, with one corner at patient's midsection, side corners over each thigh and abdomen, and last corner over perineum (see illustration).</p> <p>b Male patient</p> <p>(1) Drape patient by covering upper part of body with small sheet or towel; drape with separate sheet or bath blanket so only perineum is exposed (see illustration).</p> <p>9 Apply clean gloves. Wash perineal area with soap and water, rinse, and dry (see Chapter 17). Use gloves to examine patient and identify urinary meatus. Remove and discard gloves.</p> <p>10 Position light to illuminate genitals or have assistant available to hold light source to visualize urinary meatus.</p> <p>11 Perform hand hygiene.</p> | <p>Exposes perineum and allows hip joints to be externally rotated.</p> <p>Alternate position is more comfortable if patient cannot abduct leg at hip joint (e.g., patient has arthritic joints or contractures).</p> <p>Comfortable position for patient aids in visualization of penis.</p> <p>Protects patient dignity by avoiding unnecessary exposure of body parts.</p> <p>Hygiene before initiating aseptic catheter insertion removes secretions, urine, and feces that could contaminate sterile field and increase risk for CAUTI.</p> <p>Adequate visualization of urinary meatus helps with speed and accuracy of catheter insertion.</p> <p>Reduces transmission of microorganisms.</p> |
|---|--|

STEP	RATIONALE
<p>12 Open outer wrapping of catheterization kit. Place inner wrapped catheter kit tray on clean, accessible surface such as bedside table or, if possible, between patients' open legs. Patient size and positioning dictate exact placement.</p>	Provides easy access to supplies during catheter insertion.
<p>13 Open inner sterile wrap covering tray containing catheterization supplies, using sterile technique (see Chapter 8). Fold back each flap of sterile covering one at a time, with last flap opened toward patient.</p>	Sterile wrap serves as sterile field.
<p>a Indwelling catheterization open system: Open separate package containing drainage bag, check to make sure that clamp on drainage port is closed, and place drainage bag and tubing in an easily accessible location. Open outer package of sterile catheter, maintaining sterility of inner wrapper (see Chapter 8).</p>	Open drainage bag systems have separate sterile packaging for sterile catheter, drainage bag and tubing, and insertion kit.
<p>b Indwelling catheterization closed system: All supplies are in sterile tray and are arranged in sequence of use.</p>	Closed drainage bag systems have catheter preattached to drainage tubing and bag.
<p>c Straight catheterization: All needed supplies are in sterile tray that contains supplies and can be used for urine collection.</p>	Maintains surgical asepsis.
<p>14 Put on sterile gloves. (Or apply sterile drape with ungloved hands when drape is packed as first item. Touch only edges of drape. Then apply clean gloves.)</p>	Sterile drapes provide sterile field over which you will work during catheterization.
<p>15 Drape perineum, keeping gloves sterile.</p>	When creating the cuff over sterile gloved hands, sterility of gloves and workspace is maintained.
<p>a <i>Drape female:</i></p> <ol style="list-style-type: none"> (1) Pick up square sterile drape touching only edges (2.5 cm [1 inch]). (2) Allow drape to unfold without touching unsterile surfaces. Allow top edge of drape (2.5 to 5 cm [1 to 2 in]) to form cuff over both hands. (3) Place drape with shiny side down on bed between patient's thighs. Slip cuffed edge just under buttocks as you ask patient to lift hips. Take care not to touch contaminated surfaces with sterile gloves (4) Pick up fenestrated sterile drape out of tray. Allow drape to unfold without touching unsterile surfaces. Allow top edge of drape to form cuff over both hands. Apply drape over perineum, exposing labia (see illustration). 	Opening in drape creates sterile field around labia.

STEP 8a(1) Female patient draped and in dorsal recumbent position.

STEP 8b(1) Draping male patient with blankets.

STEP

RATIONALE

b *Drape male:*

- (1) Use of square drape is optional; you may apply fenestrated drape instead.
- (2) Pick up edges of square drape and allow to unfold without touching unsterile surfaces. Place over thighs, with shiny side down, just below penis.
- (3) Place fenestrated drape with opening centered over penis (see illustration).

16 Move tray closer to patient. Arrange remaining supplies on sterile field, maintaining sterility of gloves. Place sterile tray with cleaning medium (premoistened swab sticks or cotton balls, forceps, and solution) lubricant, catheter, and prefilled syringe for inflating balloon (indwelling catheterization only) on sterile drape.

- a** If kit contains sterile cotton balls, open package of sterile antiseptic solution and pour over cotton balls. Some kits contain a package of premoistened swab sticks. Open end of package for easy access (see illustration and Fig. 33-4).
- b** Open sterile specimen container if specimen to be obtained (see Chapter 43).
- c** For indwelling catheterization, open sterile wrapper of catheter and leave catheter on sterile field. If part of a closed system kit, remove tray with catheter and pre-attached drainage bag and place on sterile drape. Make sure that clamp on drainage port of bag is closed. If needed and if part of sterile tray, attach catheter to drainage tubing.

Provides easy access to supplies during catheter insertion and helps to maintain aseptic technique. Appropriate placement is determined by size of patient and position during catheterization.

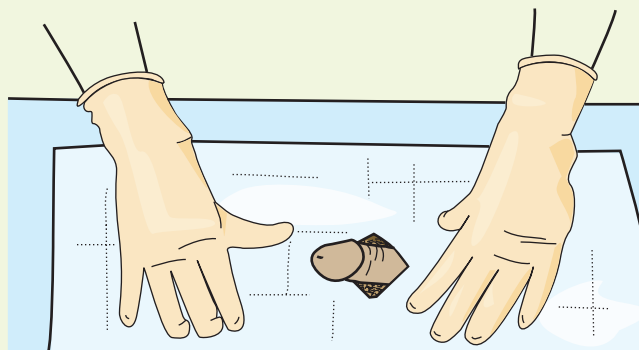

Use of sterile supplies and antiseptic solution reduces risk of CAUTI (Gould et al., 2009; Lo et al., 2008).

Makes container accessible to receive urine from catheter if specimen is needed.

Indwelling catheterization trays vary. Some have preattached catheters; others need to be attached but are part of the sterile tray; others do not have catheter or drainage system as part of tray.

STEP 15a(4) Place sterile fenestrated drape (with opening in center) over female's perineum.

STEP 15b(3) Draping male with fenestrated drape.

STEP 16a Sterile kit includes antiseptic swabs.

STEP 16d Lubricating catheter.

STEP

RATIONALE

- d Open packet of lubricant and squeeze out on sterile field. Lubricate catheter tip by dipping it into water-soluble gel 2.5 to 5 cm (1 to 2 inches) for women and 12.5 to 17.5 cm (5 to 7 inches) for men (see illustration).

Lubrication minimizes trauma to urethra and discomfort during catheter insertion.
Male catheter needs enough lubricant to cover length of catheter inserted.

Clinical Decision Point *Pretesting a balloon on an indwelling catheter by injecting fluid from the prefilled sterile water syringe into the balloon port is no longer recommended. Testing the balloon may distort and stretch it and lead to damage, causing increased trauma on insertion.*

17 Clean urethral meatus:

a Female patient:

- (1) Separate labia with fingers of nondominant hand (now contaminated) to fully expose urethral meatus.
- (2) Maintain position of nondominant hand throughout procedure.
- (3) Holding forceps in dominant hand, pick up one moistened cotton ball or pick up one swab stick at a time. Clean labia and urinary meatus from clitoris toward anus. Use new cotton ball or swab for each area that you clean. Clean by wiping far labial fold, near labial fold, and directly over center of urethral meatus (see illustration).

Optimal visualization of urethral meatus is possible.

Closure of labia during cleaning means that area is contaminated and requires cleaning procedure to be repeated.

Front-to-back cleaning moves from area of least contamination toward highly contaminated area. Follows principles of medical asepsis (see Chapter 7). Dominant gloved hand remains sterile.

b Male patient:

- (1) With nondominant hand (now contaminated) retract foreskin (if uncircumcised) and gently grasp penis at shaft just below glans. Hold shaft of penis at right angle to body. This hand remains in this position for remainder of procedure.
- (2) Using uncontaminated dominant hand, clean the meatus with cotton balls/swab sticks, using circular strokes, beginning at the meatus and working outward in a spiral motion.
- (3) Repeat cleansing three times using clean cotton ball/swab stick each time (see illustration).

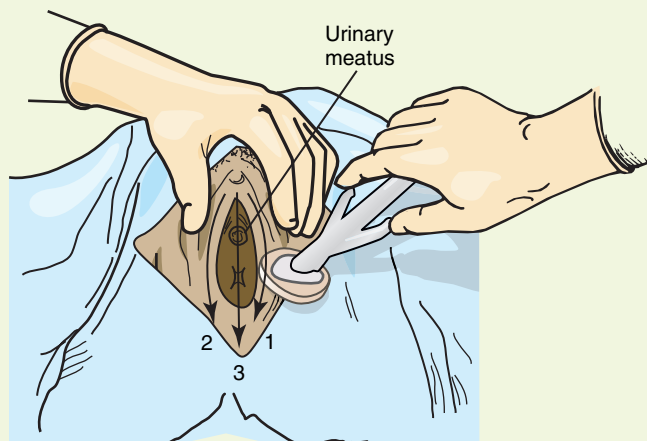

When grasping shaft of penis, avoid pressure on dorsal surface to prevent compression of urethra.

Losing grasp during cleaning means that area is contaminated and requires cleaning procedure to be repeated.

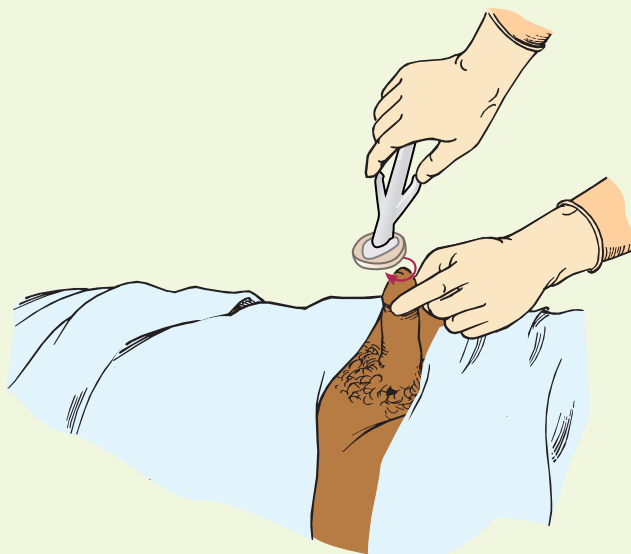

Circular cleaning pattern follows principles of medical asepsis (see Chapter 7).

- 18 Pick up and hold catheter 7.5 to 10 cm (3 to 4 inches) from catheter tip with catheter loosely coiled in palm of hand. If catheter is not attached to drainage bag, make sure to position urine tray so end of catheter can be placed there once insertion begins.

Holding catheter near tip allows for its easier manipulation during insertion. Coiling catheter in palm prevents distal end from striking nonsterile surface.

STEP 17a(3) Cleaning female perineum.

STEP 17b(3) Cleaning male urinary meatus.

STEP

RATIONALE

19 Insert catheter:

a Female patient:

- (1) Ask patient to bear down gently and slowly insert catheter through urethral meatus (see illustration).
- (2) Advance catheter total of 5 to 7.5 cm (2 to 3 inches) or until urine flows out of catheter. When urine appears, advance catheter another 2.5 to 5 cm (1 to 2 inches). Do not use force to insert catheter.
- (3) Release labia and hold catheter securely with nondominant hand.

Bearing down may help visualize urinary meatus and promotes relaxation of external urinary sphincter, aiding in catheter insertion.

Urine flow indicates that catheter tip is in bladder or lower urethra.

Clinical Decision Point *If no urine appears, catheter may be in vagina. If misplaced, leave catheter in vagina as landmark indicating where not to insert and insert another sterile catheter.*

b Male patient:

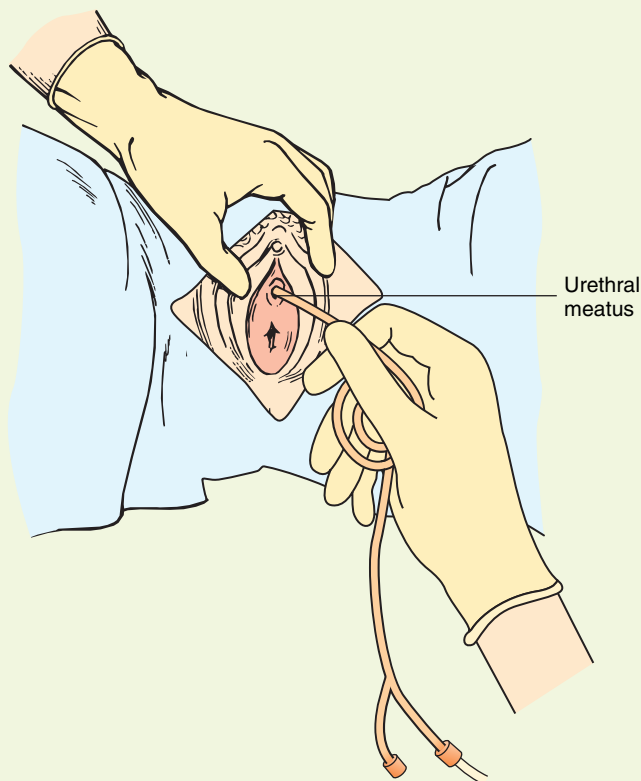

- (1) Lift penis to a position perpendicular (90 degrees) to patient's body and apply gentle upward traction (see illustration).
- (2) Ask patient to bear down as if to void and slowly insert catheter through urethral meatus.
- (3) Advance catheter 17 to 22.5 cm (7 to 9 inches) or until urine flows out end of catheter.
- (4) Stop advancing with a straight catheter. When urine appears in an indwelling catheter, advance it to bifurcation (inflation and deflation ports exposed) (see illustration).

Straightens urethra to ease catheter insertion.

Relaxation of external sphincter aids in insertion of catheter.

There are variations in length of male urethra. Flow of urine indicates that tip of catheter is in bladder or urethra but not necessarily that the balloon portion of an indwelling catheter is in bladder.

Further advancement of catheter to bifurcation of drainage and balloon inflation port ensures that balloon portion of catheter is not still in prostatic urethra (D'Cruz et al., 2009; Méndez-Probst et al., 2012; Newman and Wein, 2009).

STEP 19a(1) Inserting catheter into female urinary meatus.

STEP 19b(1) Inserting catheter into male urinary meatus.

STEP

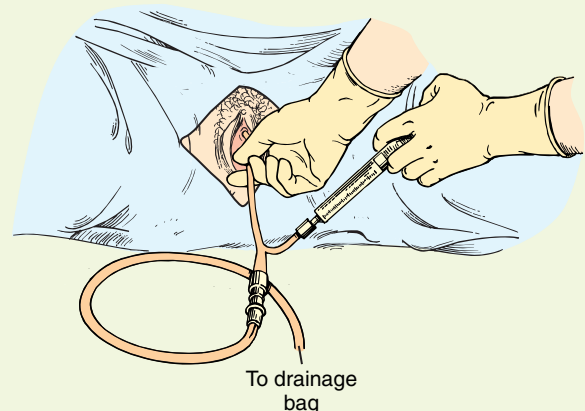

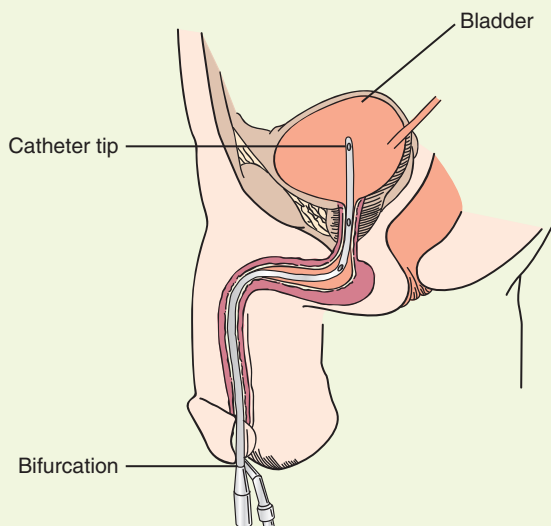

RATIONALE

Clinical Decision Point *If there is resistance or pain when advancing the catheter in a male, do not use force and stop catheter advancement. Ask patient to take slow, deep breaths to promote relaxation. Hold catheter gently in place without forcing. After a few seconds the sphincter may relax, and the catheter can be advanced. An inability to advance a catheter may mean an enlarged prostate or some other obstruction of the urethra.*

- | | |
|---|---|
| <p>(5) Lower penis and hold catheter securely in nondominant hand.</p> <p>20 Allow bladder to empty fully unless agency policy restricts maximum volume of urine drained (see agency policy).</p> <p>21 Collect urine specimen as needed (see Chapter 43). Fill specimen container to 20 to 30 mL by holding end of catheter over cup.</p> <p>a Label and bag specimen according to agency policy. Label specimen in front of patient (TJC, 2012). Send to laboratory as soon as possible.</p> <p>22 Straight catheterization: When urine stops flowing, withdraw catheter slowly and smoothly until removed.</p> <p>23 Inflate catheter balloon with amount of fluid designated by manufacturer.</p> <p>a Continue to hold catheter with nondominant hand.</p> <p>b With free dominant hand, connect prefilled syringe to injection port at end of catheter.</p> <p>c Slowly inject total amount of solution (see illustration).</p> | <p>Prevents accidental dislodgement of catheter.</p> <p>There is no definitive evidence regarding whether there is benefit in limiting maximal volume drained.</p> <p>Sterile specimen for culture analysis can be obtained.</p> <p>Fresh urine specimen ensures more accurate findings. Labeling ensures that diagnostic results will be connected to correct patient.</p> <p>Minimizes trauma to urethra.</p> <p>Indwelling catheter balloons should not be underinflated. Underinflation causes balloon distortion and potential bladder damage (Newman and Wein, 2009).</p> <p>Holding on to catheter before inflating balloon prevents expulsion of catheter from urethra.</p> |
|---|---|

Clinical Decision Point *If patient complains of sudden pain during inflation of a catheter balloon or resistance is felt when inflating the balloon, stop inflation, allow the fluid from the balloon to flow back into the syringe, advance catheter further, and reinflate balloon. The balloon may have been inflating in the urethra. If pain continues, remove catheter and notify health care provider.*

- | | |
|---|--|
| <p>d After inflating catheter balloon, release catheter from nondominant hand. Gently pull catheter until resistance is felt. Then advance catheter slightly.</p> <p>e Connect drainage tubing to catheter if it is not already preconnected.</p> <p>24 Secure indwelling catheter with catheter strap or other securement device. Leave enough slack to allow leg movement. Attach securement device at tubing just above catheter bifurcation.</p> | <p>By moving catheter slightly back into bladder, pressure on bladder neck is avoided.</p> <p>Securing catheter reduces risk of urethral erosion, CAUTI, or accidental catheter removal (Gould et al., 2009). Attachment of securement device at catheter bifurcation prevents occlusion of catheter (Gray, 2008).</p> |
|---|--|

STEP 19b(4) Male anatomy with correct catheter insertion to bifurcation.

STEP 23 Inflating balloon (indwelling catheter).

STEP

RATIONALE

a Female patient:

Secure catheter tubing to inner thigh, allowing enough slack to prevent tension (see illustration).

b Male patient:

- (1) Secure catheter tubing to upper thigh (see illustration) or lower abdomen (with penis directed toward chest). Allow slack in catheter so movement does not create tension on catheter.
- (2) If retracted, replace foreskin over glans penis.

- 25** Clip drainage tubing to edge of mattress. Position drainage bag lower than bladder by attaching to bed frame. Do not attach to side rails of bed (see illustration).
- 26** Check to make sure that there is no obstruction to urine flow. Coil excess tubing on bed and fasten to bottom sheet with clip or other securement device.
- 27** Provide hygiene as needed. Help patient to comfortable position.
- 28** Dispose of supplies in appropriate receptacles.
- 29** Measure urine and record.
- 30** Remove gloves and perform hand hygiene.

Anchoring catheter reduces traction on urethra and minimizes urethral injury (Stoller, 2008).

Leaving foreskin retracted can cause discomfort and dangerous edema.

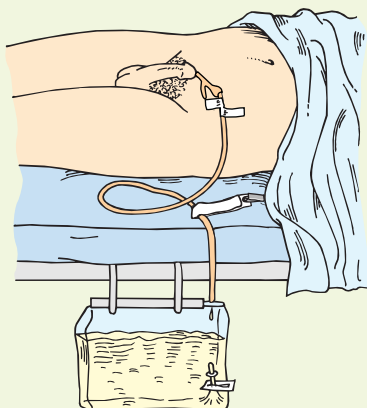

Drainage bags that are below level of bladder ensure free flow of urine, thus decreasing risk for CAUTI (Gould et al., 2009; Lo et al., 2008). Bags attached to movable objects such as a side rail increase risk for urethral trauma because of pulling or accidental dislodgement.

Obstruction to flow of urine increases risk for CAUTI (Gould et al., 2009; Lo et al., 2008).

Provides baseline for urine output.
Reduces transmission of infection.

STEP 24a Securing indwelling catheter on female with adhesive securement device.

STEP 24b(1) Securing indwelling catheter on male with tape.

STEP 25 Drainage bag below level of bladder.

STEP

RATIONALE

EVALUATION

- 1 Palpate bladder for distention or use bladder scan.
- 2 Ask patient to describe level of comfort.
- 3 Indwelling catheter: Observe character and amount of urine in drainage system.
- 4 Indwelling catheter: Determine that there is no urine leaking from catheter or tubing connections.

- Determines if distention is relieved.
 Determines if patient's sensation of discomfort or fullness has been relieved.
 Determines if urine is flowing adequately.
 Prevents injury to patient's skin and ensures closed sterile system.

Unexpected Outcomes

- 1 Catheter goes into vagina.
- 2 Sterility is broken during catheterization by nurse or patient.
- 3 Patient complains of bladder discomfort, and catheter is patent as evidenced by adequate urine flow.

Related Interventions

- Leave catheter in vagina.
- Clean urinary meatus again. Using another catheter kit, reinsert sterile catheter into meatus (check agency policy). **NOTE:** If gloves become contaminated, start procedure over.
- Remove catheter in vagina after successful insertion of second catheter.
- Replace gloves if contaminated and start over.
- If patient touches sterile field but equipment and supplies remain sterile, avoid touching that part of sterile field.
- If equipment and/or supplies become contaminated, replace with sterile items or start over with new sterile kit.
- Check catheter to ensure that there is no traction on it.
- Notify health care provider. Patient may be experiencing bladder spasms or symptoms of UTI.
- Monitor catheter output for color, clarity, odor, and amount.

Recording and Reporting

- Record and report the reason for catheterization, type and size of catheter inserted, amount of fluid used to inflate balloon, specimen collection (if applicable), characteristics and amount of urine, patient's response to procedure, and any education in nurses' notes and electronic health record (EHR).
- Record amount of urine on intake and output (I&O) flow sheet record.
- Report persistent catheter-related pain, inadequate urine output, and discomfort to health care provider.

Special Considerations

Teaching

- Explain that a feeling of burning, pinching, and/or pressure may be experienced when the catheter is inserted into the urethra. This sensation is normal and will go away.
- Discuss with the patient routine care of the catheter and drainage system that includes avoiding any kinking in the drainage tubing, keeping the drainage bag dependent, avoiding pulling on the catheter, and daily hygiene.
- Explain that adequate fluid intake helps prevent catheter blockage.

Pediatric

- When caring for an infant or young child, explain procedures to parents. Describe procedure to child at level the child is able to understand (Hockenberry and Wilson, 2011).
- Children and adolescents will experience some discomfort during catheterization. Assistance and gentle holding may be necessary, especially with younger children. Most children prefer to have the parents remain with them during the

procedure. Ask adolescents if they would like a parent to remain with them.

- Catheterization in infants and children may be made easier by use of an adequate amount of catheter lubricant containing 2% lidocaine (Xylocaine) (Hockenberry and Wilson, 2011).
- Teaching young children to blow into a straw or pinwheel can aid in relaxing pelvic muscles during catheter insertion (Hockenberry and Wilson, 2011).

Gerontologic

- The urethral meatus of an older woman may be difficult to identify because of urogenital atrophy.
- Symptoms of a UTI in an older adult may be difficult to recognize and may only be indicated by a change in mental status or fever (Smith et al., 2008).
- Older adults have an increased risk for UTI related to increased prevalence of chronic disease such as diabetes and prostatic hypertrophy and higher prevalence of incontinence (Robichard and Blondeau, 2008).
- The presence of a urinary catheter and its drainage tubing and bag can interfere with the already compromised mobility of the older adult.
- Catheter use in older adults has been associated with increased mortality (Srulovich and Chopra, 2008).

Home Care

- Patients who are at home may use a leg bag during the day and switch to a larger-volume bag at night. If a patient changes from a large-volume bag to a leg bag, instruct him or her in the importance of handwashing and cleaning the connection ports with alcohol before changing bags.

- Teach patients and/or caregivers how to properly position the drainage bag; empty the urinary drainage bag; and observe urine color, clarity, odor, and amount.
- Educate patients and/or caregivers about the signs of UTI and troubleshooting techniques for a leaking catheter.
- Arrange for home delivery of catheter supplies, always ensuring that there is at least one extra catheter, insertion kit, and drainage bag in the home.

SKILL 33-2 Care and Removal of an Indwelling Catheter

NSO Urinary Catheterization Module / Lesson 5

Providing regular perineal hygiene, preventing catheter-related trauma, and removing indwelling catheters as soon as possible are important interventions to reduce risk of catheter-associated urinary tract infection (CAUTI) (Gould et al., 2009); Parker et al., 2009). Prolonged indwelling catheterization is a major risk factor for CAUTI. When removing an indwelling catheter, it is important to ensure that the catheter balloon is fully deflated to minimize trauma to the urethra. Often clinicians clamp catheter tubing before removal in the belief that the practice allows the bladder to fill and obtain bladder tone. However, evidence is unclear that the practice of clamping a catheter before removal will improve bladder function after removal (Gould et al., 2009; Nyman et al., 2010).

All patients should have their voiding monitored after catheter removal for at least 24 to 48 hours by using a voiding record or bladder diary. Record the time and amount of each voiding, including any incontinence, in the diary. Use a bladder scan to monitor bladder functioning by measuring postvoid residual (see **Procedural Guideline 33-2**). Abdominal pain and distention, a sensation of incomplete emptying, incontinence, constant dribbling of urine, and voiding in very small amounts can indicate inadequate bladder emptying requiring intervention.

The risk of urinary tract infection (UTI) increases with the use of an indwelling catheter (Parker et al., 2009). Symptoms of infection can develop 2 to 3 or more days after catheter removal. Inform patients of the risk for infection, prevention measures, and signs and symptoms that need to be reported to the primary care provider.

Delegation and Collaboration

The skill of performing routine catheter care can be delegated to nursing assistive personnel (NAP). The skill of removing an indwelling catheter can be delegated to NAP (see agency policy);

however, the nurse must first assess a patient’s status and verify the order. The nurse directs the NAP to:

- Report characteristics of the urine (color, clarity, odor, and amount).
- Report the condition of the patient’s genital area (e.g., color, rashes, open areas, odor, soiling from fecal incontinence, trauma to tissues around urinary meatus).
- Check size of balloon and syringe needed to deflate balloon and report if balloon does not deflate and if there is bleeding after removal.
- Report time and amount of first voiding after catheter is removed.
- Report patient complaints that might indicate a CAUTI: fever, chills, burning, flank pain, back pain, and blood in the urine (Hooton et al., 2010).
- Report patient complaints that might indicate a UTI after catheter removal: dysuria, hematuria, urgency, frequency, lower abdominal pain, change in mental status, lethargy (Hooton et al., 2010).

Equipment

Catheter Care

- Clean gloves
- Waterproof pad
- Bath blanket
- Soap, washcloth, towel, and basin filled with warm water

Removing a Catheter

- 10-mL or larger syringe without needle (Information on balloon size [mL] is printed directly on balloon inflation valve [see Fig. 33-3].)
- Graduated cylinder to measure urine
- Toilet, bedside commode, urine “hat,” urinal, or bedpan
- Bladder scanner (if indicated)

STEP

RATIONALE

ASSESSMENT

1 Catheter care:

- a** Observe urinary output and urine characteristics.
- b** Assess for history or presence of bowel incontinence.
- c** Observe for any discharge, redness, bleeding, or presence of tissue trauma around urethral meatus (this may be deferred until catheter care).
- d** Assess patient’s knowledge of catheter care.

- Sudden decrease in urine output may indicate occlusion of catheter. Cloudy, foul-smelling urine associated with other systemic symptoms may indicate CAUTI.
- Most common bacteria to cause CAUTI are *Escherichia coli*, a major colonizer of the bowel; thus fecal incontinence increases risk for CAUTI (Gould et al., 2009; Jacobsen et al., 2008).
- Indicates inflammatory process, possible infection, or erosion of catheter through urethra.
- Determine need for patient education related to catheter care.

STEP	RATIONALE
2 Catheter removal: <ul style="list-style-type: none"> a Review patient's medical record, including health care provider's order and nurses' notes. Note length of time catheter was in place. b Assess patient's knowledge and prior experience with catheter removal. c Assess urine color, clarity, odor, and amount. Note any urethral discharge, irritation of genital region, or trauma to urinary meatus (this may be deferred until just before removal). d Determine size of catheter inflation balloon by looking at balloon inflation valve. 	<p>Catheters in place for more than a few days cause higher risk for catheter encrustation and UTI (Jacobsen et al., 2008).</p> <p>Reveals need for patient instruction and/or support.</p> <p>May be an indicator of inflammation or UTI and a source of discomfort during catheter removal.</p> <p>Determines size of syringe needed to deflate balloon and amount of fluid expected in syringe after deflation.</p>

NURSING DIAGNOSES

- Impaired urinary elimination
- Deficient knowledge related to catheter care
- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following catheter care: <ul style="list-style-type: none"> • Genital area is free of secretions, fecal matter, and irritation. • Patient verbalizes feeling of comfort. 	<p>Basic hygiene, especially after bowel movements, reduces risk for CAUTI (Gould et al., 2009).</p> <p>Cleaning relieves local discomfort from irritation of catheter.</p>
2 Expected outcomes after catheter removal: <ul style="list-style-type: none"> • Patient voids at least 150 mL with each voiding no more than 6 to 8 hours after removal. • Patient verbalizes feeling of complete bladder emptying and absence of discomfort. • Patient identifies signs and symptoms of UTI. 	<p>Indicates return of voluntary bladder function without urinary retention.</p> <p>Indicates patient learning.</p>
3 Explain procedure to patient. Discuss signs and symptoms of UTI. If applicable, teach patient how to perform catheter hygiene.	<p>Reduces anxiety and promotes cooperation.</p> <p>Self-care supports patient's sense of autonomy.</p>

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p>
2 Close room door and bedside curtain.	<p>Provides patient privacy.</p>
3 Perform hand hygiene.	<p>Reduces transmission of microorganisms.</p>
4 Raise bed to appropriate working height. If side rails are raised, lower side rail on working side.	<p>Promotes use of proper body mechanics.</p>
5 Organize equipment for perineal care and/or removal of catheter.	<p>Increases efficiency of procedure.</p>
6 Position patient with waterproof pad under buttocks and cover with bath blanket, exposing only genital area and catheter (see Skill 33-1). <ul style="list-style-type: none"> a Female in dorsal recumbent position. b Male in supine position. 	<p>Shows respect for patient dignity by only exposing genital area and catheter.</p>
7 Apply clean gloves.	<p>Reduces transmission of infection.</p>
8 Remove catheter securement device while maintaining connection with drainage tubing.	<p>Provides ability to easily clean around catheter or to remove it.</p>
9 Catheter care: <ul style="list-style-type: none"> a <i>Female:</i> Use nondominant hand to gently separate labia to fully expose urethral meatus and catheter. Maintain position of hand throughout procedure. b <i>Male:</i> Use nondominant hand to retract foreskin if not circumcised and hold penis at shaft just below glans. Maintain hand position throughout procedure. 	<p>Provides full visualization of urethral meatus. Full separation of labia prevents contamination of meatus during cleaning.</p> <p>Retraction of foreskin provides full visualization of urethral meatus.</p>

STEP

RATIONALE

Clinical Decision Point Accidental closing of labia or dropping of penis during cleaning requires procedure to be repeated.

- | | |
|---|---|
| <p>c Grasp catheter with two fingers to stabilize it.</p> <p>d Assess urethral meatus and surrounding tissues for inflammation, swelling, discharge, or tissue trauma and ask patient if burning or discomfort is present.</p> <p>e Provide perineal hygiene using mild soap and warm water (see Chapter 17).</p> <p>f Using clean washcloth, clean catheter.</p> <p>(1) Starting close to urinary meatus, clean catheter in circular motion along its length for about 10 cm (4 inches), moving away from body (see illustration). Remove all traces of soap. <i>For male patients:</i> Reduce or reposition foreskin after care.</p> <p>g Reapply catheter securement device. Allow slack in catheter so movement does not create tension on it.</p> | <p>Prevents unnecessary traction on catheter. Pulling on catheter is cause of discomfort for patient and can damage urethra and bladder neck.</p> <p>Determines frequency and type of ongoing care required. Indicates possibility of CAUTI or catheter erosion through urethra.</p> <p>Antiseptic cleaners have not been proven to decrease risk for CAUTI (Gould et al., 2009).</p> <p>Reduces presence of secretions or drainage on outside catheter surface.</p> <p>Securing indwelling catheter reduces risk of urethral trauma, urethral erosion, CAUTI, or accidental removal (Cipa-Tatum et al., 2011; Gould et al., 2009).</p> |
| <p>10 Routinely check drainage tubing and bag.</p> <p>a Catheter is secured to upper thigh (for women) or abdomen (for men).</p> <p>b Tubing is coiled and secured onto bed linen.</p> <p>c Tubing is not looped or positioned above level of bladder.</p> <p>d Tubing is not kinked or clamped.</p> | <p>Maintains unobstructed flow of urine out of bladder (Gould et al., 2009).</p> |

STEP 9f(1) Catheter is cleaned starting at meatus and moving downward while holding it securely.

STEP	RATIONALE
<ul style="list-style-type: none"> e Drainage bag is positioned below level of bladder with urine flowing freely into bag. f Drainage bag is not overfull. Empty drainage bag when $\frac{1}{2}$ full. 	Overfull drainage bag creates tension and pulls on catheter, resulting in trauma to urethra and/or urinary meatus (Cipa-Tatum, 2011).
<p>11 Catheter removal: (Follow Steps 1 to 10 before catheter removal.)</p> <ul style="list-style-type: none"> a Move syringe plunger up and down to loosen and then pull back plunger to 0.5 mL. Insert hub of syringe into inflation valve (balloon port). Allow balloon fluid to drain into syringe by gravity. Syringe should fill. Make sure that entire amount of fluid is removed by comparing removed amount to volume needed for inflation. b Pull catheter out smoothly and slowly. Examine it to ensure that it is whole. Catheter should slide out easily. Do not use force. If you note any resistance, repeat Step 11a to remove remaining water. c Wrap contaminated catheter in waterproof pad. Unhook collection bag and drainage tubing from bed. d Reposition patient as necessary. Provide hygiene as needed. Lower level of bed and position side rails accordingly. e Empty, measure, and record urine present in drainage bag (see Chapter 6). f Encourage patient to maintain or increase fluid intake (unless contraindicated). g Initiate voiding record or bladder diary. Instruct patient to tell you when need to empty bladder occurs and that all urine needs to be measured. Make sure that patient understands how to use collection container. h Explain that many patients experience mild burning, discomfort, or small-volume voiding with first voiding, which soon subsides. i Inform patient to report any signs of UTI. j Ensure easy access to toilet, commode, bedpan, or urinal. Place urine “hat” on toilet seat if patient is using toilet. Place call bell within easy reach. 	<p>Partially inflated balloon can traumatize urethral wall during removal. Passive drainage of catheter balloon prevents formation of ridges in balloon. These ridges can cause discomfort or trauma during removal.</p> <p>Nonwhole catheter means that pieces of catheter may still be in bladder. Notify health care provider immediately.</p> <p>Promotes patient comfort and safety.</p> <p>Promotes patient comfort and safety.</p> <p>Documents urinary output.</p> <p>Maintains normal urine output.</p> <p>Evaluates bladder function.</p> <p>Burning results from urethral irritation.</p>
<p>12 Dispose of all contaminated supplies in appropriate receptacle, remove gloves, and perform hand hygiene.</p>	<p>Reduces incidence of falls during toileting. Urine hat collects first voided urine.</p> <p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Inspect catheter and genital area for soiling, irritation, and skin breakdown. Ask patient about discomfort.</p>	<p>Determines if area is cleaned properly and/or if patient has any irritation.</p>
<p>2 Observe time and measure amount of first voiding after catheter removal.</p>	<p>Indicates return of bladder function after catheter removal.</p>
<p>3 Evaluate patient for signs and symptoms of UTI.</p>	<p>Any patient who has recently had catheter removed is at risk for UTI.</p>

Unexpected Outcomes

- 1 Water from inflation balloon does not return into syringe.
- 2 Patient has fever, chills, burning, flank pain, back pain, hematuria, painful urination, urgency, frequency, lower abdominal pain, change in mental status, and lethargy (Hooton et al., 2010).
- 3 Patient is unable to void after catheter removal, has sensation of not emptying, strains to void, or experiences small voiding amounts with increasing frequency.

Related Interventions

- Reposition patient; ensure that catheter is not pinched or kinked.
- Remove syringe. Attach new syringe and allow enough time for passive emptying.
- Attempt to empty balloon by gently pulling back on syringe plunger.
- If catheter balloon does not deflate, *do not* cut balloon inflation valve to drain water. Notify health care provider.
- Assess for bladder distention and tenderness.
- Monitor vital signs and urine output.
- Report findings to health care provider; signs and symptoms may indicate UTI.
- Assess for bladder distention.
- Help to normal position for voiding and provide privacy.
- Perform bladder ultrasound (see [Procedural Guideline 33-2](#)) to assess for excessive urine volume in bladder.
- If patient is unable to void within 6 to 8 hours of catheter removal and/or experiences abdominal pain, notify health care provider.

Recording and Reporting

- Record time for catheter care and appearance of urine; describe condition of meatus and catheter.
- Record and report time of catheter removal, amount of water removed from balloon, condition of urethral meatus and catheter, and the time, amount, and characteristics of first voided urine.
- Record teaching related to catheter care, catheter removal, and fluid intake.
- Report hematuria, dysuria, inability or difficulty voiding, and any new incontinence after a catheter is removed.

Special Considerations**Teaching**

- Unless contraindicated, patients with a catheter should drink at least 2200 mL of fluid per day to promote continuous flushing of the bladder and prevent sediment from collecting in the catheter tubing.

- Instruct patient to hold collection bag below the level of the bladder when ambulating.
- Instruct patient not to disconnect the catheter from the collection tubing and bag.

Pediatric

- During catheter removal do not force catheter out of bladder if you meet resistance. When excessive tubing has been inserted in bladder, there have been occurrences of knotting of the tube (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults may exhibit atypical signs and symptoms of CAUTI such as a change in mental status attributed to delirium. A change in mental status may include confusion, agitation, and/or lethargy.

Home Care

- Assess patient and primary caregiver for ability and motivation to participate in routine catheter care.

PROCEDURAL GUIDELINE 33-2 Bladder Scan and Catheterization to Determine Residual Urine

A bladder scanner (Fig. 33-5) is a noninvasive device that creates an ultrasound image of the bladder for measuring the volume of urine in the bladder. The device makes calculations to report accurate urine volumes, especially lower volumes (Al-Shaikh et al., 2009). Use a bladder scanner to assess bladder volume whenever inadequate bladder emptying is suspected such as after the removal of indwelling urinary catheters, in the evaluation of new-onset incontinence, and after urologic surgery. The most common use for the bladder scan is to measure postvoid residual (PVR), the volume of urine in the bladder after a normal voiding. To obtain the most reliable reading, measure PVR within 10 minutes of voiding (Newman and Wein, 2009). A volume less than 50 mL is considered normal. Two or more PVR measurements greater than 100 mL require further investigation (Newman and Wein, 2009). If a bladder scanner is not available, obtain a PVR by measuring urine emptied from the bladder after a straight catheterization.

Delegation and Collaboration

The skill of measuring bladder volume by bladder scan can be delegated to nursing assistive personnel (NAP). The nurse must

first determine the timing and frequency of the bladder scan measurement and interpret the measurements obtained. The nurse also assesses the patient's ability to toilet before measuring PVR and the abdomen for distention if urinary retention is suspected. The nurse directs the NAP to:

- Follow manufacturer recommendations for the use of the device.
- Measure PVR volumes 10 minutes after helping the patient to void.
- Report and record bladder scan volumes.

Equipment

- Bladder scanner (follow manufacturer instructions for use)
- Ultrasound gel
- Cleaning agent for scanner head, such as an alcohol pad
- Urethral catheterization tray with single-use catheter for straight/intermittent catheterization (see [Skill 33-1](#))

Procedural Steps

- 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy.

PROCEDURAL GUIDELINE 33-2 Bladder Scan and Catheterization to Determine Residual Urine—cont'd

Compare identifiers with information on patient's identification bracelet.

- 2 Assess intake and output (I&O) record to determine urine output trends and check the plan of care to verify correct timing of the bladder scan measurement.
- 3 Perform hand hygiene and apply clean gloves.
- 4 Provide privacy by closing room door and bedside curtain.
- 5 Discuss procedure with patient. If the measurement is for PVR, ask patient to void and measure voided urine volume. Measurement should be within 10 minutes of voiding.
- 6 Measurement of PVR with the bladder scan
 - a Help patient to supine position with head slightly elevated. Raise bed to appropriate working height. If side rails are raised, lower side rail on working side.
 - b Expose patient's lower abdomen.
 - c Turn on scanner per manufacturer guidelines.
 - d Set gender designation per manufacturer guidelines. Women who have had a hysterectomy should be designated as male.

FIG 33-5 Bladder scanner with image.

- e Wipe scanner head with alcohol pad or other cleaner and allow to air dry.
- f Palpate patient's symphysis pubis (pubic bone). Apply generous amount of ultrasound gel (or if available a bladder scan gel pad) to midline abdomen 2.5 to 4 cm (1 to 1.5 inches) above symphysis pubis.
- g Place scanner head on gel, ensuring that scanner head is oriented per manufacturer guidelines.
- h Apply light pressure, keep scanner head steady, and point it slightly downward toward bladder. Press and release the scan button (see illustration).

STEP 6h Placement of bladder scan head.

- i Verify accurate aim (refer to manufacturer guidelines). Complete scan and print image (if needed).
- j Remove ultrasound gel from patient's abdomen with paper towel.
- k Remove ultrasound gel from scanner head and wipe with alcohol pad or other cleaner; allow to air-dry.
- l Help patient to comfortable position. Lower bed and replace side rails accordingly.
- m Remove gloves and perform hand hygiene.
- 7 Measurement of PVR using straight/intermittent catheterization (see Skill 33-1).
- 8 Review health care provider's order to determine how often to assess residual urine.
- 9 Review I&O record to determine urine output trends.

SKILL 33-3 Performing Catheter Irrigation

Urinary catheter irrigations are performed on an intermittent or a continuous basis to maintain catheter patency. There are two types of irrigation: closed catheter irrigation and open irrigation. Closed catheter irrigation provides intermittent or continuous irrigation of a urinary catheter without disrupting the sterile connection between the catheter and the drainage system (Fig. 33-6). Intermittent irrigation involves insertion of a sterile catheter into a catheter port to irrigate a bolus of fluid. Continuous bladder

irrigation (CBI) is a continuous infusion of a sterile solution into the bladder, usually using a three-way irrigation system with a triple-lumen catheter. It is often used after genitourinary surgery to keep the bladder clear and free of blood clots or sediment.

Open catheter irrigation is used only when intermittent irrigation of the catheter and bladder is required. The skill involves breaking or opening the closed drainage system at the connection between the catheter and the drainage system. **This procedure**

FIG 33-6 Closed continuous bladder irrigation.

should be avoided unless irrigation is needed to relieve or prevent obstruction (Senese et al., 2005). Strict asepsis is required throughout the procedure to minimize contamination and subsequent development of a urinary tract infection (UTI). Both open and closed irrigation can be used to irrigate the bladder with medication.

Delegation and Collaboration

The skill of catheter irrigation cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Report if the patient complains of pain, discomfort, or leakage of fluid around the catheter.
- Monitor and record intake and output (I&O); report immediately any decrease in urine output.
- Report any change in the color of the urine, especially the presence of blood clots.

Equipment

- Sterile irrigation solution at room temperature (as prescribed)
- Antiseptic swabs
- Clean gloves

Closed Intermittent Irrigation

- Sterile container
- Sterile 30- to 60-mL irrigation syringe (piston type)
- Syringe to access system (Luer-Lok syringe without needle for needleless access port per manufacturer directions)
- Screw clamp or rubber band (used to temporarily occlude catheter as irrigant is instilled)

Closed Continuous Irrigation

- Irrigation tubing with clamp to regulate irrigation flow rate
- Y-connector (optional) to connect irrigation tubing to double-lumen catheter
- Intravenous (IV) pole (closed continuous or intermittent)

Open Intermittent Irrigation

- Disposable sterile irrigation kit that contains solution container, collection basin, drape, sterile gloves, 30- to 60-mL irrigation syringe (piston type)
- Sterile catheter plug
- Sterile gloves (optional)

STEP

RATIONALE

ASSESSMENT

- 1** Verify in medical record:
 - a** Order for irrigation method (continuous or intermittent), type (sterile saline or medicated solution), and amount of irrigant.
 - b** Type of catheter in place (see Fig. 33-2).
- 2** Palpate bladder for distention and tenderness.
- 3** Assess patient for abdominal pain or spasms, sensation of bladder fullness or catheter bypassing (leaking).
- 4** Observe urine for color, amount, clarity, and presence of mucus, clots, or sediment.
- 5** Monitor I&O. If CBI is being used, amount of fluid draining from bladder should exceed amount of fluid infused into bladder.
- 6** Assess patient’s knowledge regarding purpose of performing catheter irrigation.

Health care provider’s order is required to initiate therapy. Frequency and volume of solution used for irrigation may be in the order or standardized as part of agency policy. Single- and double-lumen catheters are used with open irrigation. Triple-lumen catheters are used for both intermittent and continuous closed irrigation. Bladder distention indicates that flow of urine may be blocked from draining. May indicate overdistention of bladder caused by catheter blockage. Offers baseline to determine if therapy is successful. Indicates if patient is bleeding or sloughing tissue, which would require increased irrigation rate or frequency of catheter irrigation. If output does not exceed irrigant infused, catheter obstruction (i.e., blood clots, kinked tubing) should be suspected, irrigation stopped, and prescriber notified (Lewis et al., 2011). Reveals need for patient instruction/support.

NURSING DIAGNOSES

- Acute pain
- Impaired urinary elimination
- Deficient knowledge regarding catheter irrigation
- Risk for infection

Related factors are individualized based on patient’s condition or needs.

STEP

RATIONALE

PLANNING

1 Expected outcomes following completion of this procedure:

- With CBI: Urine output is greater than volume of irrigating solution instilled.
- Patient reports relief of bladder pain or spasms.
- Urine output has decreased with an absence of blood clots and sediment. (NOTE: Urine will be bloody following bladder/urethral surgery, gradually becoming lighter and blood tinged in 2 to 3 days.)
- Absence of fever, lower abdominal pain, cloudy and/or foul-smelling urine.
- Patient can explain purpose of procedure and what to expect.

2 Explain procedure to patient.

Indicates patency of drainage system, allowing for drainage of urine and irrigating solution.

Indicates bladder emptying.

Indicates that catheter is at decreased risk for occlusion with blood clots.

Signs of UTI are not present.

Demonstrates learning.

Reduces anxiety and promotes cooperation.

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers in MAR/medical record with information on patient's identification bracelet and/or ask patient to state name.

Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).

2 Perform hand hygiene.

3 Provide privacy by closing room door and bedside curtain.

Reduces transmission of microorganisms.

Protects patient comfort and self-esteem.

4 Raise bed to appropriate working height. If side rails are raised, lower side rail on working side.

Promotes use of good body mechanics.

Position provides access to catheter and promotes patient dignity as much as possible.

5 Position patient supine and expose catheter junctions (catheter and drainage tubing).

Position provides access to catheter and promotes patient dignity as much as possible.

6 Remove catheter securement device.

Eases access to catheter parts.

7 Organize supplies according to type of irrigation prescribed. Apply clean gloves.

Ensures an efficient procedure.

8 Closed continuous irrigation:

- a Close clamp on new irrigation tubing and hang bag of irrigating solution on IV pole. Insert (spike) tip of sterile irrigation tubing into designated port of irrigation solution bag using aseptic technique (see illustration).

Prevents air from entering tubing. Air can cause bladder spasms. Technique prevents transmission of microorganisms.

STEP 8a Spiking bag of sterile irrigation solution for continuous bladder irrigation.

STEP	RATIONALE
<ul style="list-style-type: none"> b Fill drip chamber half full by squeezing chamber; then open clamp and allow solution to flow (prime) through tubing, keeping end of tubing sterile. Once fluid has completely filled tubing, close clamp and recap end of tubing. c Using aseptic technique, connect tubing securely to drainage port of Y-connector on double/triple-lumen catheter. d Adjust clamp on irrigation tubing to begin flow of solution into bladder. If set volume rate is ordered, calculate drip rate and adjust rate at roller clamp. If urine is bright red or has clots, increase irrigation rate until drainage appears pink (according to ordered rate or agency protocol). e Observe for outflow of fluid into drainage bag. Empty catheter drainage bag as needed. 	<p>Priming tubing with fluid prevents introduction of air into bladder.</p> <p>Reduces transmission of microorganisms.</p> <p>Continuous drainage is expected. It helps to prevent clotting in presence of active bleeding in bladder and flushes clots out of bladder.</p> <p>Discomfort, bladder distention, and possible injury can occur from overdistention of bladder when bladder irrigant cannot adequately flow from bladder. Bag will fill rapidly and may need to be emptied every 1 to 2 hours.</p>
<p>9 Closed intermittent irrigation:</p>	<p>Fluid is instilled through catheter in a bolus, flushing system. Fluid drains out after irrigation is complete.</p>
<ul style="list-style-type: none"> a Pour prescribed sterile irrigation solution into sterile container. b Draw prescribed volume of irrigant (usually 30 to 50 mL) into syringe using aseptic technique. Place sterile cap on tip of needleless syringe. c Clamp catheter tubing below soft injection port with screw clamp (or fold catheter tubing onto itself and secure with rubber band). d Using circular motion, clean catheter port (specimen port) with antiseptic swab. e Insert tip of needleless syringe using twisting motion into port. f Inject solution using slow, even pressure. g Remove syringe and remove clamp (or rubber band) allowing solution to drain into urinary drainage bag. (NOTE: Some medicated irrigants may need to dwell in bladder for prescribed period, requiring catheter to be clamped temporarily before being allowed to drain.) 	<p>Ensures sterility of irrigating fluid.</p> <p>Occluding catheter tubing below point of injection allows irrigating solution to enter catheter and flow upward toward bladder.</p> <p>Reduces transmission of microorganisms.</p> <p>Ensures that catheter tip enters lumen of catheter.</p> <p>Gentle instillation of solution minimizes trauma to bladder mucosa.</p> <p>Allows drainage to flow out by gravity.</p> <p>Medications must be instilled long enough to be absorbed by lining of bladder. Clamped drainage tubing and bag should not be left unattended.</p>
<p>10 Open intermittent irrigation:</p>	<p>Prevents introduction of microorganisms into urinary catheter and drainage system.</p> <p>Maintains sterile field.</p>
<ul style="list-style-type: none"> a Sterile gloves may be required (see agency policy). b Open sterile irrigation tray. Establish sterile field (see Chapter 8) and pour required amount of sterile solution into sterile solution container. Replace cap on large container of solution. Add sterile irrigation syringe (piston type) to sterile field. Have antiseptic wipe open and ready for use. c Position sterile drape under catheter. d Aspirate prescribed volume of irrigation solution into irrigating syringe (usually 30 mL). Place syringe in sterile solution container until ready to use. e Move sterile collection basin close to patient's thigh. f Wipe connection point between catheter and drainage tubing with antiseptic wipe before disconnecting. g Disconnect catheter from drainage tubing, allowing any urine to flow into sterile collection basin. Cover open end of drainage tubing with sterile protective cap and position tubing so it stays coiled on top of bed with end resting on sterile drape. h Insert tip of syringe into lumen of catheter and gently push plunger to instill solution (see illustration). 	<p>Prevents introduction of microorganisms into urinary catheter and drainage system.</p> <p>Maintains sterile field.</p> <p>Creates sterile field on which to work and prevents soiling of bed linen.</p> <p>Prepares solution for instillation into catheter. Maintains sterility of irrigating syringe.</p> <p>Prevents soiling of bed linen and reaching over sterile field.</p> <p>Reduces transmission of microorganisms.</p> <p>Maintains sterility of inner aspects of catheter lumen and drainage tubing. Reduces potential of infection by way of microorganism contamination.</p> <p>Gentle fluid instillation minimizes risk of trauma to bladder.</p>

STEP

RATIONALE

Clinical Decision Point When irrigating a catheter using the open method, do not force the irrigation. Catheter may be completely occluded and needs to be changed.

- | | |
|---|---|
| <ul style="list-style-type: none"> i Remove syringe, lower catheter, and allow solution to drain into collection basin. Amount of drainage solution should be equal to or greater than amount instilled. If ordered, repeat sequence of instilling solution and draining until drainage is clear of clots and sediment. j After irrigation is complete, remove protector cap from urinary drainage tubing end, clean end of tubing with antiseptic wipe, and reinsert into lumen of catheter. | <p>If clot has been removed, solution will drain freely into basin.</p> <p>Restores sterile system.</p> |
| <p>11 Anchor catheter with catheter securement device (see Skill 33-1).</p> | <p>Prevents trauma to urethral tissue caused by pulling catheter.</p> |
| <p>12 Help patient to safe and comfortable position. Lower bed and place side rails accordingly.</p> | <p>Promotes patient comfort and safety.</p> |
| <p>13 Dispose of all contaminated supplies in appropriate receptacle, remove gloves, and perform hand hygiene.</p> | <p>Reduces transmission of microorganisms.</p> |

STEP 10h Gentle instillation of sterile irrigation solution.

EVALUATION

- | | |
|--|---|
| <p>1 Measure actual urine output by subtracting total amount of irrigation fluid infused from total volume drained into basin.</p> | <p>Determines accurate urinary output.</p> |
| <p>2 Review I&O flow sheet to verify that hourly output into drainage bag is in appropriate proportion to irrigating solution entering bladder. Expect more output than fluid instilled because of urine production.</p> | <p>Determines urinary output in relation to irrigation.</p> |
| <p>3 Inspect urine for blood clots and sediment and be sure that tubing is not kinked or occluded.</p> | <p>Decrease in blood clots means that therapy is successful in maintaining catheter patency.</p> |
| <p>4 Evaluate patient's comfort level.</p> | <p>System is patent.
Indicates catheter patency by absence of symptoms of bladder distention.</p> |
| <p>5 Monitor for signs and symptoms of infection.</p> | <p>Patients with indwelling catheters remain at risk for infection.</p> |

Unexpected Outcomes

- 1 Irrigating solution does not return (intermittent irrigation) or is not flowing at prescribed rate (CBI).
- 2 Drainage output is less than amount of irrigation solution infused.
- 3 Bright-red bleeding with the irrigation (CBI) infusion wide open.
- 4 Patient experiences pain with irrigation.
- 5 Fever; cloudy, foul-smelling urine; abdominal pain; change in mental status, indicating a possible infection.

Related Interventions

- Examine tubing for clots, sediment, and kinks.
- Notify health care provider if irrigant does not flow freely from bladder, patient complains of pain, or bladder distention occurs.
- Examine drainage tubing for clots, sediment, or kinks.
- Inspect urine for presence of or increase in blood clots and sediment.
- Evaluate patient for pain and distended bladder.
- Notify health care provider.
- Assess for hypovolemic shock (vital signs, skin color and moisture, anxiety level).
- Leave irrigation infusion wide open and notify health care provider.
- Examine drainage tubing for clots, sediment, or kinks.
- Evaluate urine for presence of or increase in blood clots and sediment.
- Evaluate for distended bladder.
- Notify health care provider.
- Notify health care provider.
- Monitor vital signs and character of urine.

Recording and Reporting

- Record irrigation method, amount of and type of irrigation solution, amount returned as drainage, characteristics of output, urine output, and patient tolerance to procedure in nurses' notes.
- Report catheter occlusion, sudden bleeding, infection, or increased pain to health care provider.
- Record I&O on appropriate flow sheet.

Special Considerations**Teaching**

- Instruct patient and family caregiver to observe urine daily for changes in color, presence of mucus or blood, and odor.
- Inform patients that bleeding is common after many urologic procedures and to expect bright red-tinged urine during the first

48 hours after surgery, followed by a change in urine ranging from pink-tinged to clear.

- Instruct patient to maintain adequate oral intake of 2 L/day (unless contraindicated).

Home Care

- Patients and/or caregivers can be taught to perform catheter irrigations with adequate support, demonstration/return demonstration, and written instructions.
- Teach patients and/or caregivers to observe urine color, clarity, odor, and amount.
- Arrange for home delivery and storage of catheter/irrigation supplies.
- Teach patients and/or caregivers signs of catheter obstruction or UTI.

SKILL 33-4 Applying a Condom-Type External Catheter**NSO** Urinary Catheterization Module / Lesson 3

The external urinary catheter, also called a *condom catheter* or *penile sheath*, is a soft, pliable condom-like sheath that fits over the penis, providing a safe and noninvasive way to contain urine. Most external catheters are made of soft silicone that reduces friction. The silicone is clear, allowing for easy visualization of skin under the catheter. Latex catheters are still available and used by some patients. It is important to verify that a patient does not have a latex allergy before applying this type of catheter.

Condom-type external catheters are held in place by either an adhesive coating of the internal lining of the sheath, a double-sided self-adhesive strip, brush-on adhesive applied to the penile shaft, or in rare cases an external strap. The catheter may be attached to a small-volume (leg) drainage bag or a large-volume (bedside) urinary drainage bag, both of which need to be kept lower than the level of the bladder. The condom-type external catheter is suitable for incontinent patients who have complete and spontaneous bladder emptying. The catheters come in a variety of styles and sizes. For the best fit and correct application it is important to refer to manufacturer guidelines. Condom-type external catheters are

associated with less risk for urinary tract infection (UTI) than indwelling catheters; thus they are an excellent option for the male with urinary incontinence (Newman and Wein, 2009). Other externally applied catheters are available for men who cannot be fitted for a condom-type external catheter. One type attaches to the glans penis using hydrocolloid strips (Wells, 2008) that stay in place for multiple days and allows straight catheterization. Another option available is a reusable condom-like device that is held in place by specially designed underwear.

Delegation and Collaboration

Assessment of the skin of a patient's penile shaft and determination of a latex allergy are done by a nurse before catheter application. The skill of applying a condom catheter can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Follow manufacturer directions for applying the condom catheter and securing device.
- Monitor urine intake and output (I&O) and record if applicable.
- Immediately report any redness, swelling, or skin irritation or breakdown of glans penis or penile shaft.

Equipment

- ❑ Condom catheter kit (condom sheath of appropriate size, securement device [internal adhesive or strap], skin preparation solution [per manufacturer directions])
- ❑ Urinary collection bag with drainage tubing or leg bag and straps
- ❑ Basin with warm water and soap
- ❑ Towels and washcloth(s)
- ❑ Bath blanket
- ❑ Clean gloves
- ❑ Scissors, hair guard, or paper towel

STEP

RATIONALE

ASSESSMENT

- | | |
|---|--|
| <ol style="list-style-type: none"> 1 Assess urinary pattern, ability to empty bladder effectively, and degree of urinary continence. 2 Assess skin of penis for rashes, erythema, and/or open areas. (This may be deferred until just before catheter application.) 3 Assess patient's mental status, knowledge of purpose of using condom-type catheter, and ability to apply device. It may be appropriate to include family members in assessment. 4 Verify patient's size and type of condom catheter on plan of care or use manufacturer measuring guide to measure length and diameter of penis in flaccid state. | <p>Incontinent patients are at risk for skin breakdown and thus candidates for condom catheter.</p> <p>Provides baseline to compare changes in condition of skin after application of condom catheter. Condom catheters can be applied only to intact skin (Newman and Wein, 2009).</p> <p>Identifies patient learning needs and if self-application can be taught or if family member needs to be included in instruction.</p> <p>Identifies proper size of catheter needed. Penile shaft should be at least 2 cm (5 inches) in length to ensure successful application. If too small, condom catheter may fall off and compress urethra, stopping urine flow or causing local tissue trauma; if too big the catheter may leak or fall off (Kyle, 2011).</p> |
|---|--|

NURSING DIAGNOSES

- Deficient knowledge regarding catheter application
- Risk for impaired skin integrity
- Stress urinary incontinence (male)
- Total urinary incontinence

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient's skin is free from urine wetness. • Glans and penile shaft are free of skin irritation or breakdown. • Patient explains purpose of procedure and what to expect. 2 Explain procedure to patient. | <p>Catheter is applied correctly.</p> <p>Catheter is secure and not too tight.</p> <p>Helps to minimize anxiety and promotes cooperation.</p> <p>Reduces anxiety and promotes cooperation.</p> |
|--|--|

IMPLEMENTATION

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. 2 Perform hand hygiene. 3 Provide privacy by closing room door and bedside curtain. 4 Raise bed to appropriate working height. Lower side rail on working side. 5 Prepare urinary drainage collection bag and tubing (large-volume drainage bag or leg bag). Clamp off drainage bag port. Place nearby ready to attach to condom after applied. 6 Help patient into supine position or sitting position. Place bath blanket over upper torso. Fold sheets so only penis is exposed. 7 Apply clean gloves. Provide perineal care (see Chapter 17). Dry thoroughly before applying device. In uncircumcised male ensure that foreskin has been replaced to normal position before applying condom catheter. Do not apply barrier cream. | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Reduces transmission of microorganisms.</p> <p>Promotes patient comfort and self-esteem.</p> <p>Promotes use of good body mechanics.</p> <p>Provides easy access to drainage equipment after applying condom catheter.</p> <p>Respects patient dignity; draping prevents unnecessary exposure of body parts.</p> <p>Prevents skin breakdown from exposure to secretions. Removes any residual adhesives. Perineal care minimizes skin irritation and promotes adhesion of new external catheter. Barrier creams prevent sheath from adhering to penile shaft (Pomfret, 2008).</p> |
|--|--|

STEP

RATIONALE

8 Clip hair at base of penis as necessary before application of condom sheath. Some manufacturers provide a hair guard that is placed over penis before applying device. Remove hair guard after applying catheter. An alternative to hair guard is to tear a hole in a paper towel, place it over penis, and remove after application of device.

Hair adheres to condom and is pulled during condom removal or may get caught in adhesive as external catheter is applied.

Clinical Decision Point *The pubic area should not be shaved because it may increase risk for skin irritation (Pomfret, 2008).*

9 Apply condom catheter. With nondominant hand grasp penis along shaft. With dominant hand, hold rolled condom sheath at tip of penis with head of penis in the cone. Smoothly roll sheath onto penis. Allow 2.5 to 5 cm (1 to 2 inches) of space between tip of glans penis and end of condom catheter (see illustration).

Excessive wrinkles or creases in external catheter sheath after application may mean that patient needs smaller size (Newman and Wein, 2009).

10 Apply appropriate securement device as indicated in manufacturer guidelines.

Condom must be secured firmly so it is snug and stays on but not tight enough to cause constriction of blood flow. Application of gentle pressure ensures adherence of adhesive with penile skin.

a Self-adhesive condom catheters: After application apply gentle pressure on penile shaft for 10 to 15 seconds to secure catheter.

b Outer securing strip-type condom catheters: Spiral wrap penile shaft with strip of supplied elastic adhesive. Strip should not overlap itself. Elastic strip should be snug, not tight (see illustration).

Using spiral wrap technique allows supplied elastic adhesive to expand so blood flow to penis is not compromised.

11 Remove hair guard if used. Connect drainage tubing to end of condom catheter. Be sure that condom is not twisted. If using large drainage bag, place excess tubing on bed and secure to bottom sheet.

Allows urine to be collected and measured. Keeps patient dry. Twisted condom obstructs urine flow, causing urine pooling, skin irritation; and weakening and deterioration of adhesive, causing catheter to come off (Pomfret, 2008).

12 Help patient to safe, comfortable position. Lower bed and place side rails accordingly.

Promotes safety and comfort.

13 Dispose of contaminated supplies, remove gloves, and perform hand hygiene.

Reduces spread of microorganisms.

14 Remove and reapply daily following Steps 9 to 11 unless an extended-wear device is used. To remove condom, wash penis with warm, soapy water and gently roll sheath and adhesive off penile shaft.

Prevents trauma and irritation to penile sheath.

STEP 9 Condom catheter.

STEP 10b Spiral application of adhesive strip.

STEP

RATIONALE

EVALUATION

- 1 Observe urinary drainage.
- 2 Inspect penis with condom catheter in place within 15 to 30 minutes after application. Assess for swelling and discoloration and ask patient if there is any discomfort.
- 3 Inspect skin on penile shaft for signs of breakdown or irritation at least daily, when performing hygiene, and before reapplying condom.

Twisted condom prevents urine from draining into collection bag. Determines if condom is applied too tightly, impeding circulation to penis.

Changing external catheter will decrease the chance of infection.

Unexpected Outcomes

- 1 Skin around penis is erythematous, ulcerated, or denuded.
- 2 Penile swelling or discoloration occurs.
- 3 Condom catheter does not stay on.
- 4 Frequency and amount of urination reduced.

Related Interventions

- Check for latex allergy or allergy to skin preparation or adhesive device.
- Remove condom and notify health care provider.
- Do not reapply until penis and surrounding tissue are free from irritation.
- Ensure that condom is not twisted and urine flow is unobstructed after application.
- Remove external catheter.
- Notify health care provider.
- Reassess current condom size. See manufacturer size chart.
- Ensure that catheter tubing is anchored and that patient understands to not pull or tug on catheter.
- Reassess condom catheter size. Refer to manufacturer guidelines for sizing.
- Observe whether condom catheter outlet is kinked and urine is pooling at tip of condom, bathing penis in urine; reapply as necessary and avoid catheter obstruction.
- Assess need for another brand of external catheter (i.e., one that is self-adhesive).
- Check for bladder distention.
- Observe whether urine is pooling at tip of condom and bathing penis in urine; reapply as necessary.
- Check for kinks in tubing or in condom catheter.

Recording and Reporting

- Record condom application; condition of penis, skin, and scrotum; urinary output; and voiding pattern in nurses' notes and EHR.
- Report penile erythema, rashes, and/or skin breakdown.

Special Considerations

Teaching

- Teach about signs of skin breakdown or trauma.
- Teach patient to keep condom and catheter kink free and positioned below level of bladder.
- Teach patient with leg bag to assess leg straps periodically for tightness and loosen as necessary.

Pediatric

- Use of condom catheters are uncommon in children. When used in adolescents, take precautions to minimize embarrassment.

Gerontologic

- Evaluate patients with neuropathy carefully before applying a condom catheter. Patient may not feel sensation of pressure

from condom device. Assess penile skin at more frequent intervals, at least twice daily.

- Condom catheters are not recommended in patients with prostatic obstruction.

Home Care

- Teach patient and family caregivers appropriate assessments such as signs and symptoms of UTI, signs of skin irritation, or poor-fitting catheter sheath.
- Loose-fitting clothing may be needed to accommodate the catheter and drainage system.
- Ensure that patient and caregiver understand correct steps in applying the condom catheter. Manufacturers often supply patient educational materials.
- Teach patient or family caregiver to empty drainage bag frequently when one-half full to avoid unnecessary tension on the catheter that can lead to problems keeping the catheter intact.

SKILL 33-5 Suprapubic Catheter Care

A suprapubic catheter is a urinary drainage tube inserted surgically into the bladder through the abdominal wall above the symphysis pubis (Fig. 33-7). The catheter may be sutured to the skin, secured with an adhesive material, or retained in the bladder with a fluid-filled balloon similar to an indwelling catheter.

Suprapubic catheters are placed when there is blockage of the urethra (e.g., enlarged prostate, urethral stricture, after urologic surgery) and in situations when a long-term urethral catheter

FIG 33-7 Suprapubic catheter without a dressing.

causes irritation or discomfort or interferes with sexual functioning.

Delegation and Collaboration

The skill of caring for a newly established suprapubic catheter cannot be delegated to nursing assistive personnel (NAP); however, care of an established suprapubic catheter may be delegated (refer to agency policy). The nurse directs the NAP to:

- Report patient's discomfort related to the suprapubic catheter.
- Empty drainage bag and document urinary output on intake and output (I&O) record.
- Report any change in the amount and character of the urine.
- Report any signs of redness, foul odor, or drainage around catheter insertion site.

Equipment

- Clean gloves (sterile may be needed in some cases, see agency policy)
- Cleaning agent (sterile normal saline solution)
- Sterile cotton-tipped applicators
- Sterile surgical drainage gauze (split gauze)
- Sterile gauze dressing
- Washcloth, towel, soap, and water
- Tape
- Velcro tube holder or tube stabilizer (*optional*)

STEP

RATIONALE

ASSESSMENT

- 1 Assess urine in drainage bag for amount, clarity, color, odor, and sediment.
- 2 Observe dressing for drainage and intactness.
- 3 Assess catheter insertion site (may be deferred until you clean site) for signs of inflammation (i.e., pain, erythema, edema, and drainage) and for the growth of overgranulation tissue. Ask patient if there is any pain at site; if so, have him or her rate on scale of 0 to 10.
- 4 Assess for elevated temperature and chills.
- 5 Assess patient's knowledge of purpose of catheter and its care.
- 6 Check for allergies.

Abnormal findings indicate potential complications such as urinary tract infection (UTI), decreased urinary output, and catheter occlusion.

Drainage indicates potential complication such as infection. Dressing may become nonocclusive because of tape choice or drainage.

If insertion is new, slight inflammation may be expected as part of normal wound healing but can also indicate infection. Overgranulation tissue can develop at insertion site as reaction to catheter. In some instances intervention may be needed (Rigby, 2009).

Increased temperature may indicate UTI or skin site infection.

Determines level of instruction/support required.

Patient may be sensitive to tape, latex, or antiseptic solution.

NURSING DIAGNOSES

- Acute pain
- Deficient knowledge regarding catheter care
- Risk for infection
- Impaired skin integrity
- Impaired urinary elimination

Related factors are individualized based on patient's condition or needs.

PLANNING

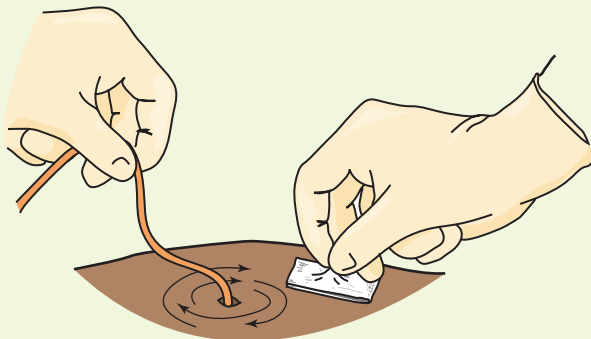

- 1 Expected outcomes following completion of procedure:
 - Patient verbalizes no pain or discomfort at insertion site and over bladder.
 - Urine output is 30 mL or greater per hour.
 - Urine remains clear without foul odor, and patient is afebrile.

Patent catheter system keeps bladder empty and patient comfortable.

Indicates that catheter is patent.

Indicates that patient is free of catheter-associated urinary tract infection (CAUTI).

STEP	RATIONALE
<ul style="list-style-type: none"> • Catheter exit site is free of infection (i.e., erythema, edema, drainage, tenderness). • Patient can explain the purpose and expected outcome of procedure. 	Indicates absence of infection and irritation of skin.
2 Explain procedure to patient.	Helps to minimize anxiety.
	Reduces anxiety and promotes cooperation.
IMPLEMENTATION	
1 Perform hand hygiene.	Reduces transmission of infection.
2 Provide privacy by closing room door and bedside curtain.	Promotes comfort and patient's self-esteem.
3 Raise bed to appropriate working height. If side rails are raised, lower side rail on working side.	Promotes use of good body mechanics.
4 Prepare supplies and open gauze packets in same manner as for applying dry dressing (see Chapter 39).	Keeps dressing sterile until application.
5 Apply clean gloves. Loosen tape and remove existing dressing. Note type and presence of drainage. Remove gloves and perform hand hygiene.	Provides baseline for condition of suprapubic wound. Reduces transmission of infection from dressing.
6 Clean insertion site using sterile aseptic technique for newly established catheter (option used less frequently; review agency policy or consider individual patient need).	Catheter site is made surgically and therefore is treated similarly to other incisions as designated by agency policy as either using aseptic or sterile technique.
a Apply sterile gloves.	
b Without creating tension, hold catheter up with nondominant hand while cleaning. Use sterile gauze moistened in saline and clean skin around insertion site in circular motion, starting near insertion site and continuing in outward widening circles for approximately 5 cm (2 inches) (see illustration).	Moves from area of least contamination to area of most contamination. Tension on catheter may cause discomfort or damage to wall of bladder or catheter to slip out of place.
c With fresh, moistened gauze, gently clean base of catheter, moving up and away from site of insertion (proximal to distal).	Removes microorganisms that reside on any drainage that adheres to tubing.
d Once insertion site is dry, use sterile gloved hand to apply drain dressing (split gauze) around catheter (see illustration). Tape in place.	Collects drainage that develops around catheter insertion site.
7 Clean using medical aseptic technique for new or established catheter:	
a Apply clean gloves.	
b Without creating tension, hold catheter up with nondominant hand while cleaning. Clean with soap and water in circular motion, starting near catheter insertion site and continuing in outward widening circles for approximately 5 cm (2 inches).	Cleansing and drying suprapubic insertion site requires general hygienic measures; dressing is an option if drainage is not present (Newman and Wein, 2009).
c With a fresh washcloth or gauze, gently clean base of catheter, moving up and away from site of insertion (proximal to distal).	Removes microorganisms that reside in any drainage that adheres to tubing.
d <i>Option:</i> Apply drain dressing (split gauze) around catheter and tape in place.	

STEP 6b Cleaning around suprapubic catheter in circular pattern.

STEP 6d Split drain dressing for suprapubic catheter.

STEP	RATIONALE
8 Secure catheter to lateral abdomen with tape or Velcro multipurpose tube holder.	Secures catheter and reduces risk of excessive tension on suture and/or catheter.
9 Coil excess tubing on bed. Keep drainage bag below level of bladder at all times.	Maintains free flow of urine, thus decreasing risk for CAUTI (Gould et al., 2009).
10 Dispose of all contaminated supplies in appropriate receptacle, remove gloves, and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Ask patient to rate pain or discomfort from suprapubic catheter on scale of 0 to 10.	Determines if bladder is draining and patient is free of infection.
2 Monitor for signs of infection. (e.g., fever, elevated white blood count) and observe urine for clarity, sediment, unusual color, or odor.	Suprapubic catheters increase risk for UTI.
3 Observe catheter insertion site for erythema, edema, discharge, tenderness. Check dressing at minimum of every 8 hours.	Indicators of a site infection.

Unexpected Outcomes

- 1 Patient develops symptoms of UTI or catheter site infection.
- 2 Urine leaks around catheter.
- 3 Suprapubic catheter becomes dislodged.
- 4 Skin surrounding catheter exit site becomes red or irritated and/or develops open areas.

Related Interventions

- Increase fluid intake to at least 2200 mL in 24 hours (unless contraindicated).
- Monitor vital signs, I&O; observe amount, color, consistency of urine; assess site.
- Notify health care provider.
- Check catheter and drainage tubing for kinks or other causes of occlusion.
- Monitor vital signs; assess urine for signs of infection.
- Change dressing frequently; protect skin from moisture.
- Notify health care provider.
- Cover site with sterile dressing.
- Notify health care provider. If newly established catheter, it will need to be reinserted immediately.
- Notify health care provider.
- Change dressing (if used) more frequently to keep site dry.
- Consult with wound care nurse.

Recording and Reporting

- Record and report character of urine and type of dressing change, including assessments of insertion site and patient's comfort level with the catheter and dressing change in nurses' notes and EHR.
- Record urine output on I&O flow sheet. When there is both a suprapubic and urethral catheter, record outputs from each catheter separately.

Special Considerations

Teaching

- If not contraindicated, encourage patients to consume a minimum of 2200 mL of fluids daily.
- Teach patient to keep the drainage bag lower than the bladder and to keep tubing free of kinks.

Home Care

- Teach patients and/or family caregivers how to clean and apply a dressing (if applicable) using a clean technique.
- Caution patients and/or family caregivers about avoiding the use of powders or creams around the catheter unless specifically instructed to do so (Newman and Wein, 2009).
- Teach patients and/or family caregivers how to properly position the drainage bag; empty the urinary drainage bag; and observe urine color, clarity, odor, and amount.
- Arrange for home delivery of catheter supplies, always ensuring that there is at least one extra catheter and drainage bag in the home.
- Teach patients and/or family caregivers signs of catheter obstruction, UTI, and wound infection.

Critical Thinking Exercises

You are caring for an 80-year-old woman of Middle Eastern heritage with a history of a stroke, type 2 diabetes, urinary retention, urinary incontinence, and recurrent urinary tract infections (UTIs). The health care provider has ordered measurement of postvoid residual (PVR) by either straight catheterization or bladder scan. There is also an order for an indwelling catheter if the PVR exceeds 400 mL.

- 1 Which assessments would be pertinent for this patient?
- 2 Explain why an assessment of PVR is important for this patient?
- 3 When measuring PVR, should the nurse use the bladder scanner, or should a straight catheterization be performed? Give the rationale for your answer.
- 4 Explain the teaching that would be appropriate when assessing PVR urine.

REVIEW QUESTIONS

- 1 The nurse is applying an external condom-type catheter. Which nursing intervention minimizes the risk of skin irritation and infection?
 - 1 Applying the condom sheath so the end of the catheter is 7 to 12.5 cm (3 to 5 inches) from the tip of the penis
 - 2 Shaving the pubic area so hair does not adhere to the condom or is pulled during removal
 - 3 Providing hygiene before applying the condom-type catheter
 - 4 Applying tape to the condom sheath to keep it securely in place
- 2 Place the following steps for insertion of an indwelling catheter in a female patient in appropriate order.
 - a Insert and advance catheter.
 - b Lubricate catheter.
 - c Inflate catheter balloon.
 - d Clean urethral meatus with antiseptic.
 - e Drape patient with the sterile square and fenestrated drapes.
 - f When urine appears, advance another 2.5 to 5 cm (1 to 2 inches).
 - g Prepare sterile field and supplies.
 - h Gently pull catheter until resistance is felt.
 - i Attach drainage tubing.
 - 1 g, d, e, b, a, f, c, h, i
 - 2 e, g, b, d, a, f, c, h, i
 - 3 g, e, b, d, f, a, c, h, i
 - 4 d, e, g, b, a, f, h, c, i
- 3 What is a critical step when inserting an indwelling catheter into a male patient?
 - 1 Quickly inflate the catheter balloon with sterile saline.
 - 2 Secure the catheter drainage tubing to the bed sheets.
 - 3 Advance to the bifurcation of the drainage and balloon ports.
 - 4 Advance until urine flows and then insert $\frac{1}{4}$ inch (0.6 cm) more.
- 4 The nurse is preparing to remove an indwelling urinary catheter. Which nursing interventions should the nurse implement? (Select all that apply.)
 - 1 Attach a 5-mL syringe to the inflation port.
 - 2 Allow the balloon to drain into the syringe by gravity.
 - 3 Initiate a voiding record/bladder diary.
 - 4 Pull catheter quickly.
 - 5 With steady force, pull back on the syringe plunger.
- 5 Which nursing interventions are appropriate in the care of a patient with an established suprapubic catheter? (Select all that apply.)
 - 1 Using sterile technique, clean the skin close to the catheter with a circular motion.
 - 2 Wipe away any drainage on the catheter by wiping down the catheter toward the insertion site.
 - 3 Inspect the insertion site for erythema, edema, discharge, or tenderness.
 - 4 Secure catheter to abdomen with tape or a tube-holder device.
 - 5 Apply tension to the catheter when cleaning the site and tubing.
- 6 The urine flow has stopped in a patient's indwelling urinary catheter, and the nurse assesses tenderness and distention over the lower abdomen. What would be an initial nursing action?
 - 1 Irrigating the catheter with sterile water or saline
 - 2 Assessing the catheter drainage tubing for kinking
 - 3 Encouraging fluid intake
 - 4 Removing the catheter
- 7 Which instructions should the nurse give the nursing assistive personnel (NAP) concerning an ambulatory patient who has had an indwelling urinary catheter removed that day?
 - 1 Limit oral fluid intake to avoid urinary incontinence.
 - 2 Expect patient complaints of suprapubic fullness and discomfort.
 - 3 Report the time and amount of first voiding.
 - 4 Have patient stay in bed and use a urinal or bedpan until first voiding.
- 8 Which patient condition is appropriate for the insertion of an indwelling urinary catheter?
 - 1 Stage I pressure ulcer exposed to leaking urine
 - 2 Patient unable to independently toilet
 - 3 Elevated postvoid residual
 - 4 Urinary incontinence
- 9 Which size indwelling urinary catheter is best for an adult female patient?
 - 1 18 Fr, 5-mL balloon
 - 2 16 Fr, 30-mL balloon
 - 3 14 Fr, 5-mL balloon
 - 4 12 Fr, 30-mL balloon
- 10 A patient with hematuria has a three-way indwelling urinary catheter with continuous bladder irrigation (CBI) and is complaining of lower abdominal pain. What should be the nurse's first action?
 - 1 Increasing the rate of the CBI
 - 2 Checking urine flow to the drainage bag
 - 3 Decreasing the rate of the CBI
 - 4 Taking the patient's temperature

KEY TERMS

Bowel management system	Decompression	Hemorrhoids	Obstipation
Cathartic	Defecation	Impaction	Occult blood
Cleansing enema	Enema	Medicated enema	Oil-retention enema
Constipation	Fracture pan		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe factors that promote and impede normal bowel elimination.
- Discuss methods to relieve constipation or impaction.
- Describe precautions to follow in administering an enema.
- Describe approaches for managing a patient's comfort during nasogastric tube insertion.
- Implement the following skills: helping a patient use a bedpan, digitally removing stool, administering an enema, and inserting a nasogastric tube.

Regular elimination of bowel waste products is essential for normal body functioning. Because bowel function depends on the balance of physical and psychological factors; elimination patterns and habits vary among individuals. When patients' functional status changes or they become ill, they may not be able to maintain normal elimination habits. They require assistance such as the use of a bedpan or enema administration. To manage patients' elimination problems, you need to understand normal elimination and factors that promote, impede, or alter elimination such as constipation, diarrhea, and fecal incontinence.

If left unrecognized, constipation can lead to fecal impaction, in which stool blocks the intestinal lumen. If a patient is constipated, you will likely administer enemas or digitally remove impacted stool (Kyle, 2009). When patients undergo surgery or experience an alteration in gastrointestinal (GI) peristalsis, the insertion of a nasogastric (NG) tube is needed

for gastric decompression. Gastric decompression reduces nausea and vomiting by keeping the stomach empty.

EVIDENCE-BASED PRACTICE

Constipation is a symptom, not a disease (Box 34-1). The signs of constipation usually include infrequent bowel movements (fewer than 3 times a week), difficulty in evacuating feces, inability to defecate, and hard feces. When intestinal motility slows, the body absorbs additional fecal water. The passage of dry, hard stools occurs when little water remains to soften and lubricate the stool. Constipation has shown to be a side effect of opioid use, decreased mobility, and change in fluid and diet intake (Linari et al., 2011). Interventions for the control of constipation initially include changes in lifestyle such as increased dietary fiber, increased fluids, moderate

exercise, and elimination of laxative use (Ostaszkiwicz et al., 2010). Use the following stepwise levels of interventions.

- Walk for 20 minutes, 3 times per week.
- Avoid skipping breakfast and increase intake of soluble and insoluble fiber by drinking one glass of a cloudy juice (e.g., pear) with breakfast and increasing fruit intake (e.g., pears, prunes, kiwi fruit).
- Increase fluid intake if less than 1200 mL per day.
- To promote optimal defecation sit on toilet with legs apart and elbows on knees. Support feet on a stool if unable to reach the floor.
- Respond to the urge to move bowels when the urge first occurs. Establish a bowel routine at the same time of day.
- Try an over-the-counter (OTC) bulk-forming laxative (e.g., psyllium [Metamucil] or methylcellulose [Citrucel]) if all other measures are unsuccessful.

BOX 34-1 Common Causes of Constipation

- Irregular bowel habits and ignoring the urge to defecate
- Chronic illnesses (e.g., Parkinson's disease, multiple sclerosis, rheumatoid arthritis, chronic bowel diseases, depression, eating disorders)
- Low-fiber diet high in animal fats (e.g., meats, dairy products, eggs), refined sugars (rich desserts), and low fluid intake that slow peristalsis
- Lengthy bed rest or lack of regular exercise
- Laxative misuse
- Older adults: Slowed peristalsis, loss of abdominal muscle elasticity, and reduced intestinal mucus secretion and often eating low-fiber foods (Touhy, 2010)
- Neurologic conditions that block nerve impulses to the colon (e.g., spinal cord injury, tumor)
- Colonic action slowed by medications such as anticholinergics, antispasmodics, anticonvulsants, antidepressants, antihistamines, antihypertensives, antiparkinsonism drugs, bile acid sequestrants, diuretics, antacids, iron supplements, calcium supplements, opioids

PATIENT-CENTERED CARE

Bowel elimination is a very private activity. It is important to show respect for a patient's privacy, provide necessary comfort and hygiene measures, and attend to his or her emotional needs when performing required skills. When caring for patients with elimination issues from other cultural and ethnic groups, modify nursing interventions to meet their elimination needs. Provide for culturally sensitive hygiene needs. For example, cultures such as Hindus and Muslims have distinct hygienic practices, which designate the left hand to perform unclean procedures such as cleansing after a bowel elimination. It is important to use the right hand to first touch a patient and then to use the left hand to handle the bedpan and help the patient to cleanse after bowel movement. When caring for a patient who speaks another language or for whom English is the second language, use an interpreter as needed. Provide gender-congruent care for patients from cultures that emphasize separate gender roles and female modesty.

To provide safe patient-centered care, you should determine a patient's normal pattern of bowel elimination and accommodate that pattern while the patient is in a health care setting. Determine the time a patient normally has a bowel movement and the amount of assistance needed. Consider developmental changes that affect bowel functioning throughout the life span. For example, an older adult who becomes less active and has decreased muscle tone and changes in eating patterns is at higher risk for experiencing constipation. Be aware of side effects of medications that impair normal elimination pattern by causing constipation or diarrhea. Also be aware of foods that promote normal peristaltic movement, including high-fiber foods such as raw fruit, whole grains, and green leafy vegetables. Make sure that these are consistent with a patient's prescribed diet and cultural preferences.

Safety Guidelines

- 1 Promote comfort when a patient uses a bedpan. Encourage patient to use the bathroom when able.
- 2 Answer the call light promptly to prevent a patient from attempting to get out of bed without assistance.

FIG 34-1 Actiflo bowel management system. (Courtesy Hollister Incorporated, Libertyville, Ill.)

- 3 When possible place patients on a toileting schedule and offer assistance with toileting at regular intervals.
- 4 When handling fecal matter, always use standard precautions (see Chapter 7).
- 5 Reduce transmission of the spores causing *Clostridium difficile* by using a bowel management system (Fig. 34-1). The system is

comprised of an intrarectal catheter that has a retention cuff, an intraluminal balloon, an inflation port, silicone tubing, and a collection bag. The contraindications for use of a bowel management system are included on the package insert and should be considered carefully before insertion.

SKILL 34-1 Assisting a Patient in Using a Bedpan

A patient restricted to bed must use a bedpan for bowel elimination. Two types of bedpans are available (Fig. 34-2). The regular and most commonly used bedpan has a curved, smooth upper end and a tapered lower end. The upper end (wide end) of the regular pan fits under a patient's buttocks toward the sacrum, with lower end (tapered end) fitting just under the upper thighs toward the foot of the bed. A fracture pan, designed for patients with body or leg casts or those who are restricted from raising their hips (e.g., following total joint replacement), slips easily under a patient. The shallow upper end of the pan with a flat, wide rim fits under a

patient's buttocks toward the sacrum, with the deep lower open end toward the foot of the bed.

Delegation and Collaboration

The skill of providing a bedpan can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Correct positioning guidelines for patients with mobility restrictions or for those who have therapeutic equipment such as wound drains, intravenous (IV) catheters, or traction.
- Providing perineal and hand hygiene for patient as necessary after using a bedpan.

FIG 34-2 Types of bedpans. *Left*, Regular bedpan. *Right*, Fracture bedpan.

Equipment

- Clean gloves
- Bedpan (regular or fracture) (see Fig. 34-2)
- Bedpan cover
- Toilet tissue
- Specimen container (if necessary), plastic bag clearly labeled with date, patient's name, and identification number
- Basin, washcloths, towels, and soap
- Waterproof, absorbent pads (if necessary)
- Clean drawsheet (if necessary)
- Stethoscope

STEP

RATIONALE

ASSESSMENT

- 1 Assess patient's normal bowel elimination habits: routine pattern, character of stool, effect of certain foods/fluids and eating habits on bowel elimination, effect of stress and level of activity on normal bowel elimination patterns, current medications, and normal fluid intake.
- 2 Auscultate abdomen for bowel sounds and palpate lower abdomen for distention.
- 3 Assess patient to determine level of mobility, including ability to sit upright and lift hips or turn.
- 4 Assess patient's level of comfort. Ask about presence of rectal or abdominal pain, presence of hemorrhoids, or irritation of skin surrounding anus.
- 5 Determine need for stool specimen.

Managing patient's elimination problems depends on thorough understanding of normal elimination and factors that create alterations. Peristalsis is strongest during the hour after first meal of the day. Anticipate when to offer bedpan.

Normal bowel sounds occur irregularly at rate of 5 to 35 per minute. Presence of feces in colon, often mistaken for an abdominal mass, can be felt as a soft, rounded, boggy mass in the cecum and ascending, descending, or sigmoid colon (Seidel et al., 2011).

Determines if patient can help in positioning on bedpan or if assistance is needed. Determines whether to use regular or fracture bedpan. Older adults, obese patients, patients who have had hip or knee surgery or spinal injury, and debilitated patients often require assistance of two or more nurses to help them onto or off bedpan.

Pain limits patient's ability to help with positioning. Rectal or abdominal pain reduces patient's ability to bear down during defecation.

Provides opportunity to obtain specimen container before placing patient on bedpan.

STEP

RATIONALE

NURSING DIAGNOSES

- | | | |
|--|--|--|
| <ul style="list-style-type: none"> • Acute pain • Bowel incontinence • Chronic pain | <ul style="list-style-type: none"> • Diarrhea • Impaired physical mobility • Perceived constipation | <ul style="list-style-type: none"> • Risk for constipation • Toileting self-care deficit |
|--|--|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Perianal skin is clean and intact. • Patient eliminates without pain or discomfort. <p>2 Explain procedure to patient, including self-help tips (e.g., how to use a trapeze, how to move hips).</p> <p>3 Obtain assistance from additional nursing personnel as warranted.</p> | <p>Hygiene technique after defecation keeps perianal skin clear of fecal secretions.</p> <p>Patient is positioned comfortably on bedpan.</p> <p>Promotes independence, reduces anxiety, and helps patient to assist during procedure.</p> <p>Adequate personnel resources minimize muscle strain for you and patient. Reduces patient's discomfort.</p> |
|--|---|

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Perform hand hygiene.</p> <p>2 Provide privacy by closing curtains around bed or door of room.</p> <p>3 Raise side rail on opposite side of bed.</p> <p>4 Raise bed horizontally according to your height.</p> <p>5 Have patient assume supine position.</p> | <p>Reduces transmission of microorganisms.</p> <p>Reduces embarrassment and promotes bowel elimination (Cohen, 2009).</p> <p>Protects patient from falling out of bed. Patient can use side rail to grasp onto and help self move about in bed and onto bedpan.</p> <p>Promotes use of good body mechanics and minimizes muscle strain for you and patient.</p> <p>Position eases eventual pan placement.</p> |
|--|---|

Clinical Decision Point *Observe for the presence of drains, dressings, IV fluids, and traction. These devices make it difficult for a patient to assist with positioning, and you will likely need more personnel to help place him or her on a bedpan.*

- | | |
|--|--|
| <p>6 Place patient who can help on a bedpan.</p> <p>a Apply clean gloves. Raise head of patient's bed 30 to 60 degrees.</p> <p>b Remove upper bed linens so they are out of the way but do not expose patient.</p> <p>c Teach patient how to flex knees and lift hips upward.</p> <p>d Place your hand, closest to patient's head, palm up under patient's sacrum to help lift. Ask patient to bend knees and raise hips. As patient raises hips, use other hand to slip bedpan under him or her (see illustrations). Be sure that open rim of bedpan is facing toward foot of bed. Do not force pan under patient's hips. (<i>Optional:</i> Have patient use overhead trapeze frame to raise hips.)</p> <p>e <i>Optional:</i> If using fracture pan, slip it under patient as hips are raised (see illustration). Be sure that deep, open, lower end of bedpan is facing toward foot of bed.</p> <p>7 Place patient who is immobile or has mobility restrictions on bedpan.</p> <p>a Apply clean gloves. Lower head of bed flat or raise head slightly (if tolerated by medical condition).</p> <p>b Remove top linens as necessary to turn patient while minimizing exposure.</p> | <p>Prevents hyperextension of back and provides support to upper torso when patient raises hips. Sitting position promotes defecation.</p> <p>Prevents embarrassment to patient; demonstrates respect for patient's sense of dignity (Cohen, 2009).</p> <p>If legs, upper torso, and arms are supporting body weight, little effort should be required of patient.</p> <p>Positions bedpan high under buttocks so feces enters pan. Incorrect placement of bedpan causes discomfort for patient and spillage of contents. Forcing bedpan under patient increases risk for friction injury to underlying skin and tissues.</p> <p>Patient requires less maneuvering and does not have to lift hips.</p> <p>Helps patient who cannot lift hips, who must remain flat, or who medically is not permitted to lift hips to roll onto bedpan.</p> <p>Prevents embarrassment to patient; demonstrates respect for patient's sense of dignity (Cohen, 2009).</p> |
|--|--|

STEP

RATIONALE

- c** Help patient roll onto side with back toward you. Place bedpan firmly against patient's buttocks and down into mattress. Be sure that open rim of bedpan is facing toward foot of bed (see illustrations).

Incorrect placement causes discomfort to patient and spillage of contents.

Clinical Decision Point *If patient has had total hip replacement, make sure that abduction pillow placed between the legs to prevent dislocation of the new joint remains in place. Use a fracture pan.*

- d** Keep one hand against bedpan; place other around far hip of patient. Ask patient to roll back onto bedpan, flat in bed. Do not force pan under patient.
- e** Raise patient's head 30 degrees or to a comfortable level (unless contraindicated).
- f** Have patient bend knees or raise knee gatch (unless contraindicated).
- 8** Maintain patient's comfort and safety. Cover patient for warmth. Place small pillow or rolled towel under lumbar curve of back.
- 9** Have call bell and toilet tissue within reach for patient.
- 10** Ensure that bed is in lowest position and raise upper side rails.
- 11** Remove and discard gloves and perform hand hygiene.
- 12** Allow patient to be alone but monitor status and respond promptly.
- 13** Perform hand hygiene and apply clean gloves.

Using minimal exertion, this places patient squarely on pan. Avoid forcing bedpan under patient to decrease risk for friction injury to underlying skin and tissues.

Patient assumes sitting position unless condition necessitates maintaining flat position.

Relieves stress on back.

Provides added comfort. Pain reduces or eliminates urge to defecate, which will result in bowel elimination problems.

Promotes safety by preventing patient from reaching over edge of bed for objects out of reach.

Promotes patient safety and enables patient to reposition pan as needed.

Reduces transmission of microorganisms.

Reassures patient. Removing bedpan in timely manner prevents pressure ulcers.

Reduces transmission of microorganisms.

STEP 6d **A**, Placing bedpan under patient's hips. **B**, Correct positioning for placing mobile patient on bedpan.

STEP 6e Patient lifts hips as fracture pan is positioned.

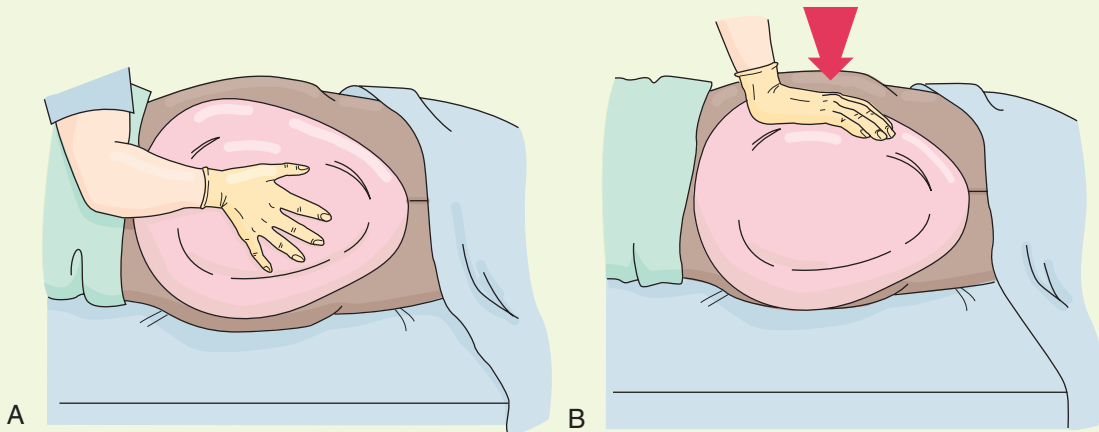

STEP

RATIONALE

14 Remove bedpan:

- a** Place patient's bedside chair close to working side of bed.
 - b** Maintain privacy; determine if patient is able to wipe own perineal area. If you clean perineal area, use several layers of toilet tissue or disposable washcloths. For female patients clean from mons pubis toward rectal area.
 - c** Deposit contaminated tissue in bedpan if no specimen or intake and output (I&O) is needed.
 - d For mobile patient:**
Ask patient to flex knees, placing body weight on lower legs, feet, and upper torso; lift buttocks up from bedpan. At same time place hand farthest from patient on side of bedpan to support it (prevent spillage) and place other hand (closest to patient) under sacrum to help lift. Have patient lift and remove bedpan. Place bedpan on draped bedside chair and cover.
 - e For immobile patient:**
Lower head of bed. Help patient roll onto side away from you and off bedpan. Hold bedpan flat and steady while patient is rolling off; otherwise spillage will occur. Place bedpan on draped bedside chair and cover.
- 15** Allow patient to perform hand hygiene. Change soiled linens, remove and dispose of gloves, and return patient to comfortable position.

- Provides area to place bedpan and contents on chair after removal from patient to prevent accidental spilling of full bedpan on bed surface.
- Maintains respect for privacy. Cleanses from clean to dirty area of perineum.
- Toilet tissue will contaminate specimen and affect accurate output measurement.
- Avoids pulling or forcing pan from under hips because this action pulls skin and causes tissue injury.
- Reduces spread of microorganisms. Reduces spread of offensive odors.
- Reduces chance of skin breakdown when bedridden patient lies on dry, wrinkle-free linens.

STEP 7c **A**, Position patient on one side and place bedpan firmly against buttocks. **B**, Push down on bedpan and toward patient. **C**, Nurse places bedpan in position. (*A and B from Sorrentino SA: Mosby's textbook for nursing assistants, ed 7, St Louis, 2009, Mosby.*)

STEP	RATIONALE
16 Place bed in its lowest position. Ensure that call bell, phone, drinking water, and desired personal items (e.g., books) are within easy access.	Promotes comfort and reduces risk for injury to patient.
17 Option: Obtain stool specimen as ordered (see Chapter 43). Wear gloves when emptying contents of bedpan into toilet or in special receptacle in utility room. Use spray faucet attached to most institution toilets to rinse bedpan thoroughly. Use disinfectant if required by agency, then store pan. Remove gloves.	If bedpan becomes very soiled, replace with clean one and send soiled one for sterilization or properly dispose (see agency policy).
18 Perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

1 Assess characteristics of stool. Note color, odor, consistency, frequency, amount, shape (see Fig. 34-3), and constituents. Assess characteristics of urine if patient voided in bedpan.	Helps to identify significant changes or findings.
2 Evaluate patient's ability to use bedpan.	Provides continual assessment of patient's self-toileting ability.
3 Inspect patient's perianal area and surrounding skin while removing bedpan.	Liquid stool predisposes patient to skin breakdown.
4 Evaluate patient's overall activity tolerance and comfort.	Defecation and use of bedpan are tiring.

Unexpected Outcomes

- 1 Patient is unable to successfully use bedpan.
- 2 Patient is incontinent of stool. Avoid use of adult briefs for bedridden patient.
- 3 Patient is constipated, resulting from pain of defecation, immobility, or unnatural position for defecation.
- 4 Patient develops irritation and breakdown of skin around perianal area.
- 5 Blood in stool or black stool.

Related Interventions

- If patient's mobility allows, obtain order for use of bedside commode.
- Establish regular schedule of offering bedpan. Adult briefs mask toileting needs and may potentiate skin breakdown.
- Discuss with staff need to answer patient's request for toileting assistance promptly and use toileting schedule.
- See [evidence-based practice](#) section, p. 842.
- Administer perianal skin care using moisture barrier.
- Perform fecal occult blood test (FOBT) (see Chapter 43).

Recording and Reporting

- Record the type of assistance needed and if patient tolerates getting on/off bedpan, character and amount of stool, and urine output if patient also voids.
- Complete laboratory requisition if you collected stool or urine specimen and send to laboratory. Record the type of specimen sent.

Special Considerations

Teaching

- Some patients on complete bed rest have an overhead trapeze frame connected to bed to help lift them on and off bedpan. Teaching this activity helps to maintain strength of patient's arms.

Pediatric

- Constipation in early childhood results from environmental changes such as being hospitalized and reluctance to use

a bedpan. Toilet-trained children often regress during hospitalization.

- Repeated withholding of stool leads to stretching or dilating of the rectum and decreases the sensation or "urge" to defecate (Hockenberry and Wilson, 2011).

Gerontologic

- Older adults have some loss of sphincter control and often require a quick response when requesting a bedpan (Kyle, 2009).
- Incidence of constipation is greater because there is impaired rectal sensation to defecate. As a result, the older adult does not perceive the need to defecate.
- With increased age transit time through the bowel increases, causing a normal lengthening of the time between bowel movements (Banning, 2008).

SKILL 34-2 Removing Fecal Impaction Digitally

Fecal impaction is the inability to pass a collection of hard stool. This condition occurs in all age-groups. Physically and mentally incapacitated individuals and institutionalized older adults are at greatest risk. Fecal impaction occurs when there is a history of constipation. However, functional constipation is defined as including two or more of the following factors for at least 3 months: (1) straining with defecation at least one fourth of the time, (2) lumpy or hard stools (or both) one fourth of the time (Fig. 34-3),

FIG 34-3 Bristol stool form scale. (From O'Donnell LJ, Virjee J, Heaton KW: Detection of pseudodiarrhoea by simple clinical assessment of intestinal transit rate, *Br Med J* 300:439, ©1990. Reprinted with permission of the BMJ Publishing Group.)

(3) sensation of incomplete evacuation at least one fourth of the time, or (4) two or fewer bowel movements in a week (Kyle, 2009). A variety of interventions successfully relieve constipation and reduce the risk for impaction (e.g., exercise and diet).

Symptoms of fecal impaction include constipation, rectal discomfort, anorexia, nausea, vomiting, abdominal pain, diarrhea (leaking around the impacted stool), and urinary frequency. Prevention is the key to managing fecal impaction. However, once it occurs, digital removal of stool is the only alternative. Digital removal of an impaction is very uncomfortable and embarrassing for a patient. Excessive rectal manipulation causes irritation to the mucosa and subsequent bleeding or vagus nerve stimulation, which can produce a reflex slowing of the heart rate. The skill is performed when the administration of enemas or suppositories is not successful at removing impacted stools.

Delegation and Collaboration

The skill of removing a fecal impaction digitally cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Help the nurse position a patient for the procedure.
- Observe the stool for color, consistency, rectal bleeding, or bloody mucus and report immediately to the nurse.
- Provide perineal care following each bowel movement.

Equipment

- Clean gloves
- Water-soluble local anesthetic lubricant (NOTE: Some agencies require use of water-soluble lubricant without anesthetic when nurse performs procedure.)
- Waterproof, absorbent pads
- Bedpan
- Bedpan cover (optional)
- Bath blanket
- Basin, washcloths, towels, and soap
- Vital sign equipment

STEP

RATIONALE

ASSESSMENT

1 Assess patient:

- Ask patient about normal and current bowel elimination pattern, including frequency and characteristics of stool; use of laxatives, enemas, and other medications; level of exercise; urge to defecate but inability to do so; feelings of incomplete emptying; and sensations of bloating, cramping, and excessive gas.
- Inspect patient's abdomen for distention.
- Auscultate all four quadrants for presence of bowel sounds.
- Palpate patient's abdomen for distention, discomfort, or masses.
- Measure patient's current vital signs and comfort level on scale of 0 to 10.

Information provides data in determining contributing factors and preventive measures. Large fecal mass causes rectal distention and increases perception of urge to evacuate rectum (Chien, 2010).

Observation identifies distended or asymmetric areas, which are then investigated on auscultation or palpation. Distention contributes to constipation.

Hypoactive bowel sounds may result from partial obstruction of the gastrointestinal (GI) tract.

Symptoms are related to accumulation of stool in intestinal tract. Palpable mass may be felt with severe constipation.

Provides baseline measurement. Sacral branch of vagus nerve is stimulated during digital stimulation; this stimulation results in reflex slowing of heart rate (Seidel et al., 2011).

STEP

RATIONALE

Clinical Decision Point Because of the potential to stimulate the sacral branch of the vagus nerve, patients with a history of dysrhythmias or heart disease have a greater risk for changes in heart rhythm. Be sure to monitor patient's pulse before and during procedure. This procedure is often contraindicated in cardiac patients; if in doubt, verify with the health care provider.

- | | |
|---|--|
| <p>f Perform hand hygiene and apply clean gloves. Observe consistency of stool (see Fig. 34-3), seepage of liquid stool, or continued passage of small amounts of hard stool. Observe anal area for signs of irritation or hemorrhoids. Remove gloves and perform hand hygiene.</p> <p>g Determine if patient is receiving anticoagulant therapy.</p> <p>2 Check patient's record for health care provider's order for digital removal of impaction and use of anesthetic lubricant.</p> | <p>Seepage of stool is symptomatic of an impaction high in colon. Patient may be able to pass small pieces of hard stool or have episodes of passing small amounts of liquid stool (Leung and Rao, 2009).</p> <p>Procedure may be contraindicated. Manipulation of rectum can cause bleeding, which is prolonged with anticoagulants. Obtain written order before performing procedure because this procedure involves excessive stimulation of vagus nerve.</p> |
|---|--|

NURSING DIAGNOSES

- Acute pain
- Constipation
- Diarrhea

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Impacted stool is successfully removed. • Patient is free of abdominal or rectal discomfort. <p>• Vital signs remain within patient's baseline.</p> <p>2 Explain procedure to patient.</p> | <p>Indicates that rectum is clear of stool.</p> <p>Fecal impaction causes direct pain to rectum and indirect abdominal discomfort through abdominal distention.</p> <p>Indicates absence of vagal stimulation.</p> <p>Information reduces anxiety and encourages patient participation in therapeutic elimination protocol.</p> |
|---|---|

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Obtain assistance to help change patient's position if necessary. Raise bed horizontally to comfortable working height.</p> <p>3 Pull curtains around bed or close door to room.</p> <p>4 Lower side rail on patient's right side. Keeping far side rail raised, help patient to left side-lying position with knees flexed and back.</p> <p>5 Drape patient's trunk and lower extremities with bath blanket and place waterproof pad under patient's buttocks.</p> <p>6 Place bedpan next to patient.</p> <p>7 Perform hand hygiene and apply clean gloves. Lubricate gloved index finger and middle finger of dominant hand with anesthetic lubricant.</p> <p>8 Instruct patient to take slow deep breaths during procedure. Gradually and gently insert gloved index finger and feel anus relax around finger. Insert middle finger.</p> <p>9 Gradually advance fingers slowly along rectal wall toward umbilicus.</p> <p>10 Gently loosen fecal mass by moving fingers in scissors motion to fragment the fecal mass. Work fingers into hardened mass.</p> <p>11 Work stool downward toward end of rectum. Remove small sections of feces and discard into bedpan.</p> <p>12 Observe patient's response and periodically assess heart rate and look for signs of fatigue.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Promotes patient safety and use of good body mechanics.</p> <p>Maintains patient's sense of privacy and prevents unnecessary exposure of body parts.</p> <p>Promotes patient safety. Provides access to rectum.</p> <p>Maintains patient's sense of privacy and prevents unnecessary exposure of body parts.</p> <p>Prevents transmission of microorganisms. Reduces discomfort and permits smooth insertion of finger into anus and rectum.</p> <p>Slow deep breaths help to relax patient. Gradual insertion of index finger helps to dilate anal sphincter.</p> <p>Allows you to reach impacted stool high in rectum.</p> <p>Loosening and penetrating mass allows for removal of stool in small pieces, resulting in less discomfort to patient.</p> <p>Prevents need to force finger up into rectum and minimizes trauma to mucosa.</p> <p>Vagal stimulation slows heart rate and causes dysrhythmias. Procedure often exhausts patient.</p> |
|--|--|

STEP

RATIONALE

Clinical Decision Point Stop procedure if heart rate drops or rhythm changes from patient's baseline or if patient has dyspnea or complaints of palpitations.

- | | |
|--|---|
| <p>13 Continue to clear rectum of feces and allow patient to rest at intervals.</p> <p>14 After removal of impaction perform perineal hygiene.</p> <p>15 Remove bedpan and inspect feces for color and consistency. Dispose of feces in toilet.</p> <p>16 If needed, help patient to toilet or clean and store the bedpan. (Procedure may be followed by enema or cathartic.)</p> <p>17 Remove gloves by turning them inside out and discarding in proper receptacle. Perform hand hygiene.</p> | <p>Rest improves patient's tolerance of procedure, allowing heart rate to return to normal.</p> <p>Promotes patient's sense of comfort and cleanliness.</p> <p>Reduces transmission of microorganisms.</p> <p>Removal of impaction stimulates defecation reflex.</p> <p>Reduces transmission of microorganisms.</p> |
|--|---|

EVALUATION

- | | |
|--|--|
| <p>1 Apply clean gloves and perform rectal examination for stool and observe anal and perianal area for irritation or skin breakdown.</p> <p>2 Reassess vital signs and compare to baseline values. Continue to monitor patient for 1 hour for bradycardia.</p> <p>3 Auscultate bowel sounds.</p> <p>4 Palpate abdomen to determine if it is soft and nontender.</p> <p>5 Ask patient to rate comfort level of on scale of 0 to 10.</p> | <p>Determines if rectum is clear.</p> <p>Determines extent of vagal stimulation.</p> <p>Determines presence of peristaltic activity.</p> <p>Discomfort is relieved.</p> <p>Procedure can cause discomfort.</p> |
|--|--|

Unexpected Outcomes

- 1 Patient experiences trauma to rectal mucosa as evidenced by rectal bleeding.
- 2 Patient experiences bradycardia, decrease in blood pressure, and decrease in level of consciousness as result of vagus nerve stimulation.
- 3 Patient has seepage of liquid stool after procedure complete.

Related Interventions

- Assess anal and perianal region for source of bleeding.
- Stop procedure if bleeding is excessive.
- Stop procedure and measure vital signs.
- Notify health care provider and remain with patient.
- Assess patient for continuing impaction.
- Notify health care provider for possible suppository or enema.
- Increase patient's fluid intake and dietary fiber.

Recording and Reporting

- Record patient's tolerance to procedure, amount and consistency of stool removed, vital signs, and adverse effects.
- Report any changes in vital signs and adverse effects to health care provider.

Special Considerations

Teaching

- If constipation and subsequent impaction are diet related, teach patient about high-fiber nutritional products to increase bulk and the need for adequate fluid intake.
- If necessary, teach family caregivers about the effects of immobility, hydration, and nutrition on normal bowel elimination.

Pediatric

- Do not digitally remove stool in a pediatric patient because of the risk for anal fissures and pain that trigger stool withholding (Hockenberry and Wilson, 2011).

Gerontological

- Many older adults are especially prone to dysrhythmias and other problems related to vagal stimulation; monitor heart rate and rhythm closely (Seidel et al., 2011).
- For older adults, instituting a diet adequate in dietary fiber (6 to 10 g per day) adds bulk, weight, and form to stool and improves defecation.
- Consider developing a regular toileting routine that includes responding to the urge to defecate.

SKILL 34-3 Administering an Enema

NSO Bowel Elimination Module / Lesson 2

An enema is the instillation of a solution into the rectum and sigmoid colon to promote defecation by stimulating peristalsis. Typically an enema is used to treat constipation or empty the bowel before diagnostic procedures or certain types of abdominal surgery. Preoperative enemas are common for some surgeries.

Cleansing enemas promote complete evacuation of feces from the colon. They act by stimulating peristalsis through infusion of large volumes of solution. Oil-retention enemas act by lubricating the rectum and colon, allowing feces to absorb oil and become softer and easier to pass. Sometimes these enemas are used before digital removal of stool. Medicated enemas contain pharmacologic therapeutic agents. Some are prescribed to reduce dangerously high serum potassium levels (e.g., sodium polystyrene sulfonate [Kayexalate] enema) or to reduce bacteria in the colon before bowel surgery (e.g., neomycin enema).

The volume or type of fluid that breaks up the fecal mass stretches the rectal wall and initiates the defecation reflex. Common types of enemas include:

- *Tap water (hypotonic) enema*: It should not be repeated after first installation because water toxicity or circulatory overload can develop.
- *Physiologic normal saline*: It is the safest enema to administer. Infants and children can tolerate only this type because of their predisposition to fluid imbalance.
- *Hypertonic solution* (e.g., commercially prepared Fleet enema): It is useful for patients who cannot tolerate large volumes of fluid. Only 120 to 180 mL (4 to 6 oz) is usually effective.
- *Harris Flush enema*: It is a return-flow enema in which fluid alternately flows into and out of the large intestine. This stimulates peristalsis in the large intestine and helps to expel intestinal gas.
- *Soapsuds enema (SSE)*: It is pure castile soap added to either tap water or normal saline, depending on patient's condition and frequency of administration. Use *only* castile pure soap. Recommended ratio of pure soap to solution is 5 mL (1 teaspoon) to 1000 mL (1 quart) warm water or saline. Add soap to enema bag *after* water is in place to reduce excessive suds.
- *Oil-retention enema*: It uses an oil-based solution. The colon absorbs a small volume, which allows the oil to soften stool for easier evacuation.
- *Carminative solution*: It provides relief from gaseous distention. An example is MGW solution, which contains 30 mL of magnesium, 60 mL of glycerin, and 90 mL of water.

Delegation and Collaboration

The skill of enema administration can be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- How to properly position patients who have mobility restrictions or therapeutic equipment such as drains, intravenous (IV) catheters, or traction.
- Informing the nurse about patient's new abdominal pain (*exception*: a patient reports cramping) or rectal bleeding.
- Informing the nurse immediately about the presence of blood in the stool or around the rectal area or any change in vital signs.

Video Clip

Equipment

- Clean gloves
- Water-soluble lubricant
- Waterproof, absorbent pads
- Toilet tissue
- Bedpan, bedside commode, or access to toilet
- Basin, washcloths, towel, and soap
- IV pole
- Stethoscope

Enema Bag Administration

- Enema container with tubing and clamp (Fig. 34-4)
- Appropriate-size rectal tube (adult: 22 to 30 Fr; child: 12 to 18 Fr)
- Correct volume of warmed (tepid) solution (adult: 750 to 1000 mL; adolescent: 500 to 700 mL; school-age child: 300 to 500 mL; toddler: 250 to 350 mL; infant: 150 to 250 mL)

Prepackaged Enema

- Prepackaged enema container with lubricated rectal tip (Fig. 34-5)

FIG 34-4 Enema bag with tubing.

FIG 34-5 Prepackaged enema container with rectal tip and cap.

STEP

RATIONALE

ASSESSMENT

1 Review health care provider's order for enema and clarify reason for administration.	Order by health care provider is usually required for hospitalized patient.
2 Assess last bowel movement, normal versus most recent bowel pattern, presence of hemorrhoids, mobility, and presence of abdominal pain or cramping.	Determines need for enema and type of enema used. Also establishes baseline for bowel function. Hemorrhoids may obscure rectal opening and cause discomfort or bleeding during evacuation.
3 Inspect abdomen for presence of distention and auscultate for bowel sounds.	Establishes baseline for determining effectiveness of enema.
4 Determine patient's level of understanding of purpose of enema.	Allows for planning appropriate teaching measures.

Clinical Decision Point "Enemas until clear" order means that you repeat enemas until patient passes fluid that is clear of fecal matter. Check agency policy, but usually patient should receive only three consecutive enemas to avoid disruption of fluid and electrolyte balance. It is essential to observe contents of solution passed.

NURSING DIAGNOSES

- Acute pain
 - Constipation
 - Risk for constipation
- Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Stool is evacuated. • Enema return is clear. • Abdomen is flat, nontender, with no distention. 	<p>Solution clears rectum and lower colon of stool.</p> <p>Indicates that all solid fecal material in colon has passed.</p> <p>Gas and feces are expelled.</p>
---	--

IMPLEMENTATION

1 If enema is medicated, check accuracy and completeness of each medication administration record (MAR) with health care provider's written order. Check patient's name, type of enema, and time for administration. Compare MAR with label of enema solution.	The order is most reliable source and only legal record of drugs or procedure that patient is to receive. Ensures that patient receives correct enema.
2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
3 Provide privacy by closing curtains around bed or closing door.	Reduces embarrassment for patient.
4 Place bedpan or bedside commode in easily accessible position. If patient will be expelling contents in toilet, ensure that toilet is available, and place patient's slippers and bathrobe in easily accessible position.	Bedpan is used if patient is unable to get out of bed.
5 Perform hand hygiene and apply clean gloves.	Reduces transmission of microorganisms.
6 Raise bed to appropriate working height; raise side rail on patient's right side.	Promotes good body mechanics and patient safety.
7 Help patient turn onto left side-lying (Sims') position with right knee flexed. Encourage him or her to remain in position until procedure is complete. Children are placed in dorsal recumbent position.	Allows enema solution to flow downward by gravity along natural curve of sigmoid colon and rectum, thus improving retention of solution.

Clinical Decision Point Patients with poor sphincter control require placement of a bedpan under the buttocks. Administering enema with patient sitting on toilet is unsafe because curved rectal tubing can abrade rectal wall.

8 Lower side rail on working side and place waterproof pad, absorbent side up, under hips and buttocks. Cover patient with bath blanket, exposing only rectal area, clearly visualizing anus.	Pad prevents soiling of linen. Blanket provides warmth, reduces exposure of body parts, and allows patient to feel more relaxed and comfortable.
9 Separate buttocks and examine perianal region for abnormalities, including hemorrhoids, anal fissure, and rectal prolapse.	Findings influence approach for inserting enema tip. Prolapse contraindicates enema.

STEP

RATIONALE

10 Administer enema.

a Administer prepackaged disposable enema:

- (1) Remove plastic cap from tip of container. Tip may already be lubricated. Apply more water-soluble lubricant as needed.
- (2) Gently separate buttocks and locate anus. Instruct patient to relax by breathing out slowly through mouth.
- (3) Expel any air from enema container.
- (4) Insert lubricated tip of container gently into anal canal toward umbilicus (see illustration).
Adult: 7.5 to 10 cm (3 to 4 inches)
Adolescent: 7.5 cm to 10 cm (3 to 4 inches)
Child: 5 to 7.5 cm (2 to 3 inches)
Infant: 2.5 to 3.75 cm (1 to 1½ inches)

Lubrication provides for smooth insertion of rectal tube without causing rectal irritation or trauma. With presence of hemorrhoids, extra lubricant provides added comfort.

Breathing out promotes relaxation of external rectal sphincter.

Introducing air into colon causes further distention and discomfort. Gentle insertion prevents trauma to rectal mucosa.

Clinical Decision Point *If pain occurs or you feel resistance at any time during procedure, stop and discuss with health care provider. Do not force insertion.*

- (5) Roll plastic bottle from bottom to tip until all of solution has entered rectum and colon. Instruct patient to retain solution until urge to defecate occurs, usually 2 to 5 minutes.

Prevents instillation of air into colon and ensures that all content enters rectum. Hypertonic solutions require only small volumes to stimulate defecation.

b Administer enema in standard enema bag:

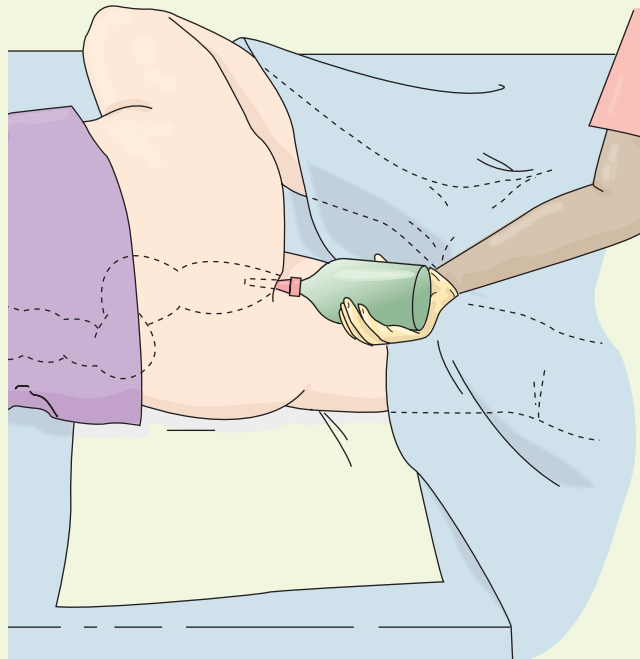

- (1) Add warmed solution to enema bag: Warm tap water as it flows from faucet, place saline container in basin of warm water before adding saline to enema bag, and check temperature of solution by pouring small amount of solution over inner wrist.
- (2) If SSE is ordered, add castile soap after water.
- (3) Raise container, release clamp, and allow solution to flow long enough to fill tubing.
- (4) Reclamp tubing.

Hot water burns intestinal mucosa. Cold water causes abdominal cramping and is difficult to retain.

Prevents suds in enema bag.

Removes air from tubing.

Prevents further loss of solution.

STEP 10a(4) With patient in left lateral Sims' position, insert tip of commercial enema into rectum. (From Sorrentino SA: Mosby's textbook for nursing assistants, ed 7, St Louis, 2009, Mosby.)

STEP

RATIONALE

- | | |
|---|--|
| (5) Lubricate 6 to 8 cm (2½ to 3 inches) of tip of rectal tube with lubricant. | Allows smooth insertion of rectal tube without risk for irritation or trauma to mucosa. |
| (6) Gently separate buttocks and locate anus. Instruct patient to relax by breathing out slowly through mouth. Touch patient's skin next to anus with tip of rectal tube. | Breathing out and touching skin with tube promotes relaxation of external anal sphincter. |
| (7) Insert tip of rectal tube slowly by pointing it in direction of patient's umbilicus. Length of insertion varies (see Step 10a[4]). | Careful insertion prevents trauma to rectal mucosa from accidental lodging of tube against rectal wall. Insertion beyond proper limit can cause bowel perforation. |

Clinical Decision Point *If tube does not pass easily, do not force. Consider allowing a small amount of fluid to infuse and then try to reinsert the tube slowly. The instillation of fluid relaxes the sphincter and provides additional lubrication. Remove an impaction (see Skill 34-2) before administering the enema.*

- | | |
|---|---|
| (8) Hold tubing in rectum constantly until end of fluid instillation. | Prevents expulsion of rectal tube during bowel contractions. |
| (9) Open regulating clamp and allow solution to enter slowly with container at patient's hip level. | Rapid infusion stimulates evacuation of tubing and can cause cramping. |
| (10) Raise height of enema container slowly to appropriate level above anus: 30 to 45 cm (12 to 18 inches) for high enema; 30 cm (12 inches) for regular enema (see illustration); 7.5 cm (3 inches) for low enema. Instillation time varies with volume of solution administered (e.g., 1 L may take 10 minutes). You may use an IV pole to hold an enema bag once you get a slow flow of fluid established. | Allows for continuous, slow instillation of solution. Raising container too high causes rapid instillation and possible painful distention of colon. High pressure causes rupture of bowel in infant. |

Clinical Decision Point *Temporary cessation of infusion minimizes cramping and promotes ability to retain solution. Lower container or clamp tubing if patient complains of cramping or if fluid escapes around rectal tube.*

STEP 10b(10) IV pole is positioned so the bottom of the enema bag is 18 inches above the anus.

STEP	RATIONALE
(11) Instill all solution and clamp tubing. Tell patient that procedure is completed and that you will be removing tubing.	Prevents entrance of air into rectum. Patients may misinterpret sensation of removing tube as loss of control.
11 Place layers of toilet tissue around tube at anus and gently withdraw rectal tube and tip.	Provides for patient's comfort and cleanliness.
12 Explain to patient that some distention and abdominal cramping is normal. Ask him or her to retain solution as long as possible until urge to defecate occurs. This usually takes a few minutes. Stay at bedside. Have patient lie quietly in bed if possible. (For infant or young child gently hold buttocks together for few minutes.)	Solution distends bowel. Length of retention varies with type of enema and patient's ability to contract rectal sphincter. Longer retention promotes stimulation of peristalsis and defecation.
13 Discard enema container and tubing in proper receptacle.	Reduces transmission and growth of microorganisms.
14 Help patient to bathroom or commode if possible. If using bedpan, help to as near normal position for evacuation as possible (see Skill 34-1).	Normal squatting position promotes defecation.
15 Observe character of stool and solution (caution patient against flushing toilet before inspection).	Determines if enema was effective.
16 Help patient as needed to wash anal area with warm soap and water (if nurse administers perineal care, use gloves).	Fecal contents irritate skin. Hygiene promotes patient's comfort.
17 Remove and discard gloves and perform hand hygiene.	Reduces transmission of microorganisms.

EVALUATION

- | | |
|--|---|
| 1 Inspect color, consistency, and amount of stool; odor; and fluid passed. | Determines if stool is evacuated or fluid is retained. Note abnormalities such as presence of blood or mucus. |
| 2 Assess for abdominal distention. | Determines if distention is relieved. |

Unexpected Outcomes

- Severe abdominal cramping, bleeding, or sudden abdominal pain develops and is unrelieved by temporarily stopping or slowing flow of solution.
- Patient is unable to hold enema solution.

Related Interventions

- Stop enema.
- Notify health care provider.
- If this occurs during installation, slow rate of infusion.

Recording and Reporting

- Record the type and volume of enema given, time of administration, characteristics of results, and patient's tolerance of the procedure.
- Report the failure of patient to defecate and any adverse effects to health care provider.

Special Considerations

Teaching

- Instruct patient that enemas are not to treat cause of constipation. Instruct in lifestyle changes to encourage peristalsis.
- Instruct patient in self-administration. Patient needs to lie in dorsal recumbent position with knees and hips flexed toward chest.

Pediatric

- The use of oral stool softeners is the initial recommended treatment of constipation in children.

- Children and infants usually do not receive prepackaged hypertonic enemas because hypertonic solutions cause rapid fluid shift (Hockenberry and Wilson, 2011).

Gerontological

- Caution is necessary when enemas are ordered "until clear" in older adults. Some older adults become fatigued, are at risk for fluid and electrolyte imbalances, and experience changes in vital signs.
- Teach older adults and their caregivers how to modify diet to avoid constipation.
- Some older adults may have difficulty retaining fluid. The nurse may gently hold buttocks together to help with retention of fluid.

Home Care

- Assess patient's and primary caregiver's ability and motivation to administer enema and provide instruction as needed.
- Assess patient's ability to manipulate equipment and self-administer enema.

SKILL 34-4 Insertion, Maintenance, and Removal of a Nasogastric Tube for Gastric Decompression

There are times following major surgery or with conditions affecting the gastrointestinal (GI) tract when normal peristalsis is temporarily altered. Because peristalsis is slowed or absent, a patient cannot eat or drink fluids without causing abdominal distention. The temporary insertion of a nasogastric (NG) tube into the stomach serves to decompress the stomach, keeping it empty until normal peristalsis returns.

An NG tube is a pliable tube inserted through the patient's nasopharynx into the stomach. The tube is hollow, which allows for the removal of gastric secretions and the introduction of solutions into the stomach. There are times when an NG tube is used for enteral feedings, but a softer small-bore feeding tube is preferred for feeding purposes (see [Chapter 31](#)). The Levin and Salem sump tubes are the most common for stomach decompression. The Levin tube is a single-lumen tube with holes near the tip ([Fig. 34-6](#)). You connect the tube to a drainage bag or an intermittent suction device to drain stomach secretions. The Salem sump tube is preferable for stomach decompression. The tube has two lumens: one for removal of gastric contents and one to provide an air vent, which prevents suctioning of gastric mucosa into eyelets at the distal tip of a tube. A blue "pigtail" is the air vent that connects with the second lumen ([Fig. 34-7](#)). When the main lumen of the sump tube is connected to suction, the air vent permits free, continuous drainage of secretions. *Never clamp off the air vent, connect to suction, or use for irrigation.* The health care provider orders the suction setting, which is usually low intermittent.

NG tube insertion uses clean technique. The procedure is uncomfortable, with patients experiencing a burning sensation as the tube passes through the sensitive nasal mucosa. One of the greatest nursing care challenges is keeping a patient comfortable because the tube is a constant irritation to mucosa. Routinely assess the condition of the nares and mucosa for inflammation and excoriation. Supportive care includes changing soiled tape or fixation devices, keeping the nares lubricated and clean, and providing frequent mouth care to minimize the dehydration from mouth breathing.

Delegation and Collaboration

The skill of inserting and maintaining an NG tube cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Measure and record the drainage from an NG tube.
- Provide oral and nasal hygiene measures.
- Perform selected comfort measures such as positioning or offering ice chips if allowed.
- Anchor the tube to patient's gown during routine care to prevent accidental displacement.

Equipment

- 14- or 16-Fr NG tube (Smaller-lumen catheters are not used for decompression in adults because they must be able to remove thick secretions.)
- Water-soluble lubricant
- pH test strips (measure gastric aspirate acidity); use paper with a range of at least 1.0 to 11.0 or higher
- Tongue blade
- Flashlight
- Emesis basin
- Asepto bulb or catheter-tipped syringe
- 2.5-cm (1-inch)-wide hypoallergenic tape or commercial fixation device
- Safety pin and rubber band
- Clamp, drainage bag, or suction machine with pressure gauge if wall suction is to be used
- Towel
- Glass of water with straw
- Facial tissues
- Normal saline
- Tincture of benzoin (*optional*)
- Suction equipment
- Stethoscope
- Clean gloves

FIG 34-6 Levin tube. (Courtesy Bard Medical, Covington, Ga.)

FIG 34-7 Salem sump tube. (Courtesy Covidien, Mansfield, Mass.)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|--|
| 1 Inspect condition of patient's nasal and oral cavity. | Determines need for special nursing hygiene measures after tube placement. |
| 2 Ask if patient has had history of nasal surgery or congestion and allergies and note if deviated nasal septum is present. | Alerts nurse to potential obstruction. Insert tube into <i>uninvolved</i> nasal passage. Procedure may be contraindicated if surgery is recent. |
| 3 Auscultate for bowel sounds. Palpate patient's abdomen for distention, pain, and rigidity. | In presence of diminished or absent bowel sounds, auscultate abdomen at least 1 minute in each quadrant (Seidel et al., 2011). Documents baseline for any abdominal distention, GI ileus, and general GI function, which later serves as comparison once tube is inserted. |
| 4 Assess patient's level of consciousness and ability to follow instructions. | Determines patient's ability to assist in procedure. |

Clinical Decision Point *If patient is confused, disoriented, or unable to follow commands, obtain assistance from another staff member to insert the tube.*

- | | |
|---|--|
| 5 Determine if patient had previous NG tube and, if so, which naris was used. | Patient's previous experience complements any explanations and prepares patient for NG tube placement. |
| 6 Verify health care provider order for type of NG tube to be placed and whether tube is to be attached to suction or drainage bag. | Requires order from health care provider. Adequate decompression depends on NG suction. |

NURSING DIAGNOSES

- | | | |
|--------------|--|------------------------------------|
| • Acute pain | • Deficient knowledge regarding purpose of gastric decompression | • Impaired oral mucous membrane |
| | • Dysfunctional gastrointestinal motility | • Risk for impaired skin integrity |

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|--|
| 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Abdomen is soft, nontender, and without distention. • Patient's nares and nasal mucosa remain clear, without abrasions or excoriation. • Patient's level of comfort improves or remains the same. | Correctly positioned NG tube remains patent, drains gastric secretions, and relieves gastric distention.
Ensures absence of irritation from NG tube. |
| 2 Inform patient that procedure may make him or her gag and there will be a burning sensation in nasopharynx as tube is passed. Develop hand signal with patient. | Correctly inserted NG tube prevents abdominal discomfort from progressing.
Increases patient's cooperation and ability to anticipate nurse's action. If patient is unable to tolerate procedure, use of hand signal will alert nurse. |

IMPLEMENTATION

- | | |
|--|---|
| 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). |
| 2 Place patient in high-Fowler's position. Place pillows behind head and shoulders. Raise bed to horizontal level comfortable for accessing patient. | Promotes patient's ability to swallow during procedure. Good body mechanics prevent injury to you or patient. |
| 3 Place bath towel over patient's chest; give facial tissues to patient. Allow to blow nose if necessary. Place emesis basin within reach. | Prevents soiling of patient's gown. Tube insertion through nasal passages may cause tearing and coughing with increased salivation. |
| 4 Pull curtain around bed or close room door. | Provides privacy. |
| 5 Wash bridge of nose with soap and water or alcohol swab. | Removes oils from nose to allow tape to adhere. |
| 6 Stand on patient's right side if right-handed, left side if left-handed. Lower side rail. | Allows easiest manipulation of tubing. |

STEP	RATIONALE
7 Instruct patient to relax and breathe normally while occluding one naris. Then repeat this action for other naris. Select nostril with greater airflow.	Tube passes more easily through naris that is more patent.
8 Measure distance to insert tube: a Traditional method: Measure distance from tip of nose, to earlobe, and to xiphoid process (see illustration). b Hanson method: First mark 50-cm (20-inch) point on tube and measure traditionally. Tube insertion should be to midway point between 50 cm (20 inches) and traditional mark.	Approximates distance from naris to stomach; distance varies with each patient. Tube tip should enter stomach.
9 With small piece of tape placed around tube, mark length that will be inserted.	Indicates length of tube you will insert.
10 Perform hand hygiene and apply clean gloves. Curve 10 to 15 cm (4 to 6 inches) of end of tube tightly around index finger and release.	Aids insertion and decreases stiffness of tube.
11 Lubricate 7.5 to 10 cm (3 to 4 inches) of end of tube with water-soluble lubricant.	Minimizes friction against nasal mucosa and aids insertion of tube. Water-soluble lubricant is less toxic than oil-soluble lubricant if aspirated.
12 Alert patient when procedure will begin.	Decreases patient anxiety and increases patient cooperation.
13 Initially instruct patient to extend neck back against pillow; insert tube gently and slowly through naris with curved end pointing downward.	Facilitates initial passage of tube through naris and maintains clear airway for open naris.
14 Continue to pass tube along floor of nasal passage, aiming down toward patient's ear. If resistance occurs, apply gentle downward pressure to advance tube (do not force past resistance).	Minimizes discomfort of tube rubbing against upper nasal turbinates. Resistance is caused by posterior nasopharynx. Downward pressure helps tube curl around corner of nasopharynx.
15 If there is continued resistance, try to rotate tube and see if it advances. If still resistant, withdraw it, allow patient to rest, lubricate it again, and insert into other naris.	Forcing against resistance causes trauma to mucosa. Allowing patient to rest helps relieve anxiety.
Clinical Decision Point <i>If unable to insert tube in either naris, stop procedure and notify health care provider.</i>	
16 Continue insertion of tube until just past nasopharynx by gently rotating it toward opposite naris.	Relieves patient's anxiety; tearing is natural response to mucosal irritation, and excessive salivation may occur because of oral stimulation.
a Once past nasopharynx, stop tube advancement, allow patient to relax, and provide tissues.	Sipping water aids passage of NG tube into esophagus.
b Explain to patient that next step requires him or her to swallow. Give patient glass of water unless contraindicated.	Flexed position closes off upper airway to trachea and opens esophagus. Swallowing closes epiglottis over trachea and helps move tube into esophagus. Swallowing water reduces gagging or choking. Remove water from stomach by suction after insertion.
17 With tube just above oropharynx, instruct patient to flex head forward, take a small sip of water, and swallow. Advance tube 2.5 to 5 cm (1 to 2 inches) with each swallow of water. If patient is not allowed fluids, instruct to dry swallow or suck air through straw. Advance tube with each swallow.	

STEP 8a Technique for measuring distance to insert NG tube.

STEP

RATIONALE

18 If patient begins to cough, gag, or choke, withdraw tube slightly and stop advancement. Instruct patient to breathe easily and take sips of water.

Cough reflex is initiated when tube accidentally enters larynx. Withdrawal of tube reduces risk for laryngeal entry. Small sips of water frequently reduce gagging. Give water cautiously to reduce risk for aspiration.

Clinical Decision Point *If vomiting occurs, help patient clear airway. Perform oral suctioning as needed.*

19 If patient continues to cough during insertion, pull tube back slightly.

Tube may enter larynx and obstruct airway.

20 If patient continues to gag and cough or complains that tube feels as though it is coiling behind throat, check back of oropharynx using flashlight and tongue blade. Withdraw tube until tip is back in oropharynx if coiled. Reinsert with patient swallowing.

Tube may coil around itself in back of throat and stimulate gag reflex.

21 After patient relaxes, continue to advance tube with swallowing until you reach tape or mark on tube that signifies that tube is in the desired distance. Temporarily anchor tube to patient's cheek with piece of tape until tube placement is verified.

Tip of tube needs to be within stomach to decompress properly. Anchoring tube prevents accidental displacement while tube placement is verified.

22 Verify tube placement. Check agency policy for preferred methods for checking tube placement.

a Ask patient to talk.

Patient is unable to talk if NG tube has passed through vocal cords. Tube is pliable and will coil up behind pharynx instead of advancing into esophagus.

b Inspect posterior pharynx for presence of coiled tube.

c Place towel under end of NG tube and attach Asepto or catheter-tipped syringe to end of tube. Aspirate gently back on syringe to obtain gastric contents, observing color (see illustration).

Gastric contents are usually grassy green, clear, and odorless. Postpyloric tube placement appears golden yellow, yellow-brown, or greenish brown with pH of greater than 6.0 (Hockenberry and Wilson, 2011; Lewis et al., 2011).

d Use gastric (Gastrocult) pH paper to measure aspirate for pH with color-coded pH paper. Be sure that paper range of pH is at least from 1.0 to 11.0 or greater (see illustration).

Gastric aspirates have decidedly acidic pH values typically less than 5.0 (Durai, Venkatraman, and Ng, 2009; Hockenberry and Wilson, 2011). Respiratory secretions are usually greater than 6.0.

e Obtain x-ray film examination of chest and abdomen as ordered.

Radiography is gold standard to verify initial placement of tube (Farrington et al., 2009; Hockenberry and Wilson, 2011; Lewis et al., 2011).

f If tube is not in stomach, advance another 2.5 to 5 cm (1 to 2 inches) and repeat Steps 22a-d to check tube position and verify with radiography.

Tube must be in stomach to provide decompression.

STEP 22c Aspiration of gastric contents.

STEP 22d Checking pH of gastric aspirate.

STEP

RATIONALE

- 23** Anchor tube.
- a** Clamp end of tube or connect tube to drainage bag or suction machine after properly inserted.
 - b** Tape tube to nose; avoid putting pressure on nares.
 - (1) Cut strip of tape about 10 cm (5 inches) and split down the middle halfway.
 - (2) Apply small amount of tincture of benzoin to lower end of nose and allow drying before taping tube to nose (*optional*). Apply prepared tape to nose, leaving split end free. Be sure that top end of tape over nose is secure.
 - (3) Carefully wrap two split ends of tape around tube in opposite directions (see illustrations).
 - (4) *Alternative:* Apply tube fixation device using shaped adhesive patch (see illustration).
 - c** Fasten end of NG tube to patient's gown by looping rubber band around tube in slipknot. Pin rubber band to gown.
 - d** When using Salem sump tube, keep pigtail above level of stomach.
- 24** Unless health care provider orders otherwise, elevate head of bed 30 degrees.
- 25** Explain to patient that sensation of tube in back of throat decreases somewhat with time.

Use gravity for drainage bag. Intermittent suction is most effective for decompression. Patient going to operating room often has tube clamped.

Prevents tissue necrosis. Tape anchors tube securely.

Benzoin prevents loosening of tape if patient perspires or has oily skin.

Reduces pressure on nares if tube moves. Provides slack for movement without dislodging NG tube.

Prevents siphoning action that clogs tube.

Helps prevent esophageal reflux and minimizes irritation of tube against posterior pharynx.

Helps patient to adapt to continued sensory stimulus.

STEP 23b(3) A and B, Tape is crossed over and around NG tube.

STEP 23b(4) Patient with tube fixation device.

STEP	RATIONALE
<p>26 Once placement is confirmed:</p> <ul style="list-style-type: none"> a Make either a red mark or use tape on tube to indicate where tube exits nose. b <i>Alternative:</i> Measure length of tube from nares to connector. c Document length of tube in patient's record. 	<p>Mark on tube or tape is guide to indicate continuous correct tube placement.</p> <p>Information helps to determine tube placement.</p>
<p>Clinical Decision Point <i>Never reposition an NG tube of a gastric surgical patient, because positioning could rupture the suture line.</i></p>	
<p>27 Attach NG tube to suction as ordered.</p>	<p>Suction setting is usually ordered low intermittent, which decreases gastric irritation from NG tube.</p>
<p>Clinical Decision Point <i>If lumen of tube is narrow and secretions are thick, NG tube will not drain as desired. Irrigate tube (Step 28). Consult with health care provider for higher suction setting if unable to irrigate tube because of thick secretions.</i></p>	
<p>28 NG tube irrigation:</p> <ul style="list-style-type: none"> a Perform hand hygiene and apply clean gloves. b Check for tube placement in stomach (see Step 22). Temporarily clamp tube or reconnect to connecting tube and remove syringe. c Draw up 30 mL of normal saline into Asepto or catheter-tip syringe. d Clamp NG tube. Disconnect from connecting tubing and lay end of connection tubing on towel. e Insert tip of irrigating syringe into end of NG tube. Remove clamp. Hold syringe with tip pointed at floor and inject saline slowly and evenly. Do not force solution. 	<p>Reduces transmission of microorganisms.</p> <p>Prevents accidental entrance of irrigating solution into lungs.</p> <p>Use of saline minimizes loss of electrolytes from stomach fluids.</p> <p>Reduces soiling of patient's gown and bed linen.</p> <p>Position of syringe prevents introduction of air into vent tubing, which causes gastric distention. Solution introduced under pressure causes gastric trauma.</p>
<p>Clinical Decision Point <i>Do not introduce saline through blue "pigtail" air vent of Salem sump tube.</i></p>	
<ul style="list-style-type: none"> f If resistance occurs, check for kinks in tubing. Turn patient onto left side. Repeated resistance should be reported to health care provider. g After instilling saline, immediately aspirate or pull back slowly on syringe to withdraw fluid. If amount aspirated is greater than amount instilled, record difference as output. If amount aspirated is less than amount instilled, record difference as intake. h Use an Asepto syringe to place 10 mL of air into blue pigtail. i Reconnect NG tube to drainage or suction. (Repeat irrigation if solution does not return.) <p>29 Removal of NG tube:</p> <ul style="list-style-type: none"> a Verify order to remove NG tube. b Auscultate abdomen for presence of bowel sounds. c Explain procedure to patient and reassure that removal is less distressing than insertion. d Perform hand hygiene and apply clean gloves. e Turn off suction and disconnect NG tube from drainage bag or suction. With irrigating syringe, insert 20 mL of air into lumen of NG tube. Remove tape or fixation device from bridge of nose and unpin tube from gown. f Stand on patient's right side if right-handed, left side if left-handed. g Hand patient facial tissue; place clean towel across chest. Instruct patient to take and hold breath. 	<p>Tip of tube may lie against stomach lining. Repositioning on left side may dislodge tube away from stomach lining. Buildup of secretions causes distention.</p> <p>Irrigation clears tubing so stomach should remain empty. Measure and document irrigation inserted in tube as intake.</p> <p>Ensures patency of air vent.</p> <p>Reestablishes drainage collection; may repeat irrigation or repositioning of tube until NG tube drains properly.</p> <p>An order is required for procedure.</p> <p>Verifies return of peristalsis.</p> <p>Minimizes anxiety and increases cooperation. Tube passes out smoothly.</p> <p>Reduces transmission of microorganisms.</p> <p>Have tube free of connections before removal. Clears gastric fluids from tube to prevent aspiration of contents or soiling of clothing and bedding.</p> <p>Allows easiest manipulation of tube.</p> <p>Some patients wish to blow nose after tube is removed. Towel keeps gown from soiling. Temporary airway obstruction occurs during tube removal.</p>

STEP	RATIONALE
<p>h Clamp or kink tubing securely and pull tube out steadily and smoothly into towel held in other hand while patient holds breath.</p>	<p>Clamping prevents tube contents from draining into oropharynx. Reduces trauma to mucosa and minimizes patient's discomfort. Towel covers tube, which is an unpleasant sight. Holding breath helps to prevent aspiration.</p>
<p>i Inspect intactness of tube.</p>	
<p>j Measure amount of drainage and note character of content. Dispose of tube and drainage equipment into proper container.</p>	<p>Provides accurate measure of fluid output. Reduces transfer of microorganisms.</p>
<p>k Clean nares and provide mouth care.</p>	<p>Promotes comfort.</p>
<p>l Position patient comfortably and explain procedure for drinking fluids if not contraindicated. Instruct patient to notify you if nausea occurs.</p>	<p>Sometimes patients are not allowed anything by mouth (NPO) for up to 24 hours. When fluids are allowed, orders usually begin with small amount of ice chips each hour and increase as patient is able to tolerate more.</p>
<p>30 For all procedures, clean equipment and return to proper place. Place soiled linen in utility room or proper receptacle.</p>	<p>Proper disposal of equipment prevents spread of microorganisms and ensures proper exchange procedures.</p>
<p>31 Remove and discard gloves and perform hand hygiene.</p>	<p>Reduces transmission of microorganisms.</p>

EVALUATION

<p>1 Observe amount and character of contents draining from NG tube. Ask if patient feels nauseated.</p>	<p>Determines if tube is decompressing stomach of contents.</p>
<p>2 Auscultate for presence of bowel sounds. Turn off suction while auscultating.</p>	<p>Sound of suction apparatus is sometimes misinterpreted as bowel sounds.</p>
<p>3 Palpate patient's abdomen periodically. Note any distention, pain, and rigidity.</p>	<p>Determines success of abdominal decompression and return of peristalsis.</p>
<p>4 Inspect condition of nares and nose.</p>	<p>Evaluates onset of skin and tissue irritation.</p>
<p>5 Observe position of tubing.</p>	<p>Prevents tension applied to nasal structures.</p>
<p>6 Ask if patient feels sore throat or irritation in pharynx.</p>	<p>Evaluates level of patient's discomfort.</p>

Unexpected Outcomes

- 1 Patient's abdomen is distended and painful.
- 2 Patient complains of sore throat from dry, irritated mucous membranes.
- 3 Patient develops irritation or erosion of skin around nares.
- 4 Patient develops signs and symptoms of pulmonary aspiration: fever, shortness of breath, or pulmonary congestion.

Related Interventions

- Assess patency of tube. NG tube may not be in stomach.
- Irrigate tube.
- Verify that suction is on as ordered.
- Notify health care provider if distention is unrelieved.
- Perform oral hygiene more frequently.
- Ask health care provider whether patient can suck on ice chips, throat lozenges, or local anesthetic medication.
- Provide frequent skin care to area.
- Tape tube on nares to avoid pressure.
- Consider switching tube to other nares.
- Perform complete respiratory assessment.
- Notify health care provider.
- Obtain chest x-ray film examination as ordered.

Recording and Reporting

- Record length, size, and type of gastric tube inserted and in which naris it was inserted. In addition, record patient's tolerance of procedure, confirmation of tube placement, character of gastric contents, pH value, results of radiography, whether the tube is clamped or connected to drainage bag or to suction, and amount of suction supplied.
- Record difference between amount of normal saline instilled and amount of gastric aspirate removed on intake and output (I&O) sheet. Record the amount and character of contents draining from NG tube every shift.

- Record removal of tube "intact," patient's tolerance of procedure, and final amount and character of drainage.

Special Considerations

Gerontologic

- Check for ill-fitting dentures and remove them for patient's safety and comfort during the insertion.
- Oral and nasal mucosal drying is sometimes present. Adequately lubricate the tube for insertion.

Critical Thinking Exercises

Mr. Simon, a 66-year-old man with a history of severe osteoarthritis, is hospitalized following a total right knee replacement performed 2 days ago. At present he is allowed touch-down weight bearing on his right leg. Mr. Simon's last bowel movement was the day before surgery; thus he has gone 3 days without a bowel movement. Since surgery he received pain medication (an opioid) through his intravenous (IV) line and began taking oral pain medication last night.

His abdomen is nontender, slightly distended, with active bowel sounds in all four quadrants. He attempted a bowel movement with a great deal of straining and expelled small, hard, brown stool. You've talked to the primary care provider and obtained orders for a Fleet enema.

- You've explained the enema procedure to Mr. Simon and have prepared your supplies. You need to provide a bedpan or commode for Mr. Simon to expel the fecal material following the enema. Make your selection of the type of bedpan or use of commode and provide the rationale.
 - Notify the health care provider.
 - Instruct the NAP to palpate Mr. Simon's abdomen.
 - Give postoperative pain medication as ordered.
 - Perform an abdominal assessment.
 - Obtain vital signs (VSs) and instruct the NAP to obtain them every 15 to 30 minutes thereafter.
- Two days later Mr. Simon has the same symptoms as before receiving the enema. This time he has liquid stool seeping from the rectum. You obtain an order to check for an impaction. You explain the procedure to Mr. Simon and begin the skill as required. As you are removing stool, the NAP who is helping you by monitoring Mr. Simon's vital signs reports that his pulse is 48 beats/min. What does this indicate, and how do you proceed?

REVIEW QUESTIONS

- One risk associated with digital removal of impacted stool is stimulation of the vagus nerve. The nurse should monitor a patient for which adverse effect?
 - Urinary incontinence
 - An elevated pulse rate
 - Abdominal cramping
 - A drop in the heart rate
- During insertion of a nasogastric tube, the nurse has a patient swallow. What is the rationale for swallowing?
 - It prevents stimulation of the gag reflex.
 - It closes off the upper airway so the tube enters the esophagus.
 - It facilitates the tube passing through the nasal passages.
 - It helps to distract the patient during the procedure.
- The nurse is placing a bedpan under a frail, immobile female patient. The nurse's actions are appropriate if which method is followed?
 - Sliding the bedpan under her
 - Rolling her onto a fracture bedpan
 - Shove the bedpan under her
 - Keep her flat after rolling her on the bedpan
- A patient has an order for enemas "until clear" in preparation for bowel surgery. Which information in a patient's medical record would cause the nurse to question the health care provider's order?
 - Hemorrhoid surgery 5 weeks ago
 - Periodic fecal incontinence
 - Taking medication for an enlarged prostate
 - A history of glaucoma
- A patient who had intestinal surgery yesterday has a nasogastric tube for gastric decompression. The patient is nauseated, and his abdomen is distended. The nurse irrigated the tube but met resistance. Which action should the nurse take?
 - Irrigate the tube again with more normal saline
 - Turn patient onto left side
 - Advance the tube several inches
 - Turn the suction on continuous instead of intermittent
- The nurse is assessing the abdomen of a patient who is 3 days postoperative from shoulder surgery. The nurse palpates a boggy mass in the transverse colon. In collaborating with the health care provider, which action would the nurse expect to take next?
 - Administer a Fleet enema
 - Obtain an x-ray film of the abdomen
 - Remove the fecal impaction digitally
 - Wait to see if the patient develops abdominal pain
- The nurse is assessing a patient's normal bowel elimination habits and anticipating his needs. When should the patient be offered the bedpan?
 - At bedtime
 - First thing in the morning
 - After eating a midday snack
 - Approximately an hour after breakfast
- After placing a mobile patient on the bedpan, how high should the nurse place the head of the bed?
 - 15 to 30 degrees
 - 30 to 60 degrees
 - 60 to 90 degrees
 - Keep the head of the bed flat
- The nurse is caring for an elderly patient who needs to use a bedpan. Which of the following comfort measures should the nurse use for proper positioning and general comfort? (Select all that apply.)
 - Keep the head of the bed flat
 - Place toilet tissue within reach
 - Stay with patient while using the bedpan
 - Place a small pillow under lumbar curve in the back
 - Place the head of the bed at 45-degree angle
- The nurse has several activities to perform. Which can be delegated to the NAP? (Select all that apply.)
 - Administering an enema
 - Removing a fecal impaction
 - Placing a patient on a bedpan
 - Inserting a nasogastric (NG) tube
 - Providing oral care for a patient with a NG tube

KEY TERMS

Colostomy	Ileal conduit	Ostomy	Stoma
Continent fecal diversion	Ileostomy	Peristomal	Urinary stent
Continent urinary diversion	Orthotopic neobladder	Skin barrier	Urostomy
Effluent			

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Identify the types of fecal and urinary diversions.
- Explain the differences in color and consistency of effluent based on the type of ostomy.
- Pouch a fecal or urinary diversion.
- Describe methods used to maintain integrity of the peristomal skin.
- Catheterize a urinary diversion.

Certain diseases or conditions require surgical intervention to create an opening into the abdominal wall for fecal or urinary elimination. Examples of these conditions include cancer, inflammatory bowel disease, perforation of the colon, or fecal incontinence. The opening is called a *stoma* and is constructed from a section of colon or small intestine. The output from the stoma is called the *effluent*. An opening in the large intestine or colon is a colostomy. A colostomy in the descending or sigmoid colon (Fig. 35-1) generally results in a stool similar to that normally passed through the rectum. If the opening is in the transverse or ascending colon, the effluent varies from thick liquid to semiformal stool. An opening in the ileal portion of the small intestine is an ileostomy (Fig. 35-2), and the fecal effluent will be watery-to-thick liquid and contain some digestive enzymes. Fecal ostomies are either temporary or permanent, depending on the underlying condition and the surgical procedure performed.

A urostomy or ileal conduit (Fig. 35-3) is created from a portion of the intestine that is resected from the ileum. One end of the conduit is sutured closed, and the ureters are implanted through the mucosa. The other end is brought out on the abdominal wall, and a stoma is formed for urine to exit

the body. This ostomy is permanent. A patient with a colostomy, ileostomy, or ileal conduit has no sensation or control over the time or frequency of the output and must wear a pouch to collect the effluent.

Surgical procedures to create continent internal fecal or urinary pouches eliminate the need for an external pouch. The continent ileostomy is a pouch made from a segment of the ileum and placed under the abdominal wall, with a small tract from the pouch opening through the skin. A patient inserts a large catheter through this opening or stoma several times a day to empty fecal effluent in the internal pouch. These procedures are done less frequently now because there are other surgical options available with higher long-term success rates. In the ileal pouch anal anastomosis the surgeon creates an internal reservoir from a segment of the ileum that is then connected to the anal canal above the anal sphincter (Fig. 35-4). The patient will usually have four to six bowel movements per day. Most frequently the surgeon will perform a temporary ileostomy to allow the reservoir to heal.

There are also two types of continent urinary diversions. One is a continent urinary reservoir (Fig. 35-5) created from the intestine. This reservoir into which the ureters are inserted

FIG 35-1 Sigmoid colostomy.

FIG 35-2 Ileostomy.

FIG 35-3 Urostomy (ileal conduit).

is situated under the abdominal wall, with a narrow tract coming out through the abdominal wall to form a small stoma. A catheter is inserted to empty the urine from the pouch. Patients must be able and willing to catheterize the pouch 4 to 6 times a day for the rest of their lives. The other type of continent urinary diversion is

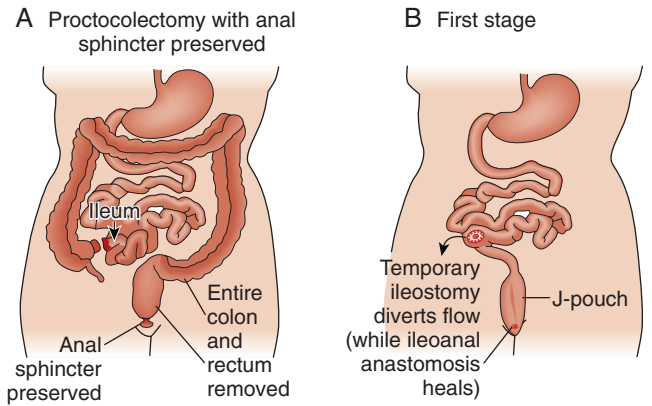

FIG 35-4 Ileal pouch anal anastomosis.

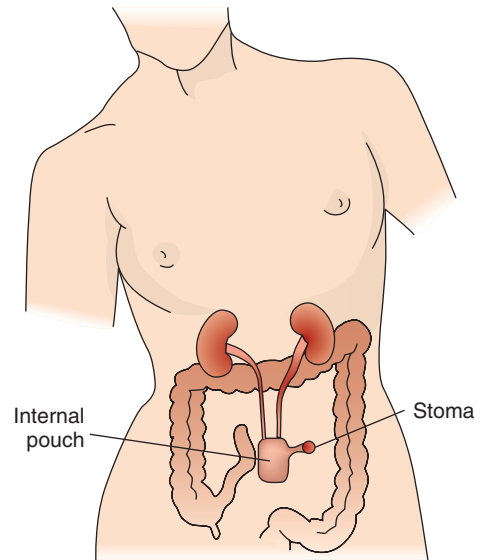

FIG 35-5 Continent urinary diversion.

an orthotopic neobladder, which also uses an intestinal pouch to replace the bladder. Anatomically the pouch is in the same position as the bladder was before removal, allowing the patient to void normally. The patient will have frequent episodes of incontinence of urine after this surgery and will need to follow a bladder-training schedule and perform pelvic muscle exercises until continence is achieved. The postoperative care of patients having continent urinary diversions varies widely with the surgical techniques used, and it is important to learn the surgeon's preferred routine or health care agency procedures before caring for these patients. A recent research study suggests that overall quality of life was rated similarly for both patients with incontinent stomas and those with continent procedures (Gemmill et al., 2010).

EVIDENCE-BASED PRACTICE

Before ostomy surgery, a health care provider or ostomy care nurse should see a patient to mark the stoma site. An ostomy care nurse is a certified wound, ostomy, continence nurse (CWOCN) or an enterostomal therapy (ET) nurse. Evaluating the patient's abdomen while he or she is lying, sitting, and standing allows the nurse and the patient to find an optimal location so it is easy to pouch the new stoma and maintain a reliable seal.

One of the primary changes in ostomy care is related to stoma care. Pouching systems are more effective, and adhesive technology more advanced. These improvements include a wider variety of sizes and shapes of skin barriers, depths of convexity from shallow to deep, and degrees of flexibility:

- The current trend is to apply a pouch directly to clean dry skin without using skin preparations, paste, or added adhesives unless a patient has a specific problem keeping a pouch intact (Goldberg et al., 2010).
- The adhesives on the skin barriers are pressure and heat sensitive; thus a patient should apply gentle pressure with the hand over the skin barrier for several minutes to adhere the barrier to the skin (Kent, 2008).
- There are new and improved accessory products such as rings or seals for managing abdominal contours that are uneven or peristomal skin that is not intact.
- Some pouches have effective gas filters that allow flatus to escape slowly from the pouch through a charcoal filter. This filter absorbs odor and does not allow leakage of liquid effluent through the filter.
- All of the ostomy companies now have pouches with integrated closures. A Velcro-like closure eliminates the need for a clip to close the bottom of the pouch. It also requires less manual dexterity to empty the pouch (Goldberg et al., 2010).
- A wider selection of products for neonatal and pediatric use has improved the care of that population (Bookout et al., 2011).

PATIENT-CENTERED CARE

With any ostomy requiring a pouching system, a secure seal to prevent leakage of the effluent and protect the skin around the stoma (peristomal skin) is vital to helping patients resume normal activities and accept the changes in their bodies as a result of surgery. It is also a very important factor in facilitating the emotional adjustment to the ostomy (Li, 2009). In addition to the stress of illness and surgical recovery, patients with ostomies face body image changes, fear of social rejection, concern about sexual function and intimacy, and the need for help with personal care.

Use a variety of teaching strategies for patients based on their physical ability, learning style, and emotional readiness to learn. Whenever possible make a referral to an ostomy care nurse (de la Quintana et al., 2010). Ostomy support groups are available to provide support for patients. Information about these groups is

available from ostomy care nurses or on the United Ostomy Association of America website, <http://www.uoaa.org>.

In any culture the presence and care of an ostomy presents unique challenges. New ostomies require monitoring and observation, and patients from some cultures may find this more invasive and embarrassing than those from cultures that are more open about bodily functions. Most patients consider bowel and urinary secretions unfit for public display. Exposure of the lower torso, which is needed for ostomy care, may also be a problem for some patients. Discuss with patients their preferences. For example, it may help to assign gender-congruent caregivers if possible and to encourage the presence of a family member if the patient finds this acceptable.

As you communicate with a patient during ostomy care, be sensitive and avoid communicating anything that the patient may interpret as disrespect or disgust. As always, prepare adequately for the procedure; seek necessary assistance; and maintain a calm, professional demeanor. Do not act offended by the odor or appearance of the effluent in the pouch or the appearance of the stoma. A negative reaction from caregivers only reinforces a patient's feelings that this alteration in bodily function makes them personally and socially unacceptable. A supportive nurse makes the initial period of adjustment easier (Burch, 2011). When a patient comes to the hospital with an ostomy, encourage him or her to resume self-care as soon as possible. Respect a patient's routine of care even if it differs from usual care in the agency.

Safety Guidelines

- 1 Change ostomy pouches before they become full to avoid leakage, which can lead to chemical or enzymatic injury to the skin.
- 2 Wear gloves during pouch and stoma care to reduce exposure and transmission of infectious microorganisms.
- 3 Know the signs of a healthy stoma and peristomal skin.
 - **Color/moisture:** Stoma should be red or pink and moist. Report a gray, purple, or black stoma to the charge nurse or health care provider.
 - **Size:** In the 4 to 6 weeks after surgery, the stoma will likely decrease in size. Measure with each pouch change.
 - **Peristomal skin normally is intact with some reddening.** Presence of blisters, a rash, or rawlike appearance is abnormal.

SKILL 35-1 Pouching a Colostomy or an Ileostomy

NSO Ostomy Module / Lessons 1, 3, and 4

Immediately after a fecal surgical diversion, it is necessary to place a pouch over the newly created stoma to contain effluent when the stoma begins to function. The pouch will keep a patient clean and dry, protect the skin from drainage, and provide a barrier against odor. A cut-to-fit, transparent pouching system is preferred because it will cover the peristomal skin without constricting the stoma and allow for visibility of the stoma.

Recognize the difference between a budded stoma (Fig. 35-6) and a flush or retracted stoma (Fig. 35-7). In the immediate post-operative period the stoma may be edematous, and the abdomen distended. These symptoms will resolve over a 4- to 6-week period after surgery, but during this time it will be necessary to revise the

pouching system to meet the changing size of the stoma and the changes in body contours (Dietz and Gates, 2010a).

There are many types of pouching systems. All have a protective layer that adheres to the skin, called a skin barrier, and a pouch. A one-piece pouching system (Fig. 35-8) has the two parts integrated together. A two-piece system (Fig. 35-9) has a separate skin barrier and pouch. The flush or retracted stoma may require a convex wafer (Fig. 35-10) for successful placement of a pouch. This type of skin barrier provides gentle pressure on the peristomal skin to push the stoma through the opening in the wafer. You apply the pouch to the skin barrier by attaching it to a flange (a plastic ring) on the barrier. You must use the skin barrier with a flange that fits

FIG 35-6 Budded stoma. (Courtesy Jane Fellows.)

FIG 35-7 Retracted stoma. (Courtesy Jane Fellows.)

FIG 35-8 One-piece pouch with Velcro closure. (Courtesy Coloplast, Minneapolis, Minn.)

FIG 35-9 Two-piece pouching system with separate skin barrier and attachable pouch. (Courtesy Coloplast, Minneapolis, Minn.)

the corresponding size pouch from the same manufacturer to avoid leakage between the skin barrier and the pouch. Some pouching systems have precut openings in the barrier for the stoma, whereas others need to be custom cut to size for the patient's stoma measurement. It is important to understand how to use each of these different pouching systems before applying them on patients (Dietz and Gates, 2010b). The websites for the companies that make ostomy supplies have both patient and health care provider instructions that are helpful in understanding how to use the pouching systems (e.g., <http://www.convatec.com>; <http://www.us.coloplast.com>; and <http://www.hollister.com>).

Delegation and Collaboration

The skill of pouching a new ostomy/ileostomy cannot be delegated to nursing assistive personnel (NAP). In some agencies care of an established ostomy (4 to 6 weeks or more after surgery) can be delegated to NAP. The nurse directs the NAP about:

FIG 35-10 Convex skin barrier wafer. (Used with permission Convatec, Inc. All rights reserved.)

- The expected amount, color, and consistency of drainage from the ostomy.
- The expected appearance of the stoma.
- Special equipment needed to complete procedure.
- Change in patient's stoma and surrounding skin integrity that should be reported.

Equipment

- ❑ Skin barrier/pouch—clear, drainable one-piece or two-piece, cut-to-fit or precut size
- ❑ Pouch closure device such as a clip if needed

- ❑ Ostomy measuring guide
- ❑ Adhesive remover (*optional*)
- ❑ Clean gloves
- ❑ Washcloth
- ❑ Towel or disposable waterproof barrier
- ❑ Basin with warm tap water
- ❑ Scissors
- ❑ Waterproof bag for disposal of pouch
- ❑ Gown and goggles optional if there is risk of splashing when emptying pouch

STEP

RATIONALE

ASSESSMENT

- 1 Perform hand hygiene and apply clean gloves.
- 2 Observe existing skin barrier and pouch for leakage and length of time in place. Pouch should be changed every 3 to 7 days for colostomy and 3 to 5 for ileostomy, not daily (Goldberg et al., 2010). In case of an opaque pouch, remove it to fully observe stoma.

Reduces transmission of microorganisms.
Assesses effectiveness of pouching system and detects potential for problems. To minimize skin irritation, avoid unnecessary changing of entire pouching system. When pouch leaks, skin damage from effluent causes more skin trauma than early removal of wafer.

Clinical Decision Point *Repeated leaking may indicate need for different type of pouch. If the pouch is leaking, change it. Taping or patching it to contain effluent leaves the skin exposed to chemical or enzymatic irritation.*

- 3 Observe amount of effluent in pouch and empty it if it is more than one-third to one-half full by opening clip and draining it into a container for measurement of output. Note consistency of effluent and record intake and output.
- 4 Observe stoma for type, location, color, swelling, presence of sutures, trauma, and healing or irritation of peristomal skin. Remove and dispose of gloves.
- 5 Observe abdomen for best type of pouching system. Consider:
 - a Abdominal contour.
 - b Presence of scars or incisions.
- 6 Explore patient's attitude toward learning self-care and identify others who will be helping patient after leaving hospital.

Weight of pouch may disrupt seal of adhesive on skin.
Monitors fluid balance and bowel function after surgery. Normal colostomy effluent is soft or formed stool, whereas normal ileostomy effluent is liquid.
Stoma characteristics influence selection of an appropriate pouching system. Convexity in skin barrier is often necessary with flush or retracted stoma.
Determines pouching system selection.
Abdominal contours, scars, or incisions affect type of system and adhesion to skin surface.
Facilitates teaching plan and timing of care to coincide with availability of caregivers.

NURSING DIAGNOSES

- Alteration in body image
- Readiness for enhanced knowledge
- Risk for impaired skin integrity

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Stoma is moist and reddish pink. Skin is intact and free of irritation; sutures are intact.
 - Stoma drains moderate amount of liquid or soft stool, and flatus is in pouch (noted by bulging of pouch). (Flatus may not be observable if pouch has gas filter.)
 - Patient, family caregiver, and/or significant others observe stoma and steps of procedure.
 - Patient asks questions about procedure and attempts to help with pouch change.
- 2 Explain procedure to patient; encourage patient's interaction and questions.
- 3 Assemble equipment and close room curtains or door.

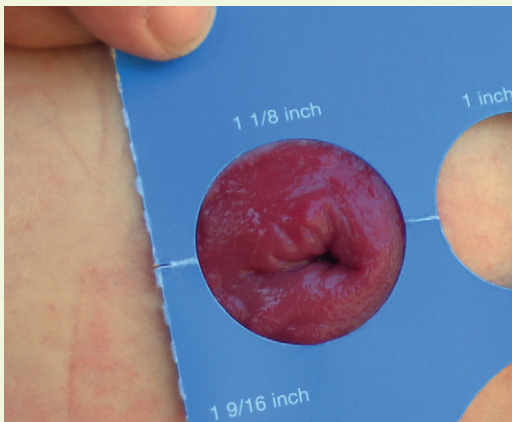

Normal findings in patient with postoperative ostomy that is healing.
Stoma is functioning normally. Snug seal around stoma has been attained. Flatus indicates return of peristalsis after surgery.
Reveals acceptance of alteration in body image and interest in self-care.
Indicates readiness to learn and begin self-care.
Lessens patient's anxiety and promotes patient's participation.
Optimizes use of time; provides privacy.

STEP

RATIONALE

IMPLEMENTATION

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. 2 Position patient in semireclining or supine during assessment and pouching (NOTE: Some patients with established ostomies prefer to stand). If possible, provide patient with mirror for observation. 3 Perform hand hygiene and apply clean gloves. 4 Place towel or disposable waterproof barrier under patient and across patient's lower abdomen. 5 If not done during assessment, remove used pouch and skin barrier gently by pushing skin away from barrier. Use an adhesive remover to facilitate removal of skin barrier. Empty pouch and dispose of in an appropriate receptacle. Measure output if needed. 6 Clean peristomal skin gently with warm tap water using washcloth; do not scrub skin. If you touch stoma, minor bleeding is normal. Pat skin dry. When pouching an ileostomy, place disposable washcloth over stoma. 7 Measure stoma (see illustration). Expect size of stoma to change for first 4 to 6 weeks after surgery. 8 Trace pattern of stoma measurement on pouch backing or skin barrier (see illustration). 9 Cut opening on backing or skin barrier wafer (see illustration). Be sure that opening is at least $\frac{1}{8}$ larger than stoma to avoid pressure on it. 10 Remove protective backing from adhesive (see illustration). 11 Apply pouch over stoma (see illustration). Press firmly into place around stoma and outside edges. Have patient hold hand over pouch to apply heat to secure seal. 12 Close end of pouch with clip or integrated closure. Remove drape from patient. 13 Remove gloves. Perform hand hygiene. | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>When patient is semireclining there are fewer skin wrinkles, which allows for ease of application of pouching system.</p> <p>Reduces transmission of microorganisms.
Protects bed linen; maintains patient's dignity.</p> <p>Reduces skin trauma. Improper removal of pouch and barrier can cause peristomal skin irritation or breakdown.</p> <p>Avoid soap. It leaves residue on skin, which may irritate skin.
Pouch does not adhere to wet skin.
Ileostomies leak continuously in some patients.</p> <p>Allows for proper fit of pouch that will protect peristomal skin.</p> <p>Prepares for cutting opening in pouch.</p> <p>Customizes pouch to provide appropriate fit over stoma.</p> <p>Prepares skin barrier for placement.
Pouch adhesives are heat and pressure sensitive and hold more securely at body temperature.</p> <p>Ensures pouch is secure. Contains effluent.</p> <p>Reduces transmission of microorganisms.</p> |

STEP 7 Measure stoma. (Courtesy Coloplast, Minneapolis, Minn.)

STEP 8 Trace measurement on skin barrier. (Courtesy Coloplast, Minneapolis, Minn.)

STEP

RATIONALE

STEP 9 Cut opening in wafer. (Courtesy Coloplast, Minneapolis, Minn.)

STEP 10 Remove protective backing. (Courtesy Coloplast, Minneapolis, Minn.)

STEP 11 Apply pouch over stoma. (Courtesy Coloplast, Minneapolis, Minn.)

EVALUATION

- 1 Observe condition of skin barrier and adherence to abdominal surface.
- 2 Observe appearance of stoma, peristomal skin, abdominal contours, and suture line during pouch change.
- 3 Observe patient's and family caregiver's willingness to view stoma and ask questions about procedure.

Determines presence of leaks.

Provides information if another type of pouching system or additional skin care products are needed.

Determines level of adjustment and understanding of stoma care and pouch application. Allows planning for future education needs and progress toward acceptance of altered body image.

Unexpected Outcomes

- 1 Skin around stoma is irritated, blistered, or bleeding; or a rash is noted. May be caused by undermining of pouch seal by fecal contents, allergic reaction, or fungal skin eruption.
- 2 Necrotic stoma is manifested by purple or black color, dry-instead of-moist texture, failure to bleed when washed gently, or tissue sloughing.
- 3 Patient refuses to view stoma or participate in care.

Related Interventions

- Remove pouch more carefully.
- Change pouch more frequently or use different type of pouching system.
- Consult ostomy care nurse.
- Report to nurse/health care provider.
- Document appearance.
- Obtain referral for ostomy care nurse.
- Allow patient to express feelings.
- Encourage family support.

Recording and Reporting

- Record type of pouch and skin barrier applied, amount and appearance of effluent in pouch, size and appearance of stoma, and condition of peristomal skin.
- Record patient/family level of participation, teaching that was done, and response to teaching.
- Report any of the following to nurse and/or health care provider: abnormal appearance of stoma, suture line, peristomal skin, or character of output.

Special Considerations

Teaching

- Include family caregiver in teaching to facilitate patient's readiness to learn.
- Some patients accept stoma with minimal emotional difficulty; some may never completely adjust to it. Individualize care according to patient's situation and circumstances (Burch, 2011).
- Give patient teaching materials that clearly state each step for a pouch change. Audiotaped or videotaped instructions are also available. For patients with learning disabilities, consider using materials that have illustrations for each step.
- Give patients a list of equipment and name, address, and phone number of a supplier.

Pediatric

- Select pediatric pouches designed especially for neonates, infants, and children; these pouches are smaller and have a more skin-sensitive adhesive on the barrier.
- Because most ostomy surgery done on neonates is for emergencies, often no time is available for preoperative selection of stoma site. The surgery is usually done because the neonate has necrotizing enterocolitis (NEC), Hirschsprung's disease, or congenital disorders (Bookout et al., 2011). The stomas are frequently temporary, with closure of the ostomy when the surgical repair has healed and the neonate is medically ready for surgery. Children and adolescents may have ostomy surgery for conditions such as cancer, inflammatory bowel disease, and trauma.

- Neonates may have multiple stomas on their tiny abdomens following corrective bowel surgeries. Select a cut-to-fit pouch that allows multiple stoma openings in skin barrier yet still fits on neonate's abdomen (Bookout et al., 2011).
- Because infants swallow large amounts of air while sucking, it is normal to expect flatus. Make sure that pouch can accommodate increased amount of flatus after feeding or be prepared to release flatus frequently (Bookout et al., 2011).
- The skin of a preterm infant is not fully developed and is more absorbent than that of a full-term infant. Do not use skin sealants and adhesive removers unless they are approved for preterm-infant use (Bookout et al., 2011).
- As an infant grows in size, so does the stoma. Measure the stoma frequently and make appropriate adjustments in pouching and skin barrier size. Skin barriers for preterm infants must have flexibility to cover the infant's rounded abdominal contour (Bookout et al., 2011).
- Adolescents requiring an ostomy benefit from presurgical contact with other adolescents who have an ostomy (Bookout et al., 2011).

Gerontologic

- Evaluate an older adult's cognitive status for understanding ostomy self-care instructions. Include a family caregiver in the care plan.
- Adapt care approaches for older patients who have impaired manual dexterity or limited vision. If a patient is unable to custom cut the size of the skin barrier, consider having barriers precut by an ostomy equipment supplier or using a precut pouching system.
- Costs of ostomy supplies and reimbursement are an issue for patients on fixed income.

Home Care

- Evaluate home toileting facilities and patients' ability to position to empty pouch directly into a toilet.
- Patient may shower without covering pouch.
- Patients should avoid storing pouches in extremely hot or cold locations. Temperature affects barrier and adhesive materials.

SKILL 35-2 Pouching a Urostomy

Because urine flows continuously from an incontinent urinary diversion, placement of the pouch is more challenging than with the fecal diversion. In the immediate postoperative period urinary stents extend out from the stoma (Fig. 35-11). A surgeon places the stents to prevent stenosis of the ureters at the site where the ureters are attached to the conduit. The stents will be removed during the hospital stay or at the first postoperative visit with the surgeon.

The stoma is normally red and moist. It is made from a portion of the intestinal tract, usually the ileum. It should protrude above the skin. An ileal conduit is usually located in the right lower quadrant. While the patient is in bed, the pouch may be connected to a bedside drainage bag to decrease the need for frequent emptying. When the patient goes home, the bedside drainage bag may be used at night to avoid having to get up to empty the pouch. Each type of urostomy pouch comes with a connector for the

FIG 35-11 Urostomy stoma with stents in place. (Courtesy Jane Fellows.)

FIG 35-12 Urostomy pouching system with adapter to connect pouch to bedside drainage bag. (Courtesy Hollister Inc., Libertyville, Ill.)

bedside drainage bag (Fig. 35-12). Incorrect pouch placement, large volumes of urine in the pouch, or a urinary pouch without an antireflux valve promotes reflux and the risk of infection. You can reduce the risk of reflux by attaching the urinary pouch to straight drainage when high urinary output is expected. A patient must understand the importance of draining the pouch frequently and using clean technique during stomal and skin care.

Delegation and Collaboration

The skill of pouching a new incontinent urinary diversion cannot be delegated to nursing assistive personnel (NAP). In some agencies, care of an established urostomy (4 or 6 weeks or more after surgery) can be delegated to NAP. The nurse directs the NAP about:

- Expected appearance of the stoma.
- Expected amount and character of the output and when to report changes.
- Change in patient's stoma and surrounding skin integrity that should be reported.
 - Special equipment needed to complete procedure.

Equipment

- Urinary pouch (with antireflux flap and skin barrier; clear, drainable one- or two-piece, cut-to-fit or precut size)
- Appropriate adapter for connection to bedside drainage bag
- Measuring guide
- Bedside urinary drainage bag
- Clean gloves
- Washcloth
- Towel or disposable waterproof barrier
- Basin with warm tap water
- Scissors
- Adhesive remover
- Absorbent wick made from gauze rolled tightly in the shape of a tampon
- Waterproof bag for disposal of pouch
- Gown and goggles optional if there is risk of splashing when emptying pouch

STEP

ASSESSMENT

- 1 Perform hand hygiene and apply clean gloves.
- 2 Observe existing skin barrier and pouch for leakage and length of time in place. Pouch should be changed every 3 to 7 days, not daily (Colwell et al., 2004). If urine is leaking under wafer, change pouch.
- 3 Observe urine in pouch or bedside drainage bag. Empty pouch if it is more than one-third to one-half full by opening valve and draining it into container for measurement.
- 4 Observe stoma for color, swelling, presence of sutures, trauma, and healing of peristomal skin. Assess type of stoma. Remove and dispose of gloves.
- 5 Explore patient's attitude toward learning self-care and identify others who will be helping patient after leaving hospital.

RATIONALE

- Reduces transmission of microorganisms.
- Assesses effectiveness of pouching system and allows for early detection of potential problems. To minimize skin irritation, avoid changing entire pouching system unnecessarily. Repeated leakage may indicate need for different type of pouch to provide reliable seal.
- Urine output provides information about renal status and whether volume is within acceptable limits (≥ 30 mL/hr). Weight of pouch can disrupt seal. Urine from ileal conduit will contain mucus because of flow through intestinal segment.
- Consider stoma characteristics in selecting appropriate pouching system. Convexity in skin barrier is often necessary with flush or retracted stoma.
- Facilitates teaching plan and timing of care to coincide with availability of caregivers.

STEP

RATIONALE

NURSING DIAGNOSES

- Readiness for enhanced knowledge
- Risk for impaired skin integrity

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Stoma is moist, reddish-pink with stents protruding from it. Peristomal skin is free of irritation and intact. Sutures are intact. • Urine drains freely from stents or stoma. Urine is yellow with mucus shreds and is without foul odor. Urine may be pink or contain small blood clots after surgery. Volume of output is within acceptable limits (≥ 30 mL/hr). • Patient and family caregiver observe stoma and procedural steps. • Patient asks questions about procedure and may help with pouch change. | <p>Normal findings for postoperative urinary diversion.</p> <p>These are normal findings after surgery. Mucus shreds are normal when urine flows through intestinal segment.</p> <p>Shows adjustment to body image change and willingness to learn self-care.</p> <p>Indicates readiness to learn and begin self-care.</p> |
| <p>2 Explain procedure to patient; encourage his or her interaction and questions.</p> | <p>Lessens patient's anxiety and promotes participation.</p> |
| <p>3 Assemble equipment and close room curtains or door.</p> | <p>Optimizes use of time; provides privacy.</p> |

IMPLEMENTATION

- | | |
|---|---|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> |
| <p>2 Position patient in semireclining or supine position. If possible provide patient a mirror for observation.</p> | <p>When patient is semireclining, there are fewer skin wrinkles, which allows for ease of pouch application.</p> |
| <p>3 Perform hand hygiene and apply clean gloves.</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>4 Place towel or disposable waterproof barrier under patient and across patient's lower abdomen.</p> | <p>Protects bed linen; maintains patient's dignity.</p> |
| <p>5 Remove used pouch and skin barrier gently by pushing skin away from barrier. If stents are present, pull pouch gently around them and lay towel underneath. Empty pouch and measure output. Dispose of pouch in appropriate receptacle.</p> | <p>Reduces risk for trauma to skin and for dislodging stents. Keeps urine from leaking onto skin.</p> |
| <p>6 Place rolled gauze at stoma opening. Maintain gauze at the stoma opening continuously during pouch measurement and change.</p> | <p>Using wick at stoma opening prevents peristomal skin from becoming wet with urine during pouch change.</p> |
| <p>7 While keeping rolled gauze in contact with the stoma, cleanse peristomal skin gently with warm tap water using washcloth; do not scrub skin. If you touch stoma, minor bleeding is normal. Pat skin dry.</p> | <p>Avoid soap. It leaves residue on skin, which can irritate it. Pouch does not adhere to wet skin.</p> |
| <p>8 Measure stoma (see Skill 35-1, Step 7). Be sure that opening is at least $\frac{1}{8}$ inch larger than stoma to avoid pressure on stoma. Expect size of stoma to change for first 4 to 6 weeks after surgery.</p> | <p>Allows for proper fit of pouch that will protect peristomal skin.</p> |
| <p>9 Trace pattern on pouch backing or skin barrier (see Skill 35-1, Step 8).</p> | <p>Prepares for cutting opening in pouch.</p> |
| <p>10 Cut opening in pouch.</p> | <p>Customizes pouch to provide appropriate fit over stoma.</p> |
| <p>11 Remove protective backing from adhesive surface. Remove rolled gauze from stoma.</p> | <p>Prepares pouch for application to skin.</p> |
| <p>12 Apply pouch. Press adhesive barrier firmly into place around stoma and outside edges. Have patient hold hand over pouch 1 to 2 minutes to apply heat to secure seal.</p> | <p>Pouch adhesives are heat activated and will hold more securely at body temperature.</p> |
| <p>13 Use adapter provided with pouches to connect pouch to bedside urinary bag. Keep tubing below level of bag.</p> | <p>Provides for collection and measurement of urine. Allows patient to rest without frequent emptying of pouch.</p> |
| <p>14 Remove drape from patient. Remove gloves and perform hand hygiene.</p> | <p>Reduces transmission of microorganisms.</p> |

STEP

RATIONALE

EVALUATION

- 1 Observe appearance of stoma, peristomal skin, and suture line during pouch change.
- 2 Evaluate character and volume of urinary drainage.
- 3 Observe patient's and family caregiver's willingness to view stoma and ask questions about procedure.

- Determines condition of stoma and peristomal skin and progress of wound healing.
- Determines if stoma and/or stents are patent. Character of urine reveals degree of concentration and alterations in renal function.
- Determines level of adjustment and understanding of stoma care and pouch application.

Unexpected Outcomes

- 1 Skin around stoma is irritated, blistered, or bleeding; or a rash is noted as a result of chronic exposure to urine.
- 2 No urine output for several hours, or output is less than 30 mL/hr. Urine has foul odor.
- 3 Patient and family caregiver are unable to observe stoma, ask questions, or participate in care.

Related Interventions

- Check stoma size and opening in skin barrier. Resize skin barrier opening if necessary.
- Remove pouch more carefully.
- Consult ostomy care nurse.
- Increase fluid intake.
- Notify health care provider.
- Obtain urine specimen for culture and sensitivity as ordered.
- Consult ostomy care nurse.
- Allow patient to express feelings.
- Encourage family support.

Recording and Reporting

- Record type of pouch, time of change, condition and appearance of stoma and peristomal skin, and character of urine.
- Record urinary output on intake and output form.
- Record patient's and family caregiver's reaction to stoma and level of participation.
- Report abnormalities in stoma or peristomal skin and absence of urinary output to nurse in charge or health care provider.

Special Considerations

Teaching

- Teach whenever doing a pouch change even if patient does not appear interested. Do not insist that patient look at stoma; allow time for adjustment.
- Teach patients significance and importance of drinking 1½ to 2 quarts of fluid daily to prevent urinary tract infections (UTIs). Explain that some mucus in urine is expected but patients should report any blood in their urine, excessively cloudy urine, chills, fever (38.3° C [101° F] or higher), and back (flank) pain to their health care provider.
- Give patient teaching materials that state each step clearly. Audiotaped or videotaped instructions are also available. For patients with learning disabilities, consider using material that has illustrations for each step.
- Give patients a list of equipment and name, address, and phone number of a supplier.

Pediatric

- In neonates urinary diversions are less common than fecal ostomies.
- Select pediatric pouches designed especially for neonates, infants, and children; these pouches are smaller and have a more skin-sensitive adhesive on the barrier.

Gerontologic

- Older patients have decreased thirst and may not normally consume adequate fluids. Explain importance of fluid intake to promote healthy renal function and decrease risk for UTIs.
- Evaluate older adult's cognitive status for understanding of ostomy self-care instructions.
- Adapt care approaches for older patients who have impaired manual dexterity or limited vision. For patients who are unable to custom cut the size of their skin barriers, consider having barriers precut by ostomy equipment supplier or using a precut two-piece system.
- Costs of ostomy supplies and reimbursement are an issue for patients on fixed income.

Home Care

- Instruct patient that pouch can be connected to straight drainage at night. Make sure that patient understands that adapter will be needed to connect pouch to the bedside drainage bag.
- Patient may shower without covering pouch.
- Patients should avoid storing pouches in extremely hot or cold locations because temperature will affect barrier and adhesive materials.

SKILL 35-3 Catheterizing a Urinary Diversion

Catheterization of a urinary diversion is the only method to obtain an accurate culture and sensitivity specimen to screen for infection. When it is necessary to obtain a urine specimen from a urinary diversion, the best method is to insert a sterile catheter into the stoma. Obtaining a specimen of urine in a pouch does not provide an accurate finding because of the likely risk for contamination by microorganisms. With the use of strict aseptic technique, catheterization is relatively safe and easy. If a patient uses a two-piece system, remove the pouch from the skin barrier and replace it after catheterization without disturbing the skin barrier. If a patient uses a one-piece system, you have to remove the pouch to obtain the specimen and replace it after the procedure. To prevent trauma to the tissues, you need to understand how the stoma and implanted ureters are constructed for a patient. Reflux of urine into the ureters can cause infection.

Delegation and Collaboration

The skill of catheterizing a urinary diversion cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Inform nurse if patient complains of peristomal or back pain.
- Inform nurse if there is a change in color, odor, or amount of urine or if there is blood in the urine.

Equipment

- Urinary catheterization supplies (contained in prepackaged sterile catheter kit or may need to be gathered separately)
 - 14- to 16-Fr sterile catheter
 - Water-soluble lubricant
 - Antiseptic swabs (e.g., povidone-iodine or chlorhexidine)
 - Sterile gloves
 - Sterile specimen container
- Absorbent gauze wick
- Bed protection barrier
- Towels
- Urinary pouch if needed
- Clean gloves

STEP **RATIONALE**

ASSESSMENT

- | | |
|--|---|
| <ol style="list-style-type: none"> 1 Observe for signs and symptoms of urinary tract infection (UTI): elevated temperature, chills, foul-smelling urine, and elevated white blood cell (WBC) count. 2 Obtain health care provider’s order for catheterization. 3 Assess patient’s understanding of need for procedure and how it is done. | <p>Determines need to perform catheterization to obtain sterile specimen from urinary diversion. Diversion poses risk for reflux of urine back to kidneys, resulting in infection.</p> <p>Invasive procedure requires health care provider’s order.</p> <p>Determines willingness to cooperate and reduces patient’s anxiety.</p> |
|--|---|

NURSING DIAGNOSES

- Deficient knowledge regarding catheterization procedure
 - Risk for infection
- Related factors are individualized based on patient’s condition or needs.*

PLANNING

- | | |
|---|--|
| <ol style="list-style-type: none"> 1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Urine specimen is not contaminated with bacteria during procedure. • Patient describes risks for infection and techniques to prevent infection. 2 Assemble equipment and close room curtain or door. 3 Explain procedure to patient; if possible, obtain specimen when patient is due to change pouch if using one-piece system. | <p>Urine obtained correctly. Laboratory results are accurate.</p> <p>Demonstrates patient’s learning.</p> <p>Optimizes use of time and provides privacy.</p> <p>Lessens anxiety and promotes patient’s cooperation. Changing pouch too frequently could result in skin trauma.</p> |
|---|--|

IMPLEMENTATION

- | | |
|---|--|
| <ol style="list-style-type: none"> 1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient’s identification bracelet. 2 Position patient sitting if possible and drape towel across lower abdomen. 3 Perform hand hygiene and apply clean gloves. 4 Remove pouch. If patient uses two-piece system, remove pouch but leave barrier attached to skin. 5 Remove gloves and perform hand hygiene. | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Gravity facilitates flow of urine. Maintains patient’s dignity. Towel absorbs urine.</p> <p>Reduces transmission of microorganisms.</p> <p>Allows access to stoma.</p> <p>Avoids contamination.</p> |
|---|--|

STEP	RATIONALE
6 Open sterile catheterization set according to instructions or open needed equipment and place on sterile barrier using aseptic technique (see Chapter 7). If not using catheterization kit, place gauze pad on sterile field and squeeze small amount of lubricant onto gauze. Apply sterile gloves.	Prepares sterile work field.
7 If needed, have patient hold absorbent gauze wick on stoma while you prepare catheterization supplies.	Prevents leakage of urine on peristomal skin, linens, and clothing.
8 Cleanse surface of stoma with antiseptic swabs using circular motion from center outward. Use new swab each time; repeat twice. Wipe off excess antiseptic with dry sterile gauze or cotton ball.	Removes surface bacteria.
Clinical Decision Point <i>If patient has stents in place, use antiseptic swab to clean the ends of the stents and place the stents in the sterile cup. Allow urine to drip into the cup until you obtain an adequate amount for a specimen. Then go directly to Step 13.</i>	
9 Remove lid from sterile specimen container.	Sterile container collects a small volume of urine.
10 Lubricate tip of catheter with water-soluble lubricant, keeping catheter sterile.	Facilitates passage of catheter through stoma.
11 With dominant hand gently insert catheter tip into stoma. Do not force catheter; redirect course as needed. Place distal end of catheter into specimen container. Use gentle but firm pressure similar to regular catheterization of urethra (see Skill 33-1). Have patient cough or turn slightly.	Use care to avoid trauma to conduit. Movement and coughing may facilitate flow of urine.
12 Hold container below level of stoma. If needed, wait several minutes to get adequate amount of urine.	Culture and sensitivity studies only require 3 to 5 mL of urine (check agency policy).
13 Withdraw catheter slowly; place absorbent pad over stoma.	Keeps skin dry.
14 Apply lid to specimen container.	Prevents accidental spillage.
15 Reapply new pouch or reattach pouch if patient uses two-piece system (see Skill 35-2).	Pouch is necessary to contain urine.
16 Dispose of used pouch and equipment properly.	Avoids unpleasant odor in room.
17 Remove gloves; perform hand hygiene. Label specimen in presence of patient, place in biohazard bag, and send to laboratory at once.	Ensures that laboratory results are assigned to correct patient. Labeling ensures acceptance and processing of specimen by laboratory. Urine that sits for long periods at room temperature will adversely affect laboratory results.

EVALUATION

1 Compare results of culture and sensitivity with expected findings. Mucus is a normal finding if patient has an ileal conduit.	Determines presence of infection. If contamination appears likely, second specimen will be needed.
2 Instruct patient about signs and symptoms of UTI.	Informed patients will seek attention for a problem earlier if aware of signs and symptoms.

Unexpected outcomes

- 1 Unable to obtain urine specimen.
- 2 Skin or stoma reveals complications.

Related Interventions

- Reposition patient.
- If there is still no urine, push fluids and try again later.
- Notify nurse and/or health care provider.
- Consult with ostomy care nurse.

Recording and Reporting

- Record time specimen collected; patient's tolerance of procedure; and appearance of urine, skin, and stoma.
- Report results of laboratory test to nurse in charge or health care provider.

Special Considerations

Teaching

- Explain common symptoms of UTI: flank pain, dark or bloody urine, foul-smelling urine, fever (38.3° C [101° F] or higher), confusion.
- Encourage patient to notify health care provider if symptoms of infection develop.
- Reinforce importance of fluid intake (2 L/day).

Critical Thinking Exercises

You are assigned to care for Janeé Bell, a 28-year-old engineer. She has been admitted for elective colon removal secondary to a 10-year history of ulcerative colitis. She is scheduled for an ileal pouch anal anastomosis with J-pouch construction and will have a temporary ileostomy.

- Which of the following will be part of her preoperative preparation?
 - A chance to empty a pouch
 - A nutrition consultation
 - Stoma site marking with a qualified ostomy care nurse
 - A barium enema
 Explain your choice.
- When Janeé returns from surgery, the nurse assesses the stoma. How should the stoma look immediately after surgery? Explain your choice.
 - Red and moist
 - Appear just below the skin level
 - Have stents protruding from it
 - Pink and dry
- What information about the ostomy pouch should the nurse include when teaching Janeé about care at home? It must be: Explain your choice.
 - changed daily.
 - emptied when it is one-third to one-half full.
 - emptied every 4 to 6 hours.
 - changed weekly.
- Janeé notes that her bowel movement is always liquid. She asks when it will be formed as it was before she got sick. What does the nurse tell her?

REVIEW QUESTIONS

- The nurse has inserted a catheter into a patient's urinary diversion, but only a few drops of urine have drained. Which action should the nurse perform first to try to obtain an adequate sample? (Select all that apply.)
 - Remove the catheter and obtain urine from the pouch.
 - Gently insert the catheter a little more.
 - Massage the patient's abdomen.
 - Have the patient turn to side.
- A patient has a new urostomy secondary to bladder cancer. Which patient behaviors suggest acceptance of his change in bodily function? (Select all that apply.)
 - He watches you change his pouch.
 - He asks questions about how the ostomy works.
 - He empties his pouch.
 - He says his spouse will be doing the pouch changes.
- The nurse is caring for a patient with a new permanent sigmoid colostomy and explaining information about care once the patient returns home. Which statement by the patient indicates that he or she requires further instruction on the topic?
 - "When I wash the stoma, I should just use warm water to clean the skin."
 - "If I eat a well balanced diet, the stool will be soft and formed."
 - "I'll need to look at the skin around the stoma each time I change the pouch to be sure that there is no irritation."
 - "The stoma will stay the shape it is; so it will be easy to buy bags that fit."
- A patient anticipating an ileostomy because of severe ulcerative colitis asks, "Will I really be able to have a normal life after having this procedure?" What is the most appropriate reply?
 - "Let's talk about this when you're recovering from the surgery."

- "I'm going to have a person with an ostomy visit you before the surgery."
- "Why don't you talk with your surgeon about your concerns?"
- "Tell me the specific questions you have about life after the surgery."
- A patient with a urostomy notes a raw, weeping area of the skin in an area under the skin barrier. Which action is most appropriate in this situation?
 - Cleaning the area with alcohol to help dry it
 - Consulting an ostomy care nurse
 - Scheduling the patient for an appointment next week with the health care provider
 - Having the patient continue his usual skin care regimen of cleaning gently with water
- The intestinal opening surgically created in the abdomen for a colostomy, ileostomy, or urostomy is called a _____.
- Place the steps for an ostomy pouch change in the correct order.
 - Close the end of the pouch.
 - Measure the stoma.
 - Cut the hole in the wafer.
 - Press the pouch into place over the stoma.
 - Remove the old pouch.
 - Trace the correct measurement onto the back of the wafer.
 - Observe the stoma and the skin around it.
 - Clean and dry the peristomal skin.
- The pathway created for urine to exit the body when the bladder is removed is called an _____.
- A patient who had colostomy surgery 3 days ago now has air that is filling his pouch, but he has not had any fecal matter from his stoma. Which of the following is the accurate assessment of this situation?
 - There is infection present causing air to fill the pouch.
 - The patient has an ileus and should not be allowed to have any oral intake.
 - This is normal flatus, indicating that bowel function is returning.
 - The patient should be given a laxative because his bowels are not moving.
- A patient with a urostomy enters the clinic. Which of the following signs would make you suspect a urinary tract infection (UTI)? (Select all that apply.)
 - Difficulty recalling name
 - Pain in the upper abdomen
 - Dark urine
 - Foul-smelling urine

KEY TERMS

Analgesia	Hemostasis	Penrose drain	Postural hypotension
Anesthesia	Hemovac drain	Phlebotrombosis	Preoperative
Atelectasis	Hypovolemic shock	Positive expiratory pressure	Preoperative checklist
Coagulopathies	Incentive spirometer	Postanesthesia care unit (PACU)	Procedural sedation
Decompression	Informed consent	PACU phase I	Thrombophlebitis
Dehiscence	Jackson-Pratt drain	PACU phase II	Urinary retention
Ecchymosis	Malignant hyperthermia	Postoperative	Venous thromboembolism (VTE)
Evisceration	Obstructive sleep apnea		
Extended care	Paralytic ileus		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe the activities needed to prepare a patient for surgery.
- Explain the rationale for preoperative procedures.
- Discuss cultural differences that might affect the implementation of preoperative and postoperative procedures.
- Describe the benefits of structured preoperative teaching.
- Explain the rationale for each of the postoperative exercises.
- Successfully instruct a patient in performing postoperative exercises.
- Discuss the differences in nursing assessment during the immediate postoperative period and the convalescent phase of recovery.
- Conduct an assessment of a postoperative patient.

Surgical care of patients is in a continuous state of technologic advancement. The development of new diagnostic and interventional devices (e.g., endoscopic examination, robotic techniques, and laser surgery) has contributed to a shortened surgical length of stay and changes in roles for health care providers.

Any form of surgery is a stressful event, whether it is a major or a minor surgical procedure occurring in a large medical center or an outpatient center. A patient must frequently make decisions to undergo procedures that are associated with pain, possible disfigurement, dependence, or even the threat of death. Psychologically the experience of surgery can cause considerable fear and anxiety. Physiologically the more complex the surgery, the more likely it is that a patient

will undergo changes in major body systems. Thus it is important that a patient do all preparation for surgery during preadmission testing (PAT) in which a perianesthesia nurse, nurse practitioner, and sometimes the anesthesia provider interview the patient and/or family member, perform pertinent history and physical diagnostic testing, consult if needed, and provide preoperative education to prepare the patient for surgery.

Nurses use a variety of skills to help surgical patients adequately prepare for the physiologic and psychological stressors of surgery. During the preoperative phase the nursing role focuses on physical, psychological, sociocultural, and spiritual preparation and validates existing information, reinforces preoperative teaching, reviews discharge instructions,

and provides nursing care to complete preparation for the surgical experience (ASPAN, 2010). A variety of diagnostic tests are coordinated to ensure that the surgeon and anesthesia care providers have the information needed to determine a patient's risks during surgery and the postoperative period. In preparation for surgery, you will instruct the patient and family concerning postoperative care in compliance with The Joint Commission patient and family education standards (TJC, 2012a) (Box 36-1). The instructional topics enable patients and their families to actively participate in the recovery process. Occasionally you will have to perform certain procedures such as surgical skin preparation or inserting an indwelling catheter (see Chapter 33) or nasogastric (NG) tube (see Chapter 34) to protect patients from risks associated with surgery and provide a safe environment.

Although preoperative education improves patient outcomes after surgery, the shift in the provision of surgical services poses special challenges to meet patients' educational needs in a reduced time frame. Because a majority of patients undergo surgery in an ambulatory setting, it is essential that they receive adequate information to ensure that they or their family members can manage postoperative care activities in the home setting. If a patient is to be admitted for same-day surgery, perform the preoperative assessment and teaching of postoperative care instructions several days before surgery. The surgeon's office nurse or, more typically, the preadmission nurse and/or the preoperative nurse in the outpatient department, complete these services. The nurse ensures the completion of operative informed consent permits, blood work, testing (e.g., electrocardiogram [ECG]), and any other ordered procedures based on the American Society of Anesthesiologist (ASA) guidelines before the start of the procedure (ASA, 2012).

During the postoperative phase, when a patient returns from the operating room (OR), you are initially responsible for

completing a thorough assessment of physical and mental status and providing continuous monitoring of his or her condition or any changes during the recovery process. The American Society of PeriAnesthesia Nurses (ASPAN) identifies three levels of care provided to the surgical/procedural patient, including postanesthesia phase I, postanesthesia phase II, and extended care. Once a patient's condition stabilizes, focus your efforts on returning the patient to a functional level of wellness as soon as possible within the limitations created by surgery. The speed of a patient's recovery depends on how effectively you anticipate potential complications, initiate necessary supportive and preventive therapies, and actively involve the patient and family in the recovery process.

EVIDENCE-BASED PRACTICE TRENDS

Several evidence-based initiatives target the improvement of surgical care. These initiatives focus on surgical site infections (SSIs), the surgical care improvement project (SCIP), adverse cardiac events, and postoperative venous thromboembolism (VTE). The SCIP program, previously called the *surgical infection prevention project (SIPP)*, is sponsored by the Centers for Medicare and Medicaid Services (CMS) in collaboration with other national partners. The Centers for Disease Control and Prevention (CDC), the Institute for Healthcare Improvement (IHI), The Joint Commission (TJC), CMS, ASPAN, the Association of periOperative Registered Nurses (AORN), and the Council on Surgical and Perioperative Safety (CSPS) have implemented evidence-based initiatives that promote a culture of safety and protect patients from surgical complications.

The CDC's National Nosocomial Infections Surveillance (NNIS) system reports that SSIs account for 4% to 16% of hospital-acquired infections (Drake, 2011). Research indicates that 38% of hospital-acquired infections are SSIs (Drake, 2011). Evidence-based guidelines are identified to reduce SSIs and promote SCIP:

- Do not remove hair unless it will interfere with the operation and remove it using only electric clippers if possible.
- Give the correct antibiotic before surgery and at the appropriate time.
- Maintain blood glucose level after surgery, especially for patients undergoing cardiac surgery.
- Maintain normothermia (core temperature range of 36°C to 38°C [96.8°F to 100.4°F]).
- Receive beta blocker during the perioperative period.
- Remove urinary catheter on postoperative day 1 or 2.

There are also strict guidelines for use of antibiotics. The goal of prophylactic antibiotic therapy is to select the most effective antibiotics for maximum coverage and administer them when they are most beneficial to protect patients from infection with as little risk as possible:

- Overall it is recommended that prophylactic antibiotics be given as close to the time of incision as possible (within 60 minutes) and not be given for longer than 24 hours after surgery.
- However, vancomycin and fluoroquinolones (i.e., ciprofloxacin [Cipro], levofloxacin [Levaquin]) may be given up to 2 hours before incision because of their longer infusion times. Antibiotic use after incision closure does not reduce infection rates; and, when the antibiotics are continued, infections are more likely to be caused by a resistant organism (CDC, 2011; Drake, 2011).

BOX 36-1 The Joint Commission Patient and Family Education Standards

Education provided is appropriate to the patient's needs. The assessment of learning needs addresses cultural and religious beliefs, emotional barriers, desire to learn, physical or cognitive limitations, and barriers to communication as appropriate. When called for by the age of the patient and the length of stay, the hospital assesses and provides for patient's education needs. Patients are educated about:

- The plan for care, treatment, and services (i.e., postoperative monitoring).
- Basic health practices and safety (i.e., out of bed [OOB] only with assistance).
- The safe and effective use of medication (i.e., the patient is only one allowed to self-administer patient-controlled analgesia [PCA]).
- Nutrition interventions, modified diets, or oral health (i.e., progression of diet after surgery).
- Safe and effective use of medical equipment or supplies when provided by the hospital (i.e., incentive spirometer).
- Pain—Understanding pain, the risk for pain, the importance of effective pain management, the pain assessment process, and methods for pain management (i.e., reporting pain, frequency of medications, nonpharmacologic pain-relief techniques).
- Habilitation or rehabilitation techniques to help them reach the maximum independence possible (i.e., early ambulation).

Modified from The Joint Commission: *Accreditation manual for hospitals*, Chicago, 2011, The Commission; and Schick L, Windle P: *PeriAnesthesia nursing core curriculum: preprocedure, phase I and phase II PACU nursing*, ed 2, St Louis, 2010, Saunders.

- Prophylactic antibiotics should be discontinued within 24 hours after the end of surgery in most cases.

Hyperglycemia inhibits the ability of the body to fight infection. Immediate postoperative glucose control is also correlated with a reduction in surgical infection. The presence of hyperglycemia in the immediate postoperative period increases the risk for infection in both patients with diabetes and nondiabetic patients. The higher the serum glucose level, the higher the potential for infection in both patient groups (Drake, 2011).

The prevention of adverse cardiac events calls for the continued use of beta-blocker therapy before and after surgery. Often this medication may be missed because the surgeon is not the patient's primary care provider or the patient continues to be allowed nothing by mouth (NPO) for a period after surgery. This is one of many reasons why The Joint Commission now requires medication reconciliation on admission (or patient encounter with ambulatory care patients) with each transfer and before discharge (Drake, 2011).

It is reported that approximately 15% of all postoperative deaths can be attributed to pulmonary embolus (PE). In addition, it is reported that 15% to 40% of routine surgical patients develop deep vein thrombosis (DVT). This rate is higher for some patients such as those following orthopedic procedures or in critical care units (Ouellette and Patocka, 2012):

- In response to this, the American College of Chest Physicians in 2008 recommends the use of prophylactic pharmacologic and mechanical therapies to prevent venous thromboembolism (VTE). The term VTE is now used because it incorporates both DVT and PE.
- Each patient's risk for VTE should be assessed, and patients treated appropriately.
- Mechanical therapies include the use of graduated compression stockings (see Chapter 10) along with intermittent pneumatic compression (IPC) or a venous foot pump. The venous foot pump is primarily limited to when IPC cannot be used such as when surgery or injury occurs to the affected lower extremity.
- Aside from the mechanical device, it is important that pharmacologic regimens such as the administration of low-dose unfractionated heparin, low-molecular-weight heparin, factor Xa inhibitor (fondaparinux [Arixtra]), or warfarin (Coumadin) be included after surgery.

Another trend seen in the United States is the increased prevalence of obesity. Researchers estimate that 68% of adults 20 years of age and older are overweight or obese, with 33.8% of the adult population considered obese (CDC, 2012). Of children and adolescents ages 2 to 19 years, 17% are obese. Being overweight or obese increases the risk for many diseases and health conditions, including hypertension, dyslipidemia, coronary heart disease, type 2 diabetes, stroke, cancers (endometrial, breast, and colon), sleep apnea, and respiratory problems. These conditions increase risks of postoperative complications. Obese patients are at risk for obstructive sleep apnea (OSA), and a majority of patients undergoing surgery are overweight and present signs and symptoms of OSA. After surgery patients with OSA have a greater incidence of airway management problems in postanesthesia care units (PACUs) and postoperative floors and develop postoperative pulmonary complications. Longer lengths of stay and unanticipated postoperative admission to the intensive care unit are common (ASA, 2006; Kaw et al., 2012). The latest trend is to monitor these patients longer in PACU (ASA, 2006; Kaw et al., 2012), admit them to floors with continuous pulse oximetry 24 hours after surgery, encourage deep-breathing exercises, and limit opioid medications.

PATIENT-CENTERED CARE

To provide culturally competent care to a surgical patient, begin by assessing the family hierarchy to determine who needs to be involved in the patient's decisions regarding surgery. When providing preoperative teaching, include family members. The use of professional interpreters for patients who do not speak English is beneficial in providing competent informed patient care.

Before surgery it is important to accommodate a patient's religious and cultural needs and adapt the patient's care to encompass his or her practices and beliefs whenever possible. Identify cultural and religious beliefs and practices that affect patients' and/or family members' reactions to the surgical experience such as who can give consent; blood transfusions; and disposal of body parts, including hair. Preoperative and postoperative time is valued as family time to support a patient by many cultures such as African-Americans. Some Mormons who have received full sacraments request to wear an undergarment. A male Sikh may request to wear a turban or metal bracelet and keep his long hair and beard. An East Indian woman may wish to wear her wedding necklace. For example, allow religious articles (e.g., medals, underclothing) to be worn until just before surgery. It is important to request information from the patient, family, or religious leader about how to remove these articles if absolutely necessary. Similarly, return these articles promptly after surgery.

Before and after surgery it will be helpful to assess patient preferences for pain medication. Some patients believe that pain

TABLE 36-1 Information Needed for Informed Consent

Parameters	Examples
Name of procedure/surgery	Abdominal hysterectomy under general anesthesia
Description of procedure/surgery	Removal of uterus only through an incision in the abdominal wall at the top of the pubic hairline; done while unconscious
Person performing procedure/surgery	Dr. Richard Jones assisted by Dr. William Smith
Benefits of procedure/surgery	To remove uterus with fibroids and stop excessive bleeding Abdominal route necessary because of anticipated adhesions from prior abdominal surgery
Potential risks and adverse effects of procedure/surgery	Risk of hemorrhage and infection from surgery; risk of excessive sedation and allergic reaction to drugs used with general anesthesia; accidental damage to bladder, intestines, and/or nerves controlling these organs
Approximate length of time for procedure/surgery	About 1 hour; 1 to 2 hours in postanesthesia care unit (PACU)
Approximate length of time needed for recovery	3 to 4 days on surgical unit; 4 to 6 weeks before resuming physically stressful work
Alternative treatments	Removal of uterus vaginally; radiation to shrink fibroids
Consequences of refusing treatment	Continuation of pain and vaginal bleeding, risk for developing anemia; after menopause fibroids should regress

medication leads to addiction. Buddhists and Hindus prefer to endure the pain without medication. Cultures that value men being in control of their emotions may prevent members from verbalizing pain.

Safety Guidelines

- 1 Know the type and nature of any previous surgery. Anatomic and physiologic alterations affect a patient's risk for operative problems.
- 2 Identify the factors and conditions that increase a patient's risks during surgery. Preoperative preparation and postoperative care depend on knowledge of these risk factors.
- 3 Know the rationale for and extent of impending surgery. Each type of surgical procedure requires a different type of nursing care.
- 4 Ensure that the patient has signed the informed consent. You are witnessing a patient's signature only and not his or her knowledge. Informed consent is required by law to help protect patient's rights, their autonomy, and their privacy. The surgeon should give the patient information about the extent and type of surgery, alternative therapies, usual risks, benefits, and consequences of not having surgery. See agency policy regarding consent (Table 36-1).
- 5 Complete the preoperative checklist. Include the global initiative of the World Health Organization (WHO) Surgical Safety Checklist (WHO, 2008).
- 6 Administer pain-relief therapies according to a patient's perioperative needs. Pain can slow a surgical patient's recovery.
- 7 Restrict patient activity after administration of preoperative and postoperative sedatives to minimize the risk for patient falls.

SKILL 36-1 Preparing a Patient for Surgery

Video Clip

Preparing a patient for surgery involves activities and procedures that help to decrease anxiety, ensure patient safety, and decrease the risk for complications. A thorough nursing assessment documents baseline data for future comparisons to determine the effect of instruction and monitor patients at risk for complications during the perioperative experience.

Anxiety interferes with the effectiveness of anesthesia and the ability of patients to actively participate in their care. Provide information to patients about what will occur during the perioperative experience and which sensations a patient can expect to feel. Demonstration of a caring attitude toward a patient, family members, and significant others increases feelings of trust and reduces anxiety (Fig. 36-1). Provide assurance that comfort measures will be implemented to manage pain (see Chapter 15).

Some patients with “do not resuscitate” (DNR) orders require surgery for palliative care. DNR orders should not be upheld or suspended routinely during anesthesia and surgery. A patient's surgeon (attending surgeons and anesthesiologists) are responsible for discussing and documenting issues with a patient and/or family to determine whether to maintain the DNR order or whether it

should be partially or completely suspended during surgery. This discussion should describe potential resuscitation efforts that may be required during surgery and whether withholding resuscitation initiatives would alter the patient's goals for having the surgery. Considerations that should be included in the discussion are the goals of the surgical treatment, the possibility of resuscitative measures, a description of what these measures include, and possible outcomes with and without resuscitation. Advance directives must be encouraged and included in a patient's chart. If the patient has opted to alter the DNR order during the intraoperative period, clear documentation should be in the medical record indicating when the DNR order is to be reinstated (AORN, 2010d; ASPAN, 2010).

The risks for postoperative complications are decreased in a number of ways, some of which are specific to the type of procedure. For example, any patient with a surgical incision of the thorax or abdomen will have pain after surgery, and this reduces lung expansion. Before surgery a patient will be encouraged to learn how to use an incentive spirometer to reduce the incidence of atelectasis after surgery. Deep-breathing and coughing exercises are examples of other procedures used to reduce complications.

Food and fluids are withheld routinely for a period of time before surgery. Each patient should have orders written by anesthesia personnel outlining preoperative fasting requirements. Practice guidelines for preoperative fasting in healthy patients undergoing elective procedures allow for the consumption of clear liquids up to 2 hours before surgery, a light breakfast (e.g., tea and toast) 6 hours before the procedure, and a heavier meal 8 hours before the procedure (ASA, 2011). However, in general, to minimize the risk for aspiration, food and fluids are withheld for 8 hours before surgery requiring general anesthesia. The patient may need to be NPO even when spinal or epidural anesthesia is administered. Hypotension caused by autonomic nervous system blockade can induce nausea and vomiting (Lewis et al., 2011). Patients who are dehydrated or are at risk for hypovolemia will have intravenous (IV) fluids ordered. Medications may be given to decrease respiratory and gastrointestinal (GI) secretions, as an adjunct to anesthesia, and to decrease the risk for infection and development of stress ulcers.

The type of surgery determines the preparation required before surgery (e.g., low-residue and clear-liquid diets, enemas, cathartics,

FIG 36-1 Nurse establishes trusting relationship with patient.

and oral antibiotics are for patients who undergo bowel surgery). Encourage patients who smoke to stop the use of all tobacco products for at least 30 days before surgery. Nicotine delays wound healing and increases the risk for wound infection by constricting blood flow (Tonnesen et al., 2009). Patients whose blood work indicates a low hemoglobin level and/or abnormal electrolyte levels or coagulopathies often require inpatient therapy before surgery.

Because many patients are admitted on the day of surgery, much of the preoperative preparation is often the responsibility of the patient or the primary caregiver. Therefore it is important that a preadmission nurse or nurse in the surgeon's practice provide adequate instructions. Patient teaching should include any food and fluid restrictions; which medications, if any, are permitted on the morning of surgery; and the need for surgical site preparation the evening before surgery. It is also important to include action that a patient will need to take if any of these instructions are mistakenly omitted. Written instructions are a useful adjunct to teaching because a patient and/or family can refer to them for any points that are unclear or forgotten. Videos and pamphlets are also useful adjuncts in preparing patients and their families.

The revised Joint Commission standards (2012b) incorporated in the National Patient Safety Goals (NPSGs) implemented the Universal Protocol for Preventing Wrong Site, Wrong Procedure, Wrong Person surgery. This protocol was implemented as an added safety measure to ensure that correct person, procedure, and surgical site are verified at the time of scheduling the procedure, on admission or entry into the agency, and each time the responsibility for care of the patient is transferred to another caregiver. A final verification check involving the entire surgical team occurs immediately before the start of the procedure. If the case involves laterality (right versus left), multiple structures (e.g., fingers, toes, lesions), or multiple levels (e.g., spine), the final verification should include a site marking by the person performing the procedure. The site markings need to be visible after the patient has been prepared and draped. Involve patients in this process when they are awake and aware. Immediately before starting the procedure a "time out" is called. The entire operative team, using active communication, verifies correct patient identity, correct side and site, agreement on the procedure to be done, correct patient position, and availability of correct implants and any special equipment or special requirements. This final verification process should be documented.

Delegation and Collaboration

The skills of preoperative assessment and teaching cannot be delegated to nursing assistive personnel (NAP). Each state has its

own delegation rules based on the Board of Nurses. Here are some examples for delegation (ASPAN, 2010).

- Basic infection prevention and control practices
- Care of a patient requiring monitoring and providing comfort measures
- Care of a patient with nausea and vomiting who is receiving IV fluids and oral intake
- Care of a patient with thermoregulatory problems, including hyperthermia and hypothermia
- Care of a patient on continual antiembolism devices who requires assistance with ambulation

Equipment

Equipment for Preanesthesia Phase

- Stethoscope
- Blood pressure monitoring equipment
- Pulse oximetry
- Thermometer
- Preoperative checklist

Preadmission

Equipment for preadmission area includes but is not limited to:

- Method to measure height and weight
- Blood pressure monitoring equipment
- Pulse oximeter
- Access to laboratory, electrocardiogram (ECG), x-ray film and other diagnostic equipment as needed
- Access to latex-free supplies
- Emergency cart for adults and pediatrics
- Stock supplies, including facial tissue; gloves, syringes, and needles (including protective needle devices); emesis basins; alcohol wipes; tongue blades; personal protective equipment; tourniquets; variety of tapes; latex-free supplies

Day of Surgery/Procedure Preparation Area

Each patient bedside unit will have the following:

- Oxygen equipment, including pulse oximeter
- Constant and intermittent suction
- Blood pressure and cardiac monitoring equipment
- Thermometer
- Blood glucose monitor
- Equipment to measure height and weight
- Surgical preparation supplies
- Antiembolism stockings and/or intermittent pneumatic compression device (if ordered) (see Chapter 10)
- Emergency cart for adult and pediatrics

STEP

RATIONALE

ASSESSMENT

- 1 Determine ability of patient to answer questions regarding health history and pending surgery.
- 2 Collect nursing history and identify surgical risk factors, medications, and history of allergies (see Table 36-2 on p. 888; see Chapter 6).

Identifies reliability of patient and need to supplement with information from family members or significant others. Indicates need for further information for informed consent.

Allows for anticipation of possible complications and planning for interventions to reduce risks. Allergies, particularly to latex, can be life threatening.

Clinical Decision Point *If patient is having emergency surgery, focus on assessment of primary body system affected.*

STEP	RATIONALE
3 Perform physical examination (see Table 36-2 and Chapter 6). Focus on body systems that surgery will affect, including a comprehensive pain assessment.	Provides baseline data for future assessments and interventions. Also confirms or disputes information from history and may uncover new information.
4 Ask about patient's and family members' knowledge of and expectations of surgery and care. Include questions concerning fears, cultural practices, and religious beliefs if applicable.	Allows you to anticipate patient's/family's priorities and adapt plan so you can give appropriate instruction and support.
5 Review patient's preoperative orders.	Identifies specific procedures, diagnostic tests, and medications that patient will receive.
6 If patient is same-day admit or ambulatory patient, validate that admission preparations were completed as ordered. Specific preparations to review include NPO status, administration of medications, skin preparation, and bowel preparation if applicable.	Failure to complete preparation could lead to perioperative or postoperative complications and may necessitate postponement or cancellation of surgery.
7 Ask if patient has an advance directive. If so, place it in his or her record.	Document conveys patient's wishes if life support measures are necessary.

NURSING DIAGNOSES

- Acute pain
- Anxiety
- Deficient knowledge regarding the surgical experience
- Fear
- Impaired oral mucous membrane
- Impaired physical mobility
- Ineffective airway clearance
- Ineffective breathing pattern
- Ineffective tissue perfusion
- Risk for aspiration
- Risk for impaired skin integrity
- Risk for infection
- Risk for perioperative-positioning injury

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient can state which surgical procedure is being performed and risks and benefits of surgery. • Patient participates in preoperative and postoperative care. • Patient states that anxiety is decreased. 	Identifies readiness to sign informed consent. Preoperative preparations are effective. Anxiety interferes with effectiveness of teaching and anesthesia. Decreases anxiety and increases cooperation.
2 Explain procedures and allow patient, family members, and significant others to ask questions and express concerns.	

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012b) .
2 Apply allergy/sensitivity band and other safety bands if applicable.	Alerts surgeons to potential safety issues such as patient's allergies and sensitivities, risk for falls, presence of obstructive sleep apnea, or other conditions.
3 Orient patient to room or presurgical (holding) area. Surgeon obtains informed consent. Act as patient advocate as needed; include considering any culturally sensitive issues. Witness form if allowed by agency.	Decreases anxiety and promotes feelings of control. Surgery cannot be performed legally without informed consent. Patient must receive information about need and extent of surgery, alternatives, risks, and benefits. Patient and/or family may be afraid to ask questions or express concerns regarding diverse practices.

Clinical Decision Point *Patients who are illiterate can sign with a mark if properly witnessed. Minors, unless married or declared emancipated, and individuals considered incompetent cannot legally sign a consent form. Parent or legal guardian must provide consent. Some cultures do not allow female members to give consent. Refer to each state and agency protocol for implementing informed consent.*

4 Check medical record and review or complete preoperative checklist.	Ensures that pertinent laboratory and diagnostic test results are available and that all preoperative preparations are completed (Litwack, 2009).
5 Provide preoperative teaching, including explanation of postoperative exercises (see Skill 36-2), skin preparation, pain-control measures (see Chapter 15), and postoperative care in postanesthesia care unit (PACU) phases I and II and nursing division (see Skill 36-3).	Decreases anxiety and promotes cooperation in care. (Litwack, 2009 ; Stannard and Krenzschek, 2012)

STEP	RATIONALE
6 Maintain NPO status.	NPO 8 hours after regular meal before surgery in healthy adult patients (ASA, 2011; Litwack, 2009; Stannard and Krenzischek, 2012).
<p>Clinical Decision Point Patient may brush teeth but should not swallow water. Patient may take oral medications such as beta-blocker medications with sips of water (30 mL). Check with surgeon if they are specifically ordered to be taken before surgery (e.g., antiarrhythmic or seizure medications) and which medications to hold, especially herbals and aspirin. Withhold all other oral medications. You must later check postoperative orders to ensure that scheduled medications unrelated to surgery are not forgotten.</p>	
7 Insert intravenous (IV) line and/or indwelling catheter if ordered.	IV line and/or indwelling catheter may be inserted in holding or preanesthesia area to establish route for medication and fluid administration.
8 Provide for hygiene measures, ensuring patient privacy. Instruct patient to remove all clothing, including undergarments, and apply disposable cap and hospital gown with opening in back.	Prevents patient's hair from contaminating sterile surfaces and provides easy access to patient's body in operating room (OR).
9 Instruct patient to remove hairpins; clips; wigs; hairpieces; jewelry, including rings used in body piercing; and makeup (including nail polish and acrylic nails). Religious medals may be pinned to gown if policy permits. Some agencies allow you to remove acrylic nails or nail polish from only one finger if using a pulse oximeter. Check agency policy.	Hair appliances and jewelry anywhere on body may become dislodged and cause injury during positioning and intubation. Rings decrease circulation in fingers. Makeup, nail polish, and false nails impede assessment of skin and oxygenation. In addition, acrylic nails harbor pathogenic organisms (AORN, 2010a).
<p>Clinical Decision Point Tape wedding rings that cannot be removed. Be careful not to create tourniquet effect with tape around finger.</p>	
10 Help patient remove prostheses, including dentures and oral appliances, glasses and contact lenses, artificial limbs and eyes, artificial eyelashes, and hearing aids. Document list of items and their location in preoperative checklist and/or nurses' notes per agency policy.	Prostheses can be lost or damaged during surgery and could cause injury. Oral appliances may occlude airway.
<p>Clinical Decision Point If patient needs to follow instructions in the OR, leave hearing aid in place. Decision may be made to leave wig or dentures in place until entering OR suite if removal will cause embarrassment. Check agency policy.</p>	
11 Inventory all items and give to family member or significant other or have security put valuables in a locked area. Have release form signed if required by agency.	Valuables left in patient's room may be lost or stolen.
12 Apply antiembolism stockings as ordered (see Chapter 10).	Promotes venous return and reduces risk for thrombus formation.
13 Assess vital signs immediately before going to OR.	Abnormal vital signs indicate conditions that increase risk for surgery.
<p>Clinical Decision Point Report vital signs not within normal range or patient's baseline to anesthesia/surgeon. These results may require surgery to be postponed. Document abnormal vital signs and any action taken in nurses' notes and/or preoperative checklist according to agency policy.</p>	
14 If patient does not have an indwelling catheter, help him or her void before receiving preoperative medication.	Prevents incontinence and bladder distention during surgery and urinary retention with overflow after surgery. Preoperative medication causes drowsiness and decreased voiding sensation.
15 Administer preoperative medications as ordered. (These medications may be given in preoperative or holding area. Check preoperative orders.)	Reduces pain, anxiety, respiratory secretions, and amount of anesthesia required. Promotes relaxation. Antibiotics may be ordered prophylactically but are given within 60 minutes of incision.
<p>Clinical Decision Point Check that informed consent is signed before giving preoperative medications. Times on consent form and medication administration record (MAR) must attest to this. Preoperative medications may alter level of consciousness and make the consent invalid.</p>	

STEP

- 16** Place patient on bed rest with call light within reach and inform him or her not to get out of bed without assistance. Allow family members to remain at bedside until patient is transferred to surgical area. Maintain quiet and relaxing environment.

RATIONALE

There is an increased chance of injury in attempting to ambulate to void when patient is sedated and unattended.

EVALUATION

- 1** Have patient describe surgical procedure and its benefits and risks.
- 2** Compare all assessment data with patient's baseline and expected normal levels.
- 3** Have patient repeat preoperative instructions.
- 4** Monitor patient for signs and symptoms of anxiety and ask how patient and family are feeling.

Confirms level of knowledge needed to sign informed consent.

Evaluates patient's risk for complications and possible need to postpone surgery.

Provides evidence that patient understands instructions.

Increased heart rate and blood pressure, dilated pupils, dry mouth, increased sweating, and muscle rigidity or shaking are responses to stress and anxiety. Asking patient about feelings gives permission to express concerns, which can be further explored.

Unexpected Outcomes

- 1** Patient is unable to give consent, and family member is unavailable.
- 2** Vital signs are above or below patient's baseline or expected range.
- 3** Informed consent has not been signed and witnessed. Surgeon and anesthesiologist did not provide information and/or ensure that consent forms were signed.
- 4** Patient did not remain NPO, which may indicate that he or she did not understand instructions or forgot.
- 5** Patient is unable to state instructions.
- 6** Patient did not void before receiving preoperative medication.

Related Interventions

- In emergency situations obtain telephone consent from next of kin. Two persons must witness oral consent (according to agency policy).
- Document explanation of situation and fact that oral consent was obtained and witnessed.
- At earliest opportunity, person giving oral consent must sign a written consent. Signed telegram or signed fax may also be considered oral consent. Follow agency policy.
- This indicates possible infection; anxiety; pain; or cardiovascular dysfunction, which increases surgical risk.
- Patients who are dehydrated or malnourished may require hydration with IV solutions (see [Chapter 28](#)), parenteral nutrition (see [Chapter 32](#)), or antibiotic therapy before surgery.
- Patient is not ready for surgery. Patient must sign consent before administration of preoperative medications or any medication that alters central nervous system. Notify physician/surgeon/anesthesiologist.
- Notify surgeon and anesthesiologist. Surgery may be postponed or cancelled.
- Assessment of patient's level of understanding or method of instruction was insufficient. Revision of instruction is necessary.
- Patient did not need to or was unable to void. Assess for renal function and bladder distention. If distended, have patient use urinal or bedpan, or you may need an order for catheterization (see [Chapter 33](#)).

Recording and Reporting

- Document all preoperative assessment findings and preparations in nurses' notes and electronic health record (EHR) and/or checklist or flow sheet.
- Document patient's condition on transfer to OR in narrative notes or on flow sheet.
- Document presence of any allergies/sensitivities on armband, in medical record, and in MAR.
- Record disposition of patient valuables/belongings (i.e., whether locked up according to agency policy or sent with family).

- Report lack of signed and witnessed consent form or failure of patient to maintain NPO status and action taken.
- Report and record patient's cultural practices and/or religious beliefs that affect perioperative care and any modification of care planned.

Special Considerations

Teaching

- The Joint Commission patient and family education standards are guidelines to ensure that patient, family member, and/or

TABLE 36-2 Assessment of the Surgical Patient

Assessment Category	Key Criteria
Nursing history	Previous personal/family experience with surgery (e.g., complications) and anesthesia (e.g., malignant hyperthermia)
Physical examination	General system review: <ul style="list-style-type: none"> • Head and neck • Integument • Thorax and lungs • Heart and vascular • Abdomen • Neurologic status • Age • Nutrition • Radiotherapy, chemotherapy, medications that depress immune system • Fluid and electrolyte balance • Preexisting infection • Chronic respiratory disease (emphysema, bronchitis, asthma) • Immunologic disorders (leukemia, acquired immunodeficiency syndrome) • Allergies/sensitivities (including medications, food, latex, and environmental)
Risk factors	<ul style="list-style-type: none"> • Medication history (prescriptions, including pain-management medications, over-the counter [OTC], and herbal remedies) • Physical or mental impairments • Mobility limitations • Prostheses (including hearing aids) • Smoking habits • Alcohol ingestion • Family support and coping mechanisms • Occupation • Emotional health • Temperature, blood pressure, pulse and respiratory rates • Height and weight • Oxygen saturations • Electrocardiogram • Laboratory values (e.g., Hgb, K⁺, glucose, coagulation studies) • Radiology and diagnostic test findings

primary caregiver know about surgical procedure, healing process, sutures, dressing, drains, feeding tubes, pain control, and diet with rationale for each. Adults learn best when they understand the purpose or meaning of what is being taught (Schick and Windle, 2010; TJC, 2012a).

Pediatric

- Involve parents in preoperative preparation to decrease children's anxiety. Preadmission programs to prepare parents and

BOX 36-2 Postanesthesia and Ambulatory Surgery Discharge Criteria

Postanesthesia Discharge Criteria

- Patient awake (or returns to baseline)
- Vital signs stable
- No excess bleeding or drainage
- No respiratory depression
- SaO₂ greater than 90%
- Pain controlled
- Report given

Ambulatory Surgery Discharge Criteria

- All postanesthesia care unit (PACU) discharge criteria met
- No intravenous (IV) narcotics for last 30 minutes
- Minimal nausea and vomiting
- Pain controlled
- Voided (if appropriate to surgical procedure/orders)
- Able to ambulate if age-appropriate and not contraindicated
- Responsible adult present to accompany patient
- Discharge instructions given and understood

children for same-day surgery have been shown to decrease anxiety in both parents and children. Part of preoperative teaching needs to include giving children the opportunity to handle equipment they will see such as an anesthesia mask or drainage tube.

- Take the developmental level of a child into consideration during preoperative preparation. Use toys and games to demonstrate preoperative procedures (Hockenberry and Wilson, 2011).
- Allow parents to accompany their child to the holding area and consider visitation in the PACU after the procedure.

Gerontologic

- Physiologic changes that occur with aging may require admission to hospital before surgery for additional diagnostic tests and stabilization of condition (Table 36-3).
- Teach when patient is alert and rested. Keep teaching sessions short.
- Age-related changes such as decreased vision, hearing, and short-term memory may require presence of family caregiver during preoperative preparation.
- Make sure that a family member or someone will take care of ambulatory patients at home.

Home Care

- Instruct patients admitted on day of surgery about NPO status, skin preparation, and procedures such as enemas and douches before admission. Patients often use enemas or douches at home.
- Patients having surgery performed in ambulatory surgery centers must be accompanied by a family member or friend to allow for discharge after the procedure (Box 36-2).

TABLE 36-3 Physiologic Factors That Place Older Adult Patients at Risk for Surgery

Alterations	Surgery Risks	Nursing Implications
Cardiovascular		
Degenerative change in myocardium and valves	Reduced cardiac reserve	Assess baseline vital signs.
Rigidity of arterial walls and reduction in sympathetic and parasympathetic innervation to heart	Predisposes patient to postoperative hemorrhage and rise in systolic and diastolic blood pressure	Maintain adequate fluid balance to minimize stress to heart. Ensure that blood pressure is adequate to meet circulatory demands.
Increase in calcium and cholesterol deposits within small arteries; arterial walls thickened	Predisposes patient to clot formation in lower extremities	Instruct patient in techniques for performing leg exercises and proper turning. Apply antiembolism stockings, sequential compression devices (SCDs) (see Chapter 10).
Integumentary System		
Decreased subcutaneous tissue and increased fragility of skin	Prone to pressure ulcers and skin tears	Assess skin every 4 hours; pad all bony prominences during surgery. Turn or reposition (see Chapter 9).
Pulmonary		
Rib cage stiffens and enlarges	Reduced vital capacity	Instruct patient in proper technique for coughing and deep-breathing exercises and use of spirometer.
Reduced diaphragm excursion	Greater residual capacity or volume of air left in lung after normal breath increases, reducing amount of new air brought into lungs with each inspiration	Encourage deep breathing. Use incentive spirometer to enhance exhalation.
Lung tissue less distensible; alveoli enlarged	Reduced blood oxygenation	Assess oxygen saturation via oximetry (SpO ₂).
Renal		
Reduced blood flow to kidneys	Blood loss causes decrease in circulation to the kidney	Monitor urinary output and laboratory data (i.e., blood urea nitrogen [BUN], creatinine).
Reduced glomerular filtration rate and excretory times	Limits ability to remove drugs or toxic substances	Assess for adverse effects of medications.
Reduced bladder capacity	Voiding frequency increases, and larger amount of urine stays in the bladder after voiding Sensation of need to void may not occur until bladder is filled	Instruct patient to notify nurse immediately when sensation of bladder fullness develops. Keep call light or bedpan within easy reach.
Neurologic		
Sensory losses, including reduced tactile sense, increased pain tolerance	Patient less able to respond to early warning signs of surgical complications	Inspect bony prominences for signs of pressure.
Decreased reaction time	Patient becomes confused easily after anesthesia	Orient patient to surrounding environment. Observe for nonverbal signs of pain. Maintain safe environment. Institute fall precautions.
Metabolic		
Lower basal metabolic rate	Reduced total oxygen consumption and nutritional needs.	Ensure adequate nutritional intake once diet is resumed.
Reduced number of red blood cells and hemoglobin levels	Reduces ability to carry adequate oxygen to tissues.	Administer necessary blood products. Assess for adequacy of oxygenation, fatigue, and infection.
Change in total amounts of body potassium and water volume	Greater risk for fluid or electrolyte imbalance	Monitor electrolyte levels.

SKILL 36-2 Demonstrating Postoperative Exercises

Video Clip

Structured preoperative teaching has a positive influence on a surgical patient's recovery (Lewis et al., 2011). You will provide information and teach skills to help patients understand the surgical experience and participate actively in the recovery process. The skills of coughing, deep breathing, turning, and using an incentive spirometer are important in preventing circulatory and respiratory postoperative complications.

In the past teaching occurred the evening before surgery when patients were most anxious. As a result of cost reduction efforts, many patients are admitted to the hospital or ambulatory surgery center the day of surgery. Preoperative teaching is not highly effective at this time because of the patient's high anxiety level (Stannard and Krenzischek, 2012). Many health care agencies have developed comprehensive outpatient education programs to better enable patients to receive the knowledge and skills needed to participate in their own care before coming to the hospital or ambulatory care center. Teaching booklets and videotapes are often available to supplement any instruction a nurse provides.

Postoperative exercises include diaphragmatic breathing and effective coughing, turning, and leg exercises. Patients may use an incentive spirometer, a device that provides visual feedback at a preset inspiratory flow of volume of air that mimics natural sighing or yawning (see Skill 23-3). The surgeon may order incentive spirometry for patients especially at risk for atelectasis or pneumonia (e.g., chronic smokers or patients on prolonged bed rest). Positive expiratory pressure (PEP) therapy is an alternative device to conventional physiotherapy that uses inhalation and exhalation to keep the lungs healthy. When blowing the air out of the lungs, the PEP device provides increased intrathoracic pressure and stenting of the airways that move secretions toward the larger airways, where they can be expelled to prevent the alveoli from collapsing. During the discussion of these exercises, you will explain the relationship between the exercises and the physiologic principles that make them important. Through specific explanations and guided practice you will help develop patient commitment to the recovery process. Demonstrate the exercises and continue to coach the patient through several return practice sessions.

Whenever possible, include family caregivers or other significant people in the practice sessions. Frequently these individuals are with the patient during the postoperative period and can thus serve as coaches. You will also provide patients with information about the sensations typically experienced after surgery such as incisional pain, nausea, tightness of dressings, and which interventions will alleviate them. The information helps patients realistically interpret the events that occur in the postoperative period. As a result, patients are able to decrease anxiety, conserve their energy, and attend to performing the exercises that aid in their recovery.

A potential postoperative complication is venous thromboembolism, including deep vein thrombosis (DVT) and pulmonary

embolism. One of the simplest ways to prevent the formation of DVT is to encourage and assist a patient in early ambulation and leg exercises. When this is not possible or the patient's age, past history, or surgical procedure place him or her at an increased risk, use additional devices to help prevent the formation of DVT such as compression stockings and intermittent pneumatic compression devices (see Chapter 10). Another device used to prevent DVT is the venous plexus foot pump (Fig. 36-2). This pump mimics the natural action of walking by intermittently compressing the sole of the foot and then relaxing it so the venous plexus can fill with blood. Neither the intermittent pneumatic compression device nor the venous plexus foot pump should be used on patients with an acute DVT, significant peripheral vascular ischemia, large open wounds or skin grafts, or cancer of the extremity. None of these devices should replace the need for early and frequent ambulation.

Delegation and Collaboration

The skill of teaching postoperative exercises cannot be delegated to nursing assistive personnel (NAP). The NAP can reinforce and help patients perform postoperative exercises. The nurse directs the NAP about:

- Maintaining precautions unique to a particular patient.
- When to report if the patient is unable or unwilling to perform the exercises correctly.

Equipment

- Pillow (*optional*); used to splint the incision when coughing to reduce discomfort)
- Incentive spirometer
- PEP device
- Stethoscope

FIG 36-2 Venous plexus foot pump with bedside controls. (Courtesy Tyco Healthcare Group LP.)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <p>1 Assess patient's risk for postoperative respiratory complications: Identify presence of chronic pulmonary condition (e.g., emphysema, chronic bronchitis, asthma); any condition that affects chest wall movement such as obesity, advanced pregnancy, thoracic or abdominal surgery; history of smoking; and presence of reduced hemoglobin level.</p> | <p>General anesthesia predisposes patient to respiratory problems because lungs are not fully inflated during surgery, cough reflex is suppressed, and mucus collects within airway passages. After surgery inadequate lung expansion can lead to atelectasis and pneumonia. Chronic lung conditions create greater risk for developing respiratory complications. Smoking damages ciliary clearance and increases mucus secretion. A reduced hemoglobin level can lead to reduced oxygen delivery.</p> |
|---|---|

Clinical Decision Point Assess and report to surgeon and/or anesthesiologist if patient has had a cold or upper respiratory infection within past week.

- | | |
|--|--|
| <p>2 Auscultate lungs.</p> | <p>Establishes baseline for postoperative comparison.</p> |
| <p>3 Assess patient's ability to deep breathe and cough by placing hand on patient's abdomen; having him or her take a deep breath; and observing movement of shoulders, chest wall, and abdomen. Measure chest excursion during deep breath (see Chapter 6). Ask patient to cough into tissue after taking deep breath.</p> | <p>Reveals maximum potential for chest expansion and ability to cough forcefully; serves as baseline to measure patient's ability to perform exercises after surgery.</p> |
| <p>4 Assess patient's risk for postoperative thrombus formation (e.g., older adults, immobilized patients, patients with personal or family history of clots, and women over 35 taking birth control pills who smoke). Observe calves for redness, swelling, warmth, tenderness, swollen calf, calf swelling more than 3 cm (1.2 inches) compared with asymptomatic leg. Compare legs for bilateral equality. Palpate pedal pulses. Check for Homans' sign (calf pain on dorsiflexion of foot), which may or may not be present (see Skill 6-4). Calf pain is usually unilateral.</p> | <p>Following general anesthesia, circulation slows, causing a greater tendency for clot formation. Immobilization results in decreased muscular contraction in lower extremities, which promotes venous stasis. The physical stress of surgery creates a hypercoagulable state in most individuals. Manipulation and positioning during surgery may inadvertently cause trauma to leg veins. Symptoms may indicate phlebitis and thrombus formation.</p> |

Clinical Decision Point Homans' sign is not always present when a DVT exists (Schick and Windle, 2010). If you suspect a thrombus, notify surgeon and refrain from manipulating extremity any further. Surgery will usually be postponed. Antiembolism stockings or pneumatic compression cuffs may be ordered for patients at risk for thrombus formation (see Chapter 10).

- | | |
|---|---|
| <p>5 Assess patient's ability to move independently while in bed.</p> | <p>Patients confined to bed rest, even for limited periods, will need to turn regularly. Determines existence of any mobility restrictions.</p> |
| <p>6 Assess patient's willingness and capability to learn exercises; note factors such as attention span; anxiety level; level of consciousness; language skills; and level of pain, if any.</p> | <p>Capacity to learn depends on readiness, ability, and learning environment.</p> |

Clinical Decision Point Highly anxious patients or those in severe pain have difficulty learning and performing postoperative exercises.

- | | |
|--|---|
| <p>7 Assess family's caregiver willingness to learn and to support patient after surgery.</p> | <p>Family's caregiver presence after surgery can be a potential motivating factor for patient's recovery; family member or significant other can coach patient on exercise performance.</p> |
| <p>8 Assess patient's medical orders before and after surgery.</p> | <p>Requires adaptations in way patient performs exercises.</p> |

NURSING DIAGNOSES

- | | | |
|--|---|--|
| <ul style="list-style-type: none"> • Acute pain • Impaired gas exchange • Impaired memory | <ul style="list-style-type: none"> • Impaired physical mobility • Ineffective airway clearance • Ineffective breathing pattern | <ul style="list-style-type: none"> • Ineffective tissue perfusion • Risk for impaired skin integrity • Risk for infection |
|--|---|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient is able to correctly deep breathe, use incentive spirometer, cough, turn, and perform leg exercises throughout postoperative period. | <p>Patient successfully learns exercises. Ability to perform exercises reduces risk for postoperative complications.</p> |
|---|--|

STEP

- After surgery chest excursion meets or exceeds preoperative level.
 - Lungs are clear on auscultation both before and after surgery.
 - No redness, warmth, or tenderness in lower extremities; pedal pulses palpable.
 - Patient initiates exercises spontaneously.
- 2 Prepare equipment as needed.
 - 3 Prepare room for teaching.

RATIONALE

Helps patient maintain full lung expansion and clear airways after surgery.

Absence of secretions reduces risk for postoperative pneumonia.

Leg exercises prevent occurrence of circulatory and mobility problems after surgery.

Patient values importance of exercises to recovery.

Quiet, private area free from distractions enhances patient's ability to learn.

IMPLEMENTATION

- 1 Teach diaphragmatic breathing:
 - a Help patient to comfortable sitting or standing position. If patient chooses to sit, raise head of bed to semi-Fowler's or Fowler's position and help to side of bed or upright position in chair. If patient is sitting in chair, knees should be at or higher than hips. Use stool if necessary.

Upright position facilitates diaphragmatic excursion by using gravity to keep abdominal contents away from diaphragm. Prevents tension on abdominal muscles, which allows for greater diaphragmatic excursion. Diaphragmatic breathing allows for complete lung expansion and improved ventilation and increases blood oxygenation. Deep breathing also allows air to pass by partially obstructing mucus plugs, thus increasing force with which to expel plug. Coughing loosens secretions and helps to remove them from pulmonary alveoli and bronchi.

Clinical Decision Point After surgery patient can usually be positioned upright with head of bed elevated. If he or she must remain flat in bed, stress that exercises can still be performed.

- b Stand or sit facing patient.
- c Instruct patient to place palms of hands across from each other along lower borders of anterior rib cage; place tips of third finger lightly together. Demonstrate for patient.
- d Have patient take slow, deep breaths, inhaling through nose and pushing abdomen against hands (see illustration). Explain that patient will feel normal downward movement of diaphragm during inspiration. Demonstrate for patient.
- e Have patient avoid using chest and shoulder muscles while inhaling.

Patient will be able to observe breathing exercises performed by nurse.

Position of hands allows patient to feel movement of chest and abdomen as diaphragm descends and lungs expand inside chest wall.

Slow, deep breath allows for more complete lung expansion and prevents panting or hyperventilation. Inhaling through nose warms, humidifies, and filters air. Explanation and demonstration focus on normal ventilatory movement of chest. Patient learns to understand how diaphragmatic breathing feels.

Using auxiliary chest and shoulder muscles during breathing increases unnecessary energy expenditures and does not promote full lung expansion.

STEP 1d Patient and nurse practice deep breathing.

STEP

RATIONALE

- f** Take slow, deep breath and hold for count of three; slowly exhale through mouth as if blowing out a candle (pursed lips).
- g** Repeat breathing exercise 3 to 5 times.
- h** Have patient practice exercises. Instruct him or her to take 10 slow, deep breaths every hour while awake during postoperative period until mobile. Another option is to have patient use incentive spirometry (see illustration).
- 2** Teach positive expiratory pressure therapy (PEP) and “huff” coughing:
 - a** Perform hand hygiene. Set PEP device for setting ordered.
 - b** Instruct patient to assume semi-Fowler’s or high-Fowler’s position and place nose clip on patient’s nose (see illustration).
 - c** Have patient place lips around mouthpiece. Instruct him or her to take a full breath and exhale 2 or 3 times longer than inhalation. Repeat pattern for 10 to 20 breaths.
 - d** Remove device from mouth and have patient take slow, deep breath and hold for 3 seconds.
 - e** Instruct patient to exhale in quick, short, forced “huffs.”
- 3** Teach controlled coughing:
 - a** Explain importance of maintaining an upright position.
 - b** Demonstrate coughing. Take two slow, deep breaths, inhaling through nose and exhaling through (pursed lips) mouth.
 - c** Inhale deeply a third time and hold breath to count of three. Cough fully for two-to-three consecutive coughs without inhaling between coughs (see illustration). (Tell patient to push all air out of lungs.)

- Allows for gradual, controlled expulsion of air.
- Allows patient to observe slow, rhythmic breathing pattern. Repetition of exercise reinforces learning. Regular deep breathing prevents or minimizes postoperative respiratory complications. Incentive spirometer gives visual incentive to breathe as deeply as possible.
- Higher settings require more effort. Promotes optimum lung expansion and expectoration of mucus.
- Ensures that patient does all breathing through mouth. Ensures that patient uses device properly.
- Promotes lung expansion before coughing.
- “Huff” coughing, or forced expiratory technique, promotes bronchial hygiene by increasing expectoration of secretions.
- Position facilitates diaphragm excursion and enhances thorax and abdominal expansion.
- Deep breaths expand lungs fully so air moves behind mucus and facilitates effective coughing.
- Consecutive coughs help remove mucus more effectively and completely than one forceful cough.

Clinical Decision Point *Coughing may be contraindicated after brain, spinal, or eye surgery because of an increase in intracranial pressure.*

- d** Caution patient against just clearing throat instead of coughing deeply.
- e** If surgical incision is either thoracic or abdominal, teach patient to place either hands or pillow over incisional area and place hands over pillow to splint incision (see illustration). During breathing and coughing exercises, press gently against incisional area for splinting and support.

- Clearing throat does not remove mucus from deeper airways.
- Surgical incision cuts through muscles, tissues, and nerve endings. Deep-breathing and coughing exercises place additional stress on suture line and cause discomfort. Splinting incision with hands or pillow provides firm support and reduces incisional pulling and pain.

STEP 1h Patient demonstrates incentive spirometry.

STEP 2b Diagram of use of positive expiratory pressure device.

STEP

RATIONALE

- f Patient continues to practice coughing exercises, splinting imaginary incision. Instruct patient to cough 2-to-3 times every hour while awake.
- g Instruct patient to examine sputum for consistency, odor, amount, and color changes and notify nurse if any changes are noted.

Deep coughing with splinting effectively expectorates mucus with minimal discomfort.

Sputum consistency, odor, amount, and color changes indicate presence of pulmonary complication such as pneumonia.

Clinical Decision Point For patients with preexisting pulmonary disease, know usual character of mucus to determine if change has occurred.

4 Teach turning (example describes turning to right side):

- a Instruct patient to assume supine position and move toward left side of bed. He or she can do this by bending knees and pressing heels against mattress to raise and move buttocks (see illustration).
- b Instruct patient to place right hand or pillow over incisional area to splint it.
- c Instruct patient to keep right leg straight and flex left knee up (see illustration).

Positioning begins in this example on left side of bed so turning to right side will not cause patient to roll off edge of bed. Buttocks lift prevents shearing force from body moving against sheets.

Splinting incision supports and minimizes pulling on suture line during turning.

Straight leg stabilizes patient's position. Flexed left leg shifts weight for easier turning.

Clinical Decision Point Some patients such as those who have had back surgery or vascular repair are restricted from flexing their legs after surgery. Some patients are restricted from turning or may need help for positioning (see Chapter 9).

- d Have patient grab right side rail with left hand while pulling toward right and rolling onto right side.
- e Instruct patient to turn every 2 hours from side to back to other side while awake. If patient is unable to perform this maneuver, note in chart that staff or primary caregiver must turn patient every 2 hours. You will need to place pillows behind some patients to help maintain side-lying position.

Pulling toward side rail reduces effort needed for turning.

Reduces risk for vascular complications by contraction of leg muscles around veins to improve venous return. Also reduces pulmonary complications by shifting mucus to prevent consolidation.

STEP 3c Controlled coughing with placement of hands on upper abdomen.

STEP 3e Patient splinting abdomen with pillow.

STEP 4a Buttocks lift for moving to side of bed. (From Lowdermilk D, Perry S: Maternity nursing, ed 7, St Louis, 2006, Mosby.)

STEP 4c Leg position when turning to the right. (From Lowdermilk D, Perry S: Maternity nursing, ed 7, St Louis, 2006, Mosby.)

STEP

RATIONALE

5 Teach leg exercises:

- a** Have patient assume supine position in bed. Demonstrate leg exercises by performing passive range-of-motion exercises and simultaneously explaining exercise.

Provides for normal anatomic position of lower extremities and normal joint motion of each joint of lower extremities.

Clinical Decision Point *If patient's surgery involves one or both lower extremities, surgeon must order leg exercises in postoperative period. You can safely exercise leg unaffected by surgery unless patient has preexisting phlebothrombosis (blood clot formation) or thrombophlebitis (inflammation of vein wall).*

- b** Rotate each ankle in one direction and then in other direction. Instruct patient to draw imaginary circles with big toe (see illustration). Repeat 5 times.
- c** Alternate dorsiflexion and plantar flexion by moving both feet, pointing toes up toward head and then down toward end of mattress. Direct patient to feel calf muscles contract and relax alternately (see illustration). Repeat 5 times.
- d** Perform quadriceps setting by tightening thigh and bringing knee down toward mattress and relaxing (see illustration). Repeat 5 times.
- e** Patient alternately raises each leg from bed surface; patient begins by keeping leg straight and then bends leg at hip and knee (see illustration). Repeat 5 times.

Ankle circle exercises maintain joint mobility and promote venous return.

Calf pumping stretches and contracts gastrocnemius muscles, which enhances venous return.

Quadriceps-setting exercises contract muscles of upper legs, maintain knee mobility, and improve venous return to heart.

Leg raise promotes contraction and relaxation of quadriceps muscles and promotes hip and knee movements by keeping leg straight and bending hip and knee joints.

Clinical Decision Point *If patient is unable to perform exercises, note on Kardex or in electronic health record (EHR) that staff or primary caregiver must do passive range of motion to lower extremities every 2 hours while awake. Alternatively notify surgeon and request an order for pneumatic compression cuffs (see Chapter 10).*

STEP 5b Foot circles.

STEP 5c Alternate dorsiflexion and plantar flexion.

STEP 5d Quadriceps (thigh) setting.

STEP 5e Hip and knee movements. (From Lewis S et al: Medical-surgical nursing: assessment and management of clinical problems, ed 7, St Louis, 2007, Mosby.)

STEP

- f** Have patient continue to practice exercises at least every 2 hours while awake. Patient is instructed to coordinate turning and leg exercises with diaphragmatic breathing, incentive spirometry, and coughing exercises.

RATIONALE

Repetition of exercise sequence reinforces learning. Establishes routine for exercises that develops habit for performance. Sequence of exercises is leg exercises, turning, deep breathing, and coughing. Exercises before coughing enhance ability to move secretions so they may be expectorated.

EVALUATION

- 1 Observe patient performing all exercises independently.
- 2 Observe family caregiver's ability to coach patient.
- 3 Evaluate patient's chest excursion.
- 4 Auscultate patient's lungs.
- 5 Gently palpate calves for redness, warmth, swelling, and tenderness. Assess pedal pulses.

Provides opportunity for practice and return demonstration of exercises. Ensures that patient has learned correct technique. Family caregiver can help positively or interfere with correct technique. Determines extent of lung expansion. Breath sounds reveal if airways are clear. Absent signs and normal pulses usually indicate that no venous thrombosis is present.

Unexpected Outcomes

- 1 Patient is unwilling to perform exercises (deep breathing, coughing, and turning) because of incisional pain of thorax or abdomen or surgery in lower abdomen, groin, buttocks, or legs (leg exercises).
- 2 Patient is unable to perform exercises correctly. Anxiety and fatigue alter patient's performance.
- 3 Patient develops pulmonary complications such as atelectasis after surgery. Breaths are shallow; cough is ineffective.
- 4 Patient develops circulatory complications such as venous stasis or thrombophlebitis after surgery.

Related Interventions

- Offer patient pain medication 30 minutes before or have patient use patient-controlled analgesia (PCA) before performing postoperative exercises.
- Repeat teaching with more demonstrations.
- Patient may benefit from stress-reduction techniques.
- Assess for presence of anxiety, pain, and fatigue.
- Notify surgeon of findings.
- Start oxygen as ordered and increase frequency of coughing exercises.
- Assess breath sounds in all lobes.
- Place patient in upright position.
- Notify surgeon of findings.
- Place patient on bed rest with affected leg elevated as ordered.
- Continue to have patient do exercises with unaffected leg.

Recording and Reporting

- Record physical assessment findings in narrative notes or flow sheet.
- Report and record any assessed complications and action taken.
- Record in nurses' notes and EHR which exercises you have demonstrated to patient and whether or not patient can perform them independently.
- Report any problem that patient has in practicing exercises to nurse assigned to patient on next shift.

Special Considerations

Teaching

- Health literacy refers to patients' ability to understand their health care issues and effectively care for themselves. It is essential to self-care. Provide instructions in a manner that patients and their families can interpret to improve and minimize errors (Schick and Windle, 2010). Provide education with a combination of procedural explanations, skills teaching, and psychosocial support.
- Explain postoperative exercises to patient and family caregiver, including their importance to recovery and physiologic benefits.

Adults learn best when they understand how they will benefit from activity.

Pediatric

- Have parents encourage and allow children to move within limits posed by surgery.
- Adolescents need to receive same preoperative instructions and teaching as adults to support their developmental stage. Adolescents are searching for identity, and treating them with respect will enhance their self-esteem and independence and increase adherence.
- Young children's normal responses of crying and moving extremities will maintain lung expansion and peripheral circulation. Therefore teaching coughing, deep breathing, and leg exercises is not usually necessary for young children.
- Children need family members and/or nursing staff to assume coach's role of reminding and encouraging.

Gerontologic

- Changes related to aging such as decreased vision, hearing, and short-term memory affect teaching effectiveness. Shorter sessions with frequent reinforcement and use of teaching aids with large print are sometimes necessary. Include family

members or primary caregiver in teaching sessions. Take time to instruct patient properly.

- Aging process decreases ventilatory capacity and increases risk for respiratory complications.
- Aging process decreases muscle mass and decreases venous return, thus increasing the risk for venous stasis.

Home Care

- Review coughing, deep breathing, abdominal splinting, relaxation, pain management, and leg exercises before admission to hospital or surgical clinic and after discharge.

SKILL 36-3 Performing Postoperative Care of a Surgical Patient

Nursing care of a postoperative surgical patient is divided into two phases: immediate recovery and postoperative convalescence. During both phases you will make comprehensive and detailed assessments of a patient's condition. The effects of anesthesia and the physiologic stressors imposed by surgery place patients at risk for a variety of physiologic alterations. It is also important to facilitate communication among all members of the health care team, the patient, and the patient's family or significant other.

The first phase of postoperative care for hospitalized patients is known as the phase I level of care. This extends from the time a patient leaves the operating room (OR) to the time a patient has stabilized in the postanesthesia care unit (PACU), meets the discharge criteria, and has been transferred to the nursing unit or phase II level of care. The first phase is the most critical postoperative phase for assessing aftereffects of anesthesia, including airway clearance, cardiovascular complications, temperature control, and neurologic function. A patient's condition can change rapidly. The perianesthesia nurse must make timely, intelligent, and accurate assessments to select the most appropriate measures of care for a patient.

Each agency has its own policies for directing the process for recovering patients during the immediate postoperative period. For example, frequently patients undergoing cardiac or central vascular repair transfer from the OR to an intensive care unit (ICU). In this situation the patient is not sent to the PACU area. The condition of these patients is potentially unstable and requires further stabilization and monitoring in an ICU setting.

The second phase of recovery is the postoperative convalescent period. ASPAN defines the phase II level of care as when the nursing roles focus on preparation for care in the home or an extended care environment. This period extends from the time a patient is discharged from the PACU to the time he or she is discharged from the inpatient hospital. Outpatient surgical patients undergo convalescence at home. All patients who have undergone surgical procedures have similar postoperative needs. However, nursing care becomes very individualized and depends on the nature of a patient's surgery, preexisting medical conditions, the onset of complications, and the speed of recovery. Not all surgical patients recover at the same rate. During the convalescent period you begin preparation for discharge and actively include the patient, family, and significant others in the process. You promote a patient's independence, educate patient and/or family about any limitations imposed by surgery, and provide resources needed for the patient to assume an improved state of wellness.

Delegation and Collaboration

The skill of initiating and managing postoperative care of a patient cannot be delegated to nursing assistive personnel (NAP). The nurse directs NAPs to:

- Report specific changes in patient's vital signs, behavior, or level of consciousness to the nurse.
- Obtain vital signs at specific intervals.
- Provide comfort and hygiene measures.

Equipment

Phase I Level of Care

- Equipment for physical assessment
- Various types and sizes of artificial airways
- Constant and intermittent suction
- Oxygen equipment such as mask, oxygen regulator and tubing, and positive-pressure delivery system
- Pulse oximetry
- End-tidal CO₂ monitoring
- Blood pressure monitoring equipment
- Adjustable lighting
- Electrocardiogram (ECG) monitor
- Arterial blood gas supplies
- Bladder scanner
- Bedside portable ultrasound to assess pulses
- Thermoregulation equipment, including thermometers, blanket warmers, and cooling blankets
- Intravenous supplies (if ordered) (see [Chapter 28](#))
- Adult and pediatric emergency cart with defibrillator
- Stock supplies (e.g., facial tissues, dressings, bed pans, urinals, emesis basins)
- Personal protective equipment
- Latex free supplies and equipment

Phase II Level of Care

- Oxygen equipment
- Constant and intermittent suction
- Blood pressure monitoring equipment
- Thermometer
- Blood glucose testing system
- Bladder scanner
- Electrocardiogram (ECG) monitor and pulse oximeter
- Bag-valve-masks and emergency cart with defibrillator available for adult and children
- Malignant hyperthermia cart ([AORN, 2010b](#))
- Latex-free supplies and equipment
- Transport equipment, including wheelchairs and carts
- Stock supplies should include: dressings, facial tissues, gloves, bedpans and urinals, syringes, needles and protective needle devices, emesis basins, patient linens, alcohol swabs/wipes, ice bags, tongue blades, and a variety of tapes

STEP

RATIONALE

ASSESSMENT

1 Phase I: Immediate recovery period

- a Receive hand-off report from circulating nurse and anesthesia provider, including procedure performed, range of vital signs, any complications, estimated blood loss (EBL), other fluid loss, fluid replacement during surgery, type of anesthesia, medications given, type of airway and size, extent of surgical wound, restrictions to movement of position during surgery, and any preoperative medical and/or nursing diagnoses.

Determines patient's general status and allows nurse to anticipate need for special equipment, nursing care, and activities in PACU.

Clinical Decision Point *Patient's usual first complaint is of pain. Know how much sedative and/or analgesic have already been given and how long ago.*

- b On patient's arrival in PACU, review surgeon's orders.
- c Consider type of surgical procedure, restrictions to movement, and type of anesthesia used.
- d Perform thorough patient assessment, including vital signs; pulse oximetry; pain and systems assessment to include respiratory, cardiac, neurologic, gastrointestinal (GI), genitourinary (GU), metabolic, and fluid status. Assess patient's surgical site and drains, skin integrity, safety, and anxiety level.
- e Expert opinion states that vital signs should be taken every 5 to 15 minutes during initial stabilization and more frequently if clinically indicated (ASPAN, 2010).
- f Discharge from phase I level of care is based on specific criteria, not a time limit. Criteria should address assessment of airway patency, oxygenation, hemodynamic stability, thermoregulation, neurologic stability, intake and output, tube patency, dressings, pain and comfort management, and a postanesthesia scoring system if used. Each agency defines frequency of assessment.

Review provides detailed analysis of patient's physiologic status, allowing nurse to make appropriate observations and interventions. Provides baseline data to determine any change in condition.

Influences type of assessments necessary, type of complications for which to observe, and specific nursing interventions needed.

Provides baseline for ongoing postoperative evaluations. Identifies priority nursing interventions.

Check agency requirements for vital sign frequency.

Discharge instructions are developed in consultation with anesthesia department.

Clinical Decision Point *Be sure to turn patient on side (when possible) to observe underlying skin and accumulation of blood or serous drainage not visible otherwise.*

2 Phase II level of care: Convalescent period

- a Obtain phone report from PACU nurse summarizing patient's current status.
- b On patient's arrival at division, collect more detailed hand-off report from nurse accompanying patient.
- c Review patient's chart for information pertaining to type of surgery; complications; medications administered; preoperative medical risks; baseline vital signs, including PACU vitals; and patient's usual medications given/not given before surgery.
- d Review postoperative medical orders.
- e Assess patient's and family's knowledge and expectations of surgical recovery.

Allows you to prepare hospital room with necessary supplies and equipment for patient's special needs.

Detailed report helps you plan appropriate assessment and nursing care measures. Data provide baseline to detect any change in patient's condition.

Nature of surgery, intraoperative complications, and presence of medical risks dictate complications for which to observe. Vital signs provide means to detect postoperative changes. List of patient's usual medications may necessitate a call to surgeon for orders concerning timing and dose of drugs not given before surgery.

Offers additional guidelines for type of care to provide.

Patient will be better prepared to participate in care.

STEP

RATIONALE

NURSING DIAGNOSES

- | | | |
|---|---|---|
| <ul style="list-style-type: none"> • Acute confusion • Acute pain • Deficient fluid volume • Deficient knowledge regarding postoperative care • Excess fluid volume • Impaired gas exchange | <ul style="list-style-type: none"> • Impaired physical mobility • Impaired skin integrity • Impaired spontaneous ventilation • Impaired swallowing • Impaired verbal communication • Ineffective airway clearance | <ul style="list-style-type: none"> • Ineffective breathing pattern • Ineffective protection • Ineffective thermoregulation • Ineffective tissue perfusion • Risk for aspiration • Urinary retention |
|---|---|---|

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient's vital signs, including oxygen saturation, remain within previous baseline or normal expected range. • Patient reports relief of discomfort after analgesic or other pain-relief measures. • Surgical wound remains intact without redness, edema, ecchymosis, or discharge. If opaque dressing covers incision, dressing remains dry and intact. Drains, if present, remain patent. • Breath sounds remain clear to auscultation; mucus is clear. • Return of flatus present within 48 to 72 hours after bowel or abdominal surgery and/or general anesthetic. Normal bowel sounds present within 24 hours in cases of minor surgery. • Intake and output (I&O) remain relatively in balance, with urinary output greater than 30 mL/hr. • Legs remain without signs and symptoms of thrombophlebitis. • Patient is able to discuss recovery and discharge plans. Verbalizes no specific physical complaints. <p>2 Prepare equipment as necessary at bedside and test it for function.</p> <p>3 Explain to patient all procedures that you are to perform and rationale for each. On nursing division include family members and/or significant other in explanations. In ambulatory surgery centers families are allowed at bedside during recovery period.</p> | <p>No occurrence of cardiovascular, pulmonary, or thermoregulatory changes except those expected from effects of anesthetic or analgesic.</p> <p>Pain-relief measures effectively alter patient's reception or perception of pain.</p> <p>Indicates wound healing without signs of bleeding or infection.</p> <p>Postoperative exercises and activity promote lung expansion and alveolar stability.</p> <p>You assess the GI system after surgery by noting: (1) return of flatus; (2) first bowel movement; (3) normal vital signs; (4) lack of nausea/vomiting and return of appetite; and (5) absence of signs of ileus such as distention, bloating, and cramps.</p> <p>Adequate urinary elimination maintained. Fluid intake (intravenous [IV] and/or by mouth [PO]) adequately maintained.</p> <p>Postoperative leg exercises and early ambulation minimize venous stasis and clot formation.</p> <p>Patient coping with physical and psychological stress of surgery.</p> <p>Ensures proper access of functional equipment.</p> <p>Involves patient in plan of care and minimizes anxiety. As recovery progresses, patient is able to make more choices regarding how procedures should be performed. Family can serve as coach and help patient remember explanations given.</p> |
|--|---|

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Phase 1: Immediate recovery period:</p> <p>a Perform hand hygiene.</p> <p>b While receiving hand-off report as patient enters PACU on stretcher/bed, immediately attach oxygen tubing to regulator, hang IV fluids, check IV flow rates, and attach pulse oximeter (see Procedural Guideline 5-3). Connect any drainage tubes to gravity drainage or continuous or intermittent suction as ordered. Attach cardiac monitor. Ensure that indwelling catheter and bag are in drainage position and patent.</p> <p>c Conduct ongoing assessment of all vital signs every 5 to 15 minutes until patient stabilizes or per agency protocol. Compare findings with patient's baseline. Provide warm blankets as needed for patient comfort.</p> | <p>Reduces transmission of microorganisms.</p> <p>Maintaining oxygenation and circulation are two priorities. Inhaled oxygen improves percentage of oxygen delivered to alveoli. Pulse oximeter provides information on arterial oxygen saturation. IV fluids maintain circulatory volume and provide route for emergency drugs. Drainage tubes must remain patent and in proper position to allow fluid to drain.</p> <p>Vital signs reveal onset of postoperative complications from surgery or anesthesia (e.g., respiratory depression, hypo-hyperthermia, pulse irregularity, or hypotension). Acute blood loss may lead to hypovolemic shock with signs of reduced blood pressure, elevated heart and respiratory rates, pale skin, and restlessness. General anesthetic may affect temperature-regulating center, and lower metabolic rate causes hypothermia. Malignant hyperthermia is a rare inherited condition that develops after receiving an anesthetic and is a medical emergency (AORN, 2010b; Schick and Windle, 2010).</p> |
|--|---|

STEP

RATIONALE

Clinical Decision Point If patient underwent a short procedure under procedural sedation, check agency policy for sedation recovery guidelines. The perianesthesia registered nurse (RN) monitoring a patient who receives procedural sedation/analgesia should have no other responsibilities that compromise continuous patient monitoring (AORN 2010c; Schick and Windle, 2010). Monitor oxygenation until patients are no longer at risk for hypoxemia. Monitor ventilation and circulation at regular intervals until patients are suitable for discharge (ASA, 2012).

d Maintain patent airway:

- (1) Position patient on side with head facing down and neck slightly extended (see illustration). Never position patient with hands over chest (reduces chest expansion).
- (2) Place small folded towel or small pillow under patient's head. If patient is restricted to supine position, elevate head of bed approximately 10 to 15 degrees, extend neck, and turn head to side. Have emesis basin available if patient becomes nauseated.

Extension prevents occlusion of airway at pharynx. Downward position of head moves tongue forward; and mucus or vomitus can drain out of mouth, preventing aspiration. Supports head in extended position. Prevents aspiration if patient should vomit.

Clinical Decision Point If patient is not able to extend neck, turn head to side if possible; suction oropharynx (see Chapter 25) frequently.

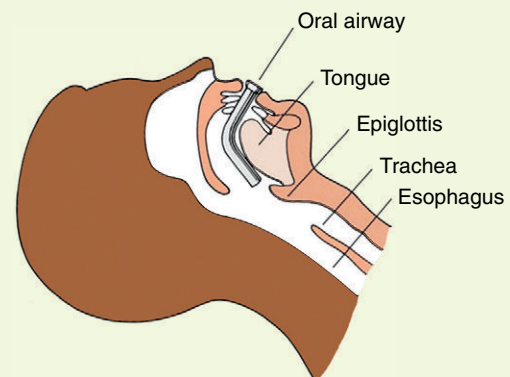

- (3) Encourage patient to cough and deep breathe on awakening and every 15 minutes.
- (4) Suction artificial airway and oral cavity as secretions accumulate.
- (5) Once gag reflex returns, have patient spit out oral airway (see illustration). Do not tape oral airway.
- (6) Avoid rapid position changes in patients who had spinal anesthesia, which can cause changes in patient's blood pressure. Good body alignment is needed. Encourage fluid intake.

Promotes lung expansion and expectoration of mucus secretions. Clears airway of secretions. Indicates that patient can clear airway independently. If airway is taped, patient will gag and may obstruct airway. Rapid movements are avoided so as not to cause spinal headache from loss of cerebrospinal fluid. Increased IV or PO fluids aid body in replacing cerebrospinal fluid.

Critical Decision Point Because of shorter half-life of drugs used today, many patients have oral airway removed before leaving the OR. PACU nurse must assess that respiratory effort is adequate; otherwise airway may need to be replaced, and patient may need a ventilator.

- e** Call patient by name in moderate tone of voice. If there is no response, attempt to arouse patient by touching or gently moving a body part. Explain that patient is in PACU.
- f** Assess circulatory perfusion by inspecting color of nail beds, mucous membranes, and skin. Palpate for skin temperature. Test for capillary refill (see Chapter 6).
- g** Monitor wound drainage:
 - (1) Observe condition of dressing and drains for any evidence of bright red blood. Look underneath patient for any pooling of bloody drainage.

Determines patient's level of consciousness and ability to follow commands. Pink or normal color of skin, nail beds, and mucous membranes and brisk (3 seconds or less) capillary refill indicate adequate perfusion. Warm extremities reveal adequate circulation. Hemorrhage from surgical wound usually occurs within first few hours, indicating that blood vessel was incompletely tied or cauterized during surgery. When dressing becomes saturated, blood oozes down patient's side and collects underneath him or her.

STEP 1d(1) Position of patient during recovery from general anesthesia. (From Lewis S et al: Medical-surgical nursing: assessment and management of clinical problems, ed 8, St Louis, 2011, Mosby.)

STEP 1d(5) Oral airway position before removal.

STEP

RATIONALE

- | | |
|---|--|
| <p>(2) Inspect surgical incision for swelling or discoloration. Note condition of surgical dressing, including amount, color, odor, and consistency of drainage. Mark dressing with circle around drainage using black pen. Place time of marking and check area every 10 to 15 minutes, marking any changes and noting vital signs.</p> <p>(3) Reinforce pressure dressing or change simple dressing if ordered (see Chapter 39). Continue to monitor condition of incision, surrounding tissue, and amount and color of any drainage if incision is exposed or covered with transparent dressing.</p> | <p>Progressive increase or changes in characteristics of drainage warrant call to surgeon because they could indicate hemorrhage (Academy of Medical-Surgical Nurses, 2009; Schick and Windle, 2010). Determines extent of fluid loss and condition of underlying wound. Size, location, and depth of wound influence amount of drainage.</p> <p>Pressure dressing should not be removed because it helps to maintain hemostasis (termination of bleeding) and absorb drainage. Changing dressings immediately after surgery can disrupt wound edges and aggravate drainage. First dressing changes most often occur 24 hours after surgery and are usually done by surgeon. Minor surgical wounds may not have dressings but simply skin closure; or wounds may be covered with transparent dressing, which allows for observation of incision and surrounding tissue (Academy of Medical-Surgical Nurses, 2009).</p> |
| <p>(4) Inspect condition and contents of any drainage tubes and collecting devices. Note character and volume of drainage (see illustration) (see Chapter 38).</p> <p>(5) Observe patency and intactness of urinary catheter system (if present). Note volume and character of urine.</p> | <p>Determines drainage tube patency and extent and character of wound drainage.</p> <p>Patent drainage system prevents bladder distention. Urine volume monitors renal function and perfusion. Decreased output (less than 30 mL/hour in an adult) is an early sign of hypovolemic shock.</p> |
| <p>(6) If nasogastric (NG) tube is present, validate correct placement and irrigate per protocol (see Chapter 34) with normal saline if ordered.</p> <p>(7) Continue monitoring IV fluid rates. Observe IV site for signs of infiltration such as swelling, edema, redness, warmth, discomfort, and leakage of IV fluid (see Chapter 28).</p> | <p>Maintains patency of tube to ensure gastric decompression (removal of pressure caused by gas or liquid). Normal saline is isotonic and will not increase loss of fluid and electrolytes from stomach.</p> <p>Continuous regular infusion of IV fluids maintains patient's fluid intake to maintain adequate hydration and circulatory function.</p> |
| <p>h As patient awakens, provide mouth care by placing moistened washcloth to lips, swabbing oral mucosa with toothette dampened in water, or applying petrolatum to lips. Sips of tap water and ice chips may also be ordered.</p> | <p>Patient remains at risk for aspiration and should not receive fluids to rinse mouth. Moist cloth, toothette, or sips of water and/or ice chips can be soothing to dry mucosa.</p> |

STEP 1g(4) Note color of drainage in Jackson-Pratt drain.

STEP

RATIONALE

- i Continue to monitor and provide pain medication as ordered and when vital signs have stabilized (Schick and Windle, 2010; TJC, 2012a).
- j Encourage patient to practice ankle circles and calf-pumping exercises.
- k Explain to patient how he or she is progressing and that plans for transfer to a nursing division are being made.
- l Once all physiologic signs have stabilized, contact surgeon for order to release patient to nursing unit. Measure all I&O before transferring patient to nursing division.

Pain increases the stress response and interferes with postoperative exercises. Pain medication can affect vital signs if effect of anesthetic is still present. Patient with spinal anesthesia is unable to feel sensation below level of spinal cord. Patient will need pain medication as regional anesthetic wears off.

These leg exercises encourage venous return. If spinal or epidural anesthetic was used, leg exercises help effects of regional anesthetic to wear off once drug has been substantially metabolized by liver.

Helps patient remain oriented to surroundings and recovery activities.

Surgeon is responsible for dictating level of observation and care required by patient. I&O while in PACU is important baseline information to include in report to nurse in nursing division.

Clinical Decision Point *If patient is to be discharged to home, ensure that patient has someone to drive him or her home and observe him or her for signs and symptoms of complications. Review with patient and driver reportable signs and symptoms and emergency care needed.*

2 Phase II level of care: Convalescent period:

- a Make final check of equipment setup in patient's room, including emesis basin and waterproof pads. Be sure that bed is in high position (level with stretcher) and wheels are locked.
- b On arrival at patient's room help PACU staff and use three-person carry or slide board to transfer patient to bed (see Chapter 9).
- c Once patient is transferred to bed, immediately attach any existing oxygen tubing, hang IV fluids, check IV flow rate, attach NG tube to suction, and place indwelling catheter in drainage position.
- d Conduct complete assessment of all vital signs. Compare findings with vital signs in recovery area and patient's baseline values. Depending on agency policy, continue monitoring as ordered and as condition warrants (e.g., a typical order might read: VS q 15 min \times 4, q 30 min \times 2, q 1 hr \times 4). Do not assume that further monitoring is unnecessary if patient appears normal during initial assessment.

During transfer patient's status may change, necessitating quick interventions on arrival. Availability of equipment ensures smooth transfer process. Locked wheels prevent bed from moving during transfer.

Technique avoids strain on nurses' back muscles and maintains patient's safety.

Maintains patient's oxygenation, circulation, and elimination functions. Allows for frequent monitoring of I&O. Provides for patient's comfort. Prevents potentially contaminated urine backflow into sterile bladder, thus decreasing incidence of bladder infections.

Patient should be stabilized once transferred to nursing division. Change in vital signs may reveal onset of postoperative complications.

Clinical Decision Point *Report to anesthesiologist and/or surgeon any findings that differ from previous assessment.*

- e Maintain a patent patient airway:
 - (1) Position patient on side (if allowed); if patient remains sleepy or lethargic, keep head extended.
 - (2) Encourage deep breathing and coughing, using pillow as an incisional splint every 1 to 2 hours (see illustration).

Positioning minimizes chances of aspiration.

Promotes lung expansion and expectoration of mucus.

STEP 2e(2) Techniques for splinting incisions. (From Lewis S et al: Medical-surgical nursing: assessment and management of clinical problems, ed 8, St Louis, 2011, Mosby.)

STEP	RATIONALE
<p>f Be sure that any drainage tubes are connected to proper suction or drainage device. If NG tube is present, validate correct placement, irrigate as ordered, and connect to proper drainage device (see Chapter 34).</p> <p>g Assess patient's surgical dressing for intactness and presence and character of drainage. Reinforce as ordered. If no dressing present, inspect condition of wound (see Chapter 38).</p>	<p>Maintains drainage tube patency so wound beds remain dry for healing. Occlusion of NG tube can lead to abdominal distention, vomiting, and aspiration.</p> <p>Wound can hemorrhage quickly during early postoperative period. Observations of wound and dressings provide data to measure progress of wound healing.</p>
<p>Critical Decision Point <i>If unable to change dressing, mark area of drainage and label with time, date, and initials. Record frequency of reinforcement. Never use felt tip marker to mark dressing because ink can bleed into gauze, contaminating incision site.</i></p>	
<p>h Assess for bladder distention if patient does not have indwelling catheter. Offer bedpan or urinal if patient senses urge to void.</p>	<p>Anesthetics and analgesics depress sensation of bladder fullness. Patient may still have no sensations below level of spinal or epidural anesthetic.</p>
<p>Critical Decision Point <i>Initiate measures to stimulate voiding within 4 hours of surgery or removal of indwelling catheter to prevent urinary retention with overflow (see Chapter 33).</i></p>	
<p>i Measure and record all sources of fluid I&O (see Chapter 6).</p> <p>j Position patient for comfort; maintain airway and correct body alignment. Avoid positioning on surgical wound site or with pressure on popliteal space.</p> <p>k Encourage patient to continue with leg exercises every 1 to 2 hours. If patient is unable or unwilling to do them, do passive range of motion (see Chapter 10).</p> <p>l If ordered, apply elastic stockings or pneumatic compression cuffs to lower extremities and attach to compressor (see Chapter 10). Explain to patient that compression cuffs will inflate and deflate intermittently.</p> <p>m Explain to patient that you have completed all observations and that you will ask family members or significant other to enter room. Place bed in lowest position with call light within reach and raise side rails as appropriate.</p> <p>n Explain patient's general status to family and/or significant other, describe purpose of any equipment in room, and explain reason for frequent observations and procedures.</p> <p>o Give family simple tasks to perform such as wiping patient's face with washcloth and coaching postoperative exercises.</p> <p>p Refer to PACU record to determine if pain medication was administered.</p> <p>(1) Always ask patient to rate severity of pain on an analog scale or whichever pain scale you use at your agency (TJC, 2012a).</p> <p>(2) Administer analgesic if vital signs remain stable or initiate patient-controlled analgesia (PCA) if ordered (see Chapter 15).</p> <p>q Provide oral hygiene and repeat as needed.</p> <p>r As patient stabilizes over next hours or days, perform following measures:</p> <p>(1) Have patient participate in postoperative exercises.</p> <p>(2) Encourage use of incentive spirometer if ordered. Watch patient use spirometer first few times to judge efficacy of breathing pattern. Chart level that patient can achieve.</p> <p>(3) Begin activity orders. Assess vital signs first time patient sits or stands to judge tolerance.</p> <p>(4) Monitor bowel sounds per protocol and ask if patient has passed flatus.</p> <p>(5) Begin dietary orders slowly according to patient's tolerance. Medicate with antiemetic if patient is nauseated. Give analgesic with antiemetic until patient is eating well.</p>	<p>Helps in monitoring fluid and electrolyte balance.</p> <p>Good positioning reduces stress on suture line and decreases risks of aspiration and impaired circulation. Comfortable position helps patient relax.</p> <p>Leg exercises increase venous return, which decreases risk for thrombophlebitis. Range-of-motion exercises maintain joint mobility.</p> <p>Increases venous return. Explanation decreases anxiety and fosters cooperation.</p> <p>Promotes patient's orientation and sense of well-being. Lowest position minimizes injury if patient becomes confused and tries to get out of bed. Call light and side-rail positioning ensure patient's safety as effects of anesthetic continue to diminish.</p> <p>Family and significant others normally are anxious to learn about patient's status. Unfamiliar sights (equipment and patient's appearance) also cause anxiety. Family's and significant other's understanding can promote their participation in patient's care.</p> <p>Give family purpose and reinforces skill in basic care measures.</p> <p>Pain relief is essential for patient to be able to perform postoperative exercises. Patient is best judge of their pain. Pain scale provides an objective measure for nurse to interpret patient's progress.</p> <p>Maintenance of moist mucous membranes facilitates expectoration of secretions and promotes comfort.</p> <p>Promotes pulmonary and circulatory function to minimize onset of postoperative complications.</p> <p>Promotes lung expansion. Helps monitor progress and demonstrates if you need to encourage patient to inhale more deeply.</p> <p>Early ambulation promotes circulation, lung expansion, and peristalsis. Sudden positional changes cause postural hypotension.</p> <p>There is evidence that return of flatus is more accurate than bowel sounds in detecting return of peristalsis after abdominal surgery.</p> <p>Promotes normal fluid and electrolyte balance, restores nutritional intake, and promotes normal GI function and wound healing.</p> <p>Analgesics often cause nausea on an empty stomach.</p>

STEP

RATIONALE

- (6) Promote normal voiding pattern. Assess bladder volume with bladder scanner. Male patients often need help to stand to void. Female patients need to sit on bedpan in bed or chair so legs can be bent and dangling or helped to bathroom.

Promotes normal urinary elimination and prevents bladder distention and urinary retention with overflow. A more natural voiding position helps patient void.

Clinical Decision Point *If patient does not void within 8 hours after surgery or bladder becomes distended, notify surgeon. You may have to insert urinary catheter.*

- (7) Closely monitor progress of wound healing and change dressings as ordered.

Wound infection occurs most often within 3 to 6 days after surgery. Wound dehiscence occurs most often 3 to 11 days after surgery.

Clinical Decision Point *Delayed wound healing may result in wound dehiscence or evisceration. This occurs most frequently after coughing, sneezing, vomiting, or getting up from a sitting position. Remind patient to use caution during these activities and use pillow to splint incision. Evisceration is a medical emergency.*

- (8) Monitor and maintain wound drainage devices such as Jackson-Pratt, Hemovac, or Penrose drains. Jackson-Pratt and Hemovac drainage systems must be emptied whenever they are half full of drainage or air and recharged (compressed to discharge air) (see illustration).
(9) Monitor drainage for color, consistency, and amount every 4 to 8 hours. Compare to previous assessment.

Wound drainage devices promote healing from inside to outside and relieve pressure on suture line. Compressing flexible closed container and then plugging drainage hole creates negative suction pressure.

- s** Gradually increase patient's involvement in decision making and any explanations about surgery and related implications.
- t** Teach patient and family signs and symptoms of complications such as infection, dehiscence, excessive bleeding; need for nutrition for wound healing; and techniques of wound care if needed.
- u** Discuss with patient and family or significant other plans for discharge.
- v** Prepare to make referral for home or convalescent care as patient's condition dictates. Obtain order from surgeon.

Drainage should progress from sanguineous to serosanguineous to serous in color, become more watery, and decrease in amount as wound heals.

Promotes patient's sense of control and independence. Encourages feeling of self-esteem.

Early discharge necessitates patient and family involvement because complications often occur after patient goes home.

Allows nurse to anticipate patient's needs in home setting and discuss any problems that might arise.

If patient continues to need nursing care or rehabilitation after discharge, surgeon's order is necessary. Referral provides continuity of care.

STEP 2r(8) Charging Jackson-Pratt drainage system.

EVALUATION

- 1 Compare all vital sign assessment measurements with patient's baseline and expected normal levels.
- 2 Measure patient's perception of pain after implementing pain-relief measures such as positioning and use of analgesics.
- 3 Monitor changes in surgical wound at least every shift.
- 4 Monitor lung sounds following postoperative exercises.

Evaluates patient's respiratory, cardiovascular, and thermoregulatory status throughout recovery.

Determines level of comfort achieved and effectiveness of pain-relief measures.

Provides data to measure progress of wound healing.

Determines status of airways.

STEP

RATIONALE

- | | |
|--|---|
| <p>5 Auscultate bowel sounds at least each shift and ask patient if he or she has passed flatus.</p> <p>6 Monitor I&O balance for each shift.</p> <p>7 Discuss with patient general level of comfort and progress toward recovery.</p> <p>8 Conduct physical assessments appropriate for patient's unique type of surgery.</p> | <p>Allows you to evaluate return of peristalsis and diet tolerance.</p> <p>Indicates onset of fluid imbalances.</p> <p>Gives patient sense of participation in care. Patient's perceptions are helpful in noting onset of complications. Reveals readiness to learn about discharge.</p> <p>Allows nurse to monitor course of recovery.</p> |
|--|---|

Unexpected Outcomes

- 1 Vital signs are above or below patient's baseline or expected range.

- 2 Patient continues to experience incisional pain. Analgesic dosage may be insufficient.
- 3 Abnormal or diminished breath sounds are auscultated. This is sometimes caused by bronchial constriction, mucus secretions in large airways, or atelectasis.

- 4 Patient exhibits signs of hypovolemia related to hemorrhage.

- 5 Patient complains of calf tenderness and warmth; may exhibit redness and edema in lower extremity (signs and symptoms of venous thrombosis or thrombophlebitis).
- 6 Bowel sounds are absent or decreased. Postoperative paralytic ileus can develop as a common complication after bowel surgery.

- 7 Patient develops fever, tenderness, and pain at wound site; increased white blood cell count (WBC) or purulent drainage is present. These are signs and symptoms of wound infection.
- 8 Patient reports feeling something in wound "give way." Increased serosanguineous drainage occurs. Possibly indicates wound dehiscence or evisceration.

- 9 I&O measurements and laboratory values reflect fluid volume excess or deficit.
- 10 Patient is unable to discuss discharge plans or has negative view of recovery. Possibly indicates that he or she is coping poorly with stress of surgery.

Related Interventions

- Ensure that patient is fully awake from anesthesia before giving large doses of opioids.
- Ensure that patient's family does not medicate patient with PCA. Monitor geriatric patient closely for opiate sensitivity—patient may require use of opiate antagonist such as naloxone in presence of bradypnea.
- Medicate for pain as indicated; titrate analgesics to maximize pain relief; assess patient's use and understanding of PCA device.
- Notify surgeon for symptoms of internal bleeding or shock such as hypotension or tachypnea.

- Initiate different nonpharmacologic relief measures (positioning, relaxation). Call surgeon for additional analgesic orders.
- Notify surgeon and request order for incentive spirometer (IS) if not already ordered.
- Change position to promote chest expansion.
- Encourage patient to turn, deep breathe, cough, and use IS more often.
- Assess history of asthma or allergic response to medication when wheezing or stridor is auscultated.

- Elevate legs but do not lower head past flat position.
- Administer oxygen as ordered.
- Increase rate of IV fluids or administer blood products as ordered.
- Monitor pulse and blood pressure every 5 to 15 minutes.
- Apply pressure dressing to external wound if not contraindicated.

- Notify surgeon and anticipate orders for bed rest, leg elevation, and initiation of anticoagulation (e.g., heparin IV drip).
- Do not massage affected leg.
- Continue to have patient do leg exercises with unaffected leg.

- Intestinal motility may return slowly, depending on anesthetic effects.
- Keep IV line in place.
- Encourage turning and ambulation.
- Continue monitoring bowel sounds and passage of flatus every 4 hours.
- Report findings to surgeon.

- Notify surgeon and anticipate orders for culture of wound drainage and IV antibiotics.

- Report wound dehiscence and/or evisceration to surgeon immediately because it could be life threatening.
- If evisceration has occurred, cover abdominal contents with sterile gauze saturated with sterile normal saline and prepare patient for emergency surgery.

- Continue to monitor strict I&O and check IV rate. Contact surgeon if 24-hour totals continue to reflect imbalance.

- Discuss discharge plans and instructions with significant family member or friend.
- Encourage patient to express fears and concerns.
- Refer patient to support group if appropriate.
- Notify surgeon and request referral for counseling if necessary.

Recording and Reporting

- Document patient's arrival in PACU or nursing division; record vital signs, level of consciousness, assessment findings, and all nursing measures initiated in nurses' notes and EHR. Depending on agency policy, continue documentation every 15 minutes until stable, then every 30 minutes $\times 2$, every hour $\times 4$, and every 4 to 8 hours as condition warrants.
- Record vital signs, oxygen saturation, temperature, and I&O on appropriate flow sheets.
- Report any abnormal assessment findings and signs of complications to nurse in charge and/or surgeon.

Special Considerations

Teaching

- If patient had spinal or epidural anesthetic, remind family or significant other that loss of extremity movement is normal for several hours.
- Reinforce preoperative teaching regarding coughing, deep breathing, leg exercises, and information concerning ambulation and pain control.
- Instruct patient and primary caregiver to identify signs and symptoms and appropriate actions to take for infection, respiratory, circulatory, or GI difficulties and wound disruptions.
- Provide important phone numbers to patient and primary caregiver for use in event of emergency and for follow-up care on discharge.
- Teach patient about appropriate wound care, diet recommendations, and activity restrictions.
- Patient teaching for ambulatory surgical patients
 - Surgeon's office and surgery center telephone number (24-hour answer)
 - Follow-up appointment, date, time
 - Review of prescribed medications
 - Guidelines related to specific surgery
 - Dressing and wound care
 - Pain control
 - Activity restrictions
 - Guidelines related to possible effects of anesthesia
 - Dietary restrictions

- Activity restrictions
- Signs and symptoms of complications

Pediatric

- Keep parent-child separation to a minimum. When a parent cannot be present, it is important to leave a transitional object (favorite possession) with child.
- Be alert for allergic responses and signs and symptoms of malignant hyperthermia in children who have not been exposed to drugs or anesthetic agents. Family history of allergies makes child at high risk for experiencing similar reactions.
- Vomiting is a major concern in young children because of increased risk for fluid and electrolyte imbalances and risk for aspiration. Vomiting is also more likely because surgery in children is often necessitated by accidental injuries without benefit of NPO status.
- Voiding before discharge from ambulatory surgery is not usually required for young children.
- Undermedicating young children may be based on myth that opiates are more dangerous for infants. The fact is that "by 3 to 6 months of age, healthy infants can metabolize opioids similarly to older children" (Hockenberry and Wilson, 2011). Observing the normalizing of vital signs and behavior after administration of analgesics is a valuable clue that pain really existed before treatment (Hockenberry and Wilson, 2011).

Gerontologic

- The ability of older adults to tolerate surgery depends on extent of physiologic changes that have occurred with aging, presence of any chronic diseases, and duration of surgical procedure.
- Undermedicating older adults is common. Asking patients to rate their pain before and after administration of analgesics and asking which numeric rating is acceptable to them are better methods of individualizing care.

Home Care

- Teach primary caregiver about any postoperative exercises, pain management, home modifications, and diet and activity limitations.
- If patient is discharged with dressing changes, bedroom or bathroom is usually an ideal location for the procedure. Have primary caregiver perform return demonstration of dressing change.

Critical Thinking Exercises

You are assigned to care for Mrs. Edmonds, a 52-year-old African-American who is 5 feet tall and weighs 113.6 kg (250 lbs). She is married with three adult children and is employed as an attorney. You just received her from the postanesthesia care unit following an abdominal hysterectomy for fibroid tumors and a bladder neck suspension. Her previous medical history includes 30-year, 2-pack-per-day cigarette smoking and type 2 diabetes; and she has been on birth control pills for 20 years. She has an abdominal dressing that has a small amount of shadowing on it, is on oxygen at 2 L via nasal cannula, and has both a Foley catheter and a suprapubic catheter draining pink-tinged urine. She has an intravenous (IV) infusion of $D_5\frac{1}{2}NS$ infusing at 125 mL/hr and a morphine patient-controlled analgesia (PCA) device. She received Ancef IV piggyback approximately 45 minutes before her incision was made and is to receive her second dose 8 hours later.

- 1 Which risk factors does Mrs. Edmonds have for developing a surgical site infection (SSI), and what is your role in infection prevention at this point in her care?
- 2 Which topics should be included in Mrs. Edmonds' postoperative teaching, and who should be included?

- 3 Which other postoperative complications is Mrs. Edmonds at risk for developing, and what are the nursing implications? Provide the rationale.
- 4 Before performing postoperative exercises, what should the patient be instructed to do?

REVIEW QUESTIONS

- 1 Prevention of surgical site infections (SSIs) requires numerous actions by both the surgical team and the patient. Select the measures that are used to reduce SSIs. (Select all that apply.)
 - 1 Discharge patient from the hospital as soon as possible.
 - 2 Shampoo hair before neck or back surgery.
 - 3 Give prophylactic antibiotic therapy as close to the time of incision as possible.
 - 4 Shave excess hair with a razor just before the surgery begins.
 - 5 Control hyperglycemia in diabetic and nondiabetic patients.
 - 6 Give a shower or bath after the preoperative enema is evacuated.

- 2 There are numerous measures to prevent venous thromboembolism during the postoperative period. Which intervention would be most appropriate before the surgery begins?
 - 1 Performing an assessment for Homans' sign
 - 2 Applying compression devices of some type
 - 3 Teaching patient coughing and breathing techniques
 - 4 Instructing patient how to ambulate after surgery
- 3 A female patient's ethnicity requires that a male member of the family give consent for the scheduled surgery. Which approach by the nurse is the most appropriate?
 - 1 Find out how much the patient understands about the scheduled procedure
 - 2 Have the patient sign the consent first with the male family member observing and then signing afterward
 - 3 Have the male member sign the consent form first and then have the patient sign
 - 4 Refer to agency protocol for implementing this type of informed consent
- 4 The risk manager is explaining the use of "do not resuscitate" (DNR) orders in the surgical environment during an in-service that is being held for the new surgical team. Which statement is true regarding DNR orders?
 - 1 DNR orders should remain in effect throughout all stages of surgical procedures.
 - 2 DNR orders should automatically be suspended during and immediately following surgical procedures.
 - 3 The surgeon should discuss and document issues with the patient and/or family to determine whether DNR orders are to be maintained or modified during surgical procedures.
 - 4 Patients with DNR orders typically are not generally candidates for surgical procedures.
- 5 A patient was admitted from the postanesthesia care unit (PACU) to the medical-surgical unit following a colectomy. On initial examination a dime-size amount of drainage is noted on the abdominal dressing. Which intervention should be implemented?
 - 1 Do nothing because this is an expected outcome for the postoperative patient.
 - 2 Mark the dressing with a circle around the drainage.
 - 3 Remove the dressing to assess the exact amount of bleeding.
 - 4 Immediately notify the surgeon.
- 6 According to the CDC, the recommended goal for use of most prophylactic antibiotic therapy is to give the antibiotic:
 - 1 Within 2 hours of incision time and for no longer than 48 hours after surgery.
 - 2 Within 1 hour of incision time and for no longer than 24 hours after surgery.
 - 3 Within 1 hour of incision time and for no longer than 48 hours after surgery.
 - 4 Within 2 hours of incision time and for no longer than 24 hours after surgery.
- 7 For patients who are unable to perform exercises, the sequence of exercises to be provided by the patient care provider is:
 - 1 Leg exercises, turn, deep breathe, cough.
 - 2 Deep breathe, cough, leg exercises, turn.
 - 3 Turn, cough, deep breathe, leg exercises.
 - 4 Cough, deep breathe, leg exercises, turn.
- 8 General anesthesia predisposes patients to the following respiratory problems except:
 - 1 The lungs are not fully inflated during surgery.
 - 2 The cough reflex is suppressed.
 - 3 Mucus collects within airway passages.
 - 4 Spontaneous postoperative pneumothorax.
- 9 Which assignment would the registered nurse (RN) delegate to the NAP?
 - 1 Manage the postoperative care of the patient
 - 2 Initial assessments on arrival to the PACU
 - 3 Discharge teaching to the ambulatory care patient
 - 4 Care of the patient requiring monitoring and providing comfort measures
- 10 The three levels of care ASPAN identified during the recovery process are: (Select all that apply.)
 - 1 Preoperative assessment level of care.
 - 2 Postanesthesia phase I level of care.
 - 3 Postanesthesia phase II level of care.
 - 4 Extended care level of care.

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Describe the meaning of a sterile conscience.
- Describe the roles of a registered nurse in the operating room.
- Identify guidelines for use of sterile technique in the operating room.
- Perform surgical hand antisepsis correctly.
- Describe how to correctly don a sterile surgical gown.
- Apply sterile gloves using the closed technique.

Nurses practicing in the operating room (OR) support patients' surgical experiences from the preoperative phase throughout the intraoperative period and into the various postoperative phases (see Chapter 36). The standards of clinical practice that registered nurses (RNs) follow within the OR provide an optimal level of care that ensures patients' safety and comfort (AORN, 2011a). One should exercise judgment, critical thinking, and interpersonal communication skills and apply the nursing process to ensure that patients receive appropriate nursing care during the perioperative experience.

Members of the surgical team include the surgeon (doctor of medicine [MD] or doctor of osteopathy [DO]), physician's assistant (PA), registered nurse first assistant (RNFA), certified registered nurse anesthetist (CRNA) and/or physician anesthesiologist (MD or DO), circulating nurse (RN), and scrub nurse/technician (RN, licensed practical nurse [LPN], or certified surgical technologist [CST]). The intraoperative phase begins when a patient enters the OR suite and ends with admission to the postanesthesia care unit (PACU). During the intraoperative phase an RN assumes the role of first assistant

to the surgeon, scrub nurse, or circulating nurse. The RNFA is a nurse with advanced education who assists the surgeon with the surgical procedure, performing a combination of nursing and delegated medical functions and/or skills (Box 37-1). The scrub nurse/technician (Box 37-2) is a "sterile" team member who provides the surgeon with instruments and supplies; disposes of soiled sponges; and accounts for sponges, sharps, and instruments on the surgical field. RNs, LPNs, or CSTs may assume the scrub nurse role. The circulating nurse (Box 37-3) is always an RN who is the charge nurse in the room (AORN, 2011b). The circulating nurse is a "nonsterile" member of the surgical team who uses the nursing process and assumes responsibility and accountability for maintaining patient safety and continuity of quality care. This includes supervising the conduct of the scrub technician and delegating tasks to licensed and nursing assistive personnel (NAP) as appropriate. The circulating nurse also assists the first assistant, scrub nurse/technician, and surgeon.

It is essential that perioperative nurses develop a sterile conscience. A sterile conscience requires knowledge of the principles of aseptic technique; self-discipline; good

BOX 37-1 Role and Responsibilities of a Registered Nurse First Assistant

The registered nurse first assistant (RNFA) role is an expansion of the traditional perioperative nursing role, and areas of responsibility overlap. Responsibilities specific to the practice of first assisting include:

- Participating in “time out” procedure with other surgical team members (safety measure taken to ensure correct patient, correct procedure, correct site and side, correct patient position, and correct implants/equipment present) (TJC, 2011).
- Providing surgical exposure (assisting in retracting tissues and suctioning surgical field).
- Providing hemostasis (control of bleeding).
- Handling and/or cutting tissue.
- Using surgical instruments/medical devices and suturing.
- Performing wound closure.
- Applying human anatomic and physiologic considerations in practice; recognizing structure, function, and location of tissues and organs; manipulating tissues accordingly to avoid injury.
- Ensuring preoperative and postoperative patient management in collaboration with other health care providers.

From Association of periOperative Registered Nurses (AORN): *AORN standards and recommended practices for perioperative nursing—position statement: AORN official statement on RN first assistants*, Denver, 2010a, The Association.

BOX 37-2 Role of the Scrub Nurse

- Helps circulating nurse prepare OR, open supplies
- Performs surgical hand antisepsis and dons sterile gown and gloves
- Prepares sterile field with procedure-appropriate supplies and instruments, verifying that all are in working order
- Participates in “time out” procedure with other surgical team members (safety measure taken to ensure correct patient, correct procedure, correct site and side, correct patient position, and correct implants/equipment present) (TJC, 2011)
- Performs sponge, sharps, and instrument counts with circulating nurse before incision is made, at the beginning of wound closure, and at the end of the surgical procedure
- Labels all liquids and/or medications on sterile field with sterile marking pen when liquid or medication is out of the original container or package
- Gowns and gloves surgeons and assistants as they enter the OR
- Assists surgeons with sterile draping of patient
- Keeps sterile field orderly and monitors progress of procedure and any breaks in aseptic technique
- Passes sterile instruments and supplies to surgeons and assistants
- Handles surgical specimens per agency policy
- Constantly monitors location of all sponges and sharps in the sterile field

OR, Operating room.

communication skills to identify, address, and correct any breaks in sterile technique; and the maturity to overcome personal preferences. If any question exists about sterility of an item, the item is unsterile. For example, if a sterile gown touches the floor while you are putting it on, you discard it and exchange it for a new one.

While the patient is in the OR and the OR team is gowned and gloved, it is recommended that a surgical safety checklist or the [World Health Organization \(WHO\) checklist](#) be completed

BOX 37-3 Role of the Circulating Nurse

- Incorporates nursing process in plan of care
- Organizes and prepares OR before start of surgical procedure; checks to see that equipment works properly
- Gathers supplies for surgical procedure and opens sterile supplies for scrub nurse/technician
- Counts sponges, sharps, and instruments with scrub nurse/technician before incision is made, at the beginning of wound closure, and at the end of the surgical procedure
- Ensures that all liquids and/or medications on the sterile field are labeled with sterile marking pen when liquid or medication is out of the original container or package
- Sends for patient at appropriate time
- Conducts preoperative patient assessment, including the following:
 - Explains role and identifies patient
 - Reviews medical record and verifies procedure and consents
 - Confirms dentures and prostheses removed
 - Confirms patient’s allergies, nothing by mouth (NPO) status, laboratory values, ECG, x-ray film studies, skin condition, circulatory and pulmonary status
- Safely assists patient to operating table and positions patient according to surgeon preference and procedure type, using safety precautions (e.g., safety belt, securing arms, padding bony prominences)
- Participates in “time out” procedure with other surgical team members (safety measure taken to ensure correct patient, correct procedure, correct site and side, correct patient position, and correct implants/equipment present) (TJC, 2011)
- Applies conductive pad to patient if electrocautery used; may prepare patient’s skin; may apply ECG electrodes
- Applies antiembolism stockings and sequential compression device per physician order
- Explains briefly to patient what the circulating nurse and the scrub nurse/technician are doing
- Assists surgical team by tying gowns and arranging equipment
- Assists anesthesia personnel during induction and extubation
- Continuously monitors procedure for any breaks in aseptic technique and anticipates needs of the team; opens additional sterile supplies for scrub nurse/technician
- Handles surgical specimens per agency policy
- Documents on perioperative nurses’ notes
- Communicates to family and PACU personnel during the surgical procedure

ECG, Electrocardiogram; OR, Operating room; PACU, postanesthesia care unit.

(WHO, 2008) (Fig. 37-1). The WHO checklist identifies three phases of an operation, each corresponding to a specific period in the normal flow of work: before the induction of anesthesia (“sign in”), before the incision of the skin (“time out”), and before the patient leaves the operating room (“sign out”). In each phase a checklist coordinator must confirm that the surgery team has completed the listed tasks before it proceeds with the operation.

This checklist verifies the patient’s identity, ascertains if the patient has any allergies, checks if the surgical site is marked and re verifies the site marking, and asks the patient if he or she has any questions. A time out is conducted immediately before starting any invasive procedure or making an incision (TJC, 2011). Time outs are standardized by each hospital, initiated by a designated member of the team, and involve all the immediate members of the surgical/procedure team who will be participating in the procedure from start to finish. It is during the time out that the team members

- shoulders to table level and on the sleeves to 5 cm (2 inches) above the elbow.
- 3 Sterile persons must keep their hands in view, above waist level and below neckline, to avoid contamination.
 - 4 When wearing a sterile gown, do not fold arms with hands tucked in the axillary region. This area is not considered sterile once you have donned the gown. Perspiration can lead to strike through, or contamination that occurs when moisture permeates a sterile barrier.
 - 5 Sterile-draped tables are sterile only at table level. Sides of the drape extending below table level are unsterile.
 - 6 All personnel moving around or within a sterile field must do so in a manner consistent with maintaining the sterility of that

- field. Scrubbed persons move from sterile areas to other sterile areas, contacting a sterile field only with sterile gowns and gloves. Unscrubbed persons always stay at least 30 cm (12 inches) away from the sterile field while keeping it in constant view; they touch only unsterile areas.
- 7 Group all sterile supplies and equipment around the sterile-draped patient.
- 8 Unsterile persons must avoid reaching over the sterile field.
- 9 Scrubbed persons remain close to the sterile field. When changing position, turn face to face or back to back.

SKILL 37-1 Surgical Hand Antisepsis

In the operating room (OR) setting it is imperative that you achieve surgical hand antisepsis through effective surgical scrub or antiseptic hand rub (AORN, 2011c). To reduce patient risk for acquiring postoperative infections, use of an antimicrobial preparation for hand antisepsis is an integral part of the presurgical scrubbing procedure for OR personnel. Although the skin cannot be sterilized, you can reduce the number of microorganisms greatly by chemical, physical, and mechanical means.

The surgical hand scrub has been the traditional method for surgical asepsis. Through the use of an antimicrobial agent and sterile brushes or sponges, the surgical hand scrub removes debris and transient microorganisms from the nails, hands, and forearms; reduces the resident microbial count to a minimum; and inhibits rapid/rebound growth of microorganisms (AORN, 2011c). Evidence suggests that a brushless technique, with or without water, containing at least 60% alcohol, is an alternative to the traditional hand scrub with a brush with the same microbial efficacy (AORN 2011c; TJC, 2011). Both hand antiseptic methods are currently used in OR settings.

Surgical attire (i.e., scrubs) is worn in the operating room to reduce the chance for contamination between surgical personnel and patients (AORN, 2011d). Keep your fingernails short (¼ inch in length), clean, and healthy. If you wear polish, make sure that it is not chipped or older than 4 days. Never wear artificial nails (AORN, 2011c). Remove watches and bracelets before the surgical scrub. Rings should not be worn in the operating room (Cook, 2011).

The Association of periOperative Registered Nurses (AORN, 2011c) recommends a 3- to 5-minute hand and arm scrub with an approved antimicrobial agent for all surgical procedures. Surgical hand-scrub procedure for all staff using either the anatomic timed scrub or the counted-stroke method should be standardized (AORN, 2011c) (see agency policy). Some procedures, described as clean procedures (e.g., laryngoscopy and proctoscopy), require performing hand hygiene but not necessarily surgical hand antisepsis.

Delegation and Collaboration

The skill of surgical hand antisepsis can be delegated to a surgical technologist or licensed practical nurse. The registered nurse routinely observes surgical hand antisepsis for staff compliance.

Equipment

- Deep sink with foot or knee controls for dispensing water and soap
- Antimicrobial agent approved by agency (dispenser with foot controls)
- Surgical scrub brush with plastic nail file
- Paper face mask, cap or hood, surgical shoe covers
- Protective eyewear/face shield
- Sterile towel
- Sterile pack containing sterile gown

STEP

RATIONALE

ASSESSMENT

- 1 Determine type and length of time for hand hygiene (see agency policy).
- 2 Remove bracelets, rings, and watches.
- 3 Inspect fingernails, which must be short (¼ inch), clean, and healthy. Nail polish that is chipped should be removed before entering surgical area. Never wear artificial nails or extenders.
- 4 Inspect condition of cuticles, hands, and forearms for presence of abrasions, cuts, or open lesions.

Guidelines vary regarding ideal time needed for surgical scrub.

Jewelry harbors and protects microorganisms from removal. Skin under rings has been shown to harbor more pathogens and should not be worn (Cook, 2011).

Long nails and chipped or old polish harbor greater numbers of bacteria (AORN, 2011c). Long fingernails can puncture gloves, causing contamination. Artificial nails harbor gram-negative microorganisms and fungus (AORN, 2011c).

Cuts, abrasions, exudative lesions, fresh tattoos, or hangnails tend to ooze serum, which may contain pathogens. Individuals with these conditions should not have patient contact until conditions heal (AORN, 2011c).

STEP

RATIONALE

NURSING DIAGNOSIS

- Risk for infection

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient does not develop signs of surgical site infection.

Indicates that microorganisms are not transferred to patient and sterile field.

IMPLEMENTATION

- 1 Don surgical shoe covers, cap or hood, face mask, and protective eyewear.

Protective eyewear prevents exposure to blood or body fluids splashing from sterile field, which causes risk for infection (e.g., human immunodeficiency virus [HIV], hepatitis B virus [HBV]).

Clinical Decision Point *Laser surgery requires special protective eyewear to prevent eye damage from stray laser energy.*

- 2 Perform prescrub wash at beginning of work shift.
 - a Turn water on using foot or knee control and adjust to comfortable temperature.
 - b Wet hands thoroughly with water. Follow manufacturer directions for application of soap.
 - c Rub hands, covering all surfaces, including backs of hands, fingertips, inner webs, and palms, washing for at least 15 seconds.
 - d Rinse well to remove all soap. Dry hands thoroughly with disposable towel and discard towel.

Prevents contamination of hands after scrub.

- 3 **Surgical hand scrub (with sponge):**

- a Turn on water using foot or knee control. Clean under nails of both hands with disposable nail pick or cleaner (see illustration). Rinse hands and forearms under running water.
- b Dispense antimicrobial scrub agent according to manufacturer instructions. Apply agent to wet hands and forearms with soft, nonabrasive sponge.
- c Time a 3- to 5-minute scrub (follow manufacturer instructions). Visualize each finger, hand, and arm as having four sides (see illustrations). Wash all four sides effectively, keeping hand elevated, elbow down. Repeat for other hand, fingers, and arm.

A short prescrub wash/rinse at least 15 seconds at beginning of work shift removes gross debris and superficial microorganisms (AORN, 2011c).

Removes dirt and organic materials that harbor microorganisms.

Ensures removal of resident microorganisms on all surfaces of hands and arms (AORN, 2011c).

Times vary by product.

Scrubbing all surfaces ensures removal of resident microorganisms on hands and arms (AORN, 2011c).

STEP 3a Cleaning under fingernails.

STEP

RATIONALE

- d Avoid splashing surgical attire. Discard sponges in appropriate container.
 - e Rinse hands and arms, running water from fingertips to elbows in one continuous motion, holding hands higher than elbows and away from surgical site (see illustration).
 - f Turn off water using foot or knee controls and back into OR holding hands higher than elbows and away from surgical attire.
 - g Approach sterile setup and grasp sterile towel, taking care not to drip water on sterile field (see illustration).
 - h Keeping hands and arms above waist and outstretched, carefully grasp one end of sterile towel to dry one hand thoroughly, moving from fingers to elbow in rotating motion (see illustration).
 - i Use opposite end of towel to dry other hand.
 - j Drop towel into linen hamper or into circulating nurse's hand.
- 4 Perform spongeless surgical hand scrub with alcohol-based hand-rub product.**
- a After prescrub wash (Step 2) turn on water using foot or knee control. Clean under nails of both hands with a disposable nail pick or cleaner and rinse hands and forearms under running water. Dry hands thoroughly with paper towel. Turn off water.

Hands remain cleanest part of upper extremities.

Water contaminates field.

Avoids sterile towel contacting unsterile scrub attire and transferring contamination to hands. Dries skin from cleanest (hands) to least clean (elbows).

Avoids transfer of microorganisms from elbow to opposite hand.

STEP 3c A, Scrubbing sides of fingers. B, Scrubbing forearms.

STEP 3e Rinsing arms.

STEP 3g Grasping sterile towel.

STEP

RATIONALE

- b** Dispense manufacturer-recommended amount of antimicrobial agent hand preparation (see illustration). Apply agent to hands and forearms according to manufacturer instructions for application, recommended volume, and specified time.
- c** Repeat antimicrobial product application if indicated in manufacturer instructions.
- d** Rub thoroughly until completely dry (see illustration). Proceed to OR to don gloves.

Promotes reduction in microorganisms on all surfaces of hands and arms (AORN, 2011c).

STEP 3h Drying hands thoroughly.

STEP 4b Dispense antimicrobial agent into hands. (Photo Courtesy 3M Health Care.)

STEP 4d Rub thoroughly until completely dry. (Photo Courtesy 3M Health Care.)

EVALUATION

- 1** Monitor patient after surgery for signs of surgical site infection (usually occurs 2 to 3 days after surgery).

Signs of infection include redness, heat, swelling, pain, and purulent drainage.

Unexpected Outcomes

- 1** Redness, heat, swelling, pain, or purulent drainage may develop at surgical site, which often indicates wound infection.

Related Interventions

- Individualize interventions based on patient's situation (e.g., wound care, antibiotic therapy).

Recording and Reporting

- No recording is required for surgical hand antisepsis. Record area and description of surgical site after surgery to provide baseline for monitoring wound.

Special Considerations

Teaching

- Instruct patient and family or significant other how to observe surgical site for signs of infection.

SKILL 37-2 Donning a Sterile Gown and Closed Gloving

Immediately following surgical hand antisepsis, apply a sterile gown and then apply sterile gloves. All members of the surgical team must prepare in this manner before entering the sterile field. Once applied, the surgical gown is considered sterile in the front from chest to waist or table level. The sleeves are considered sterile from 5 cm (2 inches) above the elbow to fingertips. The back of the gown is not considered sterile when worn. Surgical gowns should cover all garments worn underneath. All sterile gowns that are free of tears, punctures, strain, and abrasion provide an effective barrier against microorganisms, particulates, and fluids passing between unsterile and sterile areas (AORN, 2011d).

Use the closed-glove method to apply gloves when you enter the sterile field. If a glove becomes contaminated during the surgery, the circulating nurse, wearing protective unsterile gloves, grasps the outside of the glove and pulls off the glove inside out, leaving the stockinette cuff of the gown in place. Another sterile team member assists in regloving. The open method can be used when only one glove has been contaminated. In some settings the scrub nurse will wear two pairs of sterile gloves. If both of the scrub

nurse/technician's gloves become contaminated, the gown is removed first, then the gloves are removed, and then the nurse regowns and regloves using the closed-glove method.

Delegation and Collaboration

The skills of donning a sterile gown and closed gloving can be delegated to a surgical technologist or licensed practical nurse. The registered nurse routinely observes sterile gown application and closed gloving for staff compliance.

Equipment

- Package of proper-size sterile gloves (latex-free if sensitivity or allergy present)
- Sterile pack containing sterile gown
- Clean, flat, dry surface (table or Mayo stand) on which to open gown and gloves
- Paper face masks, cap or hood, surgical shoe covers
- Protective eyewear/face shield

STEP RATIONALE

ASSESSMENT

- | | |
|---|--|
| <p>1 Select proper size and type of sterile gloves. Select latex-free gloves if you know that patient or any surgical personnel in room are latex sensitive.</p> | <p>Proper fit ensures ease of handling instruments and supplies. Prevents latex allergic response.</p> |
|---|--|

Clinical Decision Point Know your agency policy, because double gloving may be recommended to reduce the risk for glove perforation during a surgical procedure (Fry, 2010; Tanner and Parkinson, 2009; Thomas-Copeland, 2009).

- | | |
|---|--|
| <p>2 Select proper size and type of sterile surgical gown.</p> | <p>Ill-fitting gown impedes movement of extremities.</p> |
|---|--|

NURSING DIAGNOSIS

- Risk for infection
- Related factors are individualized based on patient's condition or needs.*

PLANNING

- | | |
|---|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient does not develop signs of surgical site infection. | <p>Nurse maintains aseptic technique and does not contaminate gown or gloves.</p> |
|---|---|

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Donning sterile gown:</p> <ul style="list-style-type: none"> a Open sterile gown and glove package on clean, dry, flat surface. Scrub nurse (before scrubbing hands) or circulating nurse can do this for you, preferably on small table separate from sterile field containing sterile instruments and supplies. b Perform surgical hand antisepsis (see Skill 37-1). Dry hands thoroughly. c Pick up gown (folded inside out) from sterile package, grasping inside surface at collar. | <p>Provides sterile area for gloving.</p> <p>Hands are not completely sterile. Inside surface of gown will contact surface of skin and thus is considered contaminated.</p> |
|--|---|

STEP

RATIONALE

- d** Lift folded gown directly upward and step back, away from table.
- e** Locate neckband; with both hands grasp inside front of gown just below neckband.
- f** Keeping gown at arm's length away from body, allow it to unfold with inside of gown toward body. Do not touch outside of gown or allow it to touch floor.
- g** With hands at shoulder level, slip both arms into armholes simultaneously (see illustration). Do not allow hands to move through cuff opening. Have circulating nurse pull gown over shoulders by reaching inside arm seams. Pull gown on, leaving sleeves covering hands.
- h** Have circulating nurse tie gown at neck and waist (see illustration). If gown is wraparound style, do not touch sterile front flap until scrub nurse/technician has gloved (see Step 3b).
- 2** Applying gloves using closed-glove method:
- a** With hands covered by gown cuffs and sleeves, open inner sterile glove package (see illustration).
- b** Grasp folded cuff of glove for dominant hand with nondominant hand.

Prevents gown from touching unsterile object.

Clean hands may touch inside of gown without contaminating outer surface.

Outside of gown remains sterile.

Careful application prevents contamination. Gown covers hands to prepare for closed gloving.

Secures gown without contaminating it.

Sterile gown cuff will touch sterile glove surface.

Sterile gown touches sterile glove.

STEP 1g Placing arms in sleeves.

STEP 1h Circulating nurse ties scrub gown.

STEP 2a Scrub nurse opens glove package.

STEP 2d Glove applied as hands remain inside cuffs.

STEP	RATIONALE
<p>c Extend covered dominant forearm forward with palm up and place palm of glove against palm of dominant hand. Glove fingers point toward elbow.</p>	<p>Positions glove for application over cuffed hand, keeping glove sterile.</p>
<p>d While holding glove cuff through gown with dominant hand on which it was placed, grasp back of glove cuff with nondominant hand and turn glove cuff over end of dominant hand and gown cuff (see illustration).</p>	<p>Positions glove over gown for hand insertion.</p>
<p>e Grasp top of glove and underlying gown sleeve with covered nondominant hand. Carefully extend fingers into glove, being sure that cuff of glove covers cuff of gown.</p>	<p>Gloves remain sterile.</p>
<p>f Glove nondominant hand in same manner with gloved, dominant hand (see illustration A). Keep hand inside sleeve. Be sure that fingers are fully extended into both gloves (see illustration B).</p>	
<p>3 Donning wraparound gown:</p>	
<p>a Grasp sterile front flap/paper tab with gloved hands and untie.</p>	<p>Front of gown is sterile.</p>
<p>b Pass sterile paper tab to member of sterile surgical team or to nonsterile team member (e.g., circulating nurse) (see illustration). Keep gown tie in right hand. Circulating nurse stands still as scrub nurse/technician turns.</p>	<p>Nonsterile team member uses caution not to touch sterile tie when taking sterile paper tab while scrub nurse/technician turns.</p>
<p>c Allowing margin of safety, turn to left one-half turn, covering back with extended gown flap. Retrieve sterile tie only from team member and secure both ties in place.</p>	<p>Maneuver covers entire body with gown. Nonsterile team member pulls off paper tab and discards.</p>

STEP 2f A, Second glove applied. B, Gloved fingers extended.

STEP 3b Paper tab on disposable gown is passed to circulating nurse.

STEP

RATIONALE

EVALUATION

- 1 Monitor patient after surgery for signs of surgical site infection (usually occurs 2 to 3 days after surgery).

Signs of infection include redness, heat, swelling, pain, and purulent drainage.

Unexpected Outcomes

- 1 Redness, heat, swelling, pain, or purulent drainage develops at surgical site, which often indicates wound infection.

Related Interventions

- Individualize interventions based on patient's situation (e.g., wound care, antibiotic therapy).

Recording and Reporting

- No recording is required for sterile gowning and gloving. Record area and description of surgical site after surgery to provide baseline for monitoring wound.

Special Considerations

Teaching

- Instruct patient and family to observe surgical site for signs of possible infection. Both staff and patients need to be educated about surgical site infection prevention.

Critical Thinking Exercises

You are assigned to be the circulating nurse for a patient who is having an umbilical hernia repair. She is a 38-year-old Hispanic bookkeeper and mother of five children with no significant medical history except for postpartum hypothyroidism. The surgical team includes Dr. M. Klein; L. Relling, RNFA; Sarah Scott, certified surgical technologist (CST); and Dr. L. Bates, anesthesiologist. Sarah has recently completed an extended orientation but still needs much supervision.

- 1 Sarah is running late because of the staff meeting this morning. You notice that she omits the prescrub hand wash before performing a brushless antiseptic hand rub. What should you do? Explain your choice.
 - 1 Tell Sarah to apply extra hand antiseptic to both hands
 - 2 Tell Sarah that she must start over and perform the prescrub hand wash first
 - 3 Tell Sarah that she must now perform a surgical hand scrub with a brush
 - 4 Do nothing because she is going to apply sterile gloves anyway
- 2 Sarah just had artificial nails applied last night because she is in a wedding tonight. They are polished with no signs of chipping. Is it okay for Sarah to scrub for the hernia repair today? Explain your choice.
 - 1 Yes because the polish was applied just last night
 - 2 Yes because the polish is not chipped
 - 3 No because artificial nails may not be worn
 - 4 No because artificial nails require a longer scrub
- 3 While Sarah prepares the sterile field with the appropriate instruments and supplies for the umbilical hernia surgery, you notice that she reaches down to scratch the top of her leg. She continues to set up the sterile field without taking any action. What should she have done?

- 2 Many newer methods for the surgical scrub have been researched. Which is the traditional method for surgical asepsis?
 - 1 Surgical hand scrub
 - 2 Alcohol foam rub
 - 3 Brushless scrub
 - 4 Waterless scrub
- 3 The scrub nurse is getting ready to do her surgical scrub. What should be done before beginning the scrub?
 - 1 Remove nail polish even if it is not chipped
 - 2 Inspect areas from fingertips to elbows for abrasions or open areas
 - 3 Move rings higher on the knuckles before beginning the scrub
 - 4 Remove bracelets and artificial nails
- 4 The closed-glove method is standard in the operating room for many of the participants. The scrub nurse is performing it correctly if which procedure is observed?
 - 1 Both hands are covered with the cuffs of the gown.
 - 2 Both hands are exposed through the cuffs of the gown.
 - 3 The dominant hand is covered with the cuff of the gown.
 - 4 The nondominant hand is covered with the cuff of the gown.
- 5 Surgical personnel must have a sterile conscience to provide optimum patient safety. Which situation denotes a breach of sterile conscience?
 - 1 The scrub nurse accidentally touches the faucet with one hand while scrubbing and rescrubs his hands.
 - 2 The circulating nurse accidentally touches a sterile item and removes it from the sterile field.
 - 3 The surgeon thinks he contaminated a sterile glove and has the suspect glove changed.
 - 4 Before the scrub nurse dries her hands, she drips water on the sterile gown that she is about to put on and applies the gown.
- 6 If both gloves of a gowned sterile team member become contaminated, one should:
 - 1 First remove the gloves, then the gown, and regown and reglove using open-glove method.
 - 2 Remove the gown first, then the gloves, and regown and reglove using closed-glove method.
 - 3 Remove gown first, then gloves; rescrub and apply new gown and gloves using closed gloving.
 - 4 Remove gloves and gown, rescrub, and apply new gown and gloves using open gloving.

REVIEW QUESTIONS

- 1 Many individuals play a vital role as part of the surgical team. What is included in the responsibilities of the circulating nurse?
 - 1 Performing the surgical hand scrub and donning a sterile gown and gloves
 - 2 Assisting in retracting tissues and suctioning surgical field
 - 3 Conducting perioperative assessment and reviewing medical records for accuracy and completeness
 - 4 Removing liquids and medications from original packages and labels before placing on the sterile back table

- 7 Which of the following statements is true?
- 1 An unsterile item may be used on the sterile field.
 - 2 Sterile persons must keep their hands in view, above the waist and below the neckline to avoid contamination.
 - 3 When a scrubbed person changes positions at the sterile field with another, turn face to back of the other person.
 - 4 The sides of the drape extending below the table level are considered sterile.
- 8 The steps for doing a surgical hand scrub include:
- 1 Inspect hands to ensure that nails are short, no cuts or skin problems. Turn on water; dispense antimicrobial scrub; wash all four sides of fingers, hands, and arms. Do a 3- to 5-minute scrub and rinse off soap. Turn off water using foot or knee controls. Back into operating room (OR) holding hands higher than elbows.
 - 2 Turn on water; dispense antimicrobial scrub; inspect hands to ensure that nails are short, no cuts or skin problems. Wash all four sides of hands, fingers, and arms. Do a 6-minute scrub. Turn off water with paper towel at sink. Back into OR holding hands higher than elbows.
 - 3 Inspect hands to ensure that nails are short, no cuts or skin problems. Turn on water; dispense antimicrobial scrub; wash all four sides of fingers, hands, and arms. Do a 2-minute scrub. Turn off water using foot or knee controls. Back into OR holding hands higher than elbows.
 - 4 Inspect hands to ensure that nails are short, no cuts or skin problems. Use faucet handle to turn on water; dispense antimicrobial scrub; wash all four sides of fingers, hands, and arms. Do a 3-minute scrub. Using a paper towel, turn off faucets. Walk into OR keeping hands higher than elbows.
- 9 Steps for correctly scrubbing and gowning for a surgical environment include:
- 1 Applying alcohol-based rub, putting on sterile gloves, putting on sterile gown.
 - 2 Completing 3- to 5-minute hand scrub, putting on sterile gown, putting on sterile gloves.
 - 3 Putting on sterile gown, completing 3- to 5-minute hand scrub, putting on sterile gloves.
 - 4 Completing 3- to 5-minute hand scrub, putting on sterile gloves, putting on sterile gown.

- 10 Participants in the time out before a procedure or surgery include:
- 1 Immediate members of the procedure team and others who will be participating in the procedure from the beginning.
 - 2 Only the anesthesiologist, surgeon, scrub nurse, and circulating nurse.
 - 3 Only the surgeon, registered nurse first assistant (RNFA), scrub technician, and circulating nurse.
 - 4 Anesthesiologist, circulating nurse, and scrub technologist.

KEY TERMS

Dehiscence	Healing ridge	Jackson-Pratt (JP) drain	Secondary intention
Eschar	Hemostasis	Penrose drain	Tertiary intention
Evisceration	Hemovac drain	Primary intention	Staples
Granulation tissue	Irrigation		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Discuss the response of the body during each stage of the wound-healing process.
- Differentiate between primary- and secondary-intention wound healing.
- Explain factors that impair or promote normal wound healing.
- Perform a wound assessment.
- Perform a wound irrigation.
- Remove sutures or staples.
- Demonstrate care of a wound-drainage system.

Proper wound care is necessary to promote healing that results in an intact skin layer. Intact skin is the first line of defense of the body against invasion by infectious microorganisms. The skin defends the body in other ways by serving as a sensory organ for pain, touch, and temperature; and it has an acid pH, which is often called the *acid mantle*. It also plays a major role in thermoregulation, metabolism, immunity, and fluid balance regulation (Bryant and Nix, 2012).

The skin is the largest external organ. It has two layers: the epidermis and the dermis (Fig. 38-1). The outer layer, the epidermis, has five layers. The outermost layer, the stratum corneum, consists of flattened dead keratinized cells. The thin layer of the stratum corneum prevents dehydration of underlying cells and is a physical barrier to the entry of certain chemicals. The barrier is selective; it allows absorption of topical medications in paste, ointment, and dermal patch forms. The next layers of the epidermis are the stratum lucidum, stratum

granulosum, and stratum spinosum. The innermost layer of the epidermis, the stratum germinativum, is sometimes called the *basal layer*. It is from this single layer of keratinocytes that cells migrate up toward the stratum corneum. Important features of the stratum germinativum are the epidermal protrusions, or “peaks and valleys” that point downward into the dermis. These provide resiliency and integrity to the skin structure. Melanocytes, the cells that give the skin its color, are also in this layer. The area that separates the epidermis from the dermis is called the *dermoepidermal junction* or the *basement membrane zone*.

Beneath the epidermis is the dermis. Collagen (a tough fibrous protein layer), blood vessels, and nerves compose the dermal layer. Collagen composes about 70% of the dermis and is extremely important in wound healing. The dermis restores the physical properties of the skin and its structural integrity. Restoration of both the epidermal and dermal layers is

FIG 38-1 Diagram of layers of skin and subcutaneous tissue.

BOX 38-1 Phases of Wound Healing (Full-Thickness Wounds)

Hemostasis Phase

- Blood vessels constrict; clotting factors activate coagulation pathways to stop bleeding. Clot formation seals the disrupted vessels so blood loss is controlled and acts as a temporary bacterial barrier. Platelets release growth factors, which attract cells needed to begin the repair process.

Inflammatory Phase

- Vasodilation occurs, allowing plasma and blood cells to leak into the wound, noted as edema, erythema, and exudate. Leukocytes (white blood cells) arrive in the wound to begin wound cleanup. Macrophages, a type of white blood cell, appear and begin to regulate the wound repair. The result of the inflammatory phase is a clean wound bed in a patient with a noncomplicated wound.

Proliferative Phase

- Epithelialization (the construction of new epidermis) begins. At the same time new granulation tissue is formed. New capillaries (angiogenesis) are created, restoring the delivery of oxygen and nutrients to the wound bed. Collagen is synthesized and begins to provide strength and structural integrity to the wound. Contraction, which occurs in open wounds, reduces the size of the wound.

Maturation (Remodeling) Phase

- Collagen is remodeled to become stronger and provide tensile strength to the wound. Outer appearance in an uncomplicated wound will be that of a well-healed scar.

Data from Doughty DB, Sparks-Defriese B: Wound healing physiology. In Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts*, ed 4, St Louis, 2012, Mosby.

necessary to promote healing. Risk for local or systemic infection, impaired circulation, and breakdown of tissue directly impairs the wound-healing ability of the skin layers (Doughty and Sparks-Defriese, 2012).

Physiologically wound healing occurs in the same way for all patients, with skin cells and some tissues (including the vascular tissues) regenerating quickly and others regenerating slowly or not at all. The latter group includes cells of the liver, renal tubules, and central nervous system neurons.

Wound healing is complex and involves a series of physiologic processes among cells and tissues. The location, severity, and extent of the injury and the tissue layer or layers involved all affect the wound-healing process (Doughty and Sparks-Defriese, 2012). A partial-thickness wound (loss of tissue limited to epidermis and possible partial loss of the dermis) heals by the process of regeneration. However, a full-thickness wound (total loss of skin layers and some deeper tissues) heals by scar formation (Box 38-1). In

FIG 38-2 Surgical wound with epithelialization occurring: epithelial healing ridge apparent. (From Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts*, ed 3, St Louis, 2007, Mosby.)

BOX 38-2 Factors That Influence Wound Healing

- Hypovolemia, hypotension, vasoconstriction, edema, and hypoxia negatively affect wound healing because adequate perfusion and oxygenation are necessary for new vessel development, collagen synthesis, and development of tensile strength.
- An adequate nutritional status is critical for collagen synthesis, tensile strength, and immune function.
- Wound infection prolongs the inflammatory response, and the microorganisms use nutrients and oxygen needed for wound repair.
- A patient with diabetes mellitus may have impaired wound healing because of abnormal and prolonged inflammation, reduced collagen synthesis, and impaired epithelial migration. Hyperglycemia is associated with compromised neutrophil function and impaired migration.
- Corticosteroid therapy or the use of other immunosuppressive agents such as chemotherapy increases the patient's susceptibility to infection.
- Advanced age can contribute to a diminished proliferation of cells critical to repair.

From Doughty DB, Sparks-Defriese B: Wound healing physiology. In Bryant RA, Nix DP, editors: *Acute and chronic wounds: current management concepts*, ed 4, St Louis, 2012, Mosby.

addition, there are underlying factors that prevent the ability of cells and tissues to regenerate, return to normal structure, or resume normal functioning (Box 38-2).

The healing process proceeds in a series of events, generally described as *phases*. In a full-thickness wound the phases are hemostasis, inflammation, proliferation, and remodeling. During hemostasis a series of overlapping events occur that control blood loss, begin bacterial control, and seal the wound (Doughty and Sparks-Defriese, 2012). The goal of the inflammatory phase is to control infection and clean the wound bed. During the proliferative phase epithelial cells are laid down in the closed incision within 24 to 48 hours, providing a bacterial barrier. During the proliferative stage fibroblasts are at the site of injury. These fibroblasts increase synthesis of collagen, which forms the healing ridge that can be palpated under an intact healing incision by days 5 to 9 (Fig. 38-2) (Doughty and Sparks-Defriese, 2012). Lack of a ridge is cause for concern, and you will need to

begin prompt interventions to reduce mechanical strain on the wound.

Types of healing occur by primary, secondary, and tertiary intention (Fig. 38-3, A and B). Healing by primary intention occurs when the edges of a clean surgical incision remain close together. The wound heals quickly, and tissue loss is minimal or absent (Doughty and Sparks-Defriese, 2012). The skin cells regenerate quickly, and capillary walls stretch across under the suture line to form a smooth surface as they join.

Wounds that are left open and allowed to heal by scar formation are classified as healing by secondary intention (Doughty and Sparks-Defriese, 2012). There is tissue loss and open wound edges. Granulation tissue gradually fills in the area of the defect (Fig. 38-4). This process is typical of severe laceration or massive surgical intervention with skin loss. In secondary intention there is a gap between the edges. Connective tissue develops, which supports

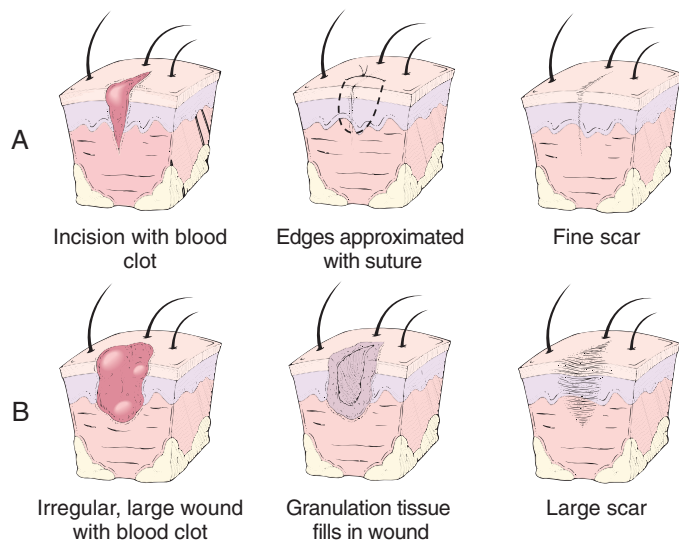

FIG 38-3 Wound healing by primary intention such as with a surgical incision. **A**, Wound healing edges are pulled together and approximated with sutures, staples, or adhesive tapes; and healing occurs by connective tissue deposition. **B**, Wound healing by secondary intention. Wound edges are not approximated, and healing occurs by granulation tissue formation and contraction of the wound edges. (From Lewis S et al: Medical-surgical nursing: assessment and management of clinical problems, ed 8, St Louis, 2011, Mosby.)

FIG 38-4 Open wound with granulation tissue.

new capillaries. This form of healing results in the formation of scar tissue to close the wound. The slowness of this process places a patient at greater risk for infection because there is no epidermal barrier until later in the healing process.

Healing by tertiary intention is sometimes called *delayed primary intention* or *closure*. It occurs when surgical wounds are not closed immediately but left open for 3 to 5 days to allow edema or infection to diminish. Then the wound edges are sutured or stapled closed. Scarring is usually minimal (Doughty and Sparks-Defriese, 2012). During the healing process some type of dressing covers a wound.

The percentage and type of tissue in the wound bed healing by secondary intention provide insight into the severity and duration of the wound, the extent to which it is progressing toward healing, and the effectiveness of current interventions (Nix, 2012). Viable tissue is normally red to pink in color and moist in appearance (Table 38-1). This type of tissue is called *granulation tissue* and indicates a wound moving toward healing. Black, brown, or tan tissue in the wound is slough or eschar and should be removed, or wound healing will be delayed.

Do not remove an initial surgical dressing for direct wound inspection until the health care provider writes an order for removal. Certain situations and some agency policies govern who changes the dressing the first time. Determine if the patient will need pain medication for the dressing change, and plan the best

TABLE 38-1 Wound Color/Tissue

Black/brown wounds/eschar	Black or brown tissue is eschar, which represents full-thickness tissue destruction. Black is used to describe necrotic tissue or desiccated tissue such as tendon. It is also related to gangrenous lesions secondary to peripheral vascular disease. If the goal for a wound covered with eschar is debridement, sharp debridement is used to quickly remove the tissue, chemical debridement is used to soften the tissue for removal, or a moist dressing is also considered to loosen the tissue. The method of debridement depends on the overall goal for the patient.
Yellow wounds/slough	Yellow tissue represents nonviable tissue and in some cases the presence of an infection. It is often yellow, cream colored, or gray slough, which is usually accompanied by purulent drainage. For patients with a low infection risk, the use of moisture-retentive dressings enhances debridement of the yellow tissue. These moisture-retentive dressings may include moist dressings, hydrocolloids, hydrogels, or alginates. If the wound is infected, topical antimicrobials are used.
Red wounds/granulation	Red tissue represents the presence of granulation tissue. The red color is the result of an increasing amount of new blood vessels in the wound and is considered healthy. The goal in management of a red granulated wound is to select a dressing that maintains a clean and moist wound environment and minimizes damage to healing tissue.

time for analgesic administration to ensure optimal medication effect before wound care. Skin cleaning in the area of the suture line or drain site is indicated when an excessive amount of drainage occurs.

Negative-pressure wound therapy (NPWT) is a wound care treatment that uses the application of subatmospheric (negative) pressure to a wound through suction to facilitate healing and collect wound fluid (Netsch, 2012). NPWT accelerates wound healing by edema and fluid removal, wound contraction, and mechanical stretch perfusion (Netsch, 2012). Several systems are available to provide NPWT; a commonly used brand is called *vacuum-assisted closure* (VAC). NPWT supports wound healing by optimizing blood flow, removing wound fluid, and maintaining a moist environment. Researchers believe that blood flow increases because of the removal of wound fluid and angiogenesis (development of new blood vessels) and that it stimulates the production of new blood vessels via a mechanical stretch of the tissue (Netsch, 2012). The removal of fluid from the wound decreases tissue edema, which increases dermal perfusion. The dressing placed into the wound maintains a moist environment to facilitate healing. A suction device is placed over the dressing; and the dressing, suction, and wound area are covered with a transparent dressing, which provides the airtight seal necessary for NPWT. The dressing is changed on a scheduled basis, usually no earlier than 48 hours. Chronic wounds such as pressure ulcers, diabetic ulcers, traumatic wounds, and venous stasis ulcers are approved for NPWT (see Chapter 39).

While cleansing a wound, use meticulous hand hygiene and proper infection control procedures before and after removing soiled dressings to limit the risk for health care–acquired infection. Use clean gloves to prevent exposure to body fluids, exudate, or bloody drainage from a wound. During wound cleansing, you deliver fluid or cleansing solution to the wound surface by means of a specific mechanical force. This force helps with the separation and removal of necrotic debris and surface bacteria (Rolstad and others, 2012). To accomplish effective wound cleansing, use an appropriate solution that does not harm the tissue and uses an adequate force to agitate and wash away surface debris and devitalized tissue that contain bacteria (Rolstad and others, 2012).

Irrigation is the most common method of wound cleansing. It uses the mechanical force (either high or low) of a stream of solution to remove debris, bacteria, and necrotic tissue from a wound. The pressure needed to irrigate wounds is between 4 and 15 psi (Table 38-2). Principles of basic wound irrigation include the following:

- 1 Cleanse in a direction from the least contaminated to the most contaminated area.
- 2 When irrigating, verify that all the solution flows from the least contaminated to the most contaminated area.

In wound care, the area you are cleansing is considered “clean,” and the surrounding skin surfaces are considered “contaminated” even if the wound is not infected. Within the wound the irrigation flow is directed from healthy tissue toward infected tissue, and the flow of irrigation moves from the area being cleansed to an area that is both distal and lower. For postoperative wounds the irrigation solutions should be sterile. For chronic wounds clean solutions can be used. In the event that the irrigant has irritating properties, protect the skin with a skin protectant product and place the collection basin close to the area of the exiting fluid.

The suture line is the “least contaminated” area, and you will always cleanse it first. The center is the most important part of the suture line; therefore, using a sterile swab or gauze, clean the suture line by starting at the center and working toward one end. With

another sterile swab or gauze, start at the center of the incision and work toward the other end. All other cleansing involves moving from one end to the other on each side of the incision. Work in straight lines, moving away from the suture line with each successive stroke.

If a drain is present, clean the drain site using a circular stroke starting with the area immediately next to the drain (Fig. 38-5). Using a new swab, cleanse immediately next to the drain and attempt to clean a little further out from the drain. Continue this process with subsequent swabs until the skin surrounding the drain is cleaned.

TABLE 38-2 Wound Cleansing Considerations

	Mechanical Force	
	High-Pressure	Low-Pressure
Wound base characteristics	Presence of necrotic tissue (eschar, fibrin slough), debris, or other particulate matter Significant bacterial burden Moderate/large amount of exudate	Presence of granulation tissue or new epithelial cells Non/minimum serous or serosanguineous exudate
Clinical outcome(s)	Loosen, soften, and remove devitalized tissue from wound Separate eschar from fibrotic tissue/fibrotic tissue from granulating base	Prevent trauma to viable wound tissue Remove wound care product residue
Solution	Normal saline Volume of solution depends on size of wound	Normal saline Volume of solution depends on size of wound
Delivery systems	35-mL syringe/19-gauge angiocatheter	Pouring saline directly from bottle Bulb syringe Piston syringe

Adapted from Spear M: Wound cleansing: solutions and techniques, *Plast Surg Nurs* 31(1):29, 2011.

FIG 38-5 Cleansing a drain site.

Infection is present in a wound when microorganisms on the wound surface penetrate into the wound tissues (Stotts, 2012). An infected acute wound usually demonstrates signs of local inflammation; redness and warmth in the area; presence of drainage, pain, or tenderness; and an unusual odor. A surgical site infection (SSI) involves the surgical site and presents within 30 days if there is no implanted device or 1 year if a device is left in place during the procedure. Superficial incision infection involves only skin and subcutaneous tissue at the incision. Deep incision infection involves organs or body cavities in the area of surgery.

Dehiscence is the failure of wound healing in which the surgical wound separates and opens to the fascial level. It occurs fairly early after surgery, by postoperative day 5 to 8 in patients in whom normal healing responses lag (Whitney, 2012). The wound edges open, and serosanguineous drainage is present. These wounds are then allowed to heal by secondary intention. Topical care options include light packing with a moist dressing covered with a dry dressing that is changed on a schedule to prevent the wound bed from drying out (i.e., often every 8 hours). Factors contributing to surgical wound dehiscence include anemia, malnutrition, obesity, and use of steroids.

Evisceration is a failure of wound healing, with total separation of the layers of the wound and protrusion of the internal organs through the wound. This is a surgical emergency, and you need to cover the wound with a moist sterile saline dressing, notify the surgeon immediately, and prepare the patient for emergent surgery.

EVIDENCE-BASED PRACTICE

Nonviable tissue in a wound can delay wound healing and contribute to wound infection. Debridement, the removal of nonviable tissue from the wound, is an essential objective of topical therapy and a critical component of optimal wound management (Ramundo, 2012). Methods of debridement include enzymatic, mechanical, autolytic, or sharp. The type of debridement chosen depends on the goal of wound treatment and the patient's overall condition (EPUAP and NPUAP, 2009). Enzymatic debridement is the topical application of enzymes over the necrotic tissue. The only enzyme available in the United States is collagenase. Collagenase digests the necrotic tissue by dissolving the collagen in the dead tissue (EPUAP and NPUAP, 2009). It is important to follow current guidelines to debride wounds.

- When collagenase is used on a wound, the necrotic tissue is covered with the collagenase, and a moisture-retentive dressing can be used to soften the tissue (Ramundo, 2012).
- Mechanical debridement may include irrigation, which can be done through the use of a 35-mL syringe with a 19-gauge angiocatheter with irrigation pressures delivered between 4 and 15 psi (WOCN, 2010).
- Autolytic debridement can be accomplished by providing moisture via semioclusive dressing to the wound to begin to loosen the nonviable tissue (Ramundo, 2012).
- Sharp debridement uses sterile instruments to remove the dead tissue and is only performed by a health care provider who is trained, competent, and qualified (EPUAP-NPUAP, 2009).

PATIENT-CENTERED CARE

When caring for patients from other cultures who have acute or chronic wounds, it is important to understand their cultural beliefs and practices and how these might impact wound care. In general, using gender-congruent caregivers and having the family caregiver or a professional translator help with translation and care issues relieves some of the patient's anxiety. In some cultures the meaning of blood and secretions is perceived as dirty; thus it would be advisable to promptly change stained bed lines and gowns. Since some cultures believe that blood is the life force, you should explain the presence of blood-stained secretions and drainage thoroughly.

Be sure to recognize family caregivers when giving explanations about the nursing care regimen. In collectivist cultures presence of family members at the bedside is customary. Among Islamic families it is important to recognize that some Muslims may not be comfortable exposing body parts to a member of the opposite sex (Padela and del Pozo, 2011). Remind patients that traditional home remedies and practices need to be avoided because they may increase the risk for infection in open wounds.

Safety Guidelines

- 1 Know a patient's age. With age vascular changes occur, collagen tissue is less pliable, and scar tissue is tighter. Because the dermoepidermal junction becomes flatter in older adults, their skin tears more easily from mechanical trauma such as tape removal.
- 2 Know a patient's nutritional status. Tissue repair and infection resistance are directly related to adequate nutrition, including proteins, carbohydrates, lipids, vitamins, and minerals. Patients who are malnourished are at increased risk for wound infections and wound infection-related sepsis (Stotts, 2012).
- 3 Understand the risks of obesity. Inadequate vascularization decreases delivery of nutrients and cellular elements required for healing. The patient is at greater risk for wound infection and dehiscence or evisceration (Gallagher-Camden, 2012).
- 4 Identify factors that decrease oxygenation such as decreased hemoglobin level, smoking, and underlying cardiopulmonary conditions. Adequate oxygenation at the tissue level is essential for white blood cell activity and phagocytosis, for fibroblast proliferation and collagen synthesis, and for reepithelialization (Doughty and Sparks-Defriese, 2012). Tissue repair is negatively influenced by a hematocrit value below 33% and a hemoglobin value below 10 g/100 mL. Hemoglobin level and oxygen release to tissues are reduced in smokers.
- 5 Know the types of medications prescribed. Steroids reduce the inflammatory response and slow collagen synthesis. Cortisone depresses fibroblast activity and capillary growth. Chemotherapy depresses bone marrow production of white blood cells and impairs immune function.
- 6 Identify the presence of chronic diseases or chronic trauma such as diabetes mellitus or radiation. Decreased tissue perfusion and failure to release oxygen to tissues result from diabetes mellitus.
- 7 Skin that has not been wounded is always stronger than healed skin.

PROCEDURAL GUIDELINE 38-1 Performing a Wound Assessment

NSO Wound Care Module / Lesson 1

Wound assessment provides the baseline for planning and evaluating the wound care plan. Normal wound healing occurs in an organized fashion, and evaluating the wound status provides an ongoing assessment of wound healing and helps to determine wound treatments. The frequency of wound assessment depends on the patient's overall condition, policy of the health care setting, type of dressings used, and overall patient goals (Nix, 2012). A variety of wound assessment tools are available, and choice depends on agency policy.

Routine wound assessments provides valuable information regarding the status of the wound. For example, is wound healing progressing as expected, or is it delayed? Is there new drainage? Wound size may increase in a wound with necrotic tissue. Removal of the necrotic tissue may result in a larger wound and is an expected finding. Obtain the health care provider's order as indicated for consultations such as a wound, ostomy, and continence (WOC) nurse or clinical nurse specialist (CNS) to discuss findings. If there is an increase in the amount and consistency of the drainage and if there is new presence of odor, these factors may indicate a wound infection; and a wound culture is often necessary to support appropriate antibiotics.

The following parameters are included in a wound assessment:

- *Location*: Note the anatomic position of the wound on the body.
- *Type of wound*: If possible, note the etiology of the wound (i.e., surgical, pressure, trauma).
- *Extent of tissue involvement*: Full-thickness wound involves both the dermis and epidermis. Partial-thickness wound involves only the epidermal layer. If it is a pressure ulcer, use the staging system of the European Pressure Ulcer Advisory Panel (EPUAP) and the National Pressure Ulcer Advisory Panel (NPUAP) (EPUAP and NPUAP, 2009; see Chapter 18).
- *Type and percentage of tissue in wound base*: Describe the type of tissue (i.e., granulation, slough, eschar) and the approximate amount.
- *Wound size*: Follow agency policy to measure wound dimensions, which includes width, length, and depth.
- *Wound exudate*: Describe the amount, color, and consistency. Serous drainage is clear like plasma; sanguineous or bright red drainage indicates fresh bleeding; serosanguineous drainage is pink; and purulent drainage is thick and yellow, pale green, or white.
- *Presence of odor*: Note the presence or absence of odor, which may indicate infection.
- *Periwound area*: Assess the color, temperature, and integrity of the skin.
- *Pain*: Use a validated pain assessment scale to evaluate pain.

Delegation and Collaboration

The skill of wound assessment cannot be delegated to nursing assistive personnel (NAP). It is the nurse's responsibility to assess and document wound characteristics. The nurse directs the NAP to:

- Report drainage from the wound that is present on sheets or as strike through from the dressing.
- Report the presence of odor in the area of the wound.

Video Clip

Equipment

- ❑ Protective equipment: clean gloves, gown, and goggles if splash/spray risk exists
- ❑ Agency tool to document assessment: measuring guide
- ❑ Cotton-tipped applicator
- ❑ Dressing supplies as ordered
- ❑ Disposable biohazard bag

Procedural Steps

- 1 Determine agency-approved wound assessment tool and review the frequency of assessment. Examine the last wound assessment to use as comparison for this assessment.
- 2 Assess comfort level or pain on a scale of 0 to 10 and identify symptoms of anxiety.
- 3 Explain procedure of wound assessment to patient.
- 4 Close room door or bed curtains and position patient.
 - a Position comfortably to permit observation of wound in well-lighted room.
 - b Expose only the wound.
- 5 Perform hand hygiene and form a cuff on waterproof biohazard bag and place near bed.
- 6 Apply clean gloves and remove soiled dressings.
- 7 Examine dressings for quality of drainage (color, consistency), presence or absence of odor, and quantity of drainage (note if dressings were saturated, slightly moist, or had no drainage). Discard dressings in waterproof biohazard bag. Discard gloves.
- 8 Perform hand hygiene and apply clean gloves.
- 9 Inspect wound and determine type of wound healing (e.g., primary or secondary intention). A partial-thickness wound heals by reepithelialization, whereas a full-thickness wound heals by the creation of scar tissue and will take longer to heal (Doughty and Sparks-Defriese, 2012).
- 10 Use agency-approved assessment tool and assess the following:
 - a Wound healing by primary intention (surgical wound):
 - (1) Assess anatomic location of wound on body.
 - (2) Note if incisional wound margins are approximated or closed together. The wound edges should be together with no gaps.
 - (3) Observe for presence of drainage. A closed incision should not have any drainage.
 - (4) Look for evidence of infection (presence of erythema, odor, or wound drainage).
 - (5) Lightly palpate along incision to feel a healing ridge. The ridge will appear as an accumulation of new tissue presenting as firmness beneath the skin, extending to about 1 cm ($\frac{1}{2}$ inch) on each side of the wound between 5 and 9 days after wounding. This is an expected positive sign (Doughty and Sparks-Defriese, 2012).
 - b Wound healing by secondary intention (e.g., pressure ulcer or contaminated surgical or traumatic wound):
 - (1) Assess anatomic location of wound.
 - (2) Assess wound dimensions: Measure size of wound (including length, width, and depth) using a centimeter measuring guide. Measure length by placing a ruler over wound at the point of greatest length (or head to foot). Measure width from side to side (Nix, 2012) (see illustration). Measure depth by inserting cotton-tipped applicator in area of greatest depth and

PROCEDURAL GUIDELINE 38-1 Performing a Wound Assessment—cont'd

placing a mark on applicator at skin level. Discard measuring guide and cotton-tipped applicator in a biohazard bag.

STEP 10b(2) Measuring wound length and width.

- (3) Assess for undermining: Use cotton-tipped applicator to gently probe wound edges. Measure depth and note location using the face of a clock as a guide. The 12 o'clock position (top of wound) would be head of patient, and the 6 o'clock position would be the bottom of the wound toward patient's feet. Document the number of centimeters that area extends from wound edge (e.g., underneath intact skin).
 - (4) Assess extent of tissue loss: If wound is a pressure ulcer, determine the deepest viable tissue layer in wound bed. If necrotic tissue does not allow visualization of base of wound, the stage cannot be determined.
 - (5) Notice tissue type, including percentage of tissue intact and presence of granulation, slough, and necrotic tissue.
 - (6) Note presence of exudate: Amount, color, consistency and odor. Indicate amount of exudate by using part of dressing saturated or in terms of quantity (e.g., scant, moderate, or copious).
 - (7) Note if any wound edges are rounded toward wound bed; this may be an indication of delayed wound healing. Describe presence of epithelialization at wound edges (if present) because this indicates movement toward healing.
 - (8) Inspect periwound skin: Include color, texture, temperature, and description of integrity (e.g., open macerated areas). Periwound assessment gives clues about the effectiveness of the wound treatment and possible wound extension (Nix, 2012).
- 11 Reapply dressings per order. Place time, date, and initials on new dressing.
 - 12 Reassess patient's pain and level of comfort, including pain at wound site, using a scale of 0 to 10, after dressing is applied.
 - 13 Discard biohazard bag, soiled supplies, and gloves per agency policy; perform hand hygiene.
 - 14 Record wound assessment findings and compare assessment with previous wound assessments to monitor wound healing.

Clinical Decision Point Compare the wound assessment to previous assessment, determine progress toward healing. If there is no movement toward healing or if you notice deterioration, consider a wound care consultation. Lack of wound healing is often related to infection. Notify health care provider and WOC nurse or team.

**SKILL 38-1** Performing a Wound Irrigation

Video Clip

Wound irrigation cleanses and irrigates surgical or chronic wounds such as pressure ulcers. Introduce the cleansing solution directly into the wound with a syringe, syringe and catheter, or pulsed lavage device. When using a syringe, the tip remains 2.5 cm (1 inch) above the wound. If a patient has a deep wound with a narrow opening, attach a soft catheter to the syringe to permit the fluid to enter the wound. Irrigation should not cause tissue injury or discomfort. Avoid fluid retention in the wound by positioning patient on his or her side to encourage the flow of the irrigant away from the wound. It is often helpful to use a 35-mL syringe with a 19-gauge angiocatheter to facilitate optimal pressure for cleansing with minimal risk for tissue injury (Rolstad, Bryant, and Nix, 2012). Ambulatory patients often benefit from the use of a handheld shower for wound cleansing, holding the shower spray approximately 30 cm (12 inches) from the wound.

There are two types of wound irrigation: high-pressure and pulsatile high-pressure lavage. High-pressure irrigation is the cleansing of a debris-filled wound with irrigating fluid delivered at

4 to 15 psi with a 35-mL syringe and a 19-gauge angiocatheter. Use a whirlpool to remove bacteria and debris from the surface of large wounds. Additional benefits include softening and loosening of adherent necrotic tissue and cleansing and removal of wound exudate (Ramundo, 2012).

Wound irrigations promote wound healing by removing debris from a wound surface, decreasing bacterial counts, and loosening and removing eschar. Solutions used for irrigations include normal saline, warm water, and commercially available wound cleansers. Skin cleansers are not the same as wound cleansers, and you never substitute a skin cleanser for a wound cleanser.

Delegation and Collaboration

The skill of sterile wound irrigation cannot be delegated to nursing assistive personnel (NAP). However, you can delegate the cleansing of chronic wounds using clean technique. It is the nurse's responsibility to assess and document wound characteristics. The nurse directs the NAP to:

- Notify the nurse when the wound is exposed so an assessment can be completed.
- Report patient pain.

TABLE 38-3 Common Wound Dressing Categories

Category	Description/Function	Indications	Side Effects	Examples
Hydrogel	Composed of water or glycerin-based polymers Provides moisture to wound bed Available in sheets or amorphous gel (usually in a tube) Autolytic debridement	Partial- and full-thickness wounds Dry-to-minimal exudate Necrotic wounds	Not indicated for heavily exuding wounds or wounds that are infected	Skintegrity Elasto-Gel Vigilon
Alginate	Highly absorptive products that are retentive gel or fiber-gelling dressings Absorption Available in pads and ropes for packing	Moderate-to-heavy wound exudate Hemostasis	May contribute to wound desiccation if wound exudate is minimal and gel dries	Restore CalciCare SeaSorb Algisite M
Foams	Absorption Available in adhesive and nonadhesive forms	Absorption of moderate-to-heavy exudate	May promote wound dehydration and desiccation if minimal exudate	Biatain Hydrocell PolyMem
Gauze	Absorption Available in woven or nonwoven, cotton or synthetic, sterile and nonsterile	Protection of surgical wounds Absorption of minimal-to-heavy exudate Deliver solution to wound	May adhere to healthy tissue and cause injury on removal	Curity Gauze Sponges KERLIX Super Sponge KLING gauze rolls NU GAUZE packing strips
Hydrocolloids	Made of gelatin, pectin, and carboxymethylcellulose particles suspended in adhesive base Maintain moist environment by forming a gelatinous mass	Autolytic debridement Absorption of minimal to moderate exudate	Some products leave residue in wound on removal; cleanse wound of residue before wound assessment	DuoDERM Exuderm Replicare

Data from Rolstad BS, Byrant RA, Nix DP: Topical management. In Bryant RA, Nix D P, editors: *Acute and chronic wounds: current management concepts*, ed 4, St Louis, 2012, Mosby.

Equipment

- Irrigant/cleansing solution (volume 1.5 to 2 times the estimated wound volume)
- Irrigation delivery system (per order), depending on amount of pressure desired: sterile irrigation 35-mL syringe with sterile soft angiocatheter or 19-gauge needle (WOCN, 2010) or handheld shower
- Protective equipment: sterile gloves, gown, and goggles if splash/spray risk exists
- Waterproof underpad if needed
- Dressing supplies (Table 38-3)
- Disposable waterproof biohazard bag
- Extra towels and padding (to use to protect bed)
- Wound assessment supplies (see Procedural Guideline 38-1)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Review order for irrigation of open wound and type of solution to be used. 2 Perform wound assessment and examine recent charted assessment of patient's open wound (see Procedural Guideline 38-1). 3 Assess patient for history of allergies to antiseptics, medications, tapes, or dressing material. | <p>Open-wound irrigation requires medical order, including type of solution(s) to use.</p> <p>Known allergies suggest applying a sample of prescribed wound treatment as skin test before flushing wound with large volume of solution or selecting different tape or dressing material.</p> |
|--|--|

NURSING DIAGNOSES

- Acute pain
- Chronic pain
- Impaired skin integrity
- Impaired tissue integrity
- Risk for injury

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- | | |
|---|--|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient states acceptable level of comfort on pain scale of 0 to 10 after wound irrigation. • Wound begins to demonstrate signs of healing; wound is free of excessive drainage, exudate, and inflammation. • Skin integrity is maintained; no redness, edema, or inflammation noted in surrounding tissue. <p>2 If needed, administer analgesic 30 to 45 minutes before starting wound irrigation procedure.</p> <p>3 Educate patient and family members about procedure.</p> | <p>Premedication, gently administered irrigation, application of clean dressing, and repositioning patient ensure comfort.</p> <p>Healing progresses in absence of debris and presence of protective coating.</p> <p>No further skin and tissue damage has resulted from wound irrigation.</p> <p>Promotes pain control and permits patient to move more easily and be positioned to facilitate wound irrigation (Krasner, 2012).</p> <p>Promotes cooperation and reduces anxiety.</p> |
|---|--|

IMPLEMENTATION

- | | |
|--|--|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Obtain appropriate supplies for wound irrigation and dressing. Form cuff on waterproof biohazard bag and place near bed.</p> <p>3 Close room door or bed curtains, perform hand hygiene, and position patient.</p> <p>a Position comfortably to permit gravitational flow of irrigating solution over wound and into collection receptacle (see illustration).</p> <p>b Position patient so wound is vertical to collection basin. Place container of irrigant/cleansing solution in basin of hot water to warm solution to body temperature.</p> <p>4 Place padding or extra towel on bed under area where irrigation will take place.</p> <p>5 Expose wound only.</p> <p>6 Apply gown and goggles. Apply sterile gloves for Steps 7 and 8 and use sterile precautions.</p> <p>7 Irrigate wound with wide opening:</p> <p>a Fill 35-mL syringe with irrigation solution.</p> <p>b Attach 19-gauge angiocatheter or 19-gauge needle.</p> <p>c Hold syringe tip 2.5 cm (1 inch) above upper end of wound and over area being cleansed.</p> <p>d Using continuous pressure, flush wound; repeat Steps 7a to c until solution draining into basin is clear.</p> <p>8 Irrigate deep wound with very small opening:</p> <p>a Attach soft catheter to filled irrigation syringe.</p> <p>b Gently insert tip of catheter into opening about 1.3 cm (0.5 inch).</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Cuffing helps to maintain large opening, thereby permitting placement of contaminated dressing without touching waste bag itself.</p> <p>Maintains privacy; frequent hand hygiene reduces microorganisms.</p> <p>Directing solution from top to bottom of wound and from clean to contaminated area prevents further infection. Position patient during planning stage, keeping in mind bed surfaces needed for later preparation of equipment.</p> <p>Warmed solution increases comfort and reduces vascular constriction response in tissues.</p> <p>Protects bedding from becoming wet.</p> <p>Provides privacy and prevents chilling of patient.</p> <p>Protects nurse from splashes or sprays of blood and body fluids.</p> <p>Flushing wound helps remove debris and facilitates healing by secondary intention.</p> <p>Catheter lumen delivers ideal pressure for cleansing and removing debris (Ramundo, 2012).</p> <p>Prevents syringe contamination. Careful placement of syringe prevents unsafe pressure of flowing solution.</p> <p>Clear solution indicates removal of debris.</p> <p>Catheter permits direct flow of irrigant into wound. Expect wound to take longer to empty when opening is small.</p> <p>Prevents tip from touching fragile inner wall of wound.</p> |
|--|--|

STEP 3a Patient position for wound irrigation.

STEP

RATIONALE

Clinical Decision Point Do not force catheter into the wound because this will cause tissue damage.

- | | |
|--|--|
| <ul style="list-style-type: none"> c Using slow, continuous pressure, flush wound. d While keeping catheter in place, pinch it off just below syringe. e Remove and refill syringe. Reconnect to catheter and repeat until solution draining into basin is clear. | <p>Use of slow mechanical force of stream of solution loosens particulate matter on wound surface and promotes healing (Ramundo, 2012).</p> |
| <p>9 Cleanse wound with handheld shower:</p> <ul style="list-style-type: none"> a Perform hand hygiene and apply clean gloves. With patient seated comfortably in shower chair, adjust spray to gentle flow; make sure that water is warm. b Shower for 5 to 10 minutes with shower head 30 cm (12 inches) from wound. | <p>Useful for patients able to shower with assistance or independently. May be accomplished at home.</p> <p>Ensures that wound is thoroughly cleansed.</p> |
| <p>10 When indicated, obtain cultures (see Chapter 43) after cleansing with nonbacteriostatic saline.</p> | <p>WOCN (2010) recommends using quantitative bacterial cultures (tissue biopsy or swab cultures).</p> |

Clinical Decision Point Consider culturing a wound if it has a foul, purulent odor; inflammation surrounds the wound; a nondraining wound begins to drain; or patient is febrile.

- | | |
|--|--|
| <p>11 Dry wound edges with gauze; dry patient after shower.</p> | <p>Prevents maceration of surrounding tissue from excess moisture.</p> |
| <p>12 Apply appropriate dressing (see Chapter 39) and label with time, date, and nurse's initials.</p> | <p>Maintains protective barrier and healing environment for wound.</p> |
| <p>13 Remove mask, goggles, and gown.</p> | <p>Prevents transfer of microorganisms.</p> |
| <p>14 Dispose of equipment and soiled supplies, remove gloves, and perform hand hygiene.</p> | <p>Reduces transmission of microorganisms.</p> |
| <p>15 Help patient to comfortable position.</p> | <p>Reduces transmission of microorganisms.</p> |

EVALUATION

- | | |
|--|---|
| <p>1 Have patient rate level of comfort on scale of 0 to 10.</p> | <p>Patient's pain should not increase as result of wound irrigation.</p> |
| <p>2 Monitor type of tissue in wound bed.</p> | <p>Identifies wound healing progress and determines type of wound cleansing and dressing needed.</p> |
| <p>3 Inspect dressing periodically (see agency policy).</p> | <p>Determines patient's response to wound irrigation and need to modify plan of care.</p> |
| <p>4 Evaluate periwound skin integrity.</p> | <p>Determines if extension of wound has occurred or signs of infection are present (warm red periwound skin).</p> |
| <p>5 Observe for presence of retained irrigant.</p> | <p>Retained irrigant is medium for bacterial growth and subsequent infection.</p> |

Unexpected Outcomes

- 1 Bleeding or serosanguineous drainage appears.
- 2 Increased pain or discomfort occurs.
- 3 Suture line opening extends.

Related Interventions

- Flush wound during next irrigation using less pressure.
- Notify health care provider of bleeding.
- Decrease force of pressure during wound irrigation.
- Assess patient for need for additional analgesia before wound care.
- Notify health care provider.
- Reevaluate amount of pressure to use for next wound irrigation.

Recording and Reporting

- Record wound assessment before and after irrigation; amount, color, and odor of drainage on dressing removed; amount and type of solution used; irrigation device used; patient's tolerance of the procedure; type of dressing applied after irrigation.
- Immediately report to the health care provider any evidence of fresh bleeding, sharp increase in pain, retention of irrigant, or signs of shock.

Special Considerations

Teaching

- Instruct patient and primary caregiver regarding wound care technique, observe them doing a return demonstration, and provide written instructions.
- Explain the need for specialized supplies such as irrigating solutions and dressings and the need to maintain asepsis when performing care.
- Instruct patient and primary caregiver in signs of improper wound healing and wound infection.
- Teach patient and caregiver how to make normal saline, especially if cost is an issue. You make normal saline by using 8 teaspoons of salt in 1 gallon of distilled water; keep it refrigerated for 1 month. The saline solution should be allowed to reach room temperature before use.

Pediatric

- Some pediatric patients are very frightened. They might verbally and physically try to prevent nurse from cleaning the wound. Having the child take active part in procedure or

working out his or her feelings about wound irrigation with play therapy on a doll with a wound helps the child to be more cooperative with the procedure.

- Neonatal skin is immature and easily damaged from pressure and wound care products. Check that products are approved for use with this population. Remember that in neonates the skin readily absorbs products.

Gerontologic

- Wound irrigations are traumatic, frightening, and painful to some older patients. Assess patient's cooperation before irrigating wound. Be aware of patient's cognitive level of understanding when performing wound irrigation.

Home Care

- Assess patient's home environment to determine adequacy of agencies for performing wound care; check especially for adequate lighting, running water, and storage of supplies.
- Plan wound care in conjunction with patient's total rehabilitation goals. The objective of wound care management in a subacute care setting is to return the patient to his or her home environment.
- Provide support for patient and caregiver during the wound-healing process. Chronic wounds do not heal properly and do not close in a timely manner (Doughty and Sparks-Defriese, 2012).
- Some patients need to receive wound care management in an outpatient wound care clinic. Be sure that patient has directions to clinic and knows where to park and where to obtain dressing supplies.

SKILL 38-2 Removing Sutures and Staples

Agency policy determines whether *only* the health care provider *and* nurse may remove sutures and staples. Always obtain the health care provider's written order before implementing either skill. The time of removal is based on the stage of incision healing and the extent of surgery.

Sutures and staples generally are removed within 7 to 14 days after surgery if healing is adequate (Whitney, 2012). Retention sutures usually remain in place 14 to 21 days. Timing the removal of sutures and staples is important. They must remain in place long enough to ensure initial wound closure with enough strength to support internal tissues and organs. Sutures left in longer than 14 days generally leave suture marks (Whitney, 2012). The health care provider determines and orders removal of all sutures or staples at one time or removal of every other suture or staple as the first phase, with the remainder removed in the second phase.

Sutures are threads of wire or other materials used to sew body tissues together. They come in different sizes and are absorbent or nonabsorbent. They are placed within tissue layers in deep wounds and superficially as the final means for wound closure. The choice of suture technique depends on the type and anatomic location of the wound, thickness of the skin, degree of tension, and desired cosmetic effect (Fig. 38-6) (Whitney, 2012). A patient's history of wound healing, site of wound, tissues involved, and the purpose of the sutures determine the suture material selected. For example, a patient with repeated abdominal surgeries might require wire sutures for greater strength to promote wound closure.

Staples are stainless-steel wire. The location of the incision sometimes restricts their use because there must be adequate distance between the skin and structures that lie below the skin, including bone and vascular structures. The cosmetic result is not always as desirable as that obtained with finer suture material.

Staples do provide ample strength. Removal requires a sterile staple extractor and aseptic technique.

The health care provider and/or nurse judge whether to remove all sutures if any sign of suture line separation is evident during the process of suture or staple removal. It is not uncommon to remove every other suture initially, removing the balance several days to a week later.

Delegation and Collaboration

The skill of staple and/or suture removal cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP by:

- Instructing to report to the nurse drainage, bleeding, swelling at the site or an elevation in patient's temperature.
- Instructing to report to the nurse patient's complaints of pain.

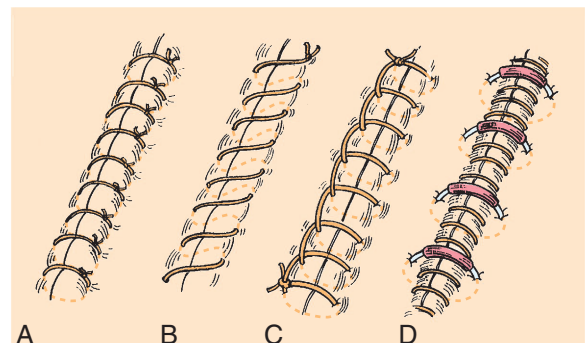

FIG 38-6 Types of sutures. A, Intermittent. B and C, Continuous. D, Blanket.

- Providing information about any special hygiene practices following suture removal.

- Sterile applicators or antiseptic swabs
- Steri-Strips or butterfly adhesive strips
- Clean gloves
- Sterile gloves

Equipment

- Disposable waterproof bag
- Sterile suture removal set (forceps and scissors) or sterile staple extractor

STEP

RATIONALE

ASSESSMENT

<p>1 Identify patient with need for suture or staple removal:</p> <ul style="list-style-type: none"> a Check health care provider's order. b Review specific directions related to suture or staple removal. c Determine history of conditions that may pose risk for impaired wound healing: advanced age, cardiovascular disease, diabetes, immunosuppression, radiation, obesity, smoking, poor cellular nutrition, very deep wounds, and infection. <p>2 Assess patient for history of allergies.</p> <p>3 Assess patient's comfort level or pain on scale of 0 to 10.</p> <p>4 Assess healing ridge and skin integrity of suture line for uniform closure of wound edges, normal color, and absence of drainage and inflammation.</p>	<p>Health care provider's order is required for removal of sutures. Indicates specifically which sutures are to be removed (e.g., every other suture).</p> <p>Preexisting health disorders affect speed of healing and sometimes result in dehiscence.</p> <p>Determines if patient is sensitive to antiseptic or latex.</p> <p>Provides baseline of patient's comfort level to determine response to therapy.</p> <p>Indicates adequate wound healing for support of internal structures without continued need for sutures or staples.</p>
--	--

Clinical Decision Point *If wound edges are separated or signs of infection are present, the wound has not healed properly. Notify the health care provider because sutures or staples may need to remain in place and/or other wound care initiated.*

NURSING DIAGNOSES

- Impaired skin integrity**
 - Risk for impaired skin integrity**
 - Risk for infection**
- Related factors are individualized based on patient's condition or needs.*

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • All suture material or staples are removed. • Suture line is intact. • Patient states acceptable level of comfort on scale of 0 to 10 following removal of sutures or staples. <p>2 Explain to patient that suture removal is usually not a painful procedure but patient may feel pulling or tugging of skin.</p>	<p>Removes source of infection or irritation from retained sutures. Wound is healing and does not require protective dressings. Some patients require pain medicine before suture or staple removal.</p> <p>Gains patient cooperation and reduces anxiety.</p>
--	--

IMPLEMENTATION

<p>1 Close curtains or room door.</p> <p>2 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p>	<p>Provides privacy.</p> <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p>
---	--

Clinical Decision Point *For patient who is highly anxious or who has an extensive wound, consider need to administer analgesic 30 minutes before suture removal.*

<p>3 Position patient comfortably while exposing suture line. Ensure that direct lighting is on suture line.</p> <p>4 Perform hand hygiene.</p> <p>5 Place cuffed waterproof disposal bag within easy reach.</p>	<p>Aids visibility and correct placement of forceps or extractor during removal process, ultimately reducing soft tissue injury.</p> <p>Reduces risk for infection.</p> <p>Provides for easy disposal of contaminated dressings and prevents passing items over sterile work area.</p>
---	--

STEP	RATIONALE
<p>6 Prepare materials needed for suture/staple removal:</p> <ul style="list-style-type: none"> a Open sterile suture removal kit or staple extractor kit. b Open sterile antiseptic swabs and place on inside surface of kit. c Obtain gloves (sterile gloves if policy indicates). 	
<p>7 Perform hand hygiene and apply clean gloves. Carefully remove dressing; discard dressing and gloves in prepared refuse disposal bag.</p>	Reduces transmission of infection.
<p>8 Inspect incision and suture line (see illustration).</p>	Determines adequacy of wound healing.
<p>9 Perform hand hygiene. Apply clean or sterile gloves as required by agency policy.</p>	
<p>10 Clean sutures or staples and healed incision with antiseptic swabs.</p>	Removes surface bacteria from incision and sutures or staples.
11 Remove staples:	
<ul style="list-style-type: none"> a Place lower tips of staple extractor under first staple. As you close handles, upper tip of extractor depresses center of staple, causing both ends of staple to be bent upward and simultaneously exit their insertion sites in dermal layer (see illustration). 	Avoids excess pressure to suture line and secures smooth removal of each staple.
<ul style="list-style-type: none"> b Carefully control staple extractor. 	Avoids suture line pressure and pain.
<ul style="list-style-type: none"> c As soon as both ends of staple are visible, move it away from skin surface (see illustration) and continue until staple is over refuse bag. 	Prevents scratching tender skin surface with sharp pointed ends of staple for comfort and infection control.

STEP 8 Suture line secured with staples.

STEP 11a Staple extractor placed under staple.

STEP 11c Metal staple removed by extractor.

STEP

RATIONALE

- d Release handles of staple extractor, allowing staple to drop into refuse bag. AVOIDS CONTAMINATING STERILE FIELD WITH USED STAPLES.
- e Repeat Steps a to d until all staples are removed.

12 Remove intermittent sutures:

- a Place gauze few inches from suture line. Hold scissors in dominant hand and forceps (clamp) in nondominant hand. GAUZE SERVES AS RECEPTACLE FOR REMOVED SUTURES. PLACEMENT OF SCISSORS AND FORCEPS ALLOWS FOR EFFICIENT SUTURE REMOVAL.

Clinical Decision Point Placement of scissors and forceps is very important. Avoid pinching the skin around the wound when lifting up the suture. Likewise avoid cutting the skin around the wound by accident when snipping the suture.

- b Grasp knot of suture with forceps and gently pull up knot while slipping tip of scissors under suture near skin (see illustration). RELEASES SUTURE.
- c Snip suture as close to skin as possible at end distal to knot.

Clinical Decision Point Never snip both ends of suture; there will be no way to remove the part of the suture situated below the surface.

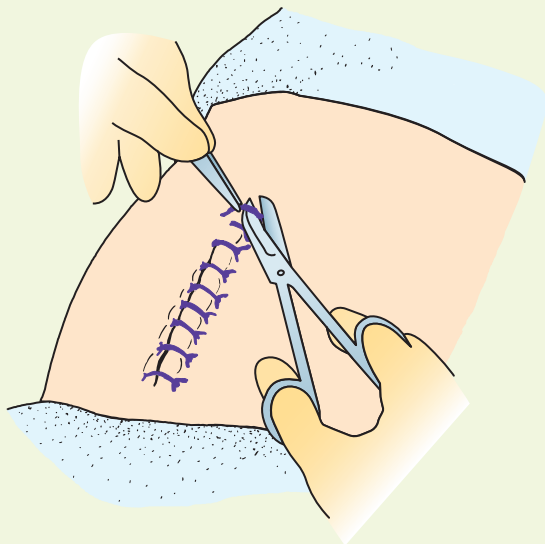

- d Grasp knotted end with forceps and in one continuous smooth action pull suture through from the other side (see illustration). Place removed suture on gauze. SMOOTHLY REMOVES SUTURE WITHOUT ADDITIONAL TENSION TO SUTURE LINE.

Clinical Decision Point Never pull exposed surface of any suture into tissue below epidermis. The exposed surface of any suture is considered contaminated.

- e Repeat Steps a through d until you have removed every other suture.
- f Observe healing level. Based on observations of wound response to suture removal and health care provider's original order, determine whether remaining sutures will be removed at this time. If so, repeat Steps a to d until you have removed all sutures. DETERMINES STATUS OF WOUND HEALING AND IF SUTURE LINE WILL REMAIN CLOSED AFTER ALL SUTURES ARE REMOVED.
- g If any doubt, stop and notify the health care provider.

13 Remove continuous and blanket stitch sutures:

- a Place sterile gauze a few inches from suture line. Grasp scissors in dominant hand and forceps in nondominant hand. GAUZE SERVES AS RECEPTACLE FOR REMOVED SUTURES. PLACEMENT OF SCISSORS AND FORCEPS ALLOWS FOR EFFICIENT SUTURE REMOVAL.
- b Snip first suture close to skin surface at end distal to knot. RELEASES SUTURE.
- c Snip second suture on same side. RELEASES INTERRUPTED SUTURES FROM KNOT.
- d Grasp knotted end and gently pull with continuous smooth action, removing suture from beneath skin. Place suture on gauze compress. SMOOTHLY REMOVES SUTURES WITHOUT ADDITIONAL TENSION TO SUTURE LINE. PREVENTS PULLING OF CONTAMINATED PORTION OF SUTURE THROUGH SKIN.

STEP 12b Removal of intermittent suture. Nurse cuts suture as close to skin as possible, away from knot.

STEP 12d Nurse removes suture and never pulls contaminated stitch through tissues.

STEP	RATIONALE
e Repeat Steps a to d in consecutive order until entire line is removed.	
14 Inspect incision to make sure that all sutures are removed and identify any trouble areas. Gently wipe suture line with antiseptic swab to remove debris and clean incision.	Reduces risk for further incision line separation.
Clinical Decision Point <i>Make sure that you remove the entire suture and that no part is retained in the patient's wound.</i>	
15 Apply Steri-Strips if <i>any</i> separation greater than two stitches or two staples in width is apparent to maintain contact between wound edges.	Supports wound by distributing tension across wound and eliminates closure technique scarring.
a Cut Steri-Strips to allow strips to extend 4 to 5 cm (1½ to 2 inches) on each side of incision.	
b Remove from backing and apply across incision (see illustration).	
c Instruct patient to take showers rather than soak in bathtub according to health care provider's preference.	Steri-Strips are not removed and are allowed to fall off gradually.
16 Apply light dressing or expose to air if no clothing will come in contact with suture line. Instruct patient about applying own dressing if needed at home.	Healing by primary intention eliminates need for dressing.
17 Discard all contaminated materials and remove and dispose of gloves.	Reduces transmission of infection.
18 Route reusable items such as staple extractor for resterilization, dispose of sharps (disposable staple extractor and/or scissors) in designated bin, and perform hand hygiene.	Reduces transmission of infection.

STEP 15b Steri-Strips over incision.

EVALUATION

1 Assess site where sutures or staples were removed; inspect condition of soft tissues, including skin. Look for any pieces of removed suture left behind.	Ensures that sources of infection have been removed.
2 Determine if patient has pain along incision.	Determines comfort level and can indicate if suture material remains in skin.

Unexpected Outcomes

- Retained suture is present.
- Patient experiences wound separation or drainage secondary to healing problems.

Related Interventions

- Notify health care provider.
- Instruct patient to notify health care provider if signs of suture line infection develop following discharge from agency.
- Leave remaining sutures or staples in place.
- Place Steri-Strip closures across suture line.
- Notify health care provider.

Recording and Reporting

- Record the time the sutures or staples were removed and the number of sutures or staples removed. Also document the cleaning of the suture line, appearance of the wound, level of healing of the wound, and type of dressing applied. Document patient's response to suture or staple removal.
- Immediately report to the health care provider if suture line separation, dehiscence, evisceration, bleeding, or purulent drainage occurs.

Special Considerations

Teaching

- Teach patient to observe for any sign of separation of wound edges before removing remaining sutures/staples and inspect incision for continued healing.
- Reinforce instruction about resuming bathing and showering activities, preventing abdominal strain during defecation, and providing adequate nutrition and ambulation.

- Teach patient not to put additional stress on suture line from such activities as lifting or bending. Patients with abdominal surgery or injury need to avoid lifting heavy packages or equipment for several weeks.
- Instruct patient that sometimes there is a small amount of drainage from wound immediately after suture removal.

Pediatric

- Assistance is sometimes necessary to keep infants from moving during the suture removal procedure.
- Topical anesthetic solutions (e.g., lidocaine [Xylocaine], EMLA) applied to intact skin may provide short-term (20 minutes) anesthesia (Krasner, 2012).

Gerontologic

- Some older adults need reassurance about suture/staple removal procedure. Depending on their mental status, they may not understand the procedure.
- Older skin is often at higher risk for dehiscence after sutures/staples are removed.

SKILL 38-3 Managing Wound Drainage Evacuation

NSO Wound Care Module / Lesson 2

If drainage accumulates in the wound bed, wound healing is delayed. Drainage is removed by using either a closed- or open-drain system, even if the amount of drainage is small. The drain is inserted directly through a small stab wound near the suture line into the area of the wound.

An open-drain system (e.g., a Penrose drain [Fig. 38-7]) removes drainage from the wound and deposits it onto the skin surface. Insert a sterile safety pin through this drain, outside the skin, to prevent the tubing from moving into the wound.

To remove the Penrose drain the health care provider may advance the drain in stages since the wound heals from the bottom up. Nursing interventions include caution to prevent accidental removal of the drain during dressing changes and to protect skin surfaces in direct contact with the irritating drainage. Because of the danger of accidental dislodgement and the need to assess the drain placement accurately, do not delegate the care of Penrose drains that are covered with gauze pads to nursing assistive personnel (NAP).

A closed-drain system such as the Jackson-Pratt (JP) drain (Fig. 38-8) or Hemovac drain relies on the presence of a vacuum to withdraw accumulated drainage from around the wound bed into the collection device. A JP drain collects fluid that is in the range of 100 to 200 mL/24 hr; whereas the Hemovac drain accommodates more drainage, usually up to 500 mL/24 hr. The collection device is connected to a clear plastic drain with multiple perforations. Drainage collects in a closed reservoir or a suction bladder (Box 38-3). The closed system collects fluid but operates only if

BOX 38-3 Attaching Wound Suction Devices to Suction

- Hemovac**
- Connect graduated adapter to emptying port and then to wall suction tubing.
 - Set suction level as prescribed or on low if suction level is not specified.
- Jackson-Pratt**
- Attach tubing to the suction device.
 - Squeeze suction device flat to allow all air to be evacuated and close port.

FIG 38-7 Penrose drain with drain-split gauze.

FIG 38-8 Jackson-Pratt wound drainage system.

the tubing is patent and a vacuum exists. You empty the drainage periodically from the reservoir, record the amount, and reestablish the vacuum.

Delegation and Collaboration

The assessment of wound drainage and maintenance of drains and the drainage system cannot be delegated to NAP. However, you may delegate emptying a closed drainage container or pouch, measuring the amount of drainage, and reporting the amount on the patient's intake and output (I&O) record to NAP. The nurse directs the NAP by:

- Discussing any increase in frequency of emptying the drain other than once a shift.

- Instructing to report to the nurse any change in amount, color, or odor of drainage.
- Reviewing the I&O procedure.

Equipment

- Graduated measuring cylinder
- Alcohol sponge
- Gauze sponges
- Goggles if needed
- Sterile specimen container if culture is needed
- Sterile dressings or pouch if drain is needed
- Clean gloves
- Safety pin(s)

STEP

RATIONALE

ASSESSMENT

- | | |
|--|---|
| <p>1 Identify presence, location, and purpose of closed wound drain and drainage system as patient returns from surgery. Assess drainage present on patient's dressing.</p> <p>2 Identify number of wound drain tubes and what each one will be draining. Label each drain tube with a number or label.</p> <p>3 Assess if drain tube needs self-suction, wall suction, or no suction by checking health care provider's orders.</p> <p>4 Inspect system to determine presence of one straight tube or Y-tube arrangement with two tube insertion sites.</p> <p>5 Inspect system to ensure proper functioning. Complete systematic inspection includes insertion site, drainage moving through tubing in direction of reservoir, patency of drainage tubing, airtight connection sites, and presence of any leaks or kinks in system.</p> | <p>Drainage tubing is usually placed near wound through small surgical incision.</p> <p>Assigning labeling system to each drain helps with consistent documentation when patient has multiple drainage tubes. Some drain tubes such as Hemovac can be used with self-suction or wall suction.</p> <p>Allows nurse to plan skin care and identifies quantity of sterile dressing supplies needed.</p> <p>Properly functioning system maintains suction until reservoir is filled. Tension on drainage tubing increases injury to skin and underlying muscle.</p> |
|--|---|

Clinical Decision Point Attach tape and a safety pin to drainage tubing with tape and pin to patient's gown so the suction device is below the level of the wound and does not pull on the insertion site.

- | | |
|--|---|
| <p>6 Be sure that Penrose drain has sterile safety pin in place. Penrose drains are sometimes covered with gauze dressing or wound pouch. Use caution and do not accidentally pull on drain while positioning gauze.</p> <p>7 Identify type of drainage containers that patient has.</p> | <p>Pin prevents drain from being pulled below surface of skin.</p> <p>Determines frequency for emptying drainage.</p> |
|--|---|

NURSING DIAGNOSES

- Impaired skin integrity
- Risk for infection
- Risk for injury

Related factors are individualized based on patient's condition or needs.

PLANNING

- | | |
|--|---|
| <p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Wound healing continues. • Vacuum is reestablished. • Tubing is patent. <p>2 Explain procedure to patient.</p> | <p>Patient is comfortable, and wound drainage is collected. Suction system is intact. Fluid is draining away from wound area. Promotes patient's cooperation and reduces anxiety.</p> |
|--|---|

IMPLEMENTATION

- | | |
|---|--|
| <p>1 Close room door or bedside curtains.</p> <p>2 Perform hand hygiene and apply clean gloves.</p> <p>3 Place open specimen container or measuring graduate on bed between you and patient.</p> <p>4 Empty Hemovac or ConstaVac:</p> | <p>Provides privacy.</p> <p>Reduces transmission of microorganisms.</p> <p>Permits measuring and discarding of wound drainage.</p> <p>Avoids entry of pathogens.</p> |
|---|--|

STEP

RATIONALE

- a Maintain asepsis while opening plug on port indicated for emptying drainage reservoir.
 - (1) Tilt suction container in direction of plug.
 - (2) Slowly squeeze two flat surfaces together, tilting toward measuring container.
 - b Drain contents into measuring container (see illustration).
 - c Hold uncovered alcohol swab in dominant hand. Place suction device on flat surface with open outlet facing upward; continue pressing downward until bottom and top are in contact (see illustration).
 - d Holding surfaces together with one hand, and using an alcohol swab, quickly clean opening and plug with other hand and immediately replace plug; secure suction device on patient's bed.
 - e Check suction device for reestablishment of vacuum, patency of drainage tubing, and absence of stress on tubing.
- 5 Empty Hemovac with wall suction:
- a Turn off suction.
 - b Disconnect suction tubing from Hemovac port.
 - c Empty Hemovac as described in Step 4.
 - d Clean port opening and end of suction tubing to open port of Hemovac.
 - e Set suction level as prescribed or on low if health care provider does not specify suction level.
- 6 Empty JP suction drain:
- a Open port on top of bulb-shaped reservoir (see illustration).
 - b Tilt bulb in direction of port and drain toward opening. Empty drainage from suction device into measuring container (see illustration). Clean end of emptying port and plug with alcohol wipe.
 - c Compress bulb over drainage container. While compressing bulb, replace plug immediately.
- 7 Place and secure drainage system below site with safety pin on patient's gown. Be sure that there is slack in tubing from reservoir to wound.
- 8 Note characteristics of drainage: measure volume and discard by flushing in commode.

- Vacuum will be broken, and reservoir will pull air in until chamber is fully expanded.
Drains fluid toward plug.
Prevents splashing of contaminated drainage.
- Contents counted as fluid output (see Chapter 6).
Compression of surface of Hemovac creates vacuum. Cleaning plug reduces transmission of microorganisms into drainage evacuation.
- Facilitates wound drainage and prevents tension on drainage tubing.
- Empties drainage and reestablishes suction to wound bed.
- Cleaning plug reduces transmission of microorganisms.
- Breaks vacuum for drain.
Reduces transmission of microorganisms.
- Reestablishes vacuum.
- Pinning drainage tubing to patient's gown prevents tension or pulling on tubing and insertion site.
- Contents count as fluid output.

STEP 4b Hemovac contents drained into measuring container.

STEP 4c Hemovac compressed to create suction.

STEP	RATIONALE
9 Discard soiled supplies, remove gloves, and perform hand hygiene.	Reduces transmission of microorganisms.
10 Apply clean gloves. Proceed with dressing change (see Chapter 39) around drain site and inspection of skin if indicated or ordered. Split-drain sponge dressings are often used around drain tubes (see illustration) and taped in place.	Prevents entrance of bacteria into surgical wound.
11 Discard contaminated materials, remove gloves, and perform hand hygiene.	Reduces transmission of microorganisms.

STEP 6a Opening port of Jackson-Pratt device.

STEP 6b Emptying contents from Jackson-Pratt drainage device.

STEP 10 Applying split gauze dressing around Jackson-Pratt drain tube.

EVALUATION

1 Observe for drainage in suction device.	Indicates presence of vacuum, patency of tubing, and functioning of drainage suction device.
---	--

Clinical Decision Point Clots or large collections of debris may block drainage flow. The Y-site in the drainage tubing is especially prone to clogging.

2 Inspect wound for drainage or collection of drainage fluid under skin, causing seroma.	Drainage should not be significant under suture line. May indicate inadequate functioning of drainage suction device.
--	---

STEP	RATIONALE
3 Measure drainage, empty drainage system, record on I&O form.	Empty drainage collection reservoir every 8 to 12 hours and as needed for large drainage volume. Collect diagnostic specimen in presence of unexpected purulence or pungent odor, report findings to health care provider and record in progress note.
4 Assess patient's level of comfort using scale of 0 to 10.	Ensures that procedure does not increase patient's pain.

Unexpected Outcomes

- 1 Site where tube exits becomes infected.
- 2 Bleeding appears in/or around drainage collector.
- 3 Patient experiences pain.
- 4 Drainage suction device is not accumulating drainage.

Related Interventions

- Notify health care provider about presence of signs of infection: purulent drainage, odor, reddened site, increased white blood cell count, and temperature elevation.
- Use aseptic technique when changing dressings.
- Determine amount of bleeding and notify health care provider if excessive.
- Assess for tension on patient's drainage tubing.
- Secure tubing to prevent pulling and pain.
- Assess patient's level of pain.
- Medicate patient.
- Stabilize drainage tubing to reduce tension and pulling against incision.
- Notify health care provider if signs of wound infection are present.
- Assess drainage tubing for clots.
- Assess drainage system for air leaks or kinks.
- Notify health care provider.

Recording and Reporting

- Record emptying the drainage suction device; reestablishing vacuum in suction device; amount, color, odor of drainage; dressing change to drain site; and appearance of drain insertion site.
- Record amount of drainage on I&O record.
- Immediately report a sudden change in amount of drainage, either output or absence of drainage flow, to the health care provider. Also report pungent odor of drainage or new evidence of purulence, severe pain, or dislodgement of the drainage tube to the health care provider.

Special Considerations

Teaching

- Instruct patient about anticipated postoperative drainage, expected progress of wound healing and drainage volume, and estimated date of removal of drain as volume diminishes.
- Teach patient or caregiver how to empty and record amount of drainage. If patient is going home with drainage device, ask

patient or family caregiver to record amount emptied and bring the recording to the next outpatient visit.

Pediatric

- Have parents help to prevent pediatric patients from dislodging drainage tubes.

Gerontologic

- Be aware that older adults with large amounts of drainage will need additional fluid intake because they are more likely to become dehydrated.
- Take measures to prevent a confused patient from pulling out drain collector.

Home Care

- Provide written instructions in drain care. Include importance of measuring and documenting the amount of drainage. Patient should share the volume of drainage on a daily basis with the health care provider.

Critical Thinking Exercises

The nurse is assigned to care for Mrs. Pereira, who was readmitted to the hospital with wound dehiscence and infection following a colon resection. Her past medical history includes chronic obstructive lung disease and diverticulitis.

- Which factors from Mrs. Pereira's history contributed to her poor wound healing? (Select all that apply.) Provide a rationale for your answer.
 - Takes prednisone daily for respiratory disease
 - Has type 2 diabetes mellitus
 - Takes aspirin daily because of myocardial infarction (MI) 6 years earlier
 - Eats six small high-protein meals a day
 - Is 74 years old
 - Drinks 2 L of water daily
- When performing the wound assessment, the nurse notes that the wound base is covered with red, moist granulation tissue. What does the presence of granulation tissue signify in wound healing? Provide a rationale for your answer.
- Describe why the presence of a healing ridge in a wound healing by secondary intention is important for this patient?

REVIEW QUESTIONS

- A patient has a large abdominal wound, which will require irrigation and packing after discharge from the hospital. Which statement made by the patient indicates a need for further teaching related to her wound irrigation?
 - "I'll lie so the wound is vertical to the basin during the irrigation."
 - "I'll use slow, continuous pressure while irrigating my wound."
 - "I'll warm the irrigation solution to body temperature before I use it."
 - "I'll irrigate the wound, starting at the bottom and moving to the top."
- A patient tells the nurse that the health care provider said his sutures are coming out today. Which nursing action is most important before removing the sutures?
 - Assembling the required equipment
 - Checking that there is a health care provider's order for the suture removal
 - Performing hand hygiene in view of the patient
 - Explaining to the patient what will be happening during the suture removal
- A patient has an extensive abdominal wound and is to have half of the staples removed and the incision line cleaned. Which actions should the nurse take during the preparation and actual interaction with the patient? (Select all that apply.)
 - Position the patient in a semi-Fowler's position.
 - Place upper tip of staple remover under staple to ease removal.
 - Administer an analgesic 30 minutes before staple removal.
 - Lift up on the staple when depressing the extractor handles.
 - Clean the incision before removing the staples, starting at the sides next to the incision.
 - Remove all of the staples at the top of the incision and leave the rest, beginning at the middle of the incision.
- The patient is to have sutures removed from his back after surgery. The nurse is performing the procedure correctly by taking which step?
 - Snipping the suture at the end proximal to the knot
 - Wiping the area with a disinfectant swab to prevent wound infection
 - Removing the suture in a smooth, continuous manner
 - Holding the scissors in the nondominant hand and the pickups in the dominant hand

- The nurse notes approximately 60 mL of bright red drainage in the Jackson-Pratt drain 6 hours after surgery. Which nursing interventions should be included in the care for this patient? (Select all that apply.)
 - Emptying the drain 24 hours from now
 - Pinning the drainage tubing to the patient's gown
 - Placing Vaseline gauze around the tube insertion site
 - Securing the drain above the level of the wound
 - Emptying the drain now
 - Squeezing the drain flat before putting in the drainage plug
- A patient had surgery to repair an incisional hernia. His surgical incision was approximated and stapled at the time of the procedure. Which type of wound healing is occurring in the surgical site?
 - Primary intention
 - Secondary intention
 - Tertiary intention
- In preparing to irrigate a wound, which intervention helps to reduce the risk for infection during wound irrigation? (Select all that apply.)
 - Using sterile technique
 - Directing the flow of solution from healthy tissue to infected tissue
 - Warming irrigation solution to body temperature
 - Cleaning suture line after doing wound irrigation
 - Irrigating with a continuous pressure of 3 psi
- The nurse needs to empty the Jackson-Pratt drain collection device every 8 hours. After draining the fluid from the container, how should he or she reestablish the closed suction system?
 - Close the port after emptying the drain
 - Compress the bulb portion of the container and close the port
 - Pump the container several times before closing
 - Leave 10 mL of wound fluid in the container to keep the level of suction constant
- A patient's wound is managed with negative-pressure wound therapy. When you evaluate the negative pressure wound therapy dressing, you note air under the seal of the transparent dressing. What of the following interventions would be appropriate? (Select all that apply.)
 - Turn up the suction.
 - Check the seal of the transparent dressing.
 - Check to be sure that the connections to the suction are intact.
 - Remove and replace the transparent dressing.
 - Reevaluate in 30 minutes since this finding may not be significant.
- The NAP reports to you that the outer dressing from a patient's abdominal wound that is healing by secondary intention has moist, clear, red-tinged drainage. After you verify this finding, how would you describe this type of drainage?
 - Purulent
 - Slough
 - Serous
 - Blood tinged

KEY TERMS

Angiogenesis	Evisceration	Macerated	Primary dressing
Dead space	Excoriation	Negative-pressure wound therapy	Secondary dressing
Debridement	Exudate	Neovascularization	Stomahesive
Dehiscence	Granulation	Occlusive dressing	Wound vacuum-assisted closure
Epithelialization	Hydrocolloid	Pressure dressing	
Erythema	Hydrogel		

OBJECTIVES

Mastery of content in this chapter will enable the nurse to:

- Assess a wound correctly.
- Discuss the purposes of dressings, bandages, and an abdominal binder.
- Choose the correct dressing for a wound.
- Understand the technique of a dressing, bandage, or binder application.
- Describe the advantages and disadvantages of the types of dressings.
- Apply dry, moist-to-dry, pressure, transparent, and synthetic dressings correctly.
- Change a negative-pressure wound therapy dressing correctly.
- Demonstrate the technique for applying turned bandages correctly.
- Apply an abdominal binder correctly.

Wound healing is a complex physiologic process. Proper wound management involves manipulating a wound to restore a physiologic wound environment that is characteristic of normal, healthy tissue. Key features of a physiologic wound environment are adequate moisture, temperature control, pH, and control of bacterial burden (Rolstad, Bryant, and Nix, 2011). A wound heals best in a moist environment because this favors epithelial cell migration, promotes extracellular

matrix formation, reduces fibrosis, and decreases wound infection (Rolstad, Bryant, and Nix, 2011). Dressings are an important part of wound healing because of their ability to control moisture, debride dead tissue, and protect a wound. They also prevent spread of infection and increase patient comfort. Topical dressings establish and maintain a moist—not wet—wound environment by containing wound fluids, absorbing excess moisture, or donating moisture (Rolstad et al., 2011).

BOX 39-1 Dressing Characteristics and Outcomes**Characteristics**

- Is nontraumatic and reduces volume of exudate but does not allow wound to dry
- Maintains stable physiologic wound environment
- Keeps wound bed continuously moist and surrounding (periwound) intact skin dry
- Easy to apply and remove with easy-to-follow patient/family instructions
- Cost-effective: Reimbursable and/or affordable
- Appropriate for infected wounds

Outcomes

- Resolves amount of periwound erythema by 1 week
- Reduces by 50% wound dimensions or depth of sinus tract within 2 weeks
- Reduces volume of exudate
- Reduces by 25% amount of necrotic tissue (eschar) by 1 week
- Reduces pain intensity during dressing changes

Data from Bryant RA, Nix DP: *Acute and chronic wounds: nursing management*, ed 4, St Louis, 2011, Mosby.

Semiocclusive dressings keep wounds moist, even when no added moisture is supplied.

There are two types of dressings, primary and secondary. A primary dressing is a protective cover that comes in direct contact with a wound bed. Secondary dressings serve a protective or therapeutic function by holding primary dressings in place and increasing the ability to meet wound needs (Rolstad et al., 2011). The ideal dressing is based on its characteristics and outcomes (Box 39-1). For example, a pressure dressing is applied to control bleeding. Use a highly absorbent dressing such as alginate or foam to manage wound drainage. Use a hydrocolloid dressing in a noninfected wound that is draining a moderate amount of exudate.

Most dressings are semiocclusive (also called *moisture retentive*) rather than occlusive. Dressings may contain ingredients such as glycerin, polymers, carboxymethylcellulose, cotton, or rayon. A factor to consider when choosing a dressing is ease of application. A dressing should conform to body contours, be durable yet flexible, and be able to absorb or contain exudate. A dressing should be cost-effective, easy to remove without damaging the healing surface and periwound skin, and acceptable in appearance. Wound care needs can change frequently during the phases of wound healing and often require a variety of wound products (Rolstad et al., 2011).

When changing a dressing, you need to know about wound healing and how to differentiate a normal or expected appearance from abnormal changes in a wound. Assessment of the exudates absorbed by a dressing provides valuable diagnostic information (see [Procedural Guideline 38-1](#)).

Primary healing takes place when tissue is cut cleanly and the margins are reapproximated, as in the case of a surgical wound. Repair usually occurs without complication. New capillary circulation bridges the wound quickly in 3 to 4 days, and the wound heals once normal tissue oxygenation is achieved. A wound closed for primary healing is most susceptible to infection during the first 4 days.

Healing by secondary intention occurs when a wound is left open, as in the case of a traumatic wound. Healing results in the formation of granulation tissue from the bottom of the wound and eventual epithelialization from the sides of the wound to close the defect. During epithelialization epithelial cells migrate and

proliferate from the wound edges to cover the wound surface. Burns, infected wounds, and deep pressure ulcers heal in this manner (Doughty and Sparks-DeFries, 2011).

The type of dressing to use depends on the wound characteristics and the goal of wound management, which can be wound debridement or wound healing. Various types of dressings are applied to wounds. Given the many types of available dressings, it may be difficult to decide which dressing is best to use on a particular wound. Numerous dressings and products are available for the management of acute and chronic wounds (Table 39-1). The type of wound care and dressing change required also determines whether to use clean or sterile technique. Clean technique refers to the fact that the nurse maintains medical versus surgical asepsis (e.g., with chronic nonsurgical wounds). A fresh surgical wound requires sterile technique to prevent introducing microorganisms into a healing wound. Current practice recommends using sterile gloves for postoperative dressing changes in the first 24 to 48 hours after surgery.

EVIDENCE-BASED PRACTICE

Negative-pressure wound therapy (NPWT) is designed to create a moist wound healing environment, drain exudate, reduce tissue edema, contract wound edges, and mechanically stimulate a wound bed. An NPWT dressing influences blood perfusion at a wound edge, which may promote angiogenesis and the formation of granulation tissue. No clear evidence shows that NPWT accelerates wound healing compared with other interventions or that one form of NPWT is better than another (Borquist, Ingemansson, and Malmstö, 2011). A systematic review of the literature reveals benefits of NPWT:

- Maximal biologic effect of NPWT at the wound edge can be achieved at -80 mm Hg (Borquist, Ingemansson, and Malmstö, 2011).
- Foam dressings may be advantageous for large-defect wounds (Borquist et al., 2011).
- Gauze dressings may be more suitable for smaller wounds or when scar formation is a concern (Borquist et al., 2011).
- Gauze dressings are a good option for patient comfort (Hurd et al., 2010).
- Intermittent or variable pressure application has a better effect on granulation tissue formation than continuous pressure (Hurd et al., 2010).

PATIENT-CENTERED CARE

An important priority in wound care is patient comfort. Provide patients appropriate analgesic doses 30 minutes before a dressing change to maximize comfort when the dressing and tissues will be manipulated. Consider a patient's cultural view regarding pain. For example, patients from northern European and Asian backgrounds are often more stoic about pain expression, and you will need to offer the pain medication even if the patient does not complain of pain (Galanti, 2008). If a patient's pain is from eroded or denuded skin around the margin of a wound, use skin sealants or barriers. If a patient has ongoing pain from an abdominal wound, consider applying an abdominal binder, which can effectively reduce pain and distress (Cheifetz et al., 2010). It also helps to consistently position patients off of their wounds.

If a patient has a chronic wound, respect the approaches that patient or family caregivers have used to change a dressing at home. Patients might have preferences regarding the time of day to change a dressing or before or after a certain activity. If it is likely

TABLE 39-1 Comparison of Wound Care Products

Product Category	Indications for Use	Contraindications	Advantages	Disadvantages	Frequency of Change (per Manufacturer Recommendations)
Gauze Dressings					
Cotton or synthetic material; woven or nonwoven construction	<ul style="list-style-type: none"> • Protection of surgical incision • Mechanical debridement (moist-to-dry) • Secondary dressing for other wound products • Packing wounds 	<ul style="list-style-type: none"> • Granulating wounds as primary treatment 	<ul style="list-style-type: none"> • Available in many sizes and forms • Sterile and nonsterile 	<ul style="list-style-type: none"> • May adhere to healthy tissue, causing injury when removed • Lint fibers may be left on wound • May interfere with wound healing if gauze dries out in moist-to-dry dressing 	<ul style="list-style-type: none"> • Usually change 2 or 3 times per day as needed.
Transparent Films					
Adhesive membrane dressings; waterproof, impermeable to fluids and bacteria; allow oxygen and moisture vapor exchange	<ul style="list-style-type: none"> • Shallow wounds • Dry to minimally exudative wound • Promote autolytic debridement • Stage I or II pressure ulcers 	<ul style="list-style-type: none"> • Infected wounds; wounds that tunnel, undermine, or are full thickness; wounds with moderate to heavy exudate; third-degree burns 	<ul style="list-style-type: none"> • Easy to apply and remove without damage to underlying tissue • Permit viewing of wound • Create second skin; protect from friction • Waterproof • Create moist wound that softens thin slough and eschar • Protective shield to external fluids and bacteria 	<ul style="list-style-type: none"> • May cause skin maceration • May not adhere to moist areas • May cause skin stripping if improperly removed 	<ul style="list-style-type: none"> • Change every 3 or 4 days or as needed. • If using to facilitate autolytic debridement, change every 24 hours.
Hydrocolloids					
Adhesive dressings that contain gel-forming agents; mold to body contours, considered semioclusive dressings	<ul style="list-style-type: none"> • Partial- or full-thickness wound; shallow • Minimal to moderate exudating wounds • Clean stage II and noninfected shallow stage II-IV pressure ulcers • Can be used in combination with absorbent powder or alginate 	<ul style="list-style-type: none"> • Third-degree burns, acutely infected wounds; arterial or diabetic ulcers (use with caution) • Wounds with dry eschar • Use with caution in persons with diabetes or arterial disease 	<ul style="list-style-type: none"> • Available in many sizes • Promote autolytic debridement • Reduce pain • Impermeable to fluids/bacteria • Thermal insulator • Easy to apply and remove 	<ul style="list-style-type: none"> • Potential for periwound maceration if dressing left in place too long • Drainage (gelatinous mass) under dressing often mistaken for pus/infection • Adhesive possibly too aggressive for fragile skin 	<ul style="list-style-type: none"> • Change every 3 to 5 days.
Hydrogel					
Glycerin- or water-based dressings designed to maintain clean, moist wound; may also absorb small amount of exudate	<ul style="list-style-type: none"> • Partial- or full-thickness wound; shallow or deep • Dry to minimally exudative wound with or without clean granular wound base • Shallow or deep wounds • Wounds with undermining • Necrotic wounds 	<ul style="list-style-type: none"> • Third-degree burns • Wounds with heavy exudate 	<ul style="list-style-type: none"> • Nonadherent • Cool and soothing • Decrease pain • Facilitates autolysis • Conform to wound 	<ul style="list-style-type: none"> • Potential for maceration or candidiasis of periwound area 	<ul style="list-style-type: none"> • Change daily if adhesive sheets or wound fillers are not used. • Change adhesive covers up to 3 times per week.

TABLE 39-1 Comparison of Wound Care Products—cont'd

Product Category	Indications for Use	Contraindications	Advantages	Disadvantages	Frequency of Change (per Manufacturer Recommendations)
Alginates Highly absorbent, nonwoven material that forms gel when exposed to wound drainage; fibrous product derived from brown seaweed	<ul style="list-style-type: none"> Moderate to heavily exudating wounds; shallow or deep Partial- and full-thickness wounds Leg ulcers, donor sites, traumatic wounds 	<ul style="list-style-type: none"> Third-degree burns Nondraining wounds Dry necrotic wounds 	<ul style="list-style-type: none"> Nonadhering, nonocclusive Hemostatic properties May be packed into tunneled areas Promote autolytic debridement in exudating wounds Highly absorbent 	<ul style="list-style-type: none"> More expensive than gauze or gauze packing strips Not practical for large wounds Gelled material may be mistaken for purulence 	<ul style="list-style-type: none"> Change daily or as often as needed, usually every 24 to 48 hours.
Foam Dressings Absorbent, nonadherent polyurethane or film-coated layer used to protect wounds and maintain moist healing environment	<ul style="list-style-type: none"> Moderate to heavily exudating wounds Partial- and full-thickness wounds; shallow and deep Stage II to IV pressure ulcers 	<ul style="list-style-type: none"> Ischemic wound with dry eschar Third-degree burns Wounds that tunnel or sinus tracts Nondraining wounds 	<ul style="list-style-type: none"> Highly absorbent while maintaining moist wound environment Often used as secondary dressing along with films and absorbers Many nonadherent to wound bed 	<ul style="list-style-type: none"> Nonadhesive foams require secondary dressing Maceration of periwound may occur if dressing left on too long 	<ul style="list-style-type: none"> Change every 24 hours or as needed.

Modified from Collins P et al., Wound care literature review 2011, *J WOCN* 39(4S): s*, 2012.; Rolstad BS, Bryant RA, Nix DP: Topical management. In Bryant RA, Nix DP: *Acute and chronic wounds: nursing management*, ed 4, St Louis, 2011, Mosby.

that the patient will continue to have the same type of dressing while at home, be sure to educate him or her and family caregiver on the proper techniques for changing it and disposing of medical waste.

Different cultures and religious practices attribute different meanings to wounds and trauma. It is important to assess and try to understand the different meanings of blood and wounds and how they affect patients and their families. For example, some East Asian cultures interpret loss of blood and secretions as loss of one's spiritual and vital life energy. Some Muslims and Hindus perceive blood as dirty; hence you need to carefully dispose of soiled dressings and linens (Galanti, 2008). Dressing changes always require respect for a patient's privacy. However, sometimes patients from other cultures have additional privacy needs such as the need for gender-congruent caregivers, especially if dressings are located in areas considered private.

Safety Guidelines

- 1 Know the cause or type of wound. Wounds caused by vascular insufficiency, diabetes mellitus, pressure, trauma, and surgery are all very different and must have an individualized treatment plan. Not knowing the cause of a wound can have serious negative effects if you use treatments that are contraindicated for certain types of wounds.
- 2 Know the expected amount and type of wound exudate or drainage (Box 39-2). Wounds with large amounts of drainage require more frequent dressing changes or need an absorptive dressing.
- 3 Determine if wound drainage tubes are present to prevent their accidental dislocation when you remove the old dressing (see Skill 38-3).

BOX 39-2 Types of Wound Drainage

Serous, which is a clear, watery plasma

Sanguineous, which indicates fresh bleeding, bright red

Serosanguineous, which is a pale, red, more watery drainage than sanguineous drainage

Purulent, which is a thick, yellow, green, or brown drainage

4 A wound is a break in skin integrity that increases a patient's risk for infection. Use the appropriate type of gloves when changing a dressing and wash hands thoroughly before and after a dressing change.

5 Be sure that patients in the home setting know infection control principles and how to discard medical waste properly.

SKILL 39-1 Applying a Dressing (Dry and Moist-to-Dry)

NSO Wound Care Module / Lesson 3

Dry gauze dressings are for wound healing by primary intention with little drainage (Fig. 39-1). The dressing protects the wound from injury, reduces discomfort, and speeds healing (when used correctly). Dry gauze dressings do not interact with wound tissues and cause little wound irritation. However, gauze does not maintain a moist wound environment unless a wound is highly exudative (Rolstad et al., 2011). In addition, gauze dressings have the disadvantage of moisture evaporating quickly, causing a dressing to dry out. Frequent dressing changes are usually needed, and there are increased infection rates when compared with semioclusive dressings (Rolstad et al., 2011). Gauze may come impregnated with a variety of substances such as zinc oxide paste, iodinated agents, petrolatum, and crystalline sodium chloride. Impregnated gauze can hydrate a wound and absorb exudate or deliver antimicrobial agents.

Dry gauze dressings are commonly used for abrasions and non-draining postoperative incisions (see Table 39-1). Telfa gauze dressings contain a shiny, nonadherent surface on one side that does not stick to a wound. Drainage passes through the nonadherent surface to the outer gauze dressing. Dry dressings are not appropriate for debriding wounds. When gauze adheres to drainage on a wound surface, the seal can cause you to pull off healthy tissue when the gauze is removed. When gauze does adhere to a wound, moisten the dressing with sterile normal saline or sterile water before removing it to minimize wound trauma.

Moist-to-dry dressings (also called *wet-to-dry* or *damp-to-dry*) are gauze moistened with an appropriate solution. The primary purpose is to mechanically debride wounds, specifically full-thickness wounds healing by secondary intention and wounds with necrotic tissue. A moist-to-dry dressing has a moist contact dressing layer that touches the wound surface. The moistened gauze increases the absorptive ability of the dressing to collect exudate and wound debris. This layer dries and adheres to dead cells, thus debriding the wound when removed. Use a sterile isotonic solution such as normal saline or lactated Ringer's to moisten dressings. The outer

absorbent layer is a dry dressing that protects the wound from invasive organisms.

Recent advances in wound care have created a number of new debriding products for use along with moist gauze for debriding necrotic wounds. Autolytic debriding products are applied to wounds to allow enzymes to self-digest dead tissue. Enzymatic debriding agents applied directly to a wound bed act by digesting collagen in necrotic tissue (NPUAP-EPUAP, 2009; Ramundo, 2011). Both autolytic and enzymatic products are used in combination with moist gauze but may also come as prepackaged dressings that do not require any additional gauze.

Dry and moist-to-dry dressings are secured with tape, which may be paper, plastic, woven, or elastic material with adhesive. Frequent removal of tape for dressing changes irritates the skin and causes skin tears. One method to secure a dressing and reduce tape-related injury is a Montgomery tie or strap. A Montgomery tie is a wide strip of tape with holes and laces that is placed on each side of a wound and tied, thus securing gauze dressings during repeated changes. Use strips of a stomahesive or hydrocolloid dressing to create a window on the outer edges of a wound. Then apply tape for the tie over the strips, thereby reducing contact with sensitive periwound tissue.

The purpose of packing a wound is to fill dead space and avoid the potential of abscess formation by a wound closing too soon (Rolstad et al., 2011). Impregnated gauze is useful when there is undermining (i.e., the destruction of tissue under intact skin around the wound perimeter). When there is wound tunneling, a channel has formed that extends from any part of the wound through subcutaneous tissue or muscle. Strip gauze is useful for filling the narrow areas in the channel so the complete dressing can be removed easily during a dressing change (Rolstad et al., 2011). Damp gauze is useful for packing exudative wounds. If a wound is dry, use hydrating packing material such as hydrogel-impregnated or saline-moistened gauze to keep it moist. Box 39-3 summarizes principles for correctly packing a wound.

FIG 39-1 Types of gauze dressings (right to left): 4 × 4, split, ABD, roll, and Telfa.

BOX 39-3 Principles for Packing a Wound

- Use the wound characteristics to decide which type of packing is appropriate.
- Make sure that the packing material can be safely used to pack a wound.
- Moisten the packing material with a noncytotoxic solution such as normal saline. Never use cytotoxic solutions (e.g., povidone-iodine) to pack a wound.
- If using woven gauze, fluff it before packing it into the wound.
- Loosely pack the wound.
- Do not let the packing material drag or touch the surrounding wound tissue before you put it into the wound.
- Fill all the wound dead space with the packing material.
- Pack the wound until you reach the wound surface; never pack the wound higher than the wound surface.

Every open wound requires cleaning with each dressing change to remove surface bacteria and debris (Rolstad et al., 2011). Usually normal saline is the solution of choice, but commercially prepared wound cleansers are also appropriate. Use an irrigating catheter and syringe for cleaning if a wound is deep (see Chapter 38). Normal saline does not contain a preservative to prevent bacteria from growing in a container; thus any opened saline container must be discarded and replaced in 24 hours. Clearly label all solution bottles with date and time of opening.

Delegation and Collaboration

The skill of applying dry and moist-to-dry dressings may sometimes be delegated to nursing assistive personnel (NAP) if the wound is chronic (see agency policy and Nurse Practice Act). All wound assessments, care of acute new wounds, and wound care requiring sterile technique cannot be delegated. The nurse directs the NAP about:

- Any unique modifications of the dressing change such as the need for use of special tape or taping techniques to secure the dressing.
- Reporting pain, fever, bleeding, or wound drainage to the nurse immediately.

Equipment

- Clean gloves
- Sterile gloves
- Sterile dressing set (scissors, forceps) (*optional*, check agency policy)
- Sterile drape (*optional*)
- Sterile dressings: fine mesh gauze, 4 × 4-inch gauze, abdominal (ABD) pads
- Sterile basin (*optional*)
- Antiseptic ointment (as prescribed)
- Wound cleanser (as prescribed)
- Sterile normal saline or prescribed solution
 - Debriding gel as ordered
- Tape, Montgomery ties, or bandage as needed (include nonallergenic tape if necessary)
 - Skin barrier (*optional* if using Montgomery ties)
- Protective waterproof underpad
- Waterproof bag
- Adhesive remover (*optional*)
- Measurement devices (*optional*): Cotton-tipped applicator, measuring guide, camera
- Protective gown, goggles, mask (used when splashing from wound is a risk)
- Additional lighting if needed (e.g., flashlight, treatment light)

STEP	RATIONALE
------	-----------

ASSESSMENT

- 1 Ask patient to rate his or her level of pain using a pain scale of 0 to 10 and assess character of pain. Administer prescribed analgesic as needed 30 minutes before dressing change.
- 2 Assess size, location, and condition of wound. Review previous nurses' notes and electronic health record (EHR).
- 3 Assess patient for allergies, especially antiseptics, tape, or latex.
- 4 Assess patient's and family caregiver's knowledge of purpose of dressing change.
- 5 Assess need, readiness, and willingness for patient or family caregiver to participate in dressing wound.
- 6 Review medical orders for dressing change procedure.
- 7 Identify patients at risk for wound-healing problems, including aging, premature infant, obesity, diabetes mellitus, circulation disorders, nutritional deficit, immunosuppression, radiation therapy, high levels of stress, and use of steroids.

Superficial wounds with multiple exposed nerves may be intensely painful, whereas deeper wounds with destruction of dermis should be less painful (Krasner, 2011). A comfortable patient will be less likely to move suddenly, causing wound or supply contamination.

Serves as baseline to measure response to dressing therapy.

Helps to plan for proper dressing type, securement and supplies needed, and if assistance is needed during procedure.

Patients with allergies may have localized or systemic allergic reactions to these supplies.

Determines level of support and explanation required.

Prepares patient or family caregiver if dressing must be changed at home.

Indicates type of dressing or applications to use.

Physiologic changes resulting from aging, chronic illness, poor nutrition, medications that affect wound healing, and cancer treatments have potential to affect wound healing (Doughty, Sparks-DeFries, 2011).

NURSING DIAGNOSES

- | | | |
|--|--|--|
| <ul style="list-style-type: none"> • Acute pain • Chronic pain | <ul style="list-style-type: none"> • Deficient knowledge • Impaired skin integrity | <ul style="list-style-type: none"> • Risk for infection • Risk for caregiver role strain |
|--|--|--|

Related factors are individualized based on patient's condition or needs.

PLANNING

- 1 Expected outcomes following completion of procedure:
 - Patient's wound shows evidence of healing by decrease in size and less drainage, redness, or swelling.

Indicates that wound is healing appropriately.

STEP	RATIONALE
<ul style="list-style-type: none"> • Patient reports pain less than previous assessment after dressing change. • Dressing remains clean, dry, and intact. • Patient or family explains purpose of dressing and method of dressing application. 	<p>Indicates that dressing procedure and choice are appropriate.</p> <p>Indicates that proper application and securement are used for dressing.</p> <p>Indicates that learning has occurred.</p>
2 Explain procedure to patient.	Decreases patient's anxiety.

IMPLEMENTATION

1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).
2 Close room or cubicle curtains. Perform hand hygiene.	Provides for privacy.
3 Position patient comfortably and drape to expose only wound site. Instruct patient not to touch wound or sterile supplies.	Draping provides access to wound while minimizing exposure. Dressing supplies become contaminated when touched by patient's hand.
4 Place disposable waterproof bag within reach of work area. Fold top of bag to make cuff. Perform hand hygiene and apply clean gloves. Apply gown, goggles, and mask if risk for splashing exists.	Ensures easy disposal of soiled dressings. Prevents contamination of outer surface of bag. Use of personal protective equipment reduces transmission of microorganisms.
5 Gently remove tape, bandages, or ties: use nondominant hand to support dressing and, with your dominant hand, pull tape parallel to skin and toward dressing. If dressing is over hairy area, remove in direction of hair growth. Get patient permission to clip or shave area (check agency policy). Remove any adhesive from skin.	Pulling tape toward dressing reduces stress on suture line or wound edges and reduces irritation and discomfort.
6 With gloved hand or forceps remove dressing one layer at a time, observing appearance and drainage of dressing. Carefully remove outer secondary dressing first; then remove inner primary dressing that is in contact with wound bed. If drains are present, slowly and carefully remove dressings (see illustration) and avoid tension on any drainage devices. Keep soiled undersurface from patient's sight. <ul style="list-style-type: none"> a If moist-to-dry dressing adheres to wound, gently free dressing and alert patient of discomfort. b If dry dressing adheres to wound that is not to be debrided, moisten with normal saline and remove. 	<p>Purpose of primary dressing is to remove necrotic tissue and exudate. Appearance of drainage may be upsetting to patient. Avoids accidental removal of drain.</p> <p>Moist-to-dry dressing should debride wound. Do not wet dressing; it should be dry.</p> <p>Prevents injury to wound surface and periwound during dressing removal.</p> <p>Assesses condition of wound and periwound condition. Indicates status of healing.</p>
7 Inspect wound and periwound for appearance, color, size (length, width, and depth), drainage, edema, presence and condition of drains, approximation (wound edges are together), granulation tissue, or odor (see Chapters 18 and 38). Use measuring guide or ruler to measure size of wound (see Chapter 38). Gently palpate wound edges for boggy or patient report of increased pain.	
8 Fold dressings with drainage contained inside and remove gloves inside out. With small dressings remove gloves inside out over dressing (see illustrations). Dispose of gloves and soiled dressing according to agency policy. Cover wound lightly with sterile gauze pad and perform hand hygiene.	Contains soiled dressings, prevents contact of nurse's hands with drainage, and reduces cross-contamination.

STEP 6 Penrose drain with split gauze.

STEP

RATIONALE

- 9 Describe appearance of wound and any indicators of wound healing to patient.
- 10 Create sterile field with sterile dressing tray or individually wrapped sterile supplies on over-bed table (see Chapter 8). Pour any prescribed solution into sterile basin.
- 11 Cleanse wound (see Chapter 38):
 - a Perform hand hygiene and apply clean gloves. Use gauze or cotton ball moistened in saline or antiseptic swab (per health care provider order) for each cleansing stroke or spray wound surface with wound cleanser.
 - b Clean from least to most contaminated area (see Chapter 38) (see illustration).
 - c Clean around any drain (if present), using circular strokes starting near drain and moving outward and away from insertion site (see illustration) (see Chapter 38).
- 12 Use sterile dry gauze to blot in same manner as in Step 11 to dry wound.

Wounds may appear unsettling and frightening to patients; it helps patient to know that wound appearance is as expected and whether healing is taking place.

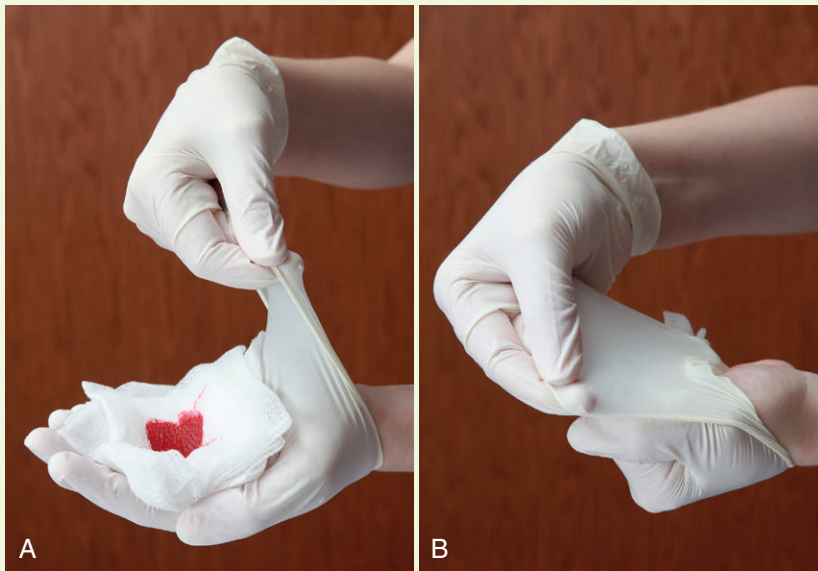

Sterile dressings remain sterile while on or within sterile surface. Preparation of all supplies prevents break in technique during dressing change.

Prevents transfer of organisms from previously cleaned area.

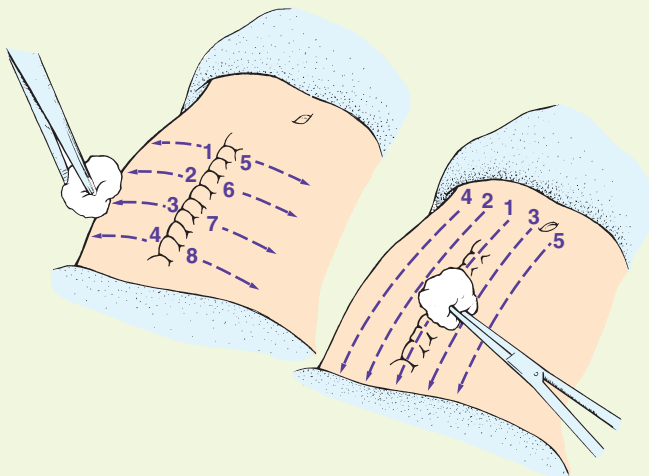

Cleaning in this direction prevents introduction of organisms into wound.

Correct aseptic technique in cleaning prevents contamination.

Drying reduces excess moisture, which could eventually harbor microorganisms.

STEP 8 A and B, Dispose of soiled dressings by placing in gloved hand and pulling glove off over dressing and then off hand.

STEP 11b Methods for cleansing a wound, cleansing from least to most contaminated.

STEP 11c Cleaning around a drain site.

STEP	RATIONALE
13 Apply antiseptic ointment (if ordered) with sterile Q-tip or gauze, using same technique to apply as for cleaning. Dispose of gloves. Perform hand hygiene.	Helps reduce growth of microorganisms.
14 Apply dressing (see agency policy):	
a Dry sterile dressing: (1) Apply clean gloves (see agency policy). (2) Apply loose woven gauze as contact layer (see illustration). (3) If drain is present, apply precut, split 4 × 4-inch gauze around drain. (4) Apply additional layers of gauze as needed. (5) Apply thicker woven pad (e.g., Surgipad, abdominal [ABD] pad) (see illustration).	Some agencies or condition of wounds may require sterile gloves. Promotes proper absorption of drainage. Secures drain and promotes drainage absorption at site. Ensures proper coverage and optimal absorption. This type of cover dressing is used on postoperative wounds when there is excessive drainage.
b Moist-to-dry dressing: (1) Apply sterile gloves (see agency policy). (2) Place fine-mesh or loose 4 × 4-inch gauze in container of prescribed sterile solution. Wring out excess solution.	Reduces transmission of infection. Moist gauze absorbs drainage and, when allowed to dry, traps debris.
Clinical Decision Point If using “packing strips,” use sterile scissors to cut the amount of dressing that you will use to pack the wound. Do not let the packing strip touch the side of the bottle. Pour prescribed solution over the packing gauze or strip to moisten it.	
(3) Apply moist fine-mesh or open-weave gauze as single layer directly onto wound surface. If wound is deep, gently pack gauze into wound with sterile gloved hand or forceps until all wound surfaces are in contact with moist gauze, including dead spaces from sinus tracts, tunnels, and undermining (see illustration A). Be sure that gauze does not touch periwound skin (see illustration B).	Inner gauze should be moist, not dripping wet, to absorb drainage and adhere to debris. When packing a wound, gauze should conform to base and side of wound (Rolstad et al, 2011). Wound is loosely packed to facilitate wicking of drainage into absorbent outer layer of dressing. Moisture that escapes dressing often macerates the periwound area.
Clinical Decision Point Do not overpack wound too tightly (Rolstad et al., 2011); it can cause wound trauma when dressing is removed.	
(4) Apply dry sterile 4 × 4-inch gauze over moist gauze. (5) Cover with ABD pad, Surgipad, or gauze.	Dry layer pulls moisture from wound. Protects wound from entrance of microorganisms.
15 Secure dressing. a <i>Tape:</i> Apply tape 1 to 2 inches (2.5 to 5 cm) beyond dressing. Use nonallergenic tape when necessary. b Montgomery ties (see illustrations):	Supports wound and ensures placement and stability of dressing. Ties allow for repeated dressing changes without removal of tape.

STEP 14a(2) Placing dry gauze dressing over simple wound.

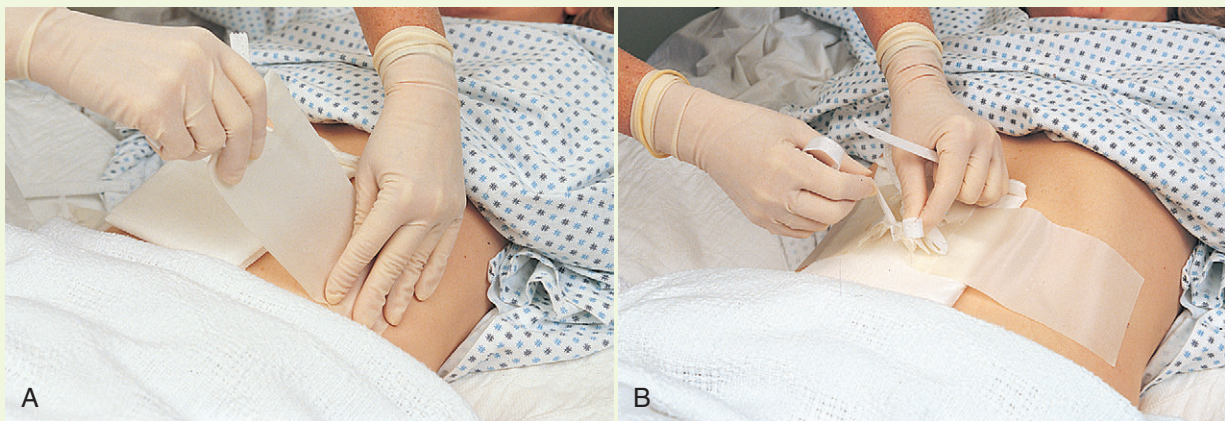

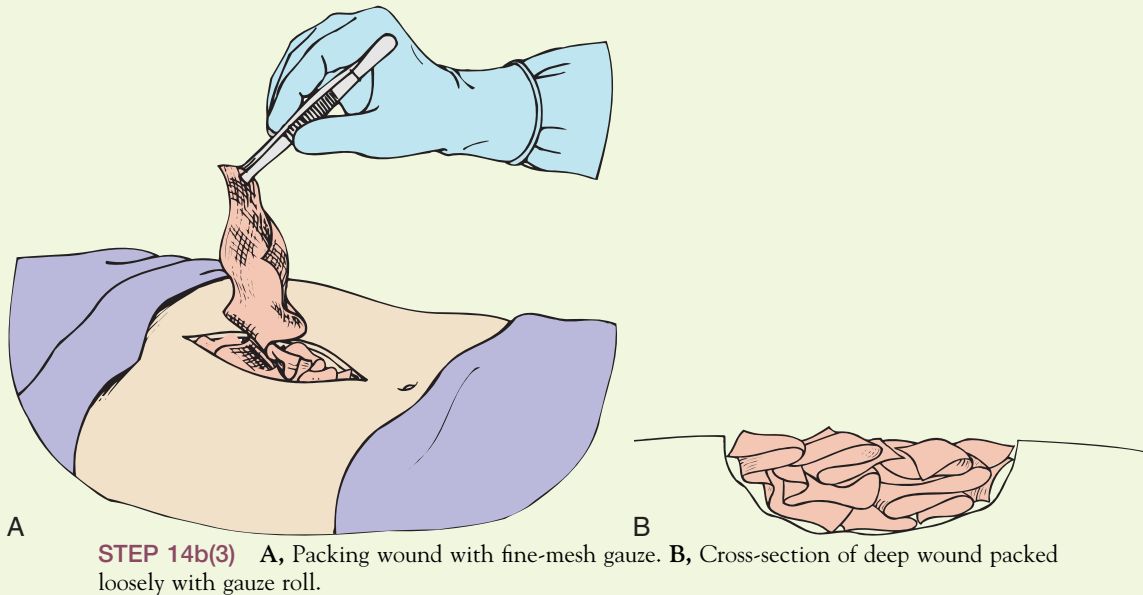

STEP 14a(5) Placing ABD pad over gauze dressing.

STEP

RATIONALE

- | | |
|--|--|
| <ul style="list-style-type: none"> (1) Be sure that skin is clean. Application of skin barrier is recommended (see Chapter 18). (2) Expose adhesive surface of tape ends. (3) Place ties on opposite sides of dressing over skin or skin barrier. (4) Secure dressing by lacing ties across dressing snugly enough to hold it secure but without placing pressure on skin. <p>c For dressing an extremity, secure with roller gauze (see illustration) or elastic net.</p> <ul style="list-style-type: none"> 16 Dispose of all dressing supplies. Remove cover gown and goggles and remove gloves inside out; dispose of them according to agency policy. 17 Label tape over dressing with your initials and date dressing is changed. 18 Help patient to comfortable position. 19 Perform hand hygiene. | <p>Skin barrier (stomahesive) protects intact skin from stretch and tension of adhesive tape.</p> <p>Roller gauze conforms to contour of foot or hand.</p> <p>Reduces transmission of microorganisms. Clean environment enhances patient comfort.</p> <p>Provides timeline for when next dressing change is to be scheduled.</p> <p>Promotes patient's sense of well-being.</p> <p>Reduces transmission of microorganisms.</p> |
|--|--|

STEP 15b Montgomery ties. A, Each tie is placed at side of gauze dressing. B, Securing ties encloses dressing.

STEP

RATIONALE

STEP 15c Wrap roller gauze around extremity to secure dressing.

EVALUATION

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Observe appearance of wound for healing: measure size of wound; observe amount, color, and type of drainage and periwound erythema or swelling. 2 Ask patient to rate pain using a scale of 0 to 10. 3 Inspect condition of dressing at least every shift. 4 Ask patient and/or family caregiver to describe steps and techniques of dressing change. | <p>Determines rate of healing.</p> <p>Increased pain is often indication of wound complications such as infection or result of dressing pulling tissue.</p> <p>Determines status of wound drainage.</p> <p>Evaluates learning.</p> |
|--|--|

Unexpected Outcomes

- 1 Wound appears inflamed and tender, drainage is evident, and/or odor is present.
- 2 Wound bleeds during dressing change.
- 3 Patient reports sensation that “something has given way under the dressing.”

Related Interventions

- Monitor patient for signs of infection (e.g., fever, increased white blood cell count).
- Notify health care provider.
- Obtain wound cultures as ordered.
- If there is yellow, tan, or brown necrotic tissue, refer to health care provider to determine need for debridement (Table 39-2).
- Observe color and amount of drainage. If excessive, may need to apply direct dressing.
- Inspect area along dressing and directly underneath patient to determine amount of bleeding.
- Obtain vital signs as needed.
- Notify health care provider.
- Observe wound for increased drainage or dehiscence (partial or total separation of wound layers) or evisceration (total separation of wound layers and protrusion of viscera through wound opening).
- Protect wound. Cover with sterile moist dressing.
- Instruct patient to lie still.
- Stay with patient to monitor vital signs.
- Notify health care provider.

Recording and Reporting

- Record appearance and size of wound, characteristics of drainage, presence of necrotic tissue, type of dressing applied, patient’s response to dressing change, and level of comfort in nurses’ notes and EHR.
- Report any unexpected appearance of wound drainage, accidental removal of drain, bright red bleeding, or evidence of wound dehiscence or evisceration.

Special Considerations

Teaching

- Explain expected wound appearance and risks of improper wound care. Provide patient and family caregiver with a written list of signs to report to the health care provider.
- After demonstrating wound care, allow patient or caregiver to perform dressing change with and without supervision.

TABLE 39-2 Problems Associated with Wounds Requiring Debridement

Problem	Nursing Activities
Solutions used may be irritating to healthy skin around wound.	Protect healthy skin with protective barrier such as stomahesive or apply topical ointments such as zinc oxide. If zinc oxide is used, it should be removed with mineral oil. Avoid scrubbing the skin because scrubbing can cause harm to the epithelial layer.
Wound becomes excessively dry.	A continually moist dressing (with a health care provider's order) might be tried. Eliminate fine-mesh gauze and lightly pack wound with fluffy gauze dampened with prescribed solution.
Wound is deep, and retention of dressing in cavity is suspected.	Irrigate wound copiously with prescribed solution to loosen dressing for removal. Use continuous "ribbon" or strip of gauze to dress deep wounds.
Wound drainage is damaging healthy tissue.	Protect healthy tissue with skin barrier such as a hydrocolloid. Wounds with large amounts of drainage may benefit from occlusive drainage collection device.
Patient's skin is irritated by tape.	Use hydrocolloid under tape, use Montgomery ties as needed, use fabric tape that has multidirectional stretch, secure dressing with binder, or wrap with roll gauze if on extremity.

Pediatric

- Some pediatric patients are fearful of dressing changes. Obtain patient's cooperation and/or have another person available to keep child from moving during dressing change procedure (Hockenberry and Wilson, 2011).
- Older children may need something to do during dressing changes. Listening to music or watching a video helps to relieve some of the boredom or stress during the procedure (Hockenberry and Wilson, 2011).

Gerontologic

- Adhesive tape often irritates older adults' skin and causes skin tears. Use paper tape, nonallergenic tape, or wraps or mesh to prevent tape from contacting patient's skin.
- Another option is to create a stomahesive window. Cut strips of stomahesive into 1-cm (1/2-inch) strips. Use a skin barrier to wipe areas of intact skin where you will place strips. Apply the adhesive strips to two or four sides of the wound, framing it. Apply dressing. Apply tape to the stomahesive strips.
- Normal aging changes of skin and tissue and the inflammatory response may delay wound healing (Wysocki, 2011).

Home Care

- Consider resources within the home, ability of a family caregiver, and the amount of time needed to change a particular dressing when selecting a dressing procedure in the home setting. More expensive dressings may be used to decrease frequency of dressing changes.
- Reimbursement for wound care requires a signed health care provider's order, treatment plan, and documentation of the actual care provided.

SKILL 39-2 Applying a Pressure Bandage

A pressure bandage is a temporary treatment to control excessive, sudden, unanticipated bleeding. Hemorrhage may occur during surgical intervention (e.g., cardiac catheterization, arterial puncture, organ biopsy) or after surgery or be a life-threatening occurrence related to accidental trauma (e.g., stabbing, suicide attempt). Pressure dressings are essential to stopping the flow of blood and promoting clotting at the site until definitive action can be taken to stop the source. A number of hemostatic wound products developed for use in trauma settings have shown promise in controlling hemorrhaging wounds (Granville-Chapman, Jacobs, and Midwinter, 2011). One example is HemCon, made from chitosan, a naturally occurring biocompatible polysaccharide that becomes extremely adherent when in contact with blood.

Given the emergent nature of an acute bleeding episode, the aseptic techniques considered essential in most dressing applications are secondary to halting the bleeding. A pressure dressing applied in an emergency is usually temporary; the wound can be cleaned, and dressing changed once the bleeding has been controlled.

Delegation and Collaboration

The skill of applying a pressure dressing in an emergency situation cannot be delegated to nursing assistive personnel (NAP). If application requires more than one person, the NAP can assist. The nurse directs the NAP to:

- Observe the pressure dressing during care activities to make sure that it remains in place and that there is no visible bleeding from the site.
- Observe underneath patient for bleeding after dressing has been applied.

Equipment

- Necessary dressings: Fine-mesh gauze, abdominal (ABD) pads, hemostatic dressings, roller gauze
- Adhesive tape; hypoallergenic if necessary
- Adhesive remover (optional)
- Clean gloves
- Protective gown, goggles, mask (used when spray from wound is a risk)
- Equipment for vital signs

STEP

RATIONALE

ASSESSMENT

1 Anticipate patients at risk for unexpected bleeding, including traumatic injury, arterial puncture, donor graft site, postoperative wound, wounds after surgical debridement, and surgical patient with history of bleeding disorder.	Be familiar with conditions associated with unexpected bleeding to rapidly respond to bleeding.
2 Assess location and circumstance of area where hemorrhage is expected.	Helps to identify proper type and amount of supplies needed.
3 Assess patient for allergies to antiseptics, tape, or latex. If patient is nonresponsive and no history is available, use nonlatex or nonallergenic supplies.	Prevents localized or systemic allergic reaction.
4 Quickly assess patient's anxiety level.	Determines need for education and positive reinforcement during procedure.
5 Consider patient's baseline vital signs before onset of hemorrhage.	If data are available, baseline vital signs indicate status of circulatory function.

NURSING DIAGNOSES

- Decreased cardiac output
- Risk for imbalanced fluid volume
- Impaired skin integrity

Related factors are individualized based on patient's condition or needs.

PLANNING

1 Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Patient shows complete cessation of bleeding and no evidence of hematoma formation. • Patient maintains stable blood pressure and heart rate. • Distal circulation is maintained with intact pulses (distal to site of injury). 	Hemostasis is achieved. Hemodynamic stability is achieved with minimal blood loss. There is no hematoma formation at site of pressure application.
--	--

IMPLEMENTATION

Phase I: Immediate action—first nurse

1 Identify external bleeding site. Look underneath patients with large abdominal dressings. NOTE: Wounds to groin area also can result in large amounts of blood loss, which is not always visible.	Quick identification increases response time to stop bleeding. Maintaining asepsis and privacy are considered only if time and severity of blood loss permit.
2 Apply immediate manual pressure to bleeding site.	Hemostasis maintained as supplies are prepared.
3 Seek assistance.	Bandage must be secured quickly.

Phase II: Applying pressure bandage—second nurse

4 Quickly identify source of bleeding. <ul style="list-style-type: none"> • <i>Arterial bleeding</i> is bright red and gushes forth in waves, related to heart rate; if vessel is very deep, flow is steady. • <i>Venous bleeding</i> is dark red and flows smoothly. • <i>Capillary bleeding</i> is oozing of dark red blood; self-sealing controls this bleeding. 	Determines method of application and supplies to use.
5 Elevate affected body part (e.g., extremity) if possible.	Helps slow rate of hemorrhage.
6 First nurse continues to apply direct pressure as second nurse unwraps roller bandage and places within easy reach. Second nurse quickly cuts three to five lengths of adhesive tape and places them within reach; <i>do not cleanse wound</i> .	Pressure dressing controls bleeding temporarily. Preparation allows for securing pressure bandage quickly.
7 In simultaneous coordinated actions: <ul style="list-style-type: none"> a Rapidly cover bleeding area with multiple thicknesses of gauze compresses. First nurse slips fingers out as other nurse exerts adequate pressure to continue controlling bleeding (see illustrations). b Place adhesive strips 7 to 10 cm (3 to 4 inches) beyond width of dressing with even pressure on both sides of fingers as close as possible to central bleeding source. Secure tape on distal end, pull tape across dressing, and keep firm pressure as proximate end of tape is secured. 	Gauze is absorbent. Layers provide bulk against which local pressure can be applied to bleeding site. Tape exerts downward pressure, promoting hemostasis. To ensure blood flow to distal tissues and prevent tourniquet effect, adhesive tape must not be continued around entire extremity.

STEP	RATIONALE
<p>c Remove fingers temporarily and quickly cover center of area with third strip of tape.</p> <p>d Continue reinforcing area with tape as each successive strip is overlapped on alternating sides of center strip. Keep applying pressure.</p> <p>e When pressure bandage is on extremity, apply roller gauze: apply two circular turns tautly on both sides of fingers that are pressing gauze. Compress over bleeding site. Simultaneously remove finger pressure and apply roller gauze over center. Continue with figure-eight turns. Secure end with two circular turns and strip of adhesive (see Procedural Guideline 39-1).</p>	<p>Provides pressure to source of bleeding.</p> <p>Prevents tape from loosening.</p> <p>Roller gauze acts as pressure bandage, exerting more even pressure over extremity.</p>

Clinical Decision Point Start pressure bandage from distal to proximal, working toward the heart.

STEP 7a A, Bleeding wound. B, Nurses apply pressure dressing.

EVALUATION

1 Observe dressing for control of bleeding.	Effective pressure bandage controls bleeding without blocking distal circulation.
2 Evaluate adequacy of circulation (distal pulse, skin characteristics).	Determines level of perfusion to distal body parts.
3 Estimate volume of blood loss (e.g., count number of dressings used, weigh saturated dressing).	Helps to determine blood and fluid replacement needs.
4 Measure vital signs.	Identifies patient's adaptation to blood loss and early stages of hypovolemic shock.

Unexpected Outcomes

- There is continued bleeding. Fluid and electrolyte imbalance, tissue hypoxia, confusion, hypovolemic shock, and cardiac arrest develop.
- Pressure dressing is too tight and occludes circulation.

Related Interventions

- Notify health care provider.
- Reinforce or adjust pressure dressing.
- Initiate intravenous (IV) therapy per order.
- Place patient in Trendelenburg's position; provide covers for warmth.
- Monitor vital signs every 5 to 15 minutes (apical pulse, distal pulses, and blood pressure).
- Inspect areas distal to pressure dressing to ensure that circulation has not been occluded.
- Adjust dressing as needed.
- Notify health care provider.

Recording and Reporting

- Report immediately to health care provider present status of patient's bleeding control, time bleeding was discovered, estimated blood loss, nursing interventions (including effectiveness of applied pressure bandage), apical and distal pulses, blood pressure, mental status, signs of restlessness, and need for health care provider to administer to patient without delay.
- Record interventions taken and patient's response in progress notes and vital sign flow sheet.

Special Considerations

Teaching

- Explain to patient and family (if present) need to monitor vital signs.
- Explain need for patient to remain quiet and stay in position to reduce bleeding.

Pediatric

- Child will calm down if care providers and family remain calm.

Gerontologic

- Because of the normal changes of aging, the older adult has an increased risk for vascular and tissue changes distal to the pressure dressing. Evaluate skin and pulse distal to the pressure bandage frequently.

Home Care

- If patient is at risk for hemorrhage, instruct on the following:
- How family caregiver or patient should apply pressure with clean towels or linen

- Immediate activation of emergency system (9-1-1)
- How to position patient by elevating affected body part (if extremity)
- CAUTION: If a puncture wound occurs from a penetrating object (e.g., knife, toy, building materials), do not remove the object. Removal will cause more rapid blood loss and may damage underlying structures.
- How to position patient to promote elevation of affected body part (if extremity) and promote relaxation

SKILL 39-3 Applying a Transparent Dressing**NSO** Wound Care Module / Lesson 3

A transparent film dressing is a clear, adherent, nonabsorptive, polyurethane sheet. Once it is applied, a moist exudate forms over the wound surface, which prevents tissue dehydration and allows for rapid, effective healing by speeding epithelial cell growth. The adhesive is inactivated by moisture and does not adhere to a moist surface. A transparent film has no absorbent capacity, and it is impermeable to fluids and bacteria (Rolstad et al., 2011). The dressings are appropriate for prophylaxis on high-risk intact skin (e.g., high friction areas), superficial wounds with minimal or no exudate, and eschar-covered wounds when autolysis is indicated and safe (NPUAP-EPUAP, 2009). Clinicians commonly use transparent dressings as the dressing of choice over an intravenous (IV) catheter insertion site. The synthetic permeable membrane acts as a temporary second skin, adheres to undamaged skin to contain exudate, minimizes wound contamination, and allows a wound to “breathe.” They are also commonly used as secondary dressing to wound products such as alginates and foam.

Transparent dressings come in a variety of sizes. Select one that allows for a 2.5-cm (1 inch) perimeter onto intact skin around the wound (Rolstad et al., 2011). Use a skin barrier on the skin around a wound before dressing application to prevent stripping thin or fragile skin. Because these dressings are clear, you can observe a wound without removing the dressing. For best results these

dressings are applied over clean, debrided wounds that are not actively bleeding. The accumulation of fluid with a white, opaque appearance and erythema of the surrounding tissue usually indicate an infectious process; the dressing should be removed, and a wound culture obtained.

Delegation and Collaboration

The skill of applying a transparent dressing for select wounds can be delegated to nursing assistive personnel (NAP) (refer to agency policy). The assessment of the wound and care of sterile or new acute wounds cannot be delegated to NAP. The nurse directs the NAP about:

- Explaining how to adapt the skill for a specific patient.
- Reporting any signs of bleeding, drainage, infection, or poor wound healing immediately to the nurse.

Equipment

- Sterile gloves (optional)
- Dressing set (optional)
- Sterile saline or other cleansing agent (as ordered)
- Clean gloves
- Cotton swabs
- Waterproof bag for disposal
- Transparent dressing (size as needed)
- Sterile 4 × 4-inch gauze pads
- Skin preparation materials (optional)

STEP**RATIONALE****ASSESSMENT**

- 1 Assess location, appearance, and size of wound (see Chapter 38). Determine size of transparent dressing needed. Review previous nurses' notes and electronic health record (EHR).
- 2 Review health care provider's orders for frequency and type of dressing change.
- 3 Assess patient for allergies, especially antiseptics, tape, or latex.
- 4 Ask patient to rate level of pain using pain scale of 0 to 10 and assess character of pain. Administer prescribed analgesic as needed 30 minutes before dressing change.
- 5 Assess patient's knowledge of purpose of dressing.
- 6 Assess patient's risks for impaired wound healing (e.g., aging, poor nutrition).

Determines type of materials needed for dressing change.

Health care provider orders frequency of dressing changes and special instructions.

Prevents local or systemic allergic reaction.

Comfortable patient will be less likely to move suddenly, causing wound or supply contamination. Serves as baseline to measure response to dressing therapy.

Identifies patient's learning needs.

Physiologic changes caused by aging, chronic illness, poor nutrition, medications, and cancer treatments have potential to affect wound healing (Doughty and Sparks-DeFries, 2011).

NURSING DIAGNOSES

- Acute pain
- Impaired skin integrity
- Risk for infection

Related factors are individualized based on patient's condition or needs.

STEP

RATIONALE

PLANNING

- | | | |
|---|---|---|
| 1 | Expected outcomes following completion of procedure: <ul style="list-style-type: none"> • Wound heals rapidly with little pain and mobility restriction for patient. • Patient experiences minimal discomfort during dressing change. | Dressing effective in preventing infection and promoting healing. |
| 2 | Explain procedure to patient. | Adequate pain control achieved. |
| 3 | Position patient comfortably and to allow for access to dressing site. | Relieves anxiety and promotes understanding of healing process.
Facilitates application of dressing. |

IMPLEMENTATION

- | | | |
|----|--|--|
| 1 | Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet. | Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012). |
| 2 | Close door or cubicle curtains; keep sheet or gown draped over body parts not requiring exposure. | Provides privacy and decreases transfer of microorganisms. |
| 3 | Expose wound site, minimizing exposure. Instruct patient not to touch wound or sterile supplies. | Dressing supplies become contaminated when touched by patient's hand. |
| 4 | Cuff top of disposable waterproof bag and place within reach of work area. | Cuff prevents accidental contamination of tip of outer bag. |
| 5 | Perform hand hygiene and apply clean gloves. Apply personal protective equipment (gown, mask, goggles as needed). | Reduces transmission of infectious organisms from soiled dressings to nurse's hands. |
| 6 | Remove old dressing by stretching film in direction parallel to wound rather than pulling. | Stretching action gently breaks dressing seal (Rolstad et al., 2011).
Reduces excoriation, tearing, or irritation of skin after dressing removal. |
| 7 | Dispose of soiled dressing in waterproof bag, remove gloves by pulling them inside out, dispose of them in waterproof bag, and perform hand hygiene. | Reduces transmission of microorganisms. |
| 8 | Prepare dressing supplies. Use sterile supplies for new wounds. | Reduces risk for break in sterile technique. |
| 9 | Pour saline or prescribed solution over 4 × 4-inch sterile gauze pads. | Maintains sterility of dressing. |
| 10 | Apply clean or sterile gloves (check agency policy). | Allows you to handle dressings. |
| 11 | Clean wound and periwound area gently with 4 × 4-inch sterile gauze pads moistened in sterile saline or spray with wound cleanser. Clean from least to most contaminated area (see Skill 39-1). | Reduces introduction of organisms into wound. |
| 12 | Pat skin around wound dry thoroughly with dry 4 × 4-inch sterile gauze pads. | Transparent dressing with adhesive backing does not adhere to damp surface (Rolstad et al., 2011). |
| 13 | Inspect wound for tissue type, color, odor, and drainage; measure if indicated (see Chapters 18 and 38). | Provides baseline for monitoring wound healing. |
| 14 | Remove gloves and perform hand hygiene. | Reduces transmission of microorganisms. |

Clinical Decision Point *If wound has a large amount of drainage, choose another dressing that can absorb drainage.*

- | | | |
|----|---|---|
| 15 | Apply transparent dressing according to manufacturer directions. <i>Do not stretch film during application and avoid wrinkles.</i> Apply clean gloves. <ul style="list-style-type: none"> a Remove paper backing, taking care not to allow adhesive areas to touch each other. b Place film smoothly over wound without stretching (see illustrations). c Use your fingers to smooth and adhere dressing. d Label dressing with date, your initials, and time of dressing change on outer label of dressing (see illustration). | Wrinkles provide tunnel for exudate drainage. |
| 16 | Discard soiled dressing materials properly. Remove gloves by pulling them inside out and discard in prepared bag. Perform hand hygiene. | Ensures coverage of wound. Prevents shearing of skin from dressing that is too tight. Stretching can also break wound seal. |
| 17 | Help patient to comfortable position. | Provides record for determining when to next change dressing. |
| | | Reduces transfer of microorganisms. |
| | | Enhances patient comfort and relaxation. |

STEP

RATIONALE

A

B

STEP 15b A, Transparent dressing placed over small wound on ankle. B, Place film smoothly without stretching.

STEP 15d Transparent dressing correctly labeled.

EVALUATION

- | | |
|--|--|
| <ol style="list-style-type: none"> 1 Inspect appearance of wound and amount of drainage and measure size. 2 Inspect periwound areas. 3 Ask patient to rate pain using scale of 0 to 10. | <p>Determines status of wound healing. Wound is easy to view.</p> <p>Identifies any injury to surrounding skin.</p> <p>Determines any change in pain during procedure.</p> |
|--|--|

Unexpected Outcomes

- 1 Wound is inflamed, tender; drainage, necrosis, and/or odor is present.
- 2 Dressing does not stay in place.
- 3 Outer layer of patient's skin tears on removal of dressing.

Related Interventions

- Remove dressing and obtain wound culture according to agency policy.
- Different type of dressing may be required.
- Notify health care provider.
- Evaluate size of dressing used for adequate wound margin (2.5 to 3.75 cm [1 to 1½ inches]).
- Dry patient's skin thoroughly before reapplication.
- Adhesive backing may be too strong for fragile skin.
- Consider other nonadhesive-backed transparent dressing.

Recording and Reporting

- Record appearance of wound, presence and characteristics of drainage, and presence of odor. Note patient response to dressing change.
- Report any signs of infection to the health care provider.

Special Considerations

Teaching

- Explain need to change dressing should edges loosen.
- Explain to patient and family that collection of wound fluid under dressing is not "pus" but normal interaction of body fluids with dressing.

Pediatric

- Adhesive backing may cause skin tears on premature babies’ immature skin (Hockenberry and Wilson, 2011).
- Children may find this procedure more tolerable if they know that the longer the dressing is left on, the easier it is to remove (Hockenberry and Wilson, 2011).

Gerontologic

- Adhesive backing may be too strong for the skin of older adults. Do not use a film dressing that has an adhesive backing with a

stronger bond to the epidermis than the epidermis has to the dermis.

Home Care

- Wound may be cleaned in shower if approved by health care provider.
- Many types of transparent dressings exist. Explore types with patient and recommend type to which patient has easy access and finds easy to apply.

SKILL 39-4 Applying a Hydrocolloid, Hydrogel, Foam, or Absorption Dressing

NSO Wound Care Module / Lesson 3

As management of wound care advances, there are numerous classes of dressings. Match the properties of a dressing with the characteristics of a wound to promote healing. Two classes of dressings include absorbent and hydrating.

Hydrocolloid dressings are a formulation of elastomeric, adhesive, and gelling agents. They promote statistically significant better wound healing outcomes compared with conventional gauze (Rolstad et al., 2011; Baranoski and Ayello, 2012). They are indicated as primary dressings for minimally-to-moderately exudative partial- and full-thickness wounds. Hydrocolloids are used as secondary dressings over fillers such as hydrocolloid powders and pastes (Rolstad et al., 2011). International pressure ulcer guidelines recommend use of hydrocolloids for clean stage II and noninfected shallow stage III pressure ulcers in anatomic locations where the product does not roll or melt (NPUAP-EPUAP, 2009). The dressings have absorptive and hydrating properties. When in contact with wound drainage, the hydrocolloid forms a gel that promotes a moist environment and autolytic and enzymatic debridement. Hydrocolloids come in the form of granules, paste, or wafers. Change dressings when the wound gel appears to have migrated beyond the margins of the wound or the seal is leaking (Rolstad et al., 20011).

Hydrogel dressings are glycerin- or water-based dressings designed to hydrate a wound, thus promoting moist wound healing and autolysis (Rolstad et al., 2011). They are recommended for dry to minimally exudative wounds with or without depth and are a good choice for painful wounds since they do not adhere to a wound base. In addition, international pressure ulcer guidelines recommend hydrogels for dry to minimally exudative pressure ulcers that are noninfected and granulating in anatomic locations that are not at risk for dressing migration (NPUAP-EPUAP, 2009). Hydrogels are nonadherent and have some absorptive properties. The dressings are available as sheets, impregnated gauze, or amorphous gel. They facilitate autolytic debridement of wounds through rehydration. They absorb exudate and encourage healing by maintaining a moist wound healing environment. The gel dressings are nonadherent and must be covered with a secondary dressing to hold them in place. Because of their “cooling” and soothing properties, hydrogel dressings are also used with burns and to soothe radiation burns.

Polyurethane foam dressings are sheets of foamed polymers that contain small open cells capable of holding wound exudate away from a wound bed (Rolstad et al., 2011). Foam dressings are used as primary or secondary dressings to absorb moderate-to-heavy exudates. They are indicated to treat superficial or deep wounds, protect friable periwound skin, pad and protect high-trauma areas (e.g., pretibial area and forearms), and treat infected wounds following appropriate intervention and close monitoring of wound healing. International pressure ulcer guidelines recommend considering foam for use on exudative stage II and shallow stage II pressure ulcers (NPUAP-EPUAP, 2009). Foam dressings are not appropriate when

there is wound tunneling because the dressing expands, which can enlarge the tunnels. The foam dressings protect the wound surface while maintaining a moist, insulated environment. Application directions for the different brands of foam dressings vary.

Alginate dressings include calcium alginate materials, which are manufactured from natural material (seaweed) and known for their absorptive properties, forming a gel over the wound surface to contain exudate. The exudate absorbers are nonadhesive, nonocclusive dressings that conform to the shape of the wound. Alginates create a moist environment and thus promote autolysis, granulation, and epithelialization (Rolstad et al., 2011). These dressings are appropriate for full-thickness wounds with moderate-to-high amounts of drainage. Some alginates become almost amorphous gels in a wound and require irrigation to be removed, whereas others retain a structure that can be lifted out of a wound (Rolstad et al., 2011). You can safely pack deep tracking wounds with calcium-sodium alginate preparation, which allows easy removal with little risk for retained dressing deep in the wound cavity. Alginates and fiber gelling dressings are changed as often as daily; or they are left in place for several days, depending on the amount of exudate and the type of secondary dressing used (Rolstad et al., 2011).

Delegation and Collaboration

The skill of applying a hydrocolloid, hydrogel, foam, or alginate dressing cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP about:

- Approach to assist in positioning patient during dressing application.
- What to observe (e.g., leakage of drainage, slippage of dressing) and report back to nurse.

Equipment

- Sterile gloves (optional)
- Clean gloves

Dressing Set (optional)

- Sterile scissors
- Sterile drape (optional)
- Necessary primary dressings: gauze, hydrocolloid, hydrogel, foam, or alginate
- Secondary dressing of choice
- Sterile 4 × 4-inch gauze pads
- Sterile saline or other cleansing solution (as ordered)
- Skin barrier wipe
- Tape (nonallergenic paper or adhesive), ties as needed
- Measuring guide (tape measure, tracing paper, camera as needed)
- Adhesive remover
- Waterproof bag
- Debriding gel (as ordered)
- Sterile 4 × 4-inch gauze pads
- Irrigating solution as supplies if indicated (see Skill 38-1)
- Protective gown, goggles, and mask (used when splashing from wound is a risk)

STEP

RATIONALE

ASSESSMENT

- | | |
|---|---|
| <ol style="list-style-type: none"> 1 Assess for presence of allergies, especially antiseptics, tape, or latex. 2 Inspect location, size, and condition of wound. 3 Ask patient to rate pain using pain scale of 0 to 10 and assess character of pain. Administer prescribed analgesic as needed 30 minutes before dressing change. 4 Review health care provider's orders for frequency and type of dressing change. <i>Do not use alginate or absorptive dressings on nonexudative wounds.</i> 5 Consider using customized shape or size of dressing. Some hydrocolloid dressings are available in custom shapes and sizes to fit difficult body parts (e.g., sacrum, heels, or elbows). 6 Assess patient's knowledge of purpose of dressing and determine need to include family caregiver in dressing wound. | <p>Prevents localized or systemic reaction to supplies.</p> <p>Determines supplies and assistance needed.</p> <p>Patient may require pain medication before dressing change. Allows for peak effect of drug during procedure.</p> <p>Health care provider orders mode of therapy.</p> <p>Dressings are designed to absorb moderate-to-large amounts of wound drainage and should not be used in wounds with minimal or no drainage (Rolstad et al., 2011).</p> <p>Variety of shapes aids in flexibility of dressing selection and better dressing adherence.</p> <p>Identifies patient's and family caregiver's learning needs.</p> |
|---|---|

NURSING DIAGNOSES

- | | | |
|--|--|--|
| <ul style="list-style-type: none"> • Acute pain • Chronic pain | <ul style="list-style-type: none"> • Deficient knowledge • Impaired skin integrity | <ul style="list-style-type: none"> • Risk for infection |

|--|--|

STEP 6 Hydrocolloid dressing after removal from venous ulcer. Purulent-appearing exudate is present on dressing and wound. This is expected with autolysis under the dressing and is not evidence of infection. (From Bryant R, Nix D: *Acute and chronic wounds: current management and concepts*, ed 4, St Louis, 2012, Mosby.)

STEP	RATIONALE
3 Expose wound site and drape patient. Instruct patient not to touch wound or sterile supplies.	Draping provides access to wound while minimizing exposure. Dressing supplies become contaminated when touched by patient's hand.
4 Cuff top of disposable waterproof bag and place within reach of work area.	Prevents accidental contamination of top of outer bag. Nurse should not reach across sterile field.
5 Perform hand hygiene and apply clean gloves. Apply moisture-proof gown, mask, and goggles if there is risk for splashing.	Reduces transmission of infectious organisms.
6 Remove old dressing one layer at a time. Note amount and character of drainage (see illustration). Use caution to avoid tension on any drains.	Reduces irritation and possible injury to skin. Prevents accidental removal of drain.

Clinical Decision Point Check removal directions for specific brand of dressing used. Some brands need to have old dressing soaked, irrigated, or moistened for removal. With some types of dressings use adhesive remover to ease off dressing but avoid contact of adhesive remover with the wound.

7 Dispose of soiled dressings in waterproof bag. Remove clean gloves by pulling them inside out and dispose of them in waterproof bag. Cover wound lightly with sterile gauze pad. Perform hand hygiene.	Reduces transmission of microorganisms.
--	---

Clinical Decision Point Hydrocolloid dressings interact with wound fluids and form a soft whitish-yellowish gel, which is sometimes hard to remove and may have a faint odor. A residual gel substance occurs in wound beds with some absorption dressings. This is a normal occurrence; do not confuse these findings with pus or purulent exudate, wound infection, or wound deterioration.

8 Prepare sterile field with sterile dressing kit or individually wrapped sterile supplies on over-bed table (see Chapter 8).	Creates sterile work area.
9 Pour saline or prescribed solution over 4 × 4–inch sterile gauze pads or open spray wound cleanser. <i>Option:</i> For hydrocolloid, alginate, or foam dressings, prepare an irrigation solution if needed (see Skill 38-1).	Hydrocolloid forms viscous, colloidal gel that is easily irrigated out of wound bed (Rolstad et al., 2011).
10 Apply sterile or clean gloves (check agency policy) or use no-touch technique with sterile forceps to clean wound. Remove gauze covering wound.	Allows nurse to handle dressings.
11 Cleanse wound: <ul style="list-style-type: none"> <li data-bbox="172 1178 805 1293">a Cleanse area gently with moist 4 × 4–inch sterile gauze pads, swabbing exudate away from wound. or spray with wound cleanser or irrigate wound bed (see Chapter 38). <li data-bbox="172 1299 805 1371">b Clean around any drain, using a circular stroke starting near drain and moving outward away from insertion site (see Skill 39-1). 	Reduces introduction of organisms into wound. Cleaning and irrigating effectively remove residual dressing gel without injuring newly formed delicate granulation tissue in healing wound bed.
12 Use sterile dry 4 × 4–inch gauze pads to blot dry excess saline or cleanser in wound bed and on skin around wound.	Dressing will not adhere to damp surface. Periwound maceration can enlarge wound and impede healing.
13 Inspect appearance and condition of wound (see Chapters 18 and 38). Measure wound size and depth.	Appearance and measurement indicate state of wound healing.
14 Remove gloves and perform hand hygiene,	Reduces transmission of microorganisms.
15 Apply dressing (see manufacturer's directions).	Ensures proper application of dressing. Different brands of dressings require different application techniques.

a Hydrocolloid dressings:

- (1) Select proper size wafer, allowing dressing to extend onto intact periwound skin at least 2.5 cm (1 inch) (Rolstad et al., 2011) (see illustration).
 - (2) In the case of a deep wound, apply hydrocolloid granules, impregnated gauze or paste before the wafer.
 - (3) Remove paper backing from adhesive side and place over wound. Do not stretch dressing and avoid wrinkles or tenting. Mold wafer to affected body part.
 - (4) If cut from larger piece, tape edges with nonallergenic tape to avoid rolling or adherence to clothing (Rolstad, Bryant, and Nix, 2011).
- Hydrocolloid design prevents shear and friction from loosening edges and circumvents need for tape along dressing borders (Rolstad et al., 2011).
- Functions as filler material to ensure contact with all wound surfaces.

STEP

RATIONALE

Clinical Decision Point Edges may be notched to help mold around wound. Consider using custom shapes to better conform to certain parts of the body such as heels, elbows, and sacrum.

- (5) Hold dressing in place for 30 to 60 seconds.
- (6) Use nonallergenic tape to secure.

b Hydrogel dressings:

- (1) Apply skin barrier wipe to surrounding skin that will come in contact with any adhesive or gel.
- (2) Apply gel or gel impregnated gauze directly into wound, spreading evenly over wound bed (see illustration). Fill wound cavity with gel about $\frac{1}{2}$ - to $\frac{2}{3}$ -full or pack gauze loosely, including any undermined or tunneled areas. Cover with moisture retentive dressing or hydrocolloid wafer. *Option:* Hydrogel sheets composed of water should be cut to size of wound *only*.
- (3) Cut hydrogel sheet containing glycerin so it extends 2.5 cm (1 inch) out on to intact periwound skin. Cover with secondary moisture-retentive dressing if needed.
- (4) Secure dressing with nonallergenic tape if secondary dressing is not self-adhering.

c Foam dressings:

- (1) Know removal and application characteristics of specific brand of foam dressing.
- (2) Apply skin barrier wipe to surrounding skin that will come in contact with thin foam dressing adhesive. **NOTE:** Traditional-thickness nonadhesive may not have adhesive border.
- (3) Cut foam sheet to extend 2.5 cm (1 inch) out onto intact periwound skin. (Verify which side of foam dressing should be placed toward wound bed and which side should be facing away from wound bed; check product instructions.)
- (4) Some brands of foam dressings need to be covered with secondary dressing (Rolstad et al., 2011).
- (5) Cut foam to fit around drain or tube.

d Alginate dressings:

- (1) Cut sheet or rope to fit size of wound or loosely pack into wound space (see illustration), filling $\frac{1}{2}$ to $\frac{2}{3}$ full.

Hydrocolloids are most effective at body temperature (Rolstad et al., 2011).

Protects periwound skin. Because of high water content of gels, care must be taken to protect periwound skin through use of skin barrier (Rolstad et al., 2011).

Hydrogels hydrate and facilitate autolytic debridement of wounds. Filling wound cavity partially full allows for expansion with absorption of exudate.

Avoids overlapping and maceration of periwound (Rolstad et al., 2011).

Protects skin around wound from maceration

Used with absorptive dressings to accommodate highly draining wounds.

Protects periwound skin from maceration or irritation from adhesive.

Ensures proper absorption and keeps wound exudate away from wound bed (Rolstad et al., 2011).

Protects wound.

Highly absorptive product expands with absorption of serous fluid or exudate (Rolstad et al., 2011).

STEP 15a(1) Variety of sizes and shapes of hydrocolloid dressings. (Courtesy Bonnie Sue Rolstad.)

STEP 15b(2) Hydrogel-impregnated gauze used to maintain moist wound bed and fill dead space in this deep abdominal wound with undermining. (From Bryant R, Nix D: *Acute and chronic wounds: current management and concepts*, ed 4, St Louis, 2012, Mosby.)

STEP

RATIONALE

- (2) Apply secondary dressing such as transparent film (see illustration) (see Skill 39-3), foam, or hydrocolloid.
- 16 Discard soiled dressing materials properly. Remove gloves by pulling them inside out and discard in prepared bag. Perform hand hygiene.
- 17 Help patient to comfortable position.

- Secondary dressing prohibits drainage on bed linens and clothing.
- Reduces transfer of microorganisms.
- Enhances patient comfort and relaxation.

STEP 15d(1) Alginate dressing applied to fill dead space and absorb exudate in full-thickness abdominal wound. (From Bryant R, Nix D: *Acute and chronic wounds: current management and concepts*, ed 4, St Louis, 2012, Mosby.)

STEP 15d(2) Alginate dressing secured with secondary transparent dressing. (From Bryant R, Nix D: *Acute and chronic wounds: current management and concepts*, ed 4, St Louis, 2012, Mosby.)

EVALUATION

- 1 Observe condition of wound for healing, including size of wound, color, and character of drainage on ongoing basis.
- 2 Evaluate patient's level of comfort.
- 3 Ask patient or family caregiver to explain wound care method. *Option:* Have family caregiver demonstrate.

- Determines status of wound healing.
- Determines if pain resulted from procedure.
- Evaluates level of learning.

Unexpected Outcomes

- 1 Wound develops more necrotic tissue and increases in size.
- 2 Dressing does not stay in place.
- 3 Periwound skin is macerated.

Related Interventions

- In rare instances some wounds do not tolerate hypoxia induced by hydrocolloid dressings. In these patients discontinue use. Notify health care provider.
- Evaluate appropriateness of wound care protocol.
- Evaluate for other factors impairing wound healing.
- Evaluate size of dressing used for adequate margin (2.5 to 3.75 cm [1 to 1½ inches]) or dry skin more thoroughly before reapplication.
- Consider custom shapes for difficult body parts. "Picture frame" edges of hydrocolloid dressing using tape.
- Dressing may be secured with roll gauze, tape, transparent dressing, or dressing sheet.
- Assess moisture control property of dressing or application technique. May need new type of dressing.

Recording and Reporting

- Record appearance of wound, color, size, characteristics of drainage, response to dressing change, condition of periwound skin, and patient's level of comfort in nurses' notes and EHR.
- Graph wound surface area or volume if wound is chronic.
- Write date, time, and nurse's initials in ink (not marker) on the dressing.
- Report signs of infection, necrosis, or deteriorating wound status to health care provider immediately.

Special Considerations

Teaching

- Explain expected wound appearance, fluid or gel accumulation in wound bed, and possible odor with use of specific dressing.
- Because application techniques can vary with different brands, tell patient and family caregiver not to purchase a brand different from the one for which the nurse gave instructions. If a different brand must be used, patient and caregiver should

check with nurse for any additional instructions or modifications in application and removal techniques.

Pediatric

- See Pediatric Considerations for Skills 39-1, 39-2, and 39-3.

Gerontologic

- See Gerontologic Considerations for Skills 39-1, 39-2, and 39-3.
- Avoid early and frequent removal of a hydrocolloid dressing to reduce injury to surrounding intact skin.

SKILL 39-5 Negative-Pressure Wound Therapy (NPWT)

Negative-pressure wound therapy (NPWT) is the application of a vacuum (negative pressure) to a wound through suction to draw edges of a wound together while providing a moist environment to promote healing and collect wound fluid (AHRQ, 2009; Campbell, Smith, and Smith, 2008; Netsch, 2011). The development of NPWT is based on two theories: (1) the removal of excess interstitial fluid decreases edema and concentrations of inhibitory factors and increases local blood flow; and (2) stretching and deformation of the tissue by the negative pressure is believed to disturb the extracellular matrix and introduce biochemical responses that promote wound healing (AHRQ, 2009). The therapy is commonly used for dehisced wounds, diabetic foot ulcers, pressure ulcers, vascular ulcers (includes venous and arterial ulcers), burn wounds, surgical wounds (especially infected sternal wounds), and trauma-induced wounds (AHRQ, 2009; NPUAP-EPUAP, 2009; Petkar et al., 2011). The WOCN (2010) reports increased rates of healing associated with stage III and IV pressure ulcers when using NPWT.

An NPWT system (Fig. 39-2) includes a vacuum pump, drainage tubing, and dressing set. The pump is either stationary or portable, may rely on AC or battery power, allows for regulation of the suction strength, has alarms to indicate loss of suction, and has a replaceable collection canister. The dressing sets contain either foam or gauze dressing to be placed in the wound and an adhesive film drape for sealing the wound. The drainage tubes come in a variety of configurations, depending on the dressings used or wound being treated (AHRQ, 2009).

NPWT generates negative pressure at the wound surface, which removes exudate, contracts the wound bed, prepares a wound for closure, and helps form granulation tissue (Figs. 39-3 and 39-4). Added benefits of NPWT include improved patient comfort and a

reduction in the frequency of dressing changes. Contraindications to NPWT for chronic wounds are exposed vital organs, inadequately debrided wounds, untreated osteomyelitis or sepsis near a wound, untreated coagulopathy, necrotic tissue with eschar, and malignancy within a wound (AHRQ 2009; Netsch, 2011). Patient cooperation and adherence are very important for NPWT to be effective. In addition, it is critical to assess patients routinely for onset of hemorrhage (Netsch, 2011).

FIG 39-3 Dehisced wound before negative-pressure wound therapy. (Courtesy KCI Licensing, San Antonio, Tex.)

FIG 39-2 The vacuum-assisted closure ATS therapy system. Top to bottom, V.A.C. system pump, connective tubing to go between V.A.C. system and dressing, absorbent foam dressing. (Courtesy KCI Licensing, San Antonio, Tex.)

FIG 39-4 Dehisced wound after negative-pressure wound therapy. (Courtesy KCI Licensing, San Antonio, Tex.)

NPWT is delivered intermittently or continuously, but most often continuously. A health care provider or wound care specialist orders the cycle and amount of negative pressure to a wound. There are different recommendations for the level of negative pressure to use for wound healing. Check your agency policy. Research has found that the maximal biologic effect of NPWT at the wound edge often can be achieved at -80 mm Hg (Borquist et al., 2011). There has also been research to show improved microvascular blood flow and granulation tissue formation with intermittent compared to continuous therapy delivered at -125 mm Hg (WOCN, 2010). The target negative pressures for wound healing tend to range from -50 mm Hg to -175 mm Hg, but a setting of -125 mm Hg is most common (Netsch, 2011).

You will typically change an entire NPWT dressing and wound filler every 48 hours or 3 times per week (Netsch, 2011). However, the schedule for changing NPWT dressings varies based on the type and condition of wound. An infected wound may need a dressing change every 24 hours. As a wound heals, the wound base becomes redder; granulation tissue lines the surface of the wound initially, and the wound has a stippled or granulated appearance. Paler areas develop as the wound continues to heal. These changes indicate an increase in fibrous tissue. The example used in this skill is that of the KCI V.A.C. Always refer to manufacturer directions for the type of NPWT used in your agency.

Delegation and Collaboration

The skill of NPWT cannot be delegated to nursing assistive personnel (NAP). The nurse directs the NAP to:

- Use caution in positioning or turning patient to avoid tubing displacement.
- Report any change in integrity of the dressing to the nurse.
- Report any change in patient’s temperature or comfort level to the nurse.

Equipment

- 3 Pairs gloves, clean and sterile
- Scissors, sterile
- NPWT unit (requires health care provider’s order)
 - NPWT dressing (gauze or foam, see manufacturer recommendations; transparent dressing, adhesive drape)
 - NPWT suction device
 - Tubing for connection between NPWT unit and NPWT dressing
- Waterproof bag for disposal
- Skin protectant/stomaheasive/hydrocolloid dressing/skin barrier
- Protective gown, mask, goggles (used when splashing from wound is a risk)

STEP	RATIONALE
------	-----------

ASSESSMENT

<p>1 Assess location, appearance, and size of wound (see Chapter 38).</p>	<p>Provides information about status of wound, presence of complications, and type of supplies and assistance needed.</p>
<p>2 Review health care provider’s orders for frequency of dressing change, amount of negative pressure, type of foam or gauze to use, and pressure cycle (intermittent or continuous).</p>	<p>Health care provider’s orders list frequency of dressing changes and any special instructions.</p>
<p>3 Ask patient to rate level of pain using pain scale of 0 to 10. Administer prescribed analgesic as needed 30 minutes before dressing change.</p>	<p>Comfortable patient will be less likely to move suddenly, causing wound or supply contamination. Serves as baseline to measure response to dressing therapy.</p>
<p>4 Assess patient’s and family caregiver’s knowledge of purpose of dressing and whether they will participate in dressing wound.</p>	<p>Identifies patient’s learning needs. Prepares patient and family if dressing will need to be changed at home.</p>

NURSING DIAGNOSES

- | | | |
|--|--|--|
| <ul style="list-style-type: none"> • Acute pain • Chronic pain | <ul style="list-style-type: none"> • Deficient knowledge • Impaired skin integrity | <ul style="list-style-type: none"> • Risk for infection |
|--|--|--|

Related factors are individualized based on patient’s condition or needs.

PLANNING

<p>1 Expected outcomes following completion of procedure:</p> <ul style="list-style-type: none"> • Patient’s wound shows evidence of healing as wound decreases in size with less drainage, redness, or swelling. • Patient reports less pain on a scale of 0 to 10 during and after dressing changes. • Dressing remains intact with airtight seal and prescribed negative pressure. • Patient or family member demonstrates correct method of dressing changes. 	<p>Dressing is effective in promoting healing and preventing infection.</p>
<p>2 Explain procedure to patient.</p>	<p>Analgesic and comfort measures effective in controlling pain.</p>
<p>3 When using a KCI V.A.C., put system into “de-V.A.C.” mode (see following steps) over period of 45 minutes before removing old dressings.</p>	<p>Dressing is applied correctly and maintains negative pressure.</p> <p>Indicates that patient and family learning has occurred.</p>
	<p>Relieves anxiety and promotes understanding of healing process.</p> <p>Found to loosen dressing for easier, less painful removal (Price et al., 2006).</p>

STEP

RATIONALE

IMPLEMENTATION

- | | |
|--|---|
| <p>1 Identify patient using two identifiers (i.e., name and birthday or name and account number) according to agency policy. Compare identifiers with information on patient's identification bracelet.</p> <p>2 Close room door or cubicle curtains.</p> <p>3 Position patient comfortably and drape to expose only wound site. Instruct patient not to touch wound or sterile supplies.</p> <p>4 Cuff top of disposable waterproof bag and place within reach of work area.</p> <p>5 Perform hand hygiene and put on clean gloves. If risk for spray exists, apply protective gown, goggles, and mask.</p> <p>6 Follow manufacturer directions for removal and replacement because each NPWT unit varies slightly with approach. Turn off NPWT unit by pushing therapy on/off button.</p> <p>a Raise tubing above unit and clamp and engage clamp on dressing tubing.</p> <p>b Allow drainage to flow from tubing into drainage collector.</p> <p>c Gently stretch transparent dressing horizontally and remove slowly from dressing and skin.</p> <p>d Remove old dressing one layer at a time and discard in bag.
Keep soiled surfaces away from patient's sight.</p> <p>7 Perform wound assessment. Observe surface area and tissue type, color, odor, and drainage within wound. Measure length, width, and depth of wound.</p> | <p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2012).</p> <p>Provides for patient privacy and reduces transmission of organisms. Promotes patient's cooperation and completion of procedure smoothly. Prevents contamination of sterile supplies. Cuff prevents accidental contamination of top of outer bag.</p> <p>Reduces transmission of infectious organisms from soiled dressings to nurse's hands.</p> <p>Deactivates therapy and allows for proper drainage of fluid in drainage tubing.</p> <p>Prevents backflow of any drainage in tubing back into wound.</p> <p>Prevents drainage from exiting tubing when removed. Protects periwound skin. Prevents injury to wound tissue.</p> <p>Measurement of wound is necessary to assess wound healing progression and justify continuation of NPWT for third-party payers (Netsch, 2011).</p> <p>Determines condition of wound and need for replacement of dressing.</p> |
| <p>Clinical Decision Point <i>This is a time when a wound care nurse or physician might debride the wound. Debridement of eschar or slough, if present, should be performed for removal of devitalized tissue to prepare the wound bed (Netsch, 2011).</i></p> | |
| <p>8 Remove and discard gloves in waterproof bag. Avoid having patient see old dressing because sight of wound drainage may be upsetting. Perform hand hygiene.</p> <p>9 Clean wound.</p> <p>a Apply sterile or clean gloves (see agency policy).</p> <p>b Clean wound per agency policy. It may be necessary to irrigate with normal saline or other solution ordered by health care provider (see Skill 38-1). Gently blot periwound with gauze to dry thoroughly.</p> | <p>Reduces transmission of microorganisms. Lessens patient anxiety during procedure.</p> <p>Irrigation removes wound debris and cleans wound bed. Cleaning periwound is essential for an airtight seal.</p> |
| <p>Clinical Decision Point <i>Health care providers may order wound cultures routinely. However, when drainage looks purulent or has a foul odor or if there is a change in amount or color, obtain wound culture. This may be an indication that NPWT may need to be discontinued (Martindell, 2012).</i></p> | |
| <p>10 Apply skin protectant, barrier film, stomahesive wafer, or hydrocolloid dressing to periwound skin. It may be necessary to frame periwound with these products.</p> <p>11 Fill any uneven skin surfaces (e.g., creases, scars and skinfolds) with skin barrier product (e.g., paste, strip).</p> <p>12 Remove and discard gloves. Perform hand hygiene.</p> <p>13 Depending on type of wound, apply sterile or new clean gloves (see agency policy).</p> <p>14 Apply NPWT.</p> <p>a Prepare NPWT foam (gauze is an option in other types of NPWT devices).</p> | <p>Maintains airtight seal needed for NPWT wound therapy (Netsch, 2011). Protects periwound skin from moisture-associated skin damage (Martindell, 2012).</p> <p>Further helps to maintain airtight seal (Netsch, 2011).</p> <p>Prevents transmission of microorganisms. Fresh sterile wounds require sterile gloves. Chronic wounds require clean technique, except when sharp debridement is used at bedside (Wooten and Hawkins, 2005). Do not use same gloves worn to clean wound because cross-contamination may occur.</p> <p>There are several manufacturers; this skill reviews use of foam in KCI V.A.C.</p> |

STEP

RATIONALE

- (1) Check wound measurement and select appropriate foam dressing.
- (2) Using sterile scissors, cut foam to exact wound size, making sure to fit size and shape of wound, including tunnels and undermined areas.

Establishes baseline for wound size.
 Black polyurethane (PU) foam has larger pores and is most effective in stimulating granulation tissue and wound contraction. White soft foam is denser with smaller pores and used when the growth of granulation tissue needs to be restricted (Netsch, 2011; Martindell, 2012).
 Proper size of foam dressing maintains negative pressure to entire wound.

Clinical Decision Point Use of black PU foam may cause patients to experience more pain because of excessive wound contraction. You will need to switch patient to the PVA soft foam.

- (3) Option: Instill antimicrobial product (e.g., silver impregnated gauze) or topical antibiotic into wound.
- b** Gently place foam in wound (see illustration). Be sure that foam is in contact with entire wound base, margins, and tunneled and undermined areas. Count number of foam dressings and document in patient's chart.
- c** Apply NPWT transparent dressing over foam wound dressing.
 - (1) Trim dressing to cover wound so it will extend onto periwound skin approximately 2.5 to 5 cm (1 to 2 inches).
 - (2) Apply transparent dressing, keeping it wrinkle-free (see illustration).

Limited research suggests that these products may reduce bioburden of wound (Orgill et al., 2009).
 Maintains negative pressure to entire wound. Edges of foam dressing must be in direct contact with patient's skin.
 Ensures that wound is properly covered and negative pressure seal can be achieved (Box 39-4). Dressing should be airtight with no tunnels or gaps to ensure a good seal when suction is activated.

STEP 14b Place foam in wound. The V.A.C. GranuFoam transparent dressing. (Courtesy KCI Licensing, San Antonio, Tex.)

STEP 14c(2) V.A.C. drape. (Courtesy KCI Licensing, San Antonio, Tex.)

BOX 39-4 Maintaining an Airtight Seal in Negative-Pressure Wound Therapy

Once negative-pressure wound therapy (NPWT) is initiated, negative pressure must be maintained, and the wound must stay sealed to avoid wound desiccation. Wounds around joints and near the sacrum are problem areas to seal. The following points may help to maintain an airtight seal:

- Choose a wound suitable for therapy.
- Clip hair around wound (check agency policy).
- Cut transparent film to extend 2.5 to 5 cm (1 to 2 inches) beyond wound perimeter.
- Frame the periwound area with skin sealant, skin barrier, hydrocolloid, or transparent film dressing.
- Fill uneven skin surfaces with a skin barrier product.
- Cut or mold transparent dressing to fit wound.
- Avoid wrinkles in transparent film.
- Identify any air leak with a stethoscope and repair with a sealant dressing (e.g., transparent dressing). Only use one or two additional layers for large leaks. Multiple layers reduce moisture vapor transmission and cause maceration of wound.
- Avoid adhesive remover because it leaves a residue that hinders film adherence.

From Netsch DS: Negative-pressure wound therapy. In Bryant RA, Nix DP: *Acute and chronic wounds: nursing management*, ed 4, St Louis, 2011, Mosby; and Thompson G: An overview of negative-pressure wound therapy (NPWT), *Wound Care* 6:523, 2008.

STEP**RATIONALE**

(3) After wound is completely covered, secure tubing of NPWT unit to transparent film, aligning end of tubing to drainage hole to ensure occlusive seal (see illustration). Do not apply tension to drape and tubing. Set at ordered suction level. Examine system to be sure that seal is intact and therapy is working (see illustration) (this step is different for each type of NPWT).

Excessive tension may compress foam dressing and impede wound healing. It also produces shear force on periwound area (*Kinetic Concepts, 2012*). Intermittent or continuous negative pressure can be administered at -50 mm Hg to -175 mm Hg, according to health care provider's orders and patient comfort. Average is -125 mm Hg (*Netsch, 2011*).

- 15 Record initials and date and time on new dressing.
- 16 Help patient to comfortable position. Patients may ambulate with NPWT.
- 17 Discard gloves, dispose of any dressing material, and perform hand hygiene.

Provides reference for next dressing change.
Enhances patient comfort and relaxation.

Prevents transmission of microorganisms.

STEP 14c(3) A, Secure tubing to the foam and transparent dressing unit. (A and B Courtesy KCI Licensing, San Antonio, Tex.)

EVALUATION

- 1 Inspect condition of wound on ongoing basis; note drainage and odor.
- 2 Ask patient to rate pain using scale of 0 to 10.
- 3 Verify airtight dressing seal and correct negative pressure setting.
- 4 Measure wound drainage output in canister on regular basis.
- 5 Observe patient's or family caregiver's ability to perform dressing change.

Determines status of wound healing.

Determines patient's level of comfort following procedure.
Determines effective negative pressure being applied.
Monitors fluid balance and wound drainage.
Indicates that learning has occurred.

Unexpected Outcomes

- 1 Wound appears inflamed and tender, drainage has increased, and odor is present.
- 2 Patient reports increase in pain.
- 3 Negative pressure seal has broken.
- 4 Wound hemorrhages.
- 5 Patient or caregiver is unable to perform dressing change.

Related Interventions

- Notify health care provider.
- Obtain wound culture.
- Increase frequency of dressing changes.
- Patient may need more analgesia.
- Instill normal saline to moisten foam and other filler dressings to allow them to loosen from granulation tissue.
- If using black foam, switch to PVA white soft foam.
- Decrease pressure setting.
- Change from intermittent to continuous cycling.
- Change type of NPWT system.
- Take preventive measures (see [Box 39-4](#)).
- Stop NPWT immediately and notify health care provider
- Provide additional teaching and support.
- Obtain services of home care agency.

Recording and Reporting

- Chart in nurses' notes and EHR appearance of wound, characteristics of drainage, placement of NPWT (type of dressing, pressure mode and setting), and patient response to dressing change.
- Report brisk, bright-red bleeding, evidence of poor wound healing, evisceration or dehiscence, and possible wound infection to health care provider immediately.

Special Considerations**Teaching**

- Successful NPWT relies on patient's and family caregiver's cooperation with treatment. NPWT can be difficult to use when patient is unable to consciously cooperate (e.g., dementia) ([Netsch, 2011](#)).
- Patients and family caregivers need to learn how to administer analgesics appropriately. Patient tolerance of and adherence to NPWT are difficult if dressing changes are painful ([Netsch, 2011](#)).
- Educate patients and family caregivers on the signs and symptoms that indicate development of an infection and to report to health care provider immediately.

- Explain expected wound appearance with use of dressing. Instruct patient and caregiver in appearance of foam dressings.
- Instruct patient and family in points to follow to maintain negative pressure seal.
- Explain frequency of dressing changes required. Often the dressing is not changed daily.

Pediatric

- NPWT therapy is not appropriate for fragile neonatal skin.
- Parents need to actively participate in NPWT treatment.

Gerontologic

- Use skin care practices to protect periwound tissue. Transparent film may be irritating to fragile skin. A skin protectant is one method to reduce the risk for tissue injury.
- Therapy may need to start with lower negative pressures such as -75 mm Hg and slowly titrate to more negative pressure.

Home Care

- Patient and family caregiver may benefit from visits from a home care agency to monitor initial treatments.
- Provide information to family and caregiver regarding proper disposal of contaminated products.

PROCEDURE GUIDELINE 39-1 Applying Gauze and Elastic Bandages**NSO** Wound Care Module / Lesson 3

Video Clip

Gauze and elastic bandages secure or wrap hard-to-cover areas of the body such as dressings on extremities, amputation stumps, and the hand. Bandages are a secondary dressing, providing protection, pressure, immobilization, and anchoring of underlying dressings or splints. There are numerous types of and applications for bandages. Bandages are available in rolls of various widths and materials, including gauze, elastic, webbing, elasticized knit, and muslin. Gauze bandages are lightweight and inexpensive, mold easily around body contours, and permit air circulation to prevent skin maceration. Elastic bandages apply compression to a body part. Elastic compression to a lower extremity prevents edema by promoting the return of blood from the peripheral to the central circulation. Compression also supports varicosities. Many patients use elastic bandages in the form of stockings to reduce dependent edema in the extremities.

When applying a bandage, select a type of bandage turn ([Table 39-3](#)) and width, depending on the size and shape of the

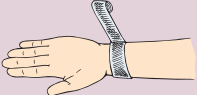

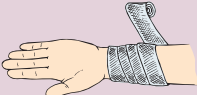

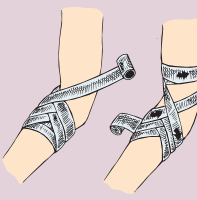

body part to be bandaged. For example, 7.5 cm (3-inch)-wide bandages are commonly used for the adult leg. Gauze and elastic bandages are supplied in a roll with an inner and outer surface for easy application. In preparation for bandaging, place the outer surface next to the skin and roll it around the surface to be covered. Apply even tension during application. When applying an elastic bandage to an extremity, start the bandage at the site farthest from the heart (distal) and proceed toward the heart (proximal).

Delegation and Collaboration

The skill of applying an elastic bandage for compression cannot be delegated to nursing assistive personnel (NAP). A nurse assesses the condition of any wound or dressing before applying a bandage. The skill of applying bandages to secure nonsterile dressings can be delegated to NAP (refer to agency policy). The nurse directs the NAP by:

PROCEDURE GUIDELINE 39-1 Applying Gauze and Elastic Bandages—cont'd

TABLE 39-3 Types of Bandage Turns

Type	Description	Purpose or Use
Circular turns 	Bandage turn overlapping previous turn completely	Anchors bandage at first and final turn; covers small part (finger, toe)
Spiral turns 	Bandage ascending body part with each turn overlapping previous one by one-half or two-thirds width of bandage	Covers cylindric body parts such as wrist or upper arm
Spiral-reverse turns 	Turn requiring twist (reversal) of bandage halfway through each turn	Covers cone-shaped body parts such as forearm, thigh, or calf; useful with nonstretching bandages such as gauze or flannel
Figure-eight turns 	Oblique overlapping turns alternately ascending and descending over bandaged part; each turn crossing previous one to form figure eight	Covers joints, applies low-grade pressure for venous return; snug fit provides excellent immobilization
Recurrent turns 	Bandage first secured with two circular turns around proximal end of body part; half turn made perpendicular up from bandage edge; body of bandage brought over distal end of body part to be covered, with each turn folded back over on itself	Covers uneven body parts such as head or stump
