Jung and Latchem (2008) observe there are key competencies associated with quality online learning to deliver coherent courses and programs. It goes without saying that for learners to “learn,” the experience needs to be well planned and designed. The online environment has unique challenges that require a deep understanding of how students learn in this mode. Furthermore, what we may refer to as “the nuts and bolts” such as the technology platforms and standards associated with these add an additional complicating factor. Teachers are required to wrestle with a range of variables such as their organization policy, pedagogy, ICT, administration, student support, and assessment.

As more universities shift into blended and online modalities, workload is another key consideration. As educators balance teaching, research, and often significant administrative and engagement responsibilities, the time required to prepare holistic responses to online learning is certainly squeezed. During COVID-19, one of the main complaints from staff was the increase in workload as courses went online. A quick search reveals numerous examples of staff stress and overload resulting in impacts to their research. Staff have indicated that working from home has also meant a collision between personal and professional lives, and for women, the impacts of this on their academic career are yet to be fully understood. In a work by Ryan, Tynan, and Lamnot-Mills (2014) state that in blended and online environments that there is a lack of acknowledgment of how much effort is required to teach well and that workload models rarely detail the specific workload required for this activity.

The two cases are very different. They tackle PD of staff as a response to both longer-term strategic directions and the immediacy of a crisis to enhance quality

education outcomes. The readings provide further cases of practice, and the authors hope that readers find them instructive. As Brew (2010) highlights, there is no fixed approach or one solution that can be applied globally to PD in an institution. However, here we provide a few recommendations that have arisen from the literature and cases as detailed above.

We recommend that:

- Academic PD is framed by the context where it is situated (Brew, 2010; Evans et al., 2020; Jamieson, 2004; Macdonald & Poniatowska, 2011; Salmon, 2004; Webb, 1996, 2003).
- Strategic directions, policies, and guidelines of universities play an important role in determining the capabilities and competencies that are required of its academic staff (Brew, 2010; Jamieson, 2004; Jung & Latchem, 2008; Ryan et al., 2019; Wareng, 2019; Webb, 2003).
- Quality should be at the heart of “why” academic PD is supported and championed (Brew, 2010; Jung & Latchem, 2008).
- PD should be supported within the workload allocations and prioritized against the university’s strategy (Jamieson, 2004; Ryan et al., 2019).
- Incentivizing PD through recognition schemes, certification, promotion, etc. should be considered (van der Sluis et al., 2017).
- Providing opportunities for academic staff to reflect deeply and to immerse themselves with peers in professional conversations where they can be reflexive is important for long-term engagement and impact (Brew, 2010; Evans et al., 2020; Gregory, & Salmon, 2013; Jamieson, 2004; Macdonald & Poniatowska, 2011; Salmon, 2004; van der Sluis et al., 2017; Webb, 1996, 2003).
- Allowing staff to personalize their PD and select appropriate modes of learning from and with cohorts to individualize self-paced opportunities ensures that personal learning styles are accommodated improving the chances of positive engagement (Evans et al., 2020; Gregory, & Salmon, 2013; Jamieson, 2004; Janet Macdonald & Barbara Poniatowska, 2011; Salmon, 2004; Webb, 1996, 2003).
- Just-in-time PD for academics is a powerful driver of participation (Brew, 2010; Jamieson, 2004; Macdonald & Poniatowska, 2011).

## Abstract

Distance education (DE) has evolved over numerous generations, from correspondence study to the most recent online education, which is classified as open, distance, and digital education (ODDE). DE advances in line with technological advancements, and DE generations often correspond to the pre- and post-Internet eras. This classification also affects and prescribes the learning environment required to ensure the educational and learning process' effectiveness.

The pre-Internet period of DE was marked by a vast physical infrastructure, including a physical network of regional, local offices, and learning centers, as was widely implemented by distance teaching universities. Soft infrastructure, such as a digital learning environment, characterizes the ODDE in the Internet era. Despite the differences in ODDE infrastructure before and after the Internet, library services and a quality assurance system have always been essential components of the ODDE system. The global open movement has had an impact

## Introduction

Open, distance, and digital education (ODDE) refers to a distance education model that is based on and delivered using digital technologies. Distance education (DE) itself has been evolving through several generations starting from the era of correspondence study to the latest one known as online education. Following the correspondence model, Taylor (2001) categorized DE generations into five which correlate to the type of dominant technologies being used to deliver the education: (1) the correspondence model, (2) the multimedia model, (3) the tele-learning model, (4) the flexible learning model, and (5) the intelligent flexible learning model. The last two generations were born as the result of Internet technology, and therefore DE models can easily be viewed as those in the pre-Internet era (conventional DE) and the post-Internet era (online DE). It is in Taylor's fourth generation that terms such as e-learning, mobile learning, ubiquitous learning, virtual learning, and ODDE were born and, to some extent, are being used interchangeably. With the vast use of online technology, the DE generation continues to be related to connectivism, which assumes that learning occurs within an interrelated network of data and information, best exemplified by the connective massive open online courses (cMOOCs) model. According to Siemens (2013), cMOOCs are based on a connectivist pedagogical model that views knowledge as "a networked state and learning as the process of generating those networks and adding and pruning connections" (p. 8). Thus, **learning happens within a digital network**, where learners use various **digital platforms (e.g., blogs, wikis, social media platforms)** to make their own connections with learning resources including content and learning communities to create and construct knowledge.

The aforementioned categorization of DE generations demonstrates that each generation needs its own infrastructures, support systems, and quality standards to ensure the learning and teaching process's effectiveness. Pre-Internet DE

infrastructure was dominated by physical buildings and facilities for management offices and learning support systems; printed materials, multimedia, and radio/television broadcast as teaching media; and quality was correlated with media effectiveness in delivering learning content when compared to traditional face-to-face teaching. In the post-Internet DE, infrastructure is significantly replaced by information and communication technologies (ICTs) both for administration and the teaching and learning process, making the entire process virtual and, theoretically, globally connected. As a result, quality in the Internet DE encompasses concerns about issues such as digital learning environment, learning engagement, and learning achievement, among other things.

---

## **The Organization of Section 5**

Because infrastructure is so vital, it is important to keep track of how it evolves over time to better anticipate future development requirements. Several organizational/institutional infrastructures, including learner support systems, faculty support systems, administrative support systems, program, and course evaluation, and information and library services, appear to be essential to DE practices, regardless of which generation they belong to. As part of the institutional infrastructure, quality assurance (QA) appears to be a cross-generational necessity. This section focuses on the infrastructure features and issues as interpreted by selected authors who are well-known in the field and have gained experience in the relevant subjects. The authors come from a variety of countries and areas, including Asia, Europe, Africa, and North America.

To open the section on Infrastructure, Quality Assurance, and Support Systems of ODDE, this chapter will discuss some trends and debates about the nature of institutional infrastructure before and after the Internet era, a cross-generational supporting infrastructure related to quality assurance, as well as learning resources particularly those related to the open educational resources (OER) and open licenses, and some thoughts on the metaverse as an emerging trend in education.

---

## **Institutional Infrastructures in the Pre- and Post-Internet Era**

### **Infrastructure for Course Materials Development and Student Support Services**

In its simplest form, DE management in the pre-Internet era consists of two main elements of activities: course materials development [and delivery] and student support services (Mcdougall & Apan, 2003). It is those two main elements that make the pre-Internet distance education usually requires substantial initial capital investment for producing and delivering the print-based course materials and for providing face-to-face and in-person support services, as well as for administering pencil-paper student assessment.

The best illustration of the pre-Internet DE is undoubtedly the distance teaching university (DTU) model, which includes the open university paradigm. The DTU's early teaching strategy consisted of pre-written course materials that are heavily tailored for print, complemented by multimedia resources, broadcast television, and radio programs, as well as in-person tutoring in study centers. Students at DTUs, including those with special needs, were expected to study independently using the course materials, complete the assignments, as well as participate in (optional) in-person tutorials and pass the exam anywhere. A chapter co-authored by Kocdar and Bozkurt emphasizes that ODDE is inclusive by nature and should envision equity, equality, and justice for all learners, including those who have special needs; thus, DTUs should use student support service strategies that can assist students with special needs in overcoming their challenges. To deliver these services, DTUs usually establish service centers, often referred to as regional offices, learning centers, etc., in their regional serving areas. As a result, it is customary for a DTU to have a vast physical network of facilities for its operations.

Because of the availability of ICTs and the Internet, course materials development and delivery no longer necessitate large-scale production facilities, as they can now be done electronically through the Internet. Similarly, online platforms are gradually being used to conduct and provide learning assessments and support services for students. These modifications eliminated the need for large physical facilities and networks, lowering the number of study centers required. Physical study centers at DTUs in the Internet era have changed their functions to become more promotional and symbolic of physical presence.

The evolution of ODDE's institutional infrastructure is an inevitable result of the growth and advancement of ICT. To sustainably ensure and improve the quality of its services, DTUs must be able to modify their infrastructures in line with emerging ICTs. Benke and Widger's chapter in this section further examines how the ability to dynamically develop services can be instilled within the institutional infrastructure for ODDE. It examines parts of the field's evolution, including the development of structures that support scalability, affordability, and sustainability. It also presents an overview of institutional infrastructure and models for ODDE, followed by a review of the evolving delivery strategies, institutional infrastructure, and the demand for IT infrastructure support.

## **Technological Infrastructure**

DTUs have always had a strong technological infrastructure, as seen by their vast physical hardware, which included mainframes in specialized computer facilities/buildings and personal PCs as working stations. DTUs' massification of DE necessitates a strong technology-based academic administration system, such as a comprehensive student record system, which has become the backbone of all operations and learning support services. The student record system keeps track of data that is manually entered from completed printed papers.

When the Internet became available for general usage, the Flexible Learning Model promises to combine the advantages of high-quality multimedia with increased engagement. The social contact between students and teachers as well as each student's interaction with teaching-learning resources has been enhanced by the Internet (Bates, 1995). This has highlighted the notable distinction between learning through DE before and following Internet use. According to Tait (2000), the ICTs revolution was the advancement of open and distance learning from "print at the core of a range of media" to virtual environments delivered via the Web. Internet use in ODDE has an enormous influence on the infrastructure needed to facilitate both the provision and the process of learning. With the change in the way students access the course materials and interact with both the instructors and other students, the need for massive physical infrastructure was dramatically decreasing. All functions that need physical buildings and room in an older ODDE practice can now be conducted with and by a computing system. Computer mainframes that used to be the physical storage of data have now also been replaced by cloud computing. Practically, the ODDE infrastructure in the Internet era is dominated by computer databases, platforms, and applications within a digital learning environment (DLE).

The infrastructure required to support both the delivery of and the process of learning is significantly impacted by Internet use in ODDE. The demand for extensive physical infrastructure was severely declining because of the change in how students access the course materials and communicate with both the teachers and other students. According to Panda's chapter, as globalization, technology, and perceptions of twenty-first-century learners and learning change, DTUs also gradually alter their delivery methods and learner support systems: from course design and learner support being separate to both being an integral part of blended teaching-learning; from a more physically and geographically based operation to a more technologically enabled networked operation; from behaviorist to more of constructivist and connectivist models of course design and learner support; and from a humanistic support system to more of strategic support system. Almost all operations that required physical structures and space in an older ODDE practice can now be carried out with and by a computing system. Cloud computing has now replaced computer mainframes, which were formerly the physical storage of data. Practically, computer databases, platforms, and applications within a digital learning environment (DLE) make up most of the ODDE infrastructure in the Internet era.

In 2005, Anderson created a framework to assist institutions in creating online learning (at the time known as e-learning) systems. He emphasized that quality online learning should be built within the secure fulfillment of five elements: (1) information technology (IT) infrastructure, (2) technical standards, (3) content characteristics, (4) pedagogical design, and (5) institutional management. Davis, Little, and Stewart (2011) further highlighted that quality online learning should be deployed using a learning management system (LMS) that delivers course content and resources as well as the strategies/pedagogies of the teaching and learning. Students may access their courses and all other learning resources and services with a single login owing to a user-friendly portal system that connects them to the LMS and related support services. This shows that a learning experience

platform, such as an LMS, is important to online learning and is regarded as such. The LMS is where students interact with the learning materials, with teachers and tutors, and with other students. For ODDE providers, the LMS metadata may be used as important learning analytics to increase student success. Over the past 10 years, learning analytics has grown to be a crucial component of the ODDE architecture. ODDE providers can gain a better understanding of student behaviors and their connections to learning success based on the digital data (of learning activities) captured within the LMS, students' background information in the university database, and the use of computational analysis techniques from data science and artificial intelligence.

In more recent years, the online learning system has further evolved and become a digital learning ecosystem (DLE), which is an online setting that makes use of a system's technical affordances to improve instructional experiences. DLE promotes improvements in resource sharing and collaboration, student retention, and the standardization and reduction of the supporting infrastructure (Brown, Dehoney, & Millichap, 2015). In other words, DLE functions similarly to how ODDE functioned before the Internet by serving as a virtual representation of the whole online education infrastructure. It is an ecosystem for universities in a digital form that is increasingly cloud-based. This, however, does not eliminate the physical infrastructure as most ODDE institutions still maintain their physical basic offices for management and computing center purposes.

---

## **Cross-Generational Infrastructures: Library Services and Quality Assurance**

Several parts of institutional infrastructure, such as library service and quality assurance, have been crucial to the creation and implementation of DE and ODDE systems and practices across time, whether before or after the Internet entered the picture.

### **Library Service and Digital Library**

For any university, the library has long served as the main hub of educational resources. In reality, the library building would be the most recognizable structure on every campus in the world. A library service would include book loans, interlibrary loans, as well as reading areas. The name "library" creates the illusion of bookshelves. Except for the "physical" component, a digital library is very similar to a standard conventional library. A digital library is more than just a digitized collection with information management tools, and it involves several activities that "bring together collections, services, and people in support of the full life cycle of creation, dissemination, use, and presentation of data, information, and knowledge." (Sun & Yuan, 2012, p. 13).

Since DE students are required to conduct independent study, the importance of digital libraries in ODDE cannot be overstated. DE providers typically provide supplemental materials using a digital platform, even in a more traditional DE where learning does not take place in the digital platform and is instead supplied through a pre-produced learning materials package. The digital library is typically one of the first electronic services created as part of learning support services as the use of ICT increases. All students should be able to access the educational materials in the digital library collections using a variety of technological tools. Consequently, a digital library comprises a web interface in addition to being a computer-based system for collecting, organizing, searching, and distributing digital items for end-user access. According to Sun and Yuan (2012), the digital library should offer quick and effective access to the materials with a variety of access modes, because it is intended to serve a specific community or collection of communities. A chapter in this section co-authored by Owusu-Ansah and Rodrigues further discusses that a collaboratively implemented digital library service will significantly improve distance learning library services by considering the importance of collaboration in strategic planning and policy development, the provision of digital collections and information services, and the development of technological infrastructure and skill sets in the context of distance education. The chapter suggests that adopting a collaborative model of digital libraries in ODDE can guarantee wider acceptance and utilization in ODDE.

## Quality Assurance

Government officials, institutional administrators, academic personnel, and students all have various ideas about what quality in DE means (Jung, Wong, Li, Baigaltugs, & Belawati, 2011). Therefore, to decide on the quality criteria and standards by which to evaluate the quality of input, process, and output of DE, quality assurance activities often strive to consider all those diverse perspectives (Jung et al., 2011). Quality assurance (QA) has always been a crucial component of every ODDE system, despite the various ways that stakeholders define quality. Among ODDE practitioners, QA has long been a topic of conversation. Partly, it is due to the dynamic nature of the QA system to accord to the always-changing practices of ODDE. To capture the dynamics of the QA system, we present five chapters related to QA in this section.

As discussed in Jung's chapter, QA in DE and ODDE has been the subject of numerous national, regional, and international initiatives throughout the years. These endeavors lead to the creation of numerous so-called quality assurance standards, guidelines, and statements of best practices (Jung et al., 2011). Although those guidelines and standards may have different styles and elements, they address several fundamental QA areas that remain constant throughout time. For instance, the QA framework for the Asian Association of Open Universities (<https://www.aaou.org/quality-assurance-framework/>) lists policy and planning, internal management, learners and learners' profiles, infrastructure, media, and learning resources,

learner assessment and evaluation, research and community services, human resources, learner support, program design and curriculum development, and course design and development as areas of internal quality assurance. Similarly, the European Association for Quality Assurance in Higher Education (ENQA) states that institutional policies for e-learning shall include institutional support, course development, teaching and learning, course structure, student support, faculty support with compulsory e-learning training for new members of staff, technological infrastructures, student assessment, and certification, as well as electronic security measures (Huertas et al., 2018). A chapter co-written by Ubachs and Henderikx focuses on the latest development of a QA framework for European DTUs that aligns with the Standards and Guidelines for Quality Assurance in the European Higher Education Area (ESG). Ubachs and Henderikx report that due to the growing importance of e-learning, the European Association of Distance Teaching Universities (EADTU), the ENQA, and leading universities in Europe have collaboratively developed specific guidelines that operationalize the most relevant ESG standards for application in digital education including a third version of the E-xcellence manual and instrument for blended and distance learning. In addition, a more recent publication from the International Council for Open, Distance Education – ICDE reported that an effective QA and quality enhancement appears to be multifaceted, dynamic, mainstreamed, representative, and multifunctional (Ossiannilsson, Williams, Camilleri, & Brown, 2015).

Specifically for open universities (OUs), Jung (2005) identified that although some institutions put different emphasis on different QA areas, core areas of QA across the mega universities were in the course and program development and delivery. ► Chapter 45, “Program and Course Evaluation in Open, Distance, and Digital Education,” by Bandalaria specifically discusses how quality in ODDE has been and is expressed concerning curriculum and courses and how they are evaluated for quality to identify any gaps that need to be filled to help eliminate that notion of inferior quality. According to Bandalaria, program and course evaluation methodologies can lead to innovations and improvements if they are guided by QA Frameworks and take advantage of the data that technology can produce, as in the case of learning analytics, which served as the foundation for the suggestions made. To illustrate the implementation of QA frameworks, a chapter co-authored by Darajat and LI examines how QA programs are developed and continuously conducted at two mega universities, Universitas Terbuka and the Open University of China. Both institutions constantly develop QA systems and use systematic QA programs, which over time have improved the quality of learning. A different ► Chap. 47, “Accreditation and Recognition of Prior Learning in Higher Education,” by Conrad focuses on how recognition of prior learning (RPL) may and does play a significant part in the certification of higher institutional learning, which is advantageous for students, employers, and society. Conrad asserts that by acknowledging and respecting a variety of learning possibilities, RPL helps to mitigate concerns of quality in terms of fairness, diversity, and inclusion in education.

In summary, QA has been an important element of ODDE infrastructure to continuously improve services and ensure student success. More than ever, QA

has taken the lead role in ensuring that educational emphasis is placed on both learning outcomes and high-quality teaching and learning. Additionally, the significance of employing QA to improve inclusivity, equity, and lifelong learning has been emphasized by the United Nations Sustainable Development Goals (Martin & Stamenka, 2021).

---

## **The Sharing Paradigm: Open Educational Resources and Creative Commons**

One of the greatest impacts of the global open movement in education is the birth and development of various “open” and “open-source” products that are freely available to be used by educational institutions. Because everyone may publish and share content on the second generation of the Internet, a new paradigm of sharing and sharing culture has emerged (Wiley, 2011). As a result, not only were numerous informational and instructional resources created but the entire openness phenomenon was also developed and fostered. Open education, which was previously understood to mean accessible to everyone, everywhere, at any time, has been further defined as unrestricted access to knowledge. The idea of openness has been elevated to a whole new level by the definition of open content as having the freedom to 5R: retain, revise, remix, reuse, and redistribute (Wiley, 2014).

The open content movement was also made popular when the Massachusetts Institute of Technology (MIT) opened up all its lecture materials and made them available to the public in 2001. It further gained momentum when UNESCO introduced the term OER in 2002. Many educators, policymakers, and governments are drawn to open education. At about the same time, a group of US lawyers created the Creative Commons (CC) open license framework, which makes it easier for creators to share their knowledge and information by allowing them to select the rights they want to provide to users. In many institutions and nations, the use of this CC scheme is now required for the practice of ODDE. ODDE now has a new set of infrastructures that are built on the sharing of educational resources attributable to the open movement. As this is a process of cultural transformation, Teixeira underlines in one of the chapters in this section that DTUs should work to create an open ecosystem by encouraging the usage, reuse, and remixing of OERs and guaranteeing universal accessibility and digital inclusion.

The open-source movement has altered the way educational resources are created and delivered. The sharing paradigm has had a big impact on ODDE’s infrastructure since distance education universities may now take benefit of a variety of learning resources without having to produce everything from start or constantly deal with publication concerns. As a result, they are no longer required to have their production and distribution facilities, which frees up space in their budget to address other urgent demands. Nevertheless, the widespread acceptance, usage, sharing, and future development of OER in the practice of teaching and learning in ODDE are frequently perceived as being hindered by the lack of openness on the quality of OER. A chapter authored by Zawacki-Richter, Muskens, and Marin gives an overview of

OER quality assurance mechanisms from a global viewpoint and faculty members' assessments, both of which are in line with the UNESCO Recommendation on OER. Then, based on an empirical investigation, the Instrument for Quality Assurance of OER, a quality framework, and validated instrument, is offered for the evaluation and quality assessment of OER (IQOER). The chapter further examines how such an instrument might be incorporated into a quality assurance procedure that considers the various objectives, obligations, and responsibilities of the participating stakeholders. It becomes obvious that for OER to be accepted more widely, a culture shift toward open educational practices (OEP) is also required.

---

## The Future: Metaverse-Based ODDE

A metaverse is the convergence of virtually enhanced physical reality and physically persistent virtual space (Collins, 2008), a 3D network that forms virtual worlds that focuses on social connection (Newton, 2021). Virtual worlds can be used for everything from corporate communication and planning meetings to offering a platform for instructors, staff, and students to engage in a safe and secure environment, delivering student services on a virtual campus. This type of immersive learning is not totally new. In 2005–2006, a company named Linden Labs created “Second Life,” a technology that allowed universities to create a virtual environment (Schroeder, 2021). Although it is still theoretically operational, it did not take off beyond its experimental stage, and it may now perhaps find a “second life” in the growing metaverse (Drozdowski, 2022).

If used appropriately, the metaverse is an immersive environment that can, in theory, bring the best digital technologies to bear on education (Hirsh-Pasek et al., 2022). The best educational metaverse applications can help develop engaging and immersive learning environments for students in various educational institutions (Howell, 2022). Flashy and exciting digital experiences can be transformed into ones that are instructive with genuine social interaction at their center by learning how to use active, engaging, meaningful, socially interactive, iterative, and joyful environments to support learning goals. As an illustration, Barry, Kanematsu, and Fukumura (2010) experimented with using metaverse to deliver a problem-based learning scenario and discovered that by catering to the variety of learning styles, metaverse learning might make up for the loss of socialization in e-learning. It appears that the “real-life” learning experiences that many people feel are absent in conventional online learning systems, such as LMS, can be provided by metaverse-based online learning. Students, instructors, and staff at the University of Miami use immersive technology to connect in a network of virtual worlds to explore innovative approaches to solve problems and enhance education after 4 years of research (Tannen, 2022).

The metaverse will certainly grow much quicker, along with its myriad problems that are currently unclear and mostly unregulated, as the COVID-19 pandemic has increased the use of online learning approaches in all types of educational practice. Therefore, it is essential to use a cautious application strategy. Kye, Han, Kim, Park,

and Jo (2021) stress the importance of taking the required precautions to protect student data privacy and safety when creating an educational metaverse platform. Additionally, to use the metaverse for education, instructional designers and teachers must first comprehend the technical peculiarities of each form of the metaverse and then create lessons that enable students to cooperate to solve issues or accomplish tasks.

Although the ideal metaverse for education has not yet arrived, we already know that DE has altered the way we view higher education and that the metaverse's existence will have a similar impact. While it cannot replace traveling to campus in the real world, attending university in the metaverse alongside other "avatar" students and professors may enhance the authenticity of the experience. As the "great unbundling" of higher education accelerates due to the move to the metaverse, students may increasingly prefer only that core teaching and learning product, forgoing more traditional university requirements like dorm living, campus dining, library carrels, football games, and playing on a verdant quad (Drozdowski, 2022). Therefore, the infrastructure of the metaverse would resemble that of a standard physical campus, transforming not only ODDE but also conventional in-person teaching methods. As a result, a strong DLE furnished with cutting-edge AI, ER, XR technologies, and educational products (learning materials, laboratory experiments, etc.) would significantly replace the necessary educational infrastructure. Organizationally, the structure would also require modification from a workforce that was heavily weighted with management to one that was more computer-savvy.

---

## Conclusion

ODDE has come a long way from the correspondence model to the latest one that is based on and delivered through an online platform. The characteristics of ODDE over time have impacted the need for supporting infrastructure. The pre-Internet era of ODDE (or most adequately term as just DE) that was massively practiced by open universities is characterized by large physical infrastructure including a multimedia production studio, an enormous warehouse, a bulky computing and examination center, and a physical network of regional, local offices and learning centers. The ODDE after the emergence of the Internet is more characterized by soft infrastructures such as a digital learning environment including LMS and learning analytics. Nevertheless, despite the different characteristics of ODDE infrastructure before and after the arrival of the Internet, digital libraries and quality assurance systems have always been integral parts of the ODDE system.

Another noticeable aspect of ODDE infrastructure is those impacted by the open education movement. The open education movement has provided ODDE with additional supporting infrastructures that have allowed ODDE to be more powerful and cost-effective. Among others, OER have provided ODDE with richer quality learning resources and collaboration opportunities. Finally, with technology constantly evolving, the so-called metaverse is likely to become a future learning

environment platform that combines the virtual world and the real world, facilitating various learning and social life needs like on a physical campus to provide a rich and engaging learning experience.

**Abstract**

Infrastructure for open, distance, and digital education (ODDE) needs to have the capability to dynamically develop to accommodate varying models for the delivery of the curriculum and the changing needs of students and institutions. The capability to dynamically develop can be instilled within the institutional infrastructure for ODDE which includes areas such as information technology (IT), emerging technologies, marketing and recruitment, student prospect lead management, registration, educational materials, libraries, and student supports. Organizationally, infrastructures to support affordability, scalability, sustainability, and support must be developed. Open questions and directions for future research on institutional infrastructure for ODDE along with implications for ODDE practice that arise from this research are included.

---

**Dynamic Development of Institutional Infrastructures**

While the core function of education remains unchanged, the needs of students and educational institutions are constantly evolving according to changes in sociocultural, political, demographic, and technological domains. It is essential that the infrastructure for open, distance, and digital education (ODDE) has the capability to dynamically develop to accommodate varying models for the delivery of the curriculum and the changing needs of students and institutions. This chapter will explore how the capability to dynamically develop services can be instilled within the institutional infrastructure for ODDE. It will review some of the evolution in the field such as structures to support affordability, scalability, sustainability, and support. An overview of institutional infrastructure and models for ODDE will be presented. This is followed by a discussion of evolving delivery approaches and institutional infrastructure and the need for IT infrastructure supports. The authors will produce open questions and directions for future research on institutional infrastructure for ODDE along with implications for ODDE practice that arise from this research.

---

**Overview of the Institutional Infrastructure for ODDE**

The institutional infrastructure for ODDE is complex and its core components include marketing and recruitment systems, IT and learning management systems, and administration platforms for student services, educational materials, and libraries including open education resources. The requirements for infrastructure depend

upon the institutional mission, strategy, and associated business models combined with the characteristics and size of the intended student audience, variety of academic programs, proposed learning outcomes, and other program development needs. The needs of infrastructure will differ for stand-alone open and distance programs offered in an online mode when compared with those which are more integrated into a traditional campus. Underlying the core components and associated requirements for institutional infrastructure for ODDE is the tension from competing strategic priorities, limited budgets, and staffing resources.

### **Standard Institutional Infrastructure Model for ODDE**

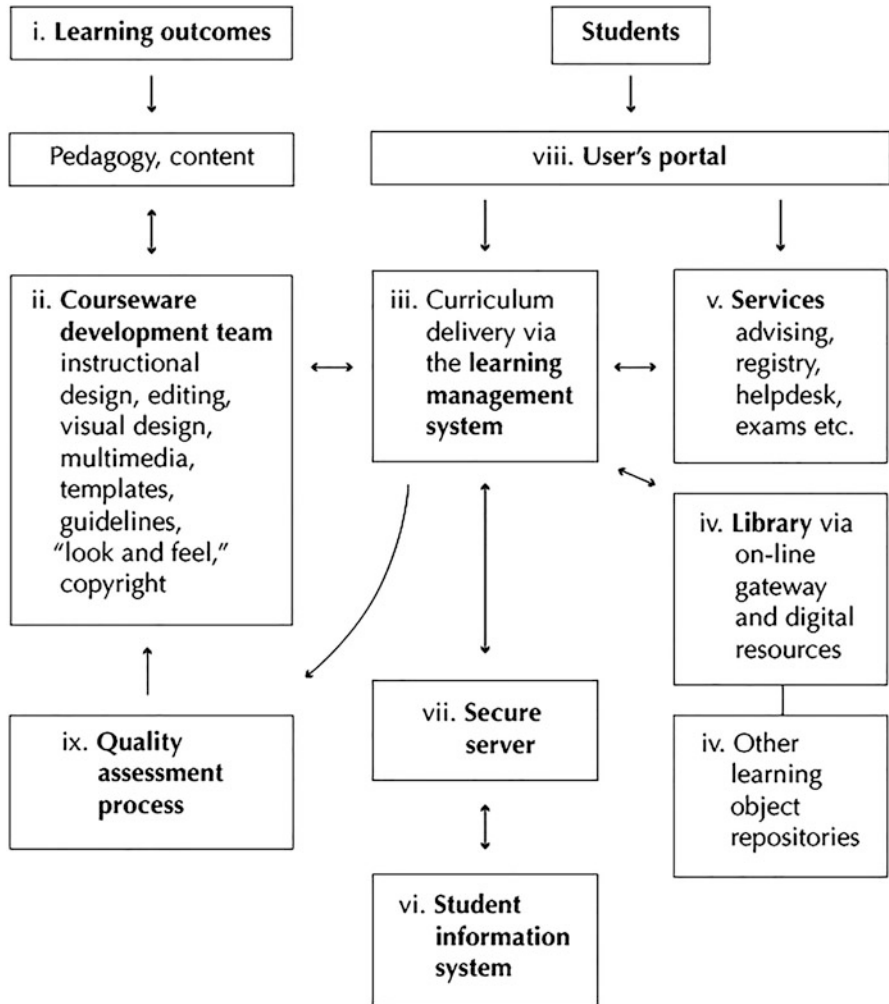

Infrastructure as an area has been intensely examined as part of professional exchange at conferences. However, there has not been significant formal research particularly related to infrastructure in distance education. A special issue of the *International Review of Open and Distance Learning* (2001) presented case studies of seven different international institutions identifying the drivers of organizational and infrastructure models. Building the infrastructure for online learning has had significant open science or open scholarship exchange in many countries, as an example of that conducted in Ireland with the *Irish Journal of Technology Enhanced Learning* (Concannon, Costello, & Farrelly, 2019).

Figure 1 presents a model developed by Davis, Little, and Stewart (2008) to illustrate several of the areas of the institutional infrastructure for ODDE.

This model assumes starting with a business plan and the learning plan related to course content and teaching and learning strategies. Starting with the left-hand column, learning outcomes (i) must be developed by the faculty or instructional staff and ideas considered for pedagogy and course content. There is a development unit of instructional designers who share the responsibility with faculty to translate the pedagogical strategies and learning content into a learning management system (ii). There also needs to be an interface with registration and advising, library and other academic services, and digital or open resources (iii, iv, v). Attention must be paid to areas such as authentication and security, a student portal and interface, and the student information system (vi, vii, viii) and, finally, quality review (ix).

### **Evolving the Institutional Infrastructure Model for ODDE**

A more recent evolution has been the creation of a unit and/or a chief officer for innovation. The responsibility for different components of the infrastructure for ODDE has typically been spread across multiple departments and vice presidents within an institution, especially in institutions where open and distance learning is only a part of the overall business model. The specialized position of chief officer for innovation has been developed to address the struggles between standardization and innovation and separation of control between academic and administrative computing. This position often straddles academic and administrative infrastructure and

**Fig. 1** Developing an infrastructure for online learning (Davis, Little, and Stewart, 2008, n.p)

serves as a conduit for promoting innovations in efficiency, improving learning and student retention, increasing scale, and reducing cost. Research conducted by Entangled Solutions (Selingo, 2018) showed at least 400 colleges in the United States having this title at the Vice President level or as a core role in either academic affairs or in IT. These positions balance priorities such as working with academic affairs on student success, working with finance on return on investment, and working with IT on data analytics and decision-making related to innovation and technology investments.

There are two important aspects related to infrastructure from the development of the innovation unit approach. Firstly, these units often have a greater external perspective and the capability to consider partnerships or shared service models.

Early open and distance programs often had a “build your own” infrastructure. As the field has matured, shared services with companies may be less resource intensive. Secondly, these innovation units often build systems that promote the review for innovation in academics, technology, or services. They help build more of a problem solving or design thinking approach (Selingo, 2018). Selingo (2018) did research on various approaches to support innovation and came up with three models. The most common model is a skunk works or autonomous entity which is in place at Southern New Hampshire University or Arizona State University. In this model, a separate innovation unit is resourced and staffed within the institution, having relatively less impact on the rest of the institution and more freedom to innovate. The second model was labelled by Selingo as the Internal Consultancy. This innovation unit stands alone but consults with willing departments across the university. The third is an integrated model that is more prevalent at a smaller institution, where innovation is integrated into the existing structure.

---

## **Considerations for an Integrated Institutional Infrastructure for ODDE**

### **Infrastructure for Planning, Marketing, and Recruitment of Programs for ODDE**

Once the institutional strategy for ODDE is developed, the institution needs to either create a stand-alone functional office for planning, marketing and recruitment, registration, and financing or to make sure that other functional offices embed the ODDE needs into those office functions. During the Covid-19 transition, many traditional dual-mode institutions moved quickly to the delivery of these types of services from their functional departments. Post-Covid-19, dual-mode institutions new to distance delivery need to more reflectively consider the need for infrastructure for these important functions. Other sections of this handbook explore organizational structures and change management, but there are infrastructure provisions to consider. The marketing approach for ODDE has matured into professional practices for generating leads related to potential students, lead generation, lead follow-up and management, research on the success of leads, and CRM integrated platforms to support the whole student life cycle. In the last decade, some institutions partnered with online program management companies (OPMs) as the institutions did not have the internal expertise. This can be quite successful when the institution has little experience with distance marketing and cannot build the infrastructure. The strategy of using an OPM can be effective for quickly ramping-up a program, but the revenue sharing process proved to be taxing for some institutions because the share is significant.

A more recent development has been insourcing these services with consortiums of institutions in more of a shared services model. The earliest developments in this area were for libraries and information technologies, often for shared purchasing to increase scale and get better pricing. Examples in the United States include NJEdge (<https://njedge.net/>) which works with school districts, colleges, and healthcare

systems to share high speed data for research, networking, cybersecurity, and other IT needs. In the United States, centralized infrastructure shared services for libraries, IT, instructional design, marketing, recruitment, registration, and student services exist in states such as New York (<https://www.sunyonline.edu>) and Georgia (<https://ecore.usg.edu/about/how-does-it-work>) for course delivery support. One such example of successful shared service for ODDE operating at a national level is HEAnet, which was established in Ireland in 1983 by the Irish Universities with the support of the Higher Education Authority and now serves as a national education and research network delivering “high-speed internet connectivity and IT shared services to all levels of the Irish education sector.” An important aspect of this work is for institutions to be able to analyze the return on investment in lead generation but, correspondingly, to connect this to the learning analytics to make sure that students who are recruited to the institution are successful. Registration learning analytic platforms have emerged which assist institutions to better predict successful registration patterns for students. Of particular interest is systems to support less prepared or less historically advantaged students. Student services platforms to deliver academic supports and library systems should also be integrated. All of these systems require significant integration to best understand the profiles for a successful student life cycle from an operational perspective. The institution also needs to have a strategy related to the creating of these systems increasingly outsourcing or sharing these services.

## **Institutional Infrastructure for Libraries and Educational ODDE Materials**

In the United States, the Association of College and Research Libraries has standards for distance delivery of library services which were developed in 2006 and updated in 2016 (American Library Association, 2016). Infrastructure for library provision and services requires a platform for delivery of educational resources and adequate financial support so that distance students and faculty get access to similar library services as any other student of the institution. Services are now delivered primarily through the web, either by the institution, a consortia of institutions, or a commercial provider. A physical library is not required; however, it is important that students have access to books, references, and journals databases and that any fees are similar to the provision for other students. Staffing for librarian research assistance and often librarian services are embedded directly in the programs or courses. Concerns that should be addressed by library infrastructure are the timeliness, ease of access by students, and the cross-cultural perspectives.

Historically, many distance learning institutions managed or partnered with commercial providers for the physical distribution of books or other instructional materials for students such as lab kits or other supplemental materials. Increasingly, institutions are providing open education or digitally delivered resources. Early initiatives were developed course by course, but more recently institutions have moved whole programs or the entire institution to open education. This was not only to save costs for the student, but institutions were finding that a portion of

the students do not actually purchase or use the books provided or purchased outdated materials. From an infrastructure perspective, this means that institutions investing in sharing low cost digital or open education resources need to create or outsource platforms to share these resources. Commercial providers and professional associations have emerged to share these resources. Data from these platforms allow faculty and staff to better track on usage, effectiveness, and improvements.

## **Institutional Infrastructure to Support Research in ODDE**

The advent of the Covid-19 pandemic highlighted shortcomings in educational institutions in their ability to conduct timely research on students' experiences of ODDE. Research focused on the institutional infrastructure for ODDE is essential as institutions work through which aspects of blended and online delivery should be retained in the short term: What are the areas for longer term strategic development? How do institutions plan, fund, and operationalize these changes? It will be crucial that students and staff are engaged throughout the research process. Mc Vitty, Jackson, and Hutchens (2021) confirm that students are open to retaining the majority of elements of online delivery in some form but do not always know which modes will best support their learning. There is a need for further investigation in the infrastructural requirements for ODDE to provide a consistently engaging online learning experience. Most of the research on students experiences of ODDE takes place at an individual module or course level and is not used to inform institutional decision-making for the short-term or long-term investment in institutional infrastructure for ODDE. Individual faculty investigates delivery approaches or the use of a particular software or other technology. Multiple campus program research or multi-campus approaches could better inform the needs for investment in instructional infrastructure. Tyton Partners has tracked faculty adoption and use of digital software and tools and recommend developing common frameworks for evidence-based research and sharing (Fox et al., 2021, June 22).

One model for sharing research related to the infrastructure for open education is the COUP framework developed by the Open Education Group (2021). COUP allows researchers on open education to share findings related to costs, outcomes, usage and perceptions. The dimensions of cost and usage are particularly important to the area of infrastructure. This research group has developed a calculator application to look at a range of cost metrics for students and institutions such as:

- Costs of textbooks previously assigned
- OER support fee models
- Changes in campus bookstore revenue
- Changes in tuition revenue due to changes in drop rates
- Changes in tuition revenue due to changes in enrollment intensity
- Changes in tuition revenue due to changes in persistence
- Changes in access to performance-based funding due to changes in drop, enrollment intensity, and persistence

The adoption of open educational resources can impact a range of financial and cost metrics for students and institutions. Research shared using this model shows that the use of open resources will save K-12 school districts' money or in the case of higher education save students' money (Open Education Group, 2021). Correspondingly, however, there can be possible losses in institutions getting shared revenues from bookstores. The IT area needs to determine effective ways to share open education resources through repositories or other related services to promote ease of access for students.

## **Institutional Infrastructure to Support Evolving ODDE Course Delivery**

The institutional infrastructure for ODDE naturally matured over the last two decades, but it has also changed due to significant disruptions in the ways in which courses are being delivered. One substantial disruption was the emergence of Massive Open Online Courses (MOOCs) which had both significant successes and expressed concerns. MOOCs have been an important development in ODDE, and their popular growth has demonstrated a possibility for informal and inexpensive or free education. MOOCs also were supported in ways that expanded the use of technology in online education; investments were made in higher-quality video and adaptive technologies which allowed for much larger technology-supported courses at less per person expense. The growth in MOOCs demonstrates how advances in information and communications technology encourage the move to online learning and are continually facilitating new modes of delivery. For example, MOOCs are being used as a method of disseminating key research findings from research projects. MOOCs demonstrate how the infrastructure for open and distance learning needs to have the capability to evolve with the changing needs of students, institutions, and models for the delivery of the curriculum.

---

## **Institutional IT Infrastructure for ODDE**

### **Developing Institutional Infrastructure for ODDE**

Large open universities in many countries were strategic in developing and harnessing the efficiencies of advanced technologies for more scalable and lower cost delivery (Guri-Rosenblit, 2019). Covid-19 and the evolution into online and other digital technologies have made the use of advanced technologies more ubiquitous throughout higher education. Guri-Rosenblit suggests that the large open universities may need greater investments as far as infrastructure to support digital and online, along with the more complex faculty and support needs. In many dual-mode institutions, IT infrastructures are merged with campus-based infrastructures. There is little literature related to specific IT infrastructure for ODDE. Instead, literature relies on models for traditional institutional IT infrastructure. One useful model for administrators to use for the institutional IT infrastructure for ODDE

comes from Broadbent and Weill (1997) that ties IT capabilities to help to achieve organizational goals. Broadbent and Weill define three areas of infrastructure services necessary to enhance business processes: the IT component, the human infrastructure, and shared IT services. The results of their study named 23 infrastructure services which may contribute in helping an organization to reach goals. In 1999, Broadbent, Weill, and Clair (1999) and Broadbent, Weill, and Neo (1999) refined these 23 services into application management, communication management, data management, research and development, services management, security management, standards management, and IT management. In distance education, additional crossover broad impact areas such as data analytics, knowledge management, and business process mapping have emerged as areas of practice.

Several models exist to support the integration of IT into teaching and learning, but these tend to operate at an individual course or module level. The ADDIE five step model (Dick, 2001), Laurillard's Conversational framework (Laurillard, 2002), SAMR (Puentedura, 2006), TROHA (Troha, 2007), and Salmon's Carpe Diem (Salmon, 2011) constitute a sample of the models that can be used to guide the implementation of IT in education. The ADDIE instructional design model involving five stages, namely, analysis, design, development, implementation, and evaluation provides a framework to implement IT into distance learning. Laurillard's conversational framework is both a learning theory and a practical framework for designing online learning environments and involves four main components: teachers' concepts, teachers' constructed learning environment, students' concepts, and the students' specific actions. The Substitution, Augmentation, Modification, Redefinition or SAMR model was developed by Puentedura (2006) to enable educators to identify different ways in which they could integrate technology within the teaching and learning portfolio. The SAMR model provides a continuum from novice to advanced level of technology integration to encourage educators to seek ideal ways to embed technology to support and enable the learning experience. The Troha model provides a more systematic experience, while Salmon's Carpe Diem model provides a framework to integrate technology while redeveloping an entire unit of study. The aforementioned models favor an approach where an instructional designer is working with an individual instructor on individual learning units or modules but provide limited guidance on a collaborative coordinated and strategic approach to the integration of IT across a program, faculty, or educational institution. This can result in a splintered approach with instructors at varying stages of technology adoption on a single program and/or across a faculty or academic department.

---

## **The Impact of Advancements in IT on the Institutional Infrastructure for ODDE**

There are several significant developments and advancements in IT which have had a substantial impact on the institutional infrastructure for ODDE. These include cloud computing and software as a service; bring your own cloud; artificial intelligence, adaptive learning, and learning analytics; and mobile learning.

## Cloud Computing and Software as a Service

The increasing availability of the Internet has facilitated the development of cloud computing where software and computing services are delivered over the Internet. This has allowed for greater integration of technology systems and sharing of data across systems resulting in the provision of Software as a Service. The data environment for ODDE has evolved to an ecosystem with the integration of customer relationship management systems, learning management systems, and the student information system. In Software as a Service, the databases and the software are accessible online through the cloud. New technologies and pilots can be implemented in a more agile and scalable way (Anderson, Marlaire, & Shean, 2020). Institutions no longer need to manage an on-premises data center to provide their own servers to store and process data as most of these activities can be outsourced to external providers. Varying capital expenses, often consumed with replacing aging physical IT hardware, have shifted toward predictable monthly or quarterly expenditure. Compared with on-premises data centers, additional resources can be easily deployed in a cloud infrastructure at peak times, e.g., during examination periods, etc. The costs are allocated through the cloud, and the institution is charged only if the services are used. These shared services provide an alternative to higher cost in-house IT infrastructure. Moving to a cloud computing infrastructure and utilizing Software as a Service can release the in-house computing team to concentrate on the long-term IT strategy. The overall support and development of the IT infrastructure requires specialist skills. Careful consideration needs to be given to the continuing development of the skillset of in-house computing team to ensure they have the expertise to adapt as required and redirect their focus to developing different areas of IT infrastructure.

## Bring Your Own Cloud

Many institutions pre-Covid-19 were developing and implementing “bring your own device” (BYOD) policies to respond to the demands of users and facilitate those who were able to supply their own device to support their learning within both the traditional on-campus and online learning environments. Closures of campus and restrictions on the movement of people forced a radical change, almost overnight, in work and learning practices. Many educational organizations struggled to accommodate the needs of users who now required immediate remote access and support for a variety of software and services to support the learning environment. In response to restricted access to the physical and virtual campus during Covid, and as a workaround to difficulties accessing Institutional Learning Management Systems and/or virtual classroom technologies, many staff and students started to build their own clouds to support their learning and teaching. “Bring your own cloud” (BYOC) is a concept that can apply in an educational context as students and staff are piecing together institutional or third-party cloud software and services to perform certain tasks. Personal cloud storage solutions are being used to store and

share key learning resources. Academic staff are using free versions of virtual classroom technologies such as Zoom to facilitate their online engagement with their students independent of the institutional supplied systems. Widespread access to WiFi is improving, and students are willing to use personal mobile data plans to access the Internet both on and off campus. Much of this practice can be considered “rogue IT” where unsanctioned IT resources are being used to support the activities of an organization. Tensions can exist when users expect institutional support services to trouble between users and support services. Many institutions have invested heavily in installing WiFi networks on campus and on licenses for a range of software platforms to support distance learning. BYOD and BYOC practices pose serious risks to the security of student data. Responding to, and accommodating, BYOC and BYOD practices presents significant opportunities and challenges for institutional infrastructures for ODDE.

### **Artificial Intelligence, Adaptive learning, and Learning Analytics**

Institutions are now moving forward to greater technology tools to support students. Artificial intelligence is being applied to personalize learning and services, particularly when working with students across multiple time zones. Software to support the development of academic writing and assist in detecting plagiarism are continuously integrating artificial intelligence to improve their offering. Chatbots are now available on many websites which can serve student with routine questions related to courses, financial aid, and registration or library or book services. Chatbots are replacing the first layer of end user troubleshooting and support for various IT systems such as the VLE and are also provided in courses to assist as a resource related to particular topics.

Adaptive learning platforms have emerged to better support learners on individualized pathways and to support scale. There has been significant investment in promoting success, particularly in first year courses. The Gates Foundation has funded research into the efficacy of proprietary adaptive learning platforms working with educational institutions to examine the cost/benefit analysis and the potential for improvements in learning (Yarnell, Means, & Wetzel, 2016, April). The results of these early projects were mixed, with four of fifteen projects indicating a positive return on investment related to the use of different adaptive platforms. More recent work at some institutions has shown improvement in learning and student success by combining adaptive courseware and learning analytics, particularly in first year or gateway courses (Dziuban, 2020). It is a maturing field with potential. Partnering with an adaptive partner for technology allows for algorithm-based routing of learners, and there are a variety of company software platforms available such as Realizeit, Aleks, MyLabs, etc.

Learning analytics is an area of significant growth in strategic importance in the past 5 years. “Technologies for improving analysis of student data” was listed as one of the top 10 strategic technologies in the 2019 EDUCAUSE Horizon report as were “learning analytics for student success (institutional level),” showing the importance

of this work to institutions (Alexander et al., 2019). As previously mentioned, cloud computing and Software as a Service are facilitating the continuing development of an integrated IT ecosystem. The data used in these systems can also be combined with teaching and learning software including video usage data. Educational providers now have the capability to better analyze if the use of technology is improving student performance or making the organization more efficient. Many of the newer IT systems include the ability to present user data in a visual way to indicate underlying usage patterns and trends in large or small user populations. Some systems allow for data to be amalgamated from multiple platforms. Institutions can use analytics from registration and learning platforms to predict successful registration patterns for students. Improvements in the visualization and use of data need to be balanced against the users, both students and staff, right to privacy. All staff with administrative access to these systems should be provided with training on the ethical and appropriate use of the data. Educational institutions need to ensure that the benefits of learning analytics are realized. Analytics need to be used to answer pertinent questions that will inform the evolution of the infrastructure for ODDE to underpin a consistent and engaging learning experience. The aforementioned role of the chief officer for innovation can be useful in integrating learning analytics into institutional decision-making in a timely manner.

## **Mobile Learning**

Mobile learning refers to the use of mobile devices to access and engage with learning content wherever and whenever a student has a mobile device connected to the Internet. Many students own their own smartphone or mobile device, and most platforms incorporate a responsive design and/or have specialized apps to improve the user experience when accessed from a mobile device. The benefits of mobile learning are based on convenience, flexibility, and learning dependence. Mobile learning increases the availability of education as students can access the learning environment and associated resources once they have a suitable mobile device. The capital expenditure associated with the provision of computers on campus for students has shifted to implementing BYOD and BYOC policies and supporting staff in developing content that is also accessible on mobile devices. Many mobile devices incorporate push technology which can be used in the learning context to send notifications and reminders to students about key learning tasks. Learning analytics amalgamates a wide range of information from mobile devices that can inform decision-making around the institutional support needed for mobile learning. Software for learning analytics can collect data from mobile devices to detail usage patterns by mapping and comparing a range of data points including time of access, Internet service provider, geophysical location, type of device including make and model, duration and frequency of access, etc. The

addictive dimension brought about by the ubiquitous presence of digital devices and integration of push technologies poses a risk to the engagement of the learner (Pedro, Barbosa, and Santos, 2018). In a similar vein to remote working, institution infrastructure for ODDE may need to accommodate the rights of staff and students to disconnect from the learning environment. This will present a significant challenge as students and staff are using a variety of mobile devices to support their learning and teaching. There is a need for further research on the impact of mobile technologies on the engagement of the learner and the teaching and learning process.

---

## **The Impact of the User Experience on the Institutional Infrastructure for ODDE**

The discussion of infrastructure services for ODDE must also consider the user experience. Determining how to assess the user experience has become more complex as technology and systems have moved into the cloud and as the systems have become more integrated. The effective use of learning tools is dependent on the perspective of the users, defined as students, faculty, and the institutions. In looking at the IT systems, the technology acceptance model has been used in studies to assess the impact of the user experience related to technology. The model has been updated to reflect some criticisms related to its inefficiency in justifying the social influence on the acceptance of technology (Straub, 1997). It incorporates other factors like “social influence” and “self-efficacy” (Al-Marouf, R., 2020 and “perceived enjoyment” (Salloum et al. 2019). Al Kurdi et al. (2020) expanded the model to include these influences. The critical factors were subjected to a statistical analysis which showed social influence, perceived enjoyment, and computer self-efficacy maintain a positive and strong effect upon, perceived ease of use, and perceived usefulness. Additionally, behavioral intention to use the E-learning system is significantly affected by the perceived usefulness and perceived ease of use. Various other research studies assessed the positive influence of social influence, perceived enjoyment, and computer self-efficacy on perceived ease of use, perceived usefulness, and E-learning acceptance. A continuing critical concern is the cross-cultural perspective related to the acceptance and use of education technologies and the integration in countries where there are issues related to bandwidth or other connectivity (Al-Marouf, 2020).

Institutions have also evolved as to how the students are supported through help desks, call-centers, and support services that are managed by the institution or outsourced partners. Analyzing the data on the user experience has become complex, including reviewing response times, dropped call rates, web statistics and other analytical tools to improve services. Similar to IT infrastructure acceptance models discussed, review of how diverse learners or learners with less access to resources get access to support services is important.

## Impact of Covid-19 on Institutional Infrastructure for ODDE

The transitions after the worldwide Covid-19 pandemic has had institutions around the world looking at institutional infrastructure supports for ODDE. The impact of Covid-19 meant that many traditional institutions without experience immediately had change their course delivery models, student support services, and work practices to pivot to blended and fully online learning. Campuses around the world worked together to learn and deliver education.

Implementation of a national strategy for remote working will remove some of the barriers to engagement with ODDE and increase the demand for flexible and online learning. Institutions should be reviewing their infrastructure for ODDE, including their planning, marketing, and student recruitment systems, IT systems, and course delivery models and remote working policies for staff, to ensure that their organizations are evolving the institutional infrastructure to respond to the changes in work and study practices as a result of Covid-19. In Ireland, the recently published National Remote Work Strategy 2021 acknowledges the seismic shift in remote working and aims to legislate for the right to request remote working, review tax and expenditure for remote working, make home and remote work the norm for 20% of public sector employment, invest in a network of remote working hubs, develop a code of practice for the right to disconnect, and accelerate the provision of high-speed broadband to all parts of Ireland (Department-of-Enterprise-Trade-and-Employment 2021). Remote working hubs could easily become remote working and study hubs. Wonkhe and Pearsons' research on "Students' experiences of study during Covid-19 and hopes for future learning and teaching" confirmed that there are very few elements of online learning and teaching that the students surveyed in England and Wales would not like to see continue after the pandemic (Mc Vitty, Jackson, & Hutchens, 2021). Most agreed that they would like to see the continued provision of recorded lectures, core materials in the learning management system, online access to support services such as well-being and careers, and online tutorials or check-ins with tutors. Students have experienced and recognized the benefits of a more flexible approach, and the institutional infrastructure for ODDE will have to evolve and purposefully draw on the best of both online and face-to-face learning. Many will return to classroom-based learning, but many will continue in online and will need to build more solid infrastructures and student services. A survey of attitudes to upskilling conducted by the Irish Higher Education Authority reported that more than one-third of people (37%) are considering upskilling or reskilling due to the Covid-19 pandemic, and almost half the respondents would like to retrain to work in a more progressive and evolving sector (HEA, 2021). There is emergent work to share insights from building shared services for infrastructure post-Covid, one such example from China related to open education repositories (Huang et al., 2020) and infrastructure systems for both higher education and regular schools (Xue, Li & Xu, 2020).

## Infrastructure Supports for Emergent Areas

It is important that institutional infrastructure for ODDE can support emergent areas. Educause conducts research through Horizon reports on IT trends in education, a number of which are related to infrastructure. The 2019 report identifies multiple areas related to open and distance learning infrastructure (Alexander et al., 2019). Short-term trends indicate the increased interest in mobile and adaptive learning. Midterm trends include mixed reality, artificial intelligence, virtual digital assistants, and block chain. Open education resources and digital courseware also are innovation developments which continue to be expressed by IT representatives from around the world.

Since 2012, the Open University has produced an annual Innovating Pedagogy report to “explore new forms of teaching, learning and assessment in an interactive world to guide teachers and policy makers in productive innovation.” Each report proposes innovations that are due to become more widespread and have the potential to provoke a shift in educational practice. Several of the pedagogies singled out in the 2021 report will have a significant impact on the institutional infrastructure for ODDE if the adoption of these pedagogies become widespread (Kukulska-Hulme et al., 2021). “Best learning moments” and “enriched realities” with the use of technologies such as augmented reality and virtual reality top the list.

---

## Concluding Remarks: Open Questions and Directions for ODDE Practice

Despite innovations in parts of higher education, the traditional models of distance delivery in higher education have remained substantially similar. In order to scale innovations, infrastructure needs to be flexible and adaptive to support these innovations. The profession is also actively interested in infrastructure models and particularly ways to increase scale, improve student success, and reduce costs. This has been particularly driven by new entrants to the market.

Questions remain for how the institutional infrastructure for ODDE can evolve:

- How can personalization and customization for users continue to advance through developments in adaptive learning, mobile, and artificial intelligence?
- How can data analytics be used more effectively to support learner success through identifying just-in-time support services?

Further research is required in the following areas:

- Sharing models for effective deployment and training of technology staff to support the ecosystem for ODDE

- Sharing models linking ODDE strategy with organizational structures, infrastructure, and any shared services
- The cross-cultural implications related to technology use, support services, and learning environments
- The infrastructural requirements for ODDE to provide a consistently engaging online learning experience
- The cost/benefit analysis related to the decision to use a third-party service to share costs for infrastructure, particularly when these services are proprietary
- Adaptive and artificial intelligence to examine the possibilities of changing the pace of education and improving learning
- The impact of mobile technologies on the engagement of the learner and the teaching and learning process
- The investment needed to make sure that there is a seamless experience for users, particularly related to infrastructure for IT, library, educational materials, and other academic services

The state of infrastructure models in ODDE are poised for new developments, particularly as software and other services have moved to the cloud and new technologies have emerged. In addition, the developments of shared services and outsourced models will influence future practices. Also, most importantly, user influence and the capability to make greater choices regarding opportunities post-Covid-19 will impact models for services and academic programs.

## Abstract

Over the past few decades, online, open, and distance education (ODE) has enjoyed phenomenal growth across different regions, and with the spread of the COVID-19 virus, its use has adopted more quickly and widely at all levels of education in both developed and developing countries. There has also been a surge in trans-institutional online courses and programs. Despite this surge in widespread practice of ODE, an image problem that perceives ODE as a second-rate education, indicated by Daniel (Quality assurance and accreditation in distance education and e-learning: Models, policies, and research. Routledge, New York, 2011) a decade ago, still exists, meaning that there is a need for even stronger measures to ensure that ODE is as good as in-person education and that quality assurance (QA) systems are in place as it enters the mainstream of education.

Applying QA to ODE processes and outcomes is a relatively new phenomenon. Drawing upon previous literature on quality and QA in ODE, including institutional case studies, this chapter examines various definitions of quality and

QA in ODE practice, difficulties, and challenges presented by QA in ODE and the role of stakeholders in QA in ODE. It then discusses how different ODE institutions judge and assure the quality of their courses, programs, and services and what values and assumptions underpin such QA approaches. It finally draws conclusions about what still needs to be considered and actioned.

## **Introduction: Defining Quality and Quality Assurance in ODE**

Harvey and Green (1993) view quality as excellence (something exceptional and distinctive), as perfection (something perfect or consistent), as fitness for purpose (something fulfilling needs or requirements), as value for money (something worth investing), and as transformative (something empowering or enhancing). These five disparate ways of explaining quality in higher education definitely help conceptualize quality as being five interrelated ideas in ODE, but at the same time they make it difficult to univocally and explicitly define the concept of quality in relation to ODE.

Quality, moreover, in ODE may be judged in different ways depending on who defines it (Latchem, 2016). Students, governments, or employers, for example, who pay for ODE may define quality of ODE in terms of value for money, while educators might tend to focus on excellence and consistency, and researchers may highlight transformative aspects of ODE. Likewise, QA may be understood quite differently by different stakeholders as Jung and Latchem (2007) argued. Governments may be interested in the socioeconomic benefits and public accountability of ODE (Koul, 2006), while ODE institutions seek assurance in quality across planning and management, design, development and delivery of course and course materials, learner support, and assessment and completion/graduation rates (Jung, 2005). Researchers may highlight the depth and extent of learning (Ehlers, 2004) and the development of self-directed lifelong learning skills as an important aspect of QA in ODE (Paul, 1990). Students are more concerned with well-designed ODE courses and materials, support, and logistics (Daniel, Kanwar, & Uvalić-Trumbić, 2008), the applicability or relevance of assignments (Conrad, 2002), clear instructions especially related to grading policy and feedback (Song, Singleton, Hill, & Koh, 2004), and ensuring their competitiveness in the workplace (Kihwelo, 2013).

While quality is perceived as a value to be pursued for the enhancement of higher education, not everyone concurs that QA is a good thing. Seyfried and Pohlenz (2018) argue that internal and external reviews within a QA system are not always reliable and valid in evaluating the quality of teaching and learning and thus may not be a strong basis for important management decisions concerning quality enhancement. Beerkens (2018) claims that the majority of QA policies have not focused on student learning and thus it is still unknown whether all QA efforts and reforms have resulted in better learning performances of graduates.

Considering the complexity involved in defining quality and QA in ODE, Jung and Latchem (2007, 2011) categorize the varying definitions of quality in five ways:

- *Quality as conforming to the standards set for conventional education.* Here, the same criteria and standards are used to judge quality in ODE and conventional campus-based institutions' teaching and learning, management, resources, and outcomes. This approach, however, may fail to take into account unique aspects of ODE (Phipps & Merisotis, 1999; Stella & Gnanam, 2004), but as ODE is fast becoming a main delivery mode in conventional education, the difference between conventional campus-based education and ODE in higher education may not be as big as it used to be.
- *Quality as fitness for purpose.* Here, quality is judged by the extent to which ODE programs or institutions fulfill their predetermined purposes. But the problem is that this approach may fail to address conflicting purposes of ODE as defined by the various stakeholders discussed earlier.
- *Quality as meeting customers' needs.* Derived from business sectors, this approach values customer satisfaction. Some ODE institutions have adopted ISO9001 and implement course satisfaction surveys to assess the quality of their courses and services (Aisyah, Samsiyah, Wulandari, & Juliana, 2019). One problem with this approach is that it may fail to address varying needs of different customer groups.
- *Quality as continuous improvement.* Here the focus is on quality enhancement, following the cycle of input, implementation, output, and back to input. Institutional research to support and improve quality for ODE is highly valued, but the problem is that findings from QA research do not necessarily guarantee the improvement of practice.
- *Quality as compliance with national/regional/international standards and requirements.* Here, ODE institutions seek accreditation or recognition from highly regarded regional, international, or transnational agencies, often to eliminate ODE's "second-class education" image within their society. Problems with this approach include possible conflicts with national priorities and extensive reporting requirements during the evaluation process.

The above shows that quality in ODE is a relative, complex, multifaceted, and culture-related issue, as is QA (Schindler, Puls-Elvidge, Welzant, & Crawford, 2015; Zuhairi, Raymundo, & Mir, 2020). In defining quality in ODE, some (e.g., Stella & Gnanam, 2004) claim that the quality of ODE cannot be judged using conventional quality concepts as ODE is structurally different in many ways; while others (e.g., Huertas et al., 2018; Jung, 2011; Ossiannilsson, Williams, Camilleri, & Brown, 2015) argue that while some universal principles of quality can apply to both traditional face-to-face education and ODE, there are unique features to ODE that should also be noted in a different way, such as technology-based asynchronous interactions, openness in admission and learning paths, and flexibility in teaching and learning. Compared with traditional education, recent ODE relies to a greater extent on students' self-directed learning and technology competencies as well as their engagement in interaction and collaboration, making it difficult to define and

judge the quality of ODE (Beaudoin, Kurtz, Jung, Suzuki, & Grabowski, 2013; Ferreras-Garcia, Ribas, Sales-Zaguirre, & López, 2021; Jung, 2011).

These difficulties and differing views in defining quality in ODE have contributed to the discussions and development of various QA models at international, regional, national, and institutional levels. In analyzing the QA models applied in ODE worldwide, Ossiannilsson et al. (2015, p. 5) concluded that while each QA model serves specific purposes in a given time and context, it defines QA in ODE as:

- *Multifaceted.* The QA model includes “a multiplicity of measures for quality” and often considers “strategy, policy, infrastructure, processes, outputs and more so as to come to a well-rounded view of holistic quality.”
- *Dynamic.* The QA model integrates flexibility in its system in order “to accommodate for rapid changes in technology, as well as social norms.”
- *Mainstreamed.* The QA model is “intended to trickle down throughout the institution and be used as a tool for reflective practice by individual members of staff in their daily work.”
- *Representative.* The QA model seeks to “balance the perspectives and demands of various interested stakeholders, including students, staff, enterprise, government, and society at large.”
- *Multifunctional.* The QA model aims to “serve a triple function of instilling a quality culture within an institution, providing a roadmap for future improvement, as well as serving as a label of quality for outside perspectives” (Ossiannilsson et al., 2015, p. 5).

Recognizing the complexity of defining and judging the quality in ODE, Kihwelo (2013, p. 4) argues that definitions of both quality and QA should be open to change and evolution as information in ODE, challenges faced, and understanding of those challenges in the context of ODE are constantly emerging and changing. Keeping this argument in mind, attention must be turned to various models and guidelines for judging and assuring quality in ODE.

---

## Judging and Assuring Quality in ODE

### Accreditation and QA Frameworks at National, Regional, and International Levels

As Latchem (2016, p. 10) pointed out, in most countries, ODE is subject to laws, regulations, and practices imposed by national, regional, and/or international QA and accreditation agencies together with other professional and academic organizations.

At the national level, accreditation of an ODE institution or program, after internal and external reviews into the quality of the institution or program, is granted by one or more national quality and accreditation agencies for higher education and hence recognition or license is offered to the said institution. For example, in the UK, the Quality Assurance Agency oversees QA and accreditation of all higher education

institutions, including ODE institutions. But in some countries, QA and accreditation for ODE and conventional education are conducted by different agencies or units; an example of this is in India, where conventional universities are accredited by the University Grants Commission (UGC), while ODE institutions are assessed and accredited by a separate unit: the Distance Education Bureau (DEB) of UGC.

Accrediting and QA agencies have developed standards, performance indicators, and procedures to guide higher education institutions during the internal and external review processes and also to guide continuous improvement. Examples of national quality and accreditation agencies that have developed accreditation and QA standards or guidelines for ODE include:

- 1) The UK's Open and Distance Learning Quality Council which assesses providers in order to enhance quality in ODE and to protect the interests of distance learners and the Quality Assurance Agency which provides various resources on the quality of online learning including *Online Delivery & Student Experience* (<https://www.qaa.ac.uk/en/news-events/support-and-guidance-covid-19/online-delivery-student-experience>) and *Getting Your Teaching Online* (<https://www.qaa.ac.uk/scotland/en/focus-on/technology-enhanced-learning/getting-your-teaching-online>)
- 2) The US Commissions on Higher Education which published *Best Practices for Electronically Offered Degree and Certificate Programs* (<http://www.c3l.uni-oldenburg.de/cde/found/wiche2.pdf>); the US Distance Education Accrediting Commission, recognized by the US Department of Education and the Council for Higher Education Accreditation as a national accrediting agency for ODE, which offers the *DEAC Accreditation Handbook* ([https://www.deac.org/UploadedDocuments/Handbook/DEAC\\_Accreditation\\_Handbook.pdf](https://www.deac.org/UploadedDocuments/Handbook/DEAC_Accreditation_Handbook.pdf)); and the US Quality Matters (QM) which offers various standards including *Higher ED Rubric Standards* (<https://www.qualitymatters.org/qa-resources/rubric-standards>) for online and blended courses
- 3) India's Distance Education Bureau of UGC which publishes *Recognition of Open and Distance Learning (ODL) Institutions* (<https://www.ugc.ac.in/deb/pdf/RecognitionODLInstitutionsHandbook2009.pdf>)
- 4) The Malaysian Qualifications Agency which publishes *Code of Practice for Programme Accreditation: Open and Distance Learning* (<https://www2.mqa.gov.my/qad/garispenduan/COPIA/2019/Final%20COPPA-ODL%202nd%20edition%204.12.19.pdf>)
- 5) Australia's Tertiary Education Quality and Standards Agency which provides *Quality Assurance of Online Learning: Discussion Paper* ([https://www.teqsa.gov.au/sites/default/files/quality-assurance-online-learning-discussion-paper\\_0.pdf?v=1575861233](https://www.teqsa.gov.au/sites/default/files/quality-assurance-online-learning-discussion-paper_0.pdf?v=1575861233)) and *Toolkit* ([https://www.teqsa.gov.au/sites/default/files/quality-assurance-online-learning-toolkit\\_0.pdf?v=1575861567](https://www.teqsa.gov.au/sites/default/files/quality-assurance-online-learning-toolkit_0.pdf?v=1575861567)) and *Online Learning Good Practice* (<https://www.teqsa.gov.au/online-learning-good-practice>) during COVID-19
- 6) South Korea's Ministry of Education and Korea Education and Research Information Service (KERIS) which publish QA regulations and guidelines including *Standards for Evaluation and Accreditation of Cyber Universities* (available only

in Korean) and *A Manual for the Management of Academic Affairs in Cyber Universities* (available only in Korean)

In some countries across Africa, QA and accreditation systems in higher education are relatively new or do not yet exist at the national level. In such cases, regional agencies offer QA guidelines and training opportunities to support the institutions in such countries.

At the regional level, various agencies and organizations offer QA guidelines and resources for ODE institutions and programs in their region, including (1) the European Association for Distance Learning (EADL) which requires its members to follow EADL's *Quality Standards* (<https://www.eadl.org/quality-standards/>); (2) the African Council for Distance Education (ACDE) which promotes research, policy development, and quality in ODE across African region; (3) the Harmonisation, Accreditation and Quality Assurance in African Higher Education (HAQAA) Initiative with support from the European Union which has created *African Standards and Guidelines for Quality Assurance in Higher Education (ASG-QA)* ([https://haqaa2.obsglob.org/wp-content/uploads/2020/06/ASG-QA\\_Manual\\_en\\_09.FINALE-with-License-1.pdf](https://haqaa2.obsglob.org/wp-content/uploads/2020/06/ASG-QA_Manual_en_09.FINALE-with-License-1.pdf)) and included a set of guidelines for ODE; (4) the Latin American and Caribbean Institute for Quality in Distance Higher Education (CALED) which develops guidelines and instruments for QA in ODE and promotes quality culture in ODE throughout the Latin America region; and (5) the Asian Association of Open Universities which provides *Quality Assurance Framework* (<https://www.aaou.org/quality-assurance-framework/>) for ODE institutions in Asia.

At the international level, guidelines on quality in transnational ODE are offered by such agencies as (1) UNESCO/OECD's *Guidelines on Quality Provision in Cross-Border Higher Education* (<http://www.oecd.org/education/skills-beyond-school/35779480.pdf>), (2) International Council for Open and Distance Education (ICDE)'s *Quality Resources* (<https://www.icde.org/quality-education>), and (3) the UK Quality Assurance Agency which provides UK Quality Code for Higher Education Part B: Assuring and Enhancing Academic Quality Chapter B10 – *Managing Higher Education Provision with Others* ([https://www.qaa.ac.uk/docs/qaa/quality-code/chapter-b10\\_-\\_managing-higher-education-provision-with-others.pdf?sfvrsn=8c02f781\\_8](https://www.qaa.ac.uk/docs/qaa/quality-code/chapter-b10_-_managing-higher-education-provision-with-others.pdf?sfvrsn=8c02f781_8)).

From a look at QA frameworks at national, regional, and international levels, it is clear that globalization and the advancement of technology and transnational ODE have led to similar QA standards and procedures in ODE across the board. However, as Jung (2005) and Jung and Latchem (2007) indicate, while many ODE institutions share some similar QA features, they operate QA in rather different ways depending in part on their resources, size, organizational structure, and culture of quality. Now, let's delve into QA systems operated in different ODE institutions and programs.

## Institutional QA Systems

In order to meet the challenges and demands relating to public funding, social accountability, and the satisfaction of various stakeholders, not to mention the

competitiveness of the education offered, higher educational institutions have come to realize the crucial role played by QA. In recognizing the importance of QA practice, many higher education institutions, including ODE institutions and ODE programs, have established QA systems in compliance with national QA and accreditation frameworks, and some have even gone as far as adopting regional and/or international QA systems.

**QA management systems.** There are three QA management systems identified in ODE institutions and programs, namely, centralized, collective, and dispersed (Jung & Latchem, 2007, p. 241).

Centralized QA systems are run by QA centers or senior managers who oversee the whole QA process, often to be seen in relatively large-scale ODE institutions such as Universitas Terbuka in Indonesia, Open Universities of Malaysia and Sri Lanka, Allama Iqbal Open University in Pakistan, Botswana College of Distance and Open Learning, and The National Open University of Nigeria, to name but a few. Latchem (2016) reports that over 70 of 100 commonwealth universities, including both dedicated ODE institutions and ODE programs within conventional universities, have a centralized QA unit or staff dedicated to QA for their ODE programs.

Collective QA systems are, invariably, operated by committees, councils, and/or boards which play distinctive roles in the different aspects or stages of QA, an example might be that the quality of ODE programs and courses are adjudicated and approved by a program committee or program review team, whereas learning outcomes are evaluated by an Examinations Office. Several ODE institutions such as Indira Gandhi National Open University in India, Anadolu University in Turkey, and the Open University of Hong Kong adopt this collective QA management system.

In contrast, dispersed QA systems share the QA responsibility across various management units. Korea National Open University makes every administrative office and academic unit accountable for quality. The Open University UK, Athabasca University in Canada, and the Open University of China also have adopted the dispersed QA system.

While there is, as yet, no evidence demonstrating and comparing the relative effectiveness and efficiency of the different QA management systems, it is noted in Jung (2005) and Jung, Wong, and Belawati (2013) that a centralized system may be the most effective when an institution first introduces the QA system and a dispersed or collective QA system might work better once the QA system is in place and a quality culture has had time to develop at institutional level.

**Focus areas of QA.** Most institutional QA systems are focused on the input and process variables such as planning, management, courses and course materials, curriculum, teaching and learning, learner support, staff support, assessment and evaluation, and technology infrastructure – the assumption being that if an institution is adequately resourced and properly managed, it will be in a position to ensure the quality of the collective output. Unfortunately, this is not the case, and as a result, output and outcome variables such as the learning performance of students, career advancement of graduates, and/or contribution to community services have begun to be included in some QA systems (Darojat, 2018).

In defining QA focus areas, some institutions follow a regional or international QA agency's framework; an example of this is Indonesia's Universitas Terbuka, which has adopted AAOU's QA framework and specifies ten QA areas (<https://www.ut.ac.id/en/content/quality-assurance>): (1) policy and planning; (2) human resources; (3) internal management; (4) students and student profile; (5) design and development education program; (6) design and development course; (7) learning assistance services; (8) infrastructure, media, and learning resources; (9) assessment and evaluation of student; and (10) research and community services.

Other ODE institutions have followed the path of developing their own guidelines. One example is the Open University of Catalonia (OUC) in Spain which, since 2007, has implemented an Internal Quality Assurance System (IQAS) tasked with managing the internal QA process. Its IQAS specifies assessment indicators using a matrix of six standards ([https://www.uoc.edu/portal/\\_resources/EN/documents/qualitat/SGIQ/Annex\\_VI\\_Processos\\_i\\_dimensions\\_i\\_estxndards\\_d\\_avaluacix\\_EN.pdf](https://www.uoc.edu/portal/_resources/EN/documents/qualitat/SGIQ/Annex_VI_Processos_i_dimensions_i_estxndards_d_avaluacix_EN.pdf)): (1) review and improvement of the IQAS, (2) design revision and improvement of training programs, (3) support systems for learning and orientation to students, (4) teaching staff, (5) material resources and services, and (6) public information, across three processes, strategic, operational, and support.

Yet other institutions follow QA frameworks for conventional higher education. Canada's Athabasca University, which is accredited by the US Middle States Commission on Higher Education (MSCHE) adopts seven standards (<https://www.athabascau.ca/provost-vice-president-academic/msche-self-study/index.html>) specified by the MSCHE:

Standard I: Mission and goals

Standard II: Ethics and integrity

Standard III: Design and delivery of student learning experience

Standard IV: Support of student learning experience

Standard V: Educational effectiveness assessment

Standard VI: Planning, resources, and institutional improvement

Standard VII: Governance, leadership, administration

Each standard specifies a set of quality criteria. Pakistan's Allama Iqbal Open University uses two QA frameworks: Pakistan Higher Education Commission's 11 institutional performance evaluation standards (<https://www.hec.gov.pk/english/services/universities/QAA/Pages/Institutional-Performance-Evaluation.aspx>) and the Commonwealth of Learning Review and Improvement (COL-RIM) model of 10 quality indicators ([http://oasis.col.org/bitstream/handle/11599/602/COL-RIM\\_Handbook\\_2014.pdf?sequence=1&isAllowed=y](http://oasis.col.org/bitstream/handle/11599/602/COL-RIM_Handbook_2014.pdf?sequence=1&isAllowed=y)) (Zuhairi et al., 2020).

Due to the nature of ODE, particular attention has been paid to input variables such as the design, development, and delivery of courses and programs and learner support (Jung & Latchem, 2007; Latchem, 2016; Zuhairi, 2020). Examples include the Universitas Terbuka in Indonesia and the Indira Gandhi National Open University in India which specify detailed structures and components of design and development within ODE course packages, learning activities, and assessments

and require several procedural steps of internal and external reviews of those components (Darojat, 2018; Samdup & Nembiakkim, 2013).

**Standards, best practices, and performance indicators.** The terms *standards*, *criteria*, *components*, *best practices*, and *performance indicators* are used confusingly in different QA frameworks. For the purposes of this chapter, a QA framework is defined as “a system specifying a set of QA standards consisting of best practices or sub-standards across the focus areas of QA.” Several ODE institutions do indeed use best practices to guide and assess institutional quality across a set of QA areas or standards. For example, under “policy and planning,” one of the ten QA areas (<https://www.aaou.org/quality-assurance-framework/>) in Universitas Terbuka in Indonesia, best practices state the following: (1) *The institution has a well-defined vision and mission statement which incorporates the internal and external educational environment, its potential, national development agenda, and international trend in education.* (2) *The institution has vision and mission that are shared by all management and staff members.* On the other hand, under “learner support” (one of the QA standards of Quality Matters that universities in the USA widely use to assess the quality of their online and blended courses/programs), substandards state the following: (1) *The course instructions articulate or link to a clear description of the technical support offered and how to obtain it.* (2) *Course instructions articulate or link to the institution’s accessibility policies and services.* (3) *Course instructions articulate or link to the institution’s academic support services and resources that can help learners succeed in the course.* (4) *Course instructions articulate or link to the institution’s student services and resources that can help learners succeed.*

Performance indicators, meanwhile, are used to assess output and outcome performance, often based on numerical data. Common performance indicators for ODE are course/program registrations, course/program completion and graduation rates, collaborative course development and delivery with other ODE institutions, graduate students’ satisfaction, employer satisfaction, and the economic impact of an ODE institution on its local community (Shale & Gomes, 1998) and grades earned on individual assignments, course final grades, discussion board participation and thread initiation, and standardized test scores (Alstete, 2004).

From the abovementioned examples, best practices or substandards can be seen tending to focus on input and process variables and are often stated in qualitative terms, whereas performance indicators focus on the measurement of output and outcome variables and often call for quantitative data collection. While the output/outcome-based approach to QA is highly recommended, difficulties in identifying performance indicators for ODE and quantitatively measuring the quality of ODE need to be considered (Alghamdi & Alanizan, 2018; Shale & Gomes, 1998). Critical, also, is consensus among different stakeholders regarding benchmarks and performance indicators for there to be reliable and valid internal and external evaluations of both outputs and outcomes (Robinson, 2004).

**QA procedure.** QA is, in effect, a cyclical process in which an institution either as a single entity or as a summation of individual units undertakes self-evaluation, undergoes internal review, and seeks external review and (re)accreditation. This

process is often referred to as quality audit and carried out in compliance with national QA requirements.

Quality auditing within an ODE institution starts with self-evaluation, self-study, or self-monitoring. The institution in question collects and analyzes up-to-date information on its education and services and communicates the results to its members and the outside world. Some ODE institutions, such as Universitas Terbuka Indonesia, carry out self-evaluation on a continuous basis, while other institutions, such as Athabasca University in Canada, conduct self-study every few years in preparation for accreditation by a chosen external agency. Allama Iqbal Open University in Pakistan employs annual confidential reports based on staff performance evaluations by section heads; conversely, the Open University of China and Open University Malaysia adopt student evaluations to measure the quality of their courses and services (Jung & Latchem, 2007). In any case, self-evaluation addresses several questions related to QA areas such as the following as listed in the Malaysian Qualifications Agency's Code of Practice for Programme Accreditation: Open and Distance Learning (<https://www2.mqa.gov.my/qad/garispanduan/COPIA/2019/Final%20COPPA-ODL%202nd%20edition%204.12.19.pdf>) (p. 63):

- 1) What actions are undertaken in relation to each of the QA standards? Why were these actions taken? Are these actions appropriate?
- 2) How is their effectiveness measured? What performance indicators are available? Are the indicators appropriate?
- 3) What subsequent action should be taken as a result of the review?
- 4) Can the degree of achievements be measured? What are the actual outcomes?
- 5) Can the existing actions be improved, even those that are already effective?

QA standards and guidelines specifically for online education can be found in *A Guide to Quality in Online Learning* ([https://www.tonybates.ca/wp-content/uploads/Guide\\_Quality\\_Online.pdf](https://www.tonybates.ca/wp-content/uploads/Guide_Quality_Online.pdf)) (Butcher & Wilson-Strydom, 2013).

In order to answer the kind of questions posed above, ODE institutions collect and analyze data obtained from student surveys, including teaching effectiveness surveys, satisfaction surveys, and freshmen/graduates' surveys, and interviews with staff and other members, enrollment, re-enrollment figures, exam pass and dropout data, and percentage of graduate students, along with other data related to the evaluation of institutional effectiveness and efficiency. The results of the resulting self-evaluation are often published as reports and shared with the governing body of the institution and outside organizations such as the relevant Ministry of Education and national QA agency.

The purpose of an external review is to verify the self-evaluation reports and other related documents by external review teams made up of independent experts who are carefully selected having fulfilled certain criteria and training by the national QA agencies. A common model of external review can be found in the European Association for Quality Assurance in Higher Education's Considerations for Quality Assurance of E-learning Provision manual (<https://www.enqa.eu/wp-content/>

[uploads/Considerations-for-QA-of-e-learning-provision.pdf](#)). It specifies a number of methods for external review, including (1) a self-assessment or equivalent, (2) a site visit, (3) a report resulting from the external assessment, and (4) a consistent follow-up (Huertas et al., 2018, p. 18). For the self-assessment component, several indicators are suggested including the institutional strategy, pedagogical approaches, and virtual learning environment, the innovation and quality of instructional design, the qualifications and experience of academic staff, and the quality of the online courses/programs. For the site visit, indicators such as the institution's technical infrastructure, virtual learning environment, classrooms, e-library, and interviews with various stakeholders are suggested (Huertas et al., 2018, p. 19). Based on the findings of the self-assessment and the site visit, a report (or reports) is prepared by the external reviewers, and follow-up improvements with a (re)accreditation or audit decision are requested.

Some argue that quality audit conducted through internal and external reviews is pointless and bureaucratic because it tends to focus on input factors mostly in the areas of teaching and research (Cheng, 2010), use data that are not always reliable and valid (Seyfried & Pohlenz, 2018), and often exclude students' involvement (Ryan, 2015). Conversely, others report QA processes as having positive aspects; Schwegler, Altman, and Bunkowski (2014), for example, reveal that faculty members who participated in the Quality Matters peer review process for their institution's online courses thought that peer reviews were helpful for them to improve the quality of their courses, acquire new techniques with online technology, and better understand the issue of quality in online education. These contrasting studies indicate the need for more attention to be paid to QA strategies that maximize the positive and minimize the negative.

**QA manual and staff training.** Development and utilization of QA manuals are not common across ODE institutions. Latchem (2016) reports that only 36% of the ODE institutions surveyed use QA manuals while carrying out the QA activities. A typical QA manual contains QA standards, best practices or substandards, and performance indicators for important QA areas; it lists QA procedures to follow and resources and actions needed for quality enhancement and improvement. In carrying out its internal QA activities, OUC in Spain follows the *Internal Quality Assurance System Manual* ([https://www.uoc.edu/portal/\\_resources/EN/documents/qualitat/SGIQ/Manual\\_SGIQ\\_\\_v.1\\_per\\_Llengua\\_EN\\_20190219\\_PORTAL.pdf](https://www.uoc.edu/portal/_resources/EN/documents/qualitat/SGIQ/Manual_SGIQ__v.1_per_Llengua_EN_20190219_PORTAL.pdf)) developed in 2017. The Manual explains OUC's internal QA system and includes various appendices which specify OUC's QA processes, dimensions, and standards along with responsibilities. Universitas Terbuka in Indonesia uses over 200 QA manuals as working guides for all of its QA components (Belawati & Zuhairi, 2007). Each manual outlines a flowchart of all processes, steps to complete a certain task, the person in charge, timeline, and output quality indicators for each activity (Hardini, Sunarsih, Meilani, & Belawati, 2013, p. 86). To support ODE institutions in carrying out internal reviews, the Commonwealth of Learning's Quality Assurance Toolkit for Distance Higher Education Institutions and Programmes ([http://oasis.col.org/bitstream/handle/11599/105/pub\\_HE\\_QA\\_Toolkit\\_](http://oasis.col.org/bitstream/handle/11599/105/pub_HE_QA_Toolkit_)

[web.pdf?sequence=1&isAllowed=y](#)) offers QA standards, best practices, and performance indicators (Clarke-Okah & Coomaraswamy, 2009).

Several ODE institutions have provided training programs, or sessions, to develop staff competencies with a particular focus on course design and development, and more recently, the focus has shifted to online interactions and the use of various online technologies to ensure managers and staff are fully trained in QA principles and methods (Jung & Latchem, 2007); an instance of this is the Staff Training and Research Institute of Distance Education at IGNOU, which offers staff training with a manual for course/program design and multimedia development, while the Digital Media Center in collaboration with the Institute of Distance Education at Korea National Open University provides training for online course development and implementation to its academic staff. The Centre for Distance Education at Athabasca University in Canada and the eLearn Center at OUC in Spain offer both professional training sessions and MA and PhD degree programs for further postgraduate education. Many conventional universities also offer faculty training and professional development sessions aimed at improving their faculty competencies in online and blended education via the Center for Teaching and Learning or a similar unit.

---

## Conclusion: Future of QA in ODE Institutions

This chapter has shown that ODE institutions and national, regional, and international bodies are seeking to ensure quality in ODE and develop appropriate QA and accreditation models for ODE, but also that there is still a need for more balanced, effective, and yet flexible QA frameworks and guidelines for the ever-changing landscape of ODE. For just such QA systems, Jung (2010, p. 25) suggests an ecological QA framework that “emphasizes inter-relation transactions between elements, i.e., providers, learners, cultures, and policies and systemic integration of those elements, and stresses that all these elements, within a QA system, play an equal role in maintaining the balance of the whole.” The ecological QA approach argues that ODE institutions should build *an all-stakeholder-oriented QA system* as the existing provider-centered QA approach tends to focus mostly on providers’ perceptions and ignore the inter-relational and dynamic nature of the QA system. It also highlights the importance of creating a *globally oriented and yet locally adaptive QA system* to reflect socio-cultural diversity in QA concepts and practices.

While ODE institutions should undoubtedly consider both internal and external accreditation and QA requirements and standards in various areas, they need to place *quality in pedagogical dimensions* such as course design and development, learning support, and assessment and evaluation at the center of the accreditation and QA system as these dimensions define the quality for student learning (Conrad, 2002; Daniel et al., 2008; Marciniak, 2018). This can be achieved by specifying procedures for courses/material design and development; involving both internal and external experts; considering changing needs and demands of learners; offering suitable

training for faculty, tutors, and other support staff on a regular and continuous basis; and relating teaching and learning and learner supports to learning outcomes (Jung, 2013).

As Bradley (2005) argues, many QA models tend to encourage accountability and conformity rather than innovation, diversity, and inclusion. Future QA needs to consider ways to attend to, and negotiate with, a wide range of needs, values, and perspectives of stakeholders (Ryan, 2015) while addressing diverse learning paths and delivery modes in the QA process as the convergence of on-campus and online education becomes ever more widely adopted in higher education and the awareness of consumer rights is heightened. We still see many ODE institutions that have flaws in applying QA standards and guidelines regularly and consistently in both course and material design and development, assessment and evaluation methods, and learner and staff support, despite having well-established technology infrastructure and producing good reports for external QA reviews. To overcome such flaws, the ODE institutions need to move from the existing control framework to a *culture creation framework* and integrate QA activities into their institutional cultures and everyday practices.

As discussed above, ODE institutions have tended to pay more attention to input and process variables and have ignored output/outcome variables such as learning outcomes. Recent years have seen a growing demand for review by and approval of learning outcomes from various QA agencies and society in general as these can be used to guide students' learning paths, design focused learning activities, and thus improve course/program design and also provide effectiveness of a course, program, or institution. Gallavara et al. (2008, p. 12) argue that learning outcomes are "a tool to describe and define a learning and assessment process and its product, which can lead to improved pedagogical practice in education and improved student learning practice." We are observing a paradigm shift in QA in some innovative ODE institutions such as the Open University of Sri Lanka and Universitas Terbuka in Indonesia (Latchem, 2016; Zuhairi et al., 2020), with movement from applying a criterion/standard-based approach to the design, delivery, and assessment of ODE courses/programs/materials to an *outcome-based QA approach* focusing on learning performance. Yet despite the above, further elaboration of accreditation and QA indicators measuring varied types of learning outcomes and the development of outcome-based quality culture would help ODE institutions integrate the outcome-based approach into their existing QA system.

## Abstract

Within the community of distance and online education, quality and quality assurance have been one of the most talked and discussed areas. This is especially true within the context of mega open universities where policies are always designed to optimize the openness, flexibility, and accessibility of the system. Even though distance education had initially been associated with opening access to education, the quality of education has become more and more important in

line with the advancement of technology use throughout the system. It is within this quality paradigm that quality assurance (QA) has become one of the key aspects in planning and managing open, distance, and digital education (ODDE). This paradigm has also brought many ODDE providers including the mega open universities to reformulate their visions, missions, and strategies to address quality issues more adequately (Belawati & Zuhairi, 2007). This chapter explores the implementation of quality assurance (QA) programs at two mega universities, Universitas Terbuka and Open University of China, which have developed QA system and implemented systematic QA programs consistently, resulting in their enhanced quality of learning over the years. The discussion will start with a general overview about the universities, followed by their internal QA systems and implementations. The two exemplary QA systems and practices would illustrate how mega open universities undertake the quality assurance programs to ensure continuous improvement as well as to develop quality cultures within the respective institutions.

**Introduction**

The twenty-first century brings higher education institutions to focus on quality in response to stakeholders' demand and global competitive landscape. The competitive pressures on quality are also faced by distance teaching universities (DTUs) including mega universities. Mega universities are universities with student body of over 100,000 (Daniel, 1999), and many of those are open universities. Among the 62 largest mega open universities, 8 are located in Asia and are serving nearly ten million students (Belawati & Bandalaria, 2019). Those open universities have been the most significant higher education providers in Asia (Belawati & Bandalaria, 2019).

The adoption of open and distance learning by many countries in Asia is related to the issue of equity and equality for education, especially at tertiary level. Many countries are under pressure to increase the accessibility of people to quality and affordable higher education. Therefore, the issue of quality in open universities is very strategic and political as it represents the commitment of the authority to provide quality higher education to the masses (Belawati & Zuhairi, 2007).

Open universities have always been very keen with quality and quality assurance (Jung & Latchem, 2012). However, there is no standardized nor obligatory system of quality assurance. The study by Jung and Latchem (2012) shows that there are many approaches and systems that are being adopted and implemented by different open distance education (ODE) institutions. This chapter describes the development and

the employment of QA programs at two mega universities in Asia, namely, Universitas Terbuka (UT) and Open University of China (OUC).

Universitas Terbuka (UT) is one of the leading open universities in Asia. At UT, quality assurance (QA) program has been placed as the central node for every policy, regulation, as well as academic and administrative services to the students. The strategic value of QA for UT is in line with the provision of mass higher education that has become an important policy in Indonesia (Belawati & Zuhairi, 2007). Indonesia is a developing country in Southeast Asia, and it has been regarded as the world's biggest archipelago country. Indonesia has a large population, more than 268,000,000 people as of 2020, scattered all over Indonesia's 17,000 islands. Therefore, providing quality higher education for people residing in remote islands has been regarded as one of the strategic issues. For that purpose, UT has been designed by the government to increase and equalize access to higher education, for people who for some reasons do not have access to conventional campus-based higher education including those who live in remote areas. UT is now 36 years of age with massive student body and has consistently adopted and implemented QA programs as its commitment to promoting quality education.

Open University of China (OUC) is the largest university in China, and perhaps in the world, and serves as the main open distance learning (ODL) provider in China. Quality assurance (QA) has always been the strategic focus of OUC. And, as a national public university directly managed under the Ministry of Education, OUC accepts quality supervision from the Ministry of Education in various ways and means. The Open University of China (OUC) has played an important role in the expansion of higher education for the last decades. The number of students at OUC has increased from 1.15 million in 2000 to 4.6 million in 2020 (Ju, 2020). In the next 5 years which corresponds to the China 14th Five-Year Plan period, the government proposes that the higher education should be transformed from a quantity-based strategy to a quality-based strategy. High-quality education is put forward at the core. Quality becomes the key point and focus of OUC's development.

---

## **Quality Assurance at Universitas Terbuka (Indonesia Open University)**

### **General Overview of Universitas Terbuka**

Established in 1984, UT is a state university and was until recently the only university using an open and distance learning system in Indonesia. UT has been intended by the Indonesian government to deliver higher educational services for those in society who for some reasons cannot join conventional higher education (Belawati & Zuhairi, 2007). UT has set a vision to become a world-quality open and distance higher education institution. UT was named as one of the mega universities in the world (Daniel, 1999) with a student body of more than 300,000, mostly residing in Indonesia but some overseas (in about 43 countries). UT has a well-built, centralized management system with its head office located in Jakarta and

**Fig. 1** UT student body 2017–2020. (Source: UT’s Bureau for Academic Administration and Planning)

equipped with 39 regional offices spread throughout Indonesia’s 34 provinces. Figure 1 shows the trend of UT’s student body over the last 4 years.

The increasing number of student body since 2017 is the result of the new policies on student enrolment that allow new students to enroll at any time and marketing programs that are designed to attract the digital native generation. As shown by the figure, however, the number of students slightly decreased in 2020 due to COVID-19 outbreak.

## The Nature and Importance of QA at UT

Why is Universitas Terbuka and perhaps all distance higher education (DHE) institutions considering the development and implementation of a formal QA system? For decades, there are many institutions that have prospered, flourished, and established good reputations without intentionally commencing formal QA programs. Although there are considerable advantages to be gained from having a formal QA system, there are people who believe that QA is a good practice to be implemented in education. For example, Bradley (2005) contends that the adoption of QA programs from industry to education tends to simplify the conclusion of success or failure. University is different from industrial manufacturing institution that can create a QA system in an obvious approach. University provides education, which is a service process that involves the whole university system comprehensively; and, it is very difficult to translate the complexity of that process into a linear QA system. There are natural and significant differences between a university and an industrial manufacturer. Manufacturers are concerned with the production of physical products, whereas universities are concerned with educating students so they can have meaningful and productive lives in the various roles they will play in society.

It is argued that QA should be internally driven and accepted as an integral part of the institutional strategies in supporting student success. Based on the writer’s observation in three open universities in Southeast Asia, QA programs have been employed by these open universities to equip the management with quality guidelines for all departments and people involved in their respective quality areas. According to

UT's *Manual Book for Quality Assurance* (2012), for example, there are at least four reasons to why a QA system is important to UT, that is, to improve "...readiness for accreditation, accountability, competitiveness, and effectiveness" (p. 3).

(a) Improve readiness for accreditation.

Accreditation deals with policy interest of the government. As mandated by the National Education Law, the National Accreditation Board for Higher Education or BAN-PT (stands for *Badan Akreditasi Nasional – Perguruan Tinggi*) regularly conducts quality review for accreditation purposes at study program level. Obtaining accreditation from BAN-PT is compulsory for all higher education institutions in Indonesia. UT's quality criteria should correspond well with quality standards being applied by BAN-PT for external inspection.

(b) Increase public accountability.

UT is a public university with a complex system and large geographical coverage. Therefore, it needs a quality framework and guidelines to assure standardized quality of services and products for public accountability.

(c) Rivalry among higher institutions (competitiveness).

Educational global markets are now moving to experience greater competition from local and global higher education institutions, both in distance higher education and conventional campus-based education. There are almost no time and geographical boundaries in the global market. In such situations, quality that relates to teaching and learning provision as well as support services becomes a strategic issue and a competitive advantage. The QA system provides an opportunity to develop a systematic and sustainable improvement toward that quality.

(d) Increase effectiveness (economies of scale).

While existing standard operational practices might have embedded quality, these might not always be the most efficient or effective method. A comprehensive approach to university performance is considerably important in restructuring its educational approaches to reduce costs while maintaining and improving quality of the products. A QA system can present tools by which quality can be achieved and cost of producing additional products, such as learning materials, will decrease as the volume of outputs increases.

The adoption of QA program, however, "is not a way to set goals nor a procedure to reach the goals but is an effort for systematic and sustainable improvement" (UT QA Manual book, 2012). The program is necessary and a strategic tool for the university which applies "open policy for [serving] a large number of students within a large country" (Hardini, Sunarsih, Meilani, & Belawati, 2012).

The implementation practices of QA programs in open and distance universities vary significantly. There are QA approaches/methodologies that involve accreditation, quality audits, and student surveys (Chalmers & Johnston, 2012), and there is also another approach that is more industry-based quality review such as ISO standards and the Baldrige National Quality Award (Bogue, 1998; Sallis, 2002). UT currently practices both approaches through its internal quality system and external quality assessments. The external quality assessment is conducted by BAN-PT to seek

accreditation, by ISO QA agencies to seek ISO certification, and by the International Council for Open and Distance Education (ICDE) for quality review.

## UT's Internal Quality Assurance System

Universitas Terbuka has developed a comprehensive internal QA system (known as SIMINTAS or Sistem Jaminan Kualitas) and has been implementing it for almost 20 years. The current internal QA program complies with the government quality standards as laid out in the Education Law for Higher Education No. 12, 2012, and further elaborated by the Ministerial Regulation No. 50, 2018, about "National Standards for Higher Education" and Ministerial Regulation No. 109, 2013, about the Provision of Distance Education for Higher Education. The UT's SIMISTAS was developed based on the AAOU's quality assurance framework covering several key components of the open and distance education system. The SIMINTAS was developed in 2001 by a QA committee (Belawati & Zuhairi, 2007), which was formed as a strategic action for enhancing UT's quality through several steps starting from analyzing and adapting the AAOU framework to resonate UT internal requirements, as well as to comply to the Indonesian educational setting. The QA committee also identified the structure and components of quality areas, as well as selected priorities needed for developing quality guidelines of each value chain activities within the whole UT's business processes.

Over the years, UT's QA system and standards have gone through several reviews and revisions to meet stakeholder's demand and changes in both internal and external situations. Based on the current UT's QA manual (2012, p. 4), UT internal QA system consists of 10 quality areas, which are elaborated into 120 quality policies/standards in forms of statement of best practices (SOBP) as follows (Table 1):

The statements of best practices were developed and defined involving key staff (including academic, administrative, and technical staff) across departments to

**Table 1** UT's quality areas and policies/statement of best practices

No.	Area of quality	Statement of best practices (SOBP)
1.	Policy and planning	7 SOBP
2.	Human resource recruitment and development	9 SOBP
3.	Management and administration	21 SOBP
4.	Learners	10 SOBP
5.	Program design and development	6 SOBP
6.	Course design and development	14 SOBP
7.	Learning supports	18 SOBP
8.	Assessment of student learning	15 SOBP
9.	Media for learning	7 SOBP
10.	Research and community services	13 SOBP

Source: Adapted from UT's quality assurance system (2012), p. 2

ensure the comprehensiveness of the coverage. For implementation purposes, job manuals in the form of work instructions and standard operating procedures (SOPs) for each and every particular business process were developed. According to Belawati, Zuhairi, and Wardani (2012), the quality job manuals “helped to generate a quality-oriented work culture in line with systems and procedures” (p. 116).

The SOPs and work instructions have been regarded as major references for quality guidelines. It was important to note that one of the main changes at UT during the initial adoption of QA programs was the introduction and the development of various SOPs for different quality programs (Darojat, 2013). Every SOP shows the workflow and the interrelationships among all operational activities within the system. The SOPs reflect the value chain activities for different business processes and the “how” of putting quality into practices. Meanwhile, work instructions describe the time frame, the human capital needed, the financial estimation, and other resources needed to support quality programs.

Within the execution, internalization of the whole QA system and procedures that involve rigorous discussions among staff across departments was conducted continuously. This is to achieve shared perception about standards and procedures. Having the same perception is very important in respect to sharing feelings and beliefs around the QA programs. Rigorous discussion followed by orientation sessions both face-to-face and virtual briefings across departments also includes UT’s staff at the regional offices throughout the country. The discussions during the orientation step focused not only on how to implement the job quality manuals but also on how to measure achievement in all quality areas. The orientation session was very important for two reasons. Firstly, it provides people with more understanding of QA job manuals. Secondly, the orientation offers a room for staff engagement leading to higher confidence in the use of tools and implementing the program (Belawati & Darojat, 2014). The success of QA implementation is believed to be affected by the shared understanding about what quality and QA really mean and about their roles and involvement in the QA programs. All staff should be well informed on how to be involved and improve quality in their daily works. It is important to note that shifting an organization’s behavior is one of the major tasks when undertaking “transformation.” In this step, such a change requires encouragement and commitment from all staff as well as from managers at all levels.

A further organizational change has also been taken through formally establishing the Quality Assurance Centre in 2004 (Belawati & Zuhairi, 2007). The strategic role of this center was to manage and coordinate the development all quality guidelines and to monitor the employment of the quality programs. To ensure that the implementation of UT’s quality programs corresponds well with procedures, work instructions, and quality criteria that have been agreed upon, the QA Center invited and trained a number of faculty members and other relevant staff to become internal auditors. In additions, the QA Center is also responsible for coordinating external quality assessments carried out by ISO QA agencies and by the ICDE.

Regularly internal quality audits are conducted to disclose nonconformity (major and minor findings) dealing with quality process and criteria achievement in various areas such as in registration, learning materials, tutorial services, and examination.

**Fig. 2** Internal quality audit findings by quality areas in 2019 in 39 regional offices. (Source: UT Quality Assurance Center (2019))

The results of the internal quality audits provide feedback to the management for improvements. Figure 2 shows an illustration of the internal quality audit's results in UT's 39 regional offices for 2019.

The above figure shows the different nonconformances to different quality criteria, namely, office management, documentary management, infrastructure and equipment, human resources, final examination, face-to-face tutorial services, learning materials distribution, and marketing. The findings varied in terms of number, types, and weight (major and minor nonconformity). Based on quality audit in 2019, it was identified that most nonconformances were found in the area of face-to-face tutorials and infrastructure and equipment (15 minor nonconformances and 14 nonconformances, respectively). All nonconformances were analyzed and discussed in the management review meeting called as *Rapat Tinjauan Management (RTM)* involving all units in UT's head office and all regional offices. Analysis and exposure of findings of quality audits in the RTM was intended to give a general description about the problems faced by UT, especially in implementing the policies, procedures, and guidelines of the university quality programs in the regional offices. To support productive discussion during the meeting, the QA Center generated a quality implementation report with two purposes: on one hand, to provide the map and general summary of weaknesses and nonconformity faced in the implementation of quality programs and, on the other hand, to deliver recommendations to the management in respect to the university's future quality programs. The management review meeting has also been regarded as an important forum for recognizing and identifying strategic solutions and different actions that should be undertaken for future continual improvement.

## Lessons Learned

The adoption of QA program at UT reveals a number of emergent lessons learned in different aspects of organization and management. It was clear that the QA system has helped the university in providing guidelines on how to put quality programs into practices. As the means to achieve quality, the QA programs were equipped with

standards and procedures that enable faculties and administrative staff to fully understand and contribute to the quality programs in their respective daily activities. Based on the writer involvement in the implementation of the program, specifically when the writer was assigned as the head of UT's Quality Center, there are several lessons learned that have been regarded as the favorable characteristics for implementing the quality programs at UT.

(a) Involve all people within the system.

The adoption of QA called for participation of leaders/managers and the entire staff in all management levels. All people in the university should have two roles, as part of the QA system and as contributors to continuous improvement. The involvement of all people and functions within university has led to the benefit of "getting things right first time" for every single aspect of the quality activities. It is important to note that top and middle managers played a significant role in the initial stage when adopting the QA programs. The managers are not only primarily responsible for initiating and introducing the system to their subordinates, but the managers were also the first people who were trained for the QA programs. Various actions have been taken by the managers in developing, maintaining, and changing appropriate cultures to support the implementation of the QA program. They were responsible for creating new rules and policies that reinforced the desired performance of new organizational culture and simultaneously eliminating rules and policies that hindered the desired ways of operating. The top and middle management levels are also responsible for establishing a physical environment that reinforced the cultural changes, reviewing an organizational structure that strengthened operational changes, and providing training to all staff that focuses on the new skill level needed to support quality programs.

(b) Design SOPs and improve the quality process within the system.

The prerequisite to having better and organized workflows for each quality areas requires standardized operating procedures and work instructions, which would increase the awareness of faculties and administrative staff to perform more effective ways of completing their tasks as well as to enhance their feeling of ownership toward the system. The implementation of the quality programs should also be supported by necessary training activities for both top and middle managers as well as all staff to allow them develop and upgrade their new required skills. Thus, all employees would have the opportunity to perform well within the system.

(c) Integrate continuous improvement activities with the university's annual strategic plan (ASP) derived from the university's strategic business planning (SBP).

The implementation of QA programs called for integration of the continuous improvement programs within the framework of ASP as well as the mid- and long-term SBP of the university. All units should formulate their own set of quality achievements, agendas, budgets, and all necessary resources within the existing quality programs. All individual units must have clear objectives and directions regarding quality. However, those objectives and all the working plan to achieve the objectives should be flexible enough to deal with uncertainty. The

continuous changes in competitive global markets, government policies in education, and other unpredicted external factors including those coming from students would have certain impacts on how the university should be operated and moved forward from one approach and tactic to other scenarios.

Furthermore, it is also important to note that QA has an unexpected impact on quality culture. It reveals itself in several obvious ways. Since implementing QA programs, the university culture is reflected in the pride of excellence and achievement. The merit system that is part of the QA paradigm provides opportunities to all staff to perform well and receive encouraging rewards including financial rewards. The reward system is embedded in the monthly staff performance appraisal. In addition, the QA programs also generate specific values and norms, which have influenced staff's positive attitudes and behavior. It appears that all staff appreciates the university's commitment to fostering an organizational culture that is characterized by trust, integrity, and fairness; upholding the value of faculty and administrative staff; emphasizing cooperation and collegiality; ensuring flexibility, responsiveness, open communication, and transparency; as well as ensuring accountability for decisions and outcomes.

Besides gaining many benefits, nevertheless, practicing QA programs is not without challenges to encounter. The implementation of QA that requires consistency and discipline has been also felt as being too demanding and time-consuming, especially in terms of documentation activities (Darajat, 2013) and changing prevailing mindset (Belawati & Zuhairi, 2007) that leads to staff misunderstanding about QA. There were some staff who feel intimidated as the quality programs significantly impact their daily activities, performance, and remuneration. Therefore, intensive communication, well-defined quality criteria, and clear directions to all stakeholders being involved are part of important exercises to develop shared understanding and to achieve a shared purpose, which is a continuous quality improvement.

Finally, at UT, the ultimate reason of adopting QA program is derived from the shared spirit of all staff and management to produce well-educated students and graduates through quality educational programs that will equip them with knowledge, skills, and experiences to allow them to have successful and meaningful lives.

---

## **Quality Assurance at Mega University: Open University of China**

### **General Overview of the Open University of China (OUC)**

China's higher education has developed rapidly since the twenty-first century. Statistics from the Ministry of Education (2020b) show that from 2000 to 2019, the number of higher education institutions in China has increased from 1,813 to 2,956 and the students enrolled in higher education has increased from 12.3 million to 40.02 million. In 2020, the gross enrollment rate of higher education reaches 54.4%, and it has transferred from massification toward popularization. In the next 5 years which corresponds to the China 14th Five-Year Plan period, the government

proposes that the higher education should be transformed from a quantity-based strategy to a quality-based strategy. High-quality education is put forward at the core. Therefore, quality becomes the key point and focus of the Open University of China's development.

The Open University of China (OUC) has played an important role in the expansion of higher education for the last decades. The number of students at OUC has increased from 1.15 million in 2000 to 4.6 million in 2020 (Ju, 2020). OUC is the largest university in China and serves as the main open distance learning (ODL) provider in China. Quality assurance (QA) has always been the strategic focus of OUC. And, as a national public university directly managed under the Ministry of Education, OUC accepts quality supervision from the Ministry of Education in various ways and means.

OUC is established based on the China Central Radio and TV University (CCRTVU), which was officially established on February 6, 1979, with approval of Mr. Deng Xiaoping in person. On July 31, 2012, the CCRTVU was renamed as OUC with the purpose of providing a flexible and open lifelong learning system and developing a learning society (Li, 2014). OUC is designed to be open to all members of society in China, not only working adults but also school-aged students, the elderly, farmers, the unemployed, and other disadvantaged groups, and offers degree and nondegree education services to all members of society. It aims to promote equal access to education, sharing of quality education resources, and continuous improvement of the human resources quality.

OUC promotes lifelong learning for all. It has shaped a broad educational system made up of 1 headquarter, 45 provincial branches, 14 industrial and corporate colleges, and over 4,000 study centers, covering all urban and rural areas in China. Over the last 40 years, OUC has approximately 20.5 million enrollments and 15.12 million graduates, and it occupies 10% of the higher education enrollments and graduates in China (Jing, 2020). Of the 4.31 million active students of degree education, 70% are from grassroots communities and 55% are in branches located in the central and western regions of China (Ju, 2020).

## The Overview of QA at OUC

In 2012, OUC upholds five core educational ideas, including Openness, Responsibility, Quality, Diversity, and Internationalization. It is committed to integrating quality into the university's teaching and learning, scientific research, and social services. Today OUC has established a specialized organization for QA, a QA framework and standards system, with a holistic view of QA system including internal and external systems. At the same time, OUC has also strengthened research on quality assurance. Using the *Open University* and *quality* as keywords, 2186 academic papers can be found in the China National Knowledge Infrastructure (CNKI) which is an important academic journals database in China. The number, distribution, and trends of the papers are shown in Fig. 3. These research papers provide strong support for QA understanding of ODL on the concepts, methods, practices, effects, and so on.

**Fig. 3** The academic research trends on quality of Open University by CNKI. (Source: CNKI Database (2021))

**Fig. 4** Governance structure of quality assurance at OUC

### OUC’s QA Organizational Structure

In terms of QA governance, OUC established the University QA Committee in 2013. The Committee is the QA governance body and is a specialized organization that conducts research, planning, guidance, and supervision of university QA system. OUC President chairs this important committee which formulates the *Statutes of the Quality Assurance Committee of OUC*. The Committee has four subcommittees that are the Teaching Standards Committee, the Condition Guarantee Committee, the Teaching Supervision Committee, and the Evaluation and Assessment Committee (see Fig. 4).

In terms of QA management, OUC headquarters set up a specialized department called the Quality Monitoring and Evaluation Center responsible for evaluating, monitoring, and researching the quality ODL provision of each level of the university system and making suggestions for improvement. The Center currently has a full-time work team and it has set up three offices including a general office, a quality monitoring office, and a quality evaluation office (see Fig. 5). The Center is responsible for development and maintenance of the quality standards, implementation of dynamic quality monitoring, carrying out periodic evaluation of quality status, as well as doing quality research.

At each level of the university system including branches, colleges, and study centers, there are also QA departments and QA personnel. OUC carries out regular education and research training for all QA staff of the whole system.

**Fig. 5** Management structure of quality assurance at OUC headquarter

## The Quality Standards

In 2016, OUC set up quality standards framework and indicators. The quality standards framework includes 12 indicators and 40 sub-indicators (Open University of China, 2016). The 12 indicators cover general rules, university conditions, professional courses and resources, enrollment management, teaching process implementation, practical teaching, educational administration management, student affairs management, teaching process monitoring, evaluation and feedback, scientific research, and social services. The 40 sub-indicators represent specific requirement of the 12 indicators. For example, the sub-indicators of “educational administration management” are “student status management” and “examination management.” The sub-indicators of “student affairs management” are “selection of the outstanding graduates” and “scholarship.” The sub-indicators of “the scientific research” are “scientific research system,” “scientific research process,” and “scientific research results.”

OUC quality standards focus on teaching and learning process. It standardizes the quality requirements of all links and aspects of the entire process of teaching and learning, in order to clarify the basic requirements for the university to implement lifelong learning for all. The indicators of the quality standards include not only the quality requirements for graduation but also the quality requirements for educational process including the policies, mechanisms, conditions, training process, etc.

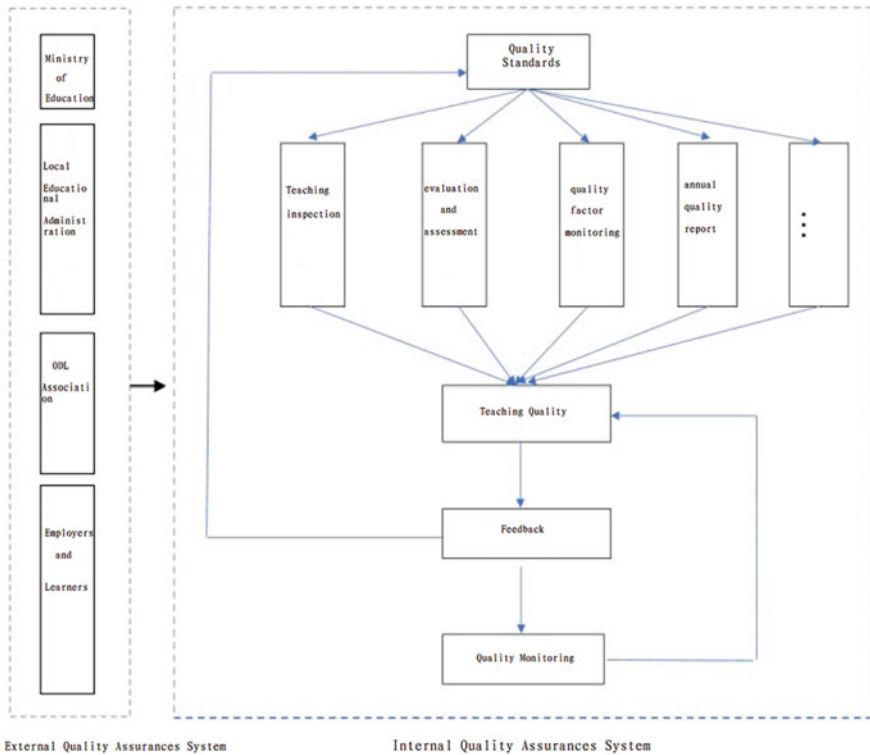

## The QA Procedure and Mechanism

OUC QA system can be divided into internal system and external system as shown in Fig. 6. The two systems have different focuses. The procedure and mechanisms are shown in the figure.

## The Internal QA System

The focus of the internal QA system is on teaching and learning. It has adopted a variety of methods to pay attention to the organization, operation, maintenance,

**Fig. 6** Quality assurance system of OUC

monitoring, and management of the teaching process by various institutions in the university system. For example, in order to support student learning, OUC provides various multimedia materials, course syllabi, formative assessment brochures, exam instructions, and other learning resources based on a comprehensive consideration of student needs, especially different learning conditions in the economically developed and less developed areas, and offers quality printed, audio, and video materials and provides the online resources (Li, Yang, & Niu, 2013).

In order to carry out all-round quality assurance, OUC adopts varieties of the QA methods, including teaching inspection, evaluation and assessment, specialized supervision, quality factor monitoring and analysis, annual quality report, etc.

### The External QA System

The external QA system of OUC includes evaluation and supervision from educational administration, various third-party agencies, employers, and learners.

### **Quality Monitoring from the Educational Administration**

There are mainly three means of monitoring. The first is making policy requirements. The development of ODL in China is closely related to the government regulation (Gaba & Li, 2015). Since 2012, the Ministry of Education has successively issued several policies related to the quality development of open universities. For example, in 2016, the *Recommendations on Improvement of the Open University* demands that the Open University should adhere to the principle of quality first (Ministry of Education, 2016). In 2020, the *OUC Comprehensive Reform Plan* issued by the Ministry of Education emphasizes the need to improve quality assurance system (Ministry of Education, 2020a). The second means is related to quality review on degree-awarding programs. The Ministry of Education reviews the academic degree-awarding programs offered by OUC every year, and only those programs that passed the review can enroll students. This regulation requires OUC to consider its quality conditions for teaching and learning. The third is related to specialized evaluation and inspection. The Ministry of Education requires OUC to submit its annual development report. In addition, it often carries out special evaluations, such as special inspection of study centers and so on.

### **Quality Management from the ODL Association**

There are not many third-party organizations related to ODL in China. The Ministry of Education has set up a National Collaboration Group for Modern Distance Education in Universities. The Group carried out many activities, for example, to select best practice of ODL in China. OUC maintains a good relationship with the organization.

### **Quality Evaluation from the Employers and Learners**

Since 2018, OUC has carried out an annual survey on employer satisfaction and has invited a third-party education consulting company (Maxus) to jointly conduct the survey (Open University of China, 2020). According to the quality annual report released by OUC Quality Monitoring and Evaluation Center (2019), the satisfaction of employers is at generally good level, with a very satisfied ratio reaching 60%.

## **Achievements and Challenges**

### **Achievements**

Since 2012, with the implementation of a series of reform practices such as the implementation of the strategy of “creating quality and improving quality,” the recognition of OUC has been greatly improved. It has been rewarded several important international awards including the ICDE Prize of Excellence (2017) and UNESCO King Hamad Bin Isa Al-Khalifa Prize (2020). These rewards generally admit OUC’s continuous commitment to high-quality development in recent years.

---

## Challenges

The first challenge is to cope with the digital transformation which has significance on OUC QA governance mechanisms and tools. In recent years, OUC has vigorously developed online education, especially during the COVID-19 epidemic period, and a large amount of teaching and learning data has been generated and restored online. This puts forward new need for the QA governance mechanisms and tools. At present, OUC has not yet been able to fully apply artificial intelligence and big data technology to optimize quality assurance governance effects.

The second challenge is to meet high-quality education development and its influence on the professional requirement of the teaching staff. Successful ODL depends largely on the quality of teaching staff (Li et al., 2013). Until the end of 2019, OUC has more than 60,000 academic teachers, 34,000 tutors, and 16,000 management staff (Ju, 2020). And many of them lack professional development opportunities (Zhang & Li, 2019). To achieve high-quality educational development, there is a huge need of upgrading teachers' professional abilities.

The third challenge is related to its social reputation and its challenge to building a quality culture for ODL providers. In China, the ODL providers and mega universities have a different quality reputation and social recognition from the on-campus education. The society must establish an appropriate quality culture and solve the problem of inconsistent understanding.

---

## Conclusion

This chapter presents some important development of and new challenges to QA system of UT and OUC today. Along with the advancement and increased use of information technology, and the demand for high-quality education, the QA of UT and OUC are also facing new pressures and challenges. Despite the uniqueness of the system adopted, UT and OUC have demonstrated that as mega universities in Asia and the world, they could develop an effective, robust, and comprehensive internal QA system. Both UT and OUC's experiences show that assuring quality is not isolated nor simple programs. The QA system has to be developed systematically and embedded in the whole university's structure and management. In addition, the ultimate goal of such QA programs is not to have a robust system but to have a continuous improvement culture that is understood, believed, and internalized by all parties involved.

## Abstract

Since the corona crisis, digital higher education practices permeate higher education in Europe. In degree education, various digital pedagogies are used in courses and programs, such as synchronous hybrid, blended, and online

G. Ubachs (✉) · P. Henderikx  
EADTU, Maastricht, The Netherlands  
e-mail: [george.ubachs@eadtu.eu](mailto:george.ubachs@eadtu.eu); [piet.henderikx@eadtu.eu](mailto:piet.henderikx@eadtu.eu)

education and distance learning. In addition to degree education, higher education institutions offer online continuing education and open education through MOOCs. Microcredentials are high on the agenda of the European Commission, national governments, and institutions.

The international dimension has also become important in all these areas. Universities organize joint curricula and virtual mobility schemes. This development has even been reinforced by the European Universities Initiatives of the European Commission (EUI), which already created 41 university alliances across Europe.

Digital education plays a vital role in creating a new pedagogical landscape shaping the Commission's Transformation of the European University 2030. This has implications for the internal and external quality assurance of education, which should lead to better quality and more robust maturity.

This chapter illustrates how quality assurance models and practices in Europe have evolved towards a multilevel and multi-stakeholder approach. It describes the development of quality assurance systems and guidelines for digital higher education in Europe in recent decades. In addition, it focuses on new quality assurance challenges to respond to the next stages of development in higher education, keeping pace with future innovations. Finally, it provides an overview of the current position of quality assurance with the most important conclusions.

## Introduction

### Quality in Digital Higher Education

The European Network of Quality Assurance Agencies (ENQA) has taken the lead in developing the common Standards and Guidelines for Quality Assurance in the European Higher Education Area (ESG, 2015), adopted by the EHEA Ministerial Conference. These are applied by internal quality assurance bodies in the universities and by national external quality assurance agencies. In addition to quality assurance, most agencies also play a role in the accreditation of universities.

The ESG sees quality as “primarily a result of the interaction between teachers, students, and the institutional learning environment.” Quality assurance ensures that “programme content, learning opportunities and facilities are fit for purpose” and focuses on “all activities within the continuous improvement cycle of higher education institutions” (ESG, p. 7).

Digital education does strengthen the interaction between teachers and students, learning processes, and the learning environment. This happens in the field of degree education, continuing education, and MOOCs but also in the field of international education and virtual mobility. This has consequences for quality assurance.

### **Quality Assurance: Multi-Stakeholder Perspectives**

From the point of view of quality assurance and quality improvement, it is important to take into account the perspectives of the different stakeholders. Stakeholders include all internal actors within an institution such as institutional leaders, students, and staff, as well as external stakeholders such as enterprises, professional organizations, regions, and governments. Examples of such perspectives are as follows:

- The learner's perspective, related to dimensions such as the learner's readiness for online learning, the digital learning environment and learning resources, flexibility, and student support
- The perspective of the teaching staff and program board, related to organizational conditions for digital course and curriculum design, the suitability of the learning environment for various digital pedagogies, the availability of media and tools, frameworks for international course collaboration and virtual mobility, and tools for e-assessment
- The perspective of teaching and learning support services, related to digital course and curriculum design, team support, ICT support, and mobility support
- The leadership perspective, related to institutional strategies and frameworks for the digitization of education, international education and virtual mobility (e.g., in European Universities Initiatives alliances or EUIs), quality assurance frameworks, institutional budgeting, the continuous professional development of staff, and continuous institutional evaluation
- The external stakeholder perspective, related to the response to needs for flexible online education in enterprises, professions, and society, possibly the co-creation of content, flexible workplace learning, and the recognition of qualifications for digital learning
- The government perspective related to the legal framework for digital education, institutional funding, quality assurance and accreditation, the ICT infrastructure for universities, and international cooperation and mobility

Stakeholders' perspectives may differ in mainstream education, continuing education and professional development, and open education through MOOCs. It is therefore important to create specific internal quality frameworks and support services for these areas, although in practice they may interact with each other.

## Multilevel Approach

At the same time, a multilevel approach is important because change processes affect stakeholders at their own level. To make change processes effective, these levels need to be in continuous dialog (Williams, Ubachs, & Bacsich, 2015):

- The microlevel constitutes the course and curriculum with students and academic staff as key players.
- The meso-level refers to the institutional organization, with institutional leaders, support staff, and representatives of external stakeholders as key actors.
- The macro-level includes national and regional decision-makers related to the organization of higher education, including national support services such as quality assurance agencies and ICT infrastructure providers, councils, and stakeholder groups.

Although processes at these levels are different, an integrated approach to quality and innovation must involve stakeholders at all levels with their own perspectives and responsibilities.

## Learning Outcomes and Processes

Ultimately, external quality assurance agencies assess quality by measuring the learning outcomes achieved. Many ways of teaching and learning can lead to quality learning outcomes, which is recognized by the ESG.

The quality assessment of digital education is typically process-oriented, e.g., related to course and curriculum design, including learning materials and learning activities; facilities in the learning environment for developing and delivering digital education; the support of teaching and learning and ICT services to course and teams; and institutional strategies for digital education and innovation.

## Quality Criteria and Benchmarking

Quality criteria are based on agreed principles or frames of reference for course and curriculum design, institutional drivers and enablers related to digital education, and national policies for digital education and innovation. These criteria are used for benchmarking, identifying internal improvement opportunities. Current practices in digital education can therefore be compared with “best in class” practices.

By benchmarking, universities learn from each other. For use in quality assurance assessment, benchmarking should be performed in a systematic manner to make strategic choices for improvement.

---

## Quality and Maturity

The concept of maturity refers to the degree of deliberate and evidence-based decision-making on digital learning courses and programs, leading to the continuous optimization of the design, development, and implementation or specific institutional conditions and strategies concerning digital practices (Van Valkenburg, Dijkstra, & De Los Arcos, 2020).

Maturity is reached when the university (or a faculty) reaches the level of a “learning organization,” which bases informed decisions on evidence. Leadership is shared, and all processes and workflows are integrated and continuously evaluated to better serve stakeholders. Technology is fully exploited to create better education.

The difference with quality is that maturity refers to a deliberate and sustained process of decision-making for the improvement of digital education. This includes the use of the results of quality assurance. Maturity can vary from initiated to piloted, deployed, institutionalized, and optimized steps in the implementation of digital education.

---

## Quality Assurance Systems in Distance Teaching Universities in Europe

Quality assurance in online and distance learning is gaining interest as the growth of online and distance learning offerings fuels the need for appropriate quality assurance systems. Two major investigations have already taken place in the past decade: first, a publication by the International Council for Distance Education (ICDE) on quality models in online and open education around the world (Ossiannilsson, Williams, Camilleri, & Brown, 2015) and, second, a study by the Working Group on Quality Assurance and e-Learning of the European Network of Quality Assurance Agencies (ENQA) on quality assurance of e-learning provisions (Huertas et al., 2018).

The European Association of Distance Teaching Universities (EADTU) as a representative body for online, open, and flexible education in Europe has been active on this topic since 2005 by launching the E-xcellence manual and tool for quality assurance in online and blended education.

## E-xcellence: Quality Benchmarking for Blended and Online Education

### A Manual

The first of three editions of the E-xcellence manual on benchmarking quality assurance in online education was published in 2006. The later versions also contain blended models and emerging developments such as open education and MOOCs (Williams, Kear, & Rosewell, 2016).

The primary purpose of the manual is to provide a reference framework of benchmarks, quality criteria, and guidance notes against which e-learning programs and their support systems can be assessed. However, the manual has also proved useful for designing, developing, and implementing e-learning courses and programs.

Course developers and teachers see the manual as a useful development and/or improvement tool to integrate into institutional systems of quality assurance and enhancement. To date, more than 50 universities across Europe have used the E-xcellence tool to benchmark their e-learning performance with peer review. The instrument is available in open license and translated in several languages worldwide.

### **A Benchmarking Instrument**

E-xcellence would initially become a tool to set standards across Europe for the delivery of quality online education. It would not only offer guidelines for universities but also prove the quality that leading universities in online education in Europe represent. However, already in the initiation phase, experts within E-xcellence from open universities, conventional universities, QA agencies, EUA, and UNESCO decided to work with benchmarks. This was necessary because the context of universities and digital learning practices across Europe differs too much to set standards. The system of benchmarking has several advantages:

- It respects the institution's own responsibility for QA and the level of ambition and pace of implementation and lays the foundation for an improvement roadmap.
- It includes self-assessment benchmarking as a basis for self-improvement, comparing university performance with best practices in e-learning in Europe.
- It uses peer reviewers as reference and input for improvement, installing collaborative processes of internal dialog.

In the many exercises with E-xcellence benchmarking at European universities, the most important feature mentioned is the guided discussion by using the tool. Not only does it ensure that all necessary aspects of delivering high-quality online education are covered, but it encourages university staff to reflect and discuss processes they take for granted or have not thought about before.

Addressing all aspects of delivering high-quality online education, the E-xcellence tool clearly represents a multilevel approach, targeting both staff and management levels under the manual's six chapters on strategic management, curriculum design, course design, course delivery, staff support, and student support.

- Strategic management: the institution should have defined policies and management processes that are used to establish strategic institutional objectives for the development of e-learning.
- Curriculum design: program boards should integrate knowledge and skills development and address challenges of active and personalized learning to meet different learning needs and aspirations.

- **Course design:** course teams should outline the relationship between learning objectives/outcomes, teaching and learning activities, and assessment methods elements (constructive alignment). A course can contain a mix of e-learning and face-to-face learning.
- **Course delivery:** includes the virtual learning environment, personal learning environments, and/or other channels, such as social media, through which students receive their course materials or communicate with fellow students and staff.
- **Staff support:** various staff support services enable all members of the academic, administrative, and technical staff to contribute fully to the development and service of digital learning, including specific professional development activities.
- **Student support:** student support services are an essential component of e-learning provision. Students' retention, success, and satisfaction are their main objectives. Institutions should develop policies and strategies for the design and provision of student support services.

### **Internal Quality Assurance Leading to the E-xcellence Associate in Quality Label**

The E-xcellence instrument consists of three steps toward the E-xcellence label, which recognizes a continuous cycle of e-learning improvement by the university.

The assessment allows the university to determine the performance of its current digital programs and to identify the requirements for further improvement. After having first performed the quick-scan as a quick self-assessment, the university can opt for a more extensive review assessment by experts. This can be done through either an online or a full on-site assessment, with locally focused recommendations for improvement by the review team.

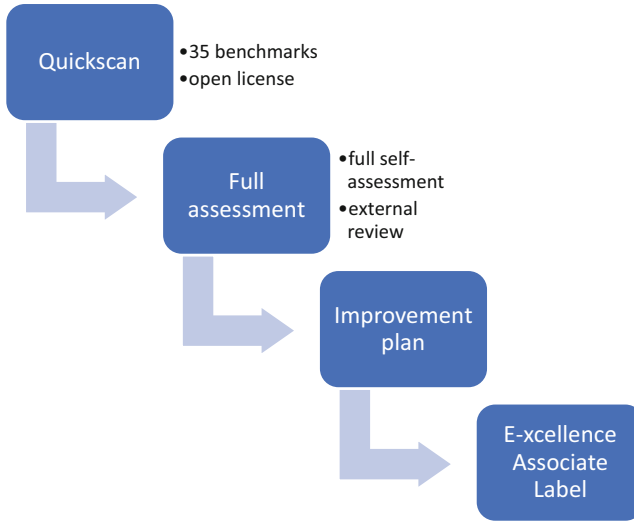

The reviewers of E-xcellence base their review on the complete reference material from the university and the evaluation of its self-assessment on 35 quick-scan benchmarks. Building on the self-assessment, the university will develop an adequate roadmap with further improvements to digital learning for the next 3 years. This roadmap is also assessed by the reviewers in consultation with university staff.

In order to guarantee a continuous cycle of self-evaluation of its e-learning performance as a university, the procedure includes the integration of the E-xcellence benchmarks into the internal quality assurance system. This is a requirement for obtaining the E-xcellence Associate in Quality Label from EADTU (Fig. 1).

The E-xcellence label was extended with the OpenupEd label as a response to the need for a quality label for MOOCs (Rosewell & Jansen, 2014).

### **The SEQUENT Handbook for Quality in E-Learning Procedures**

Building on E-xcellence, EADTU, in collaboration with ENQA, has expanded its partnership with leading QA agencies, connecting universities and QA agencies on their shared challenge to address quality assurance issues in online education. QA

**Fig. 1** E-xcellence, toward an E-xcellence associate label

agencies were aware of the need to anticipate developments in online learning and were willing to develop appropriate quality measures.

The SEQUENT project (2013–2015) funded by the European Commission aimed to promote excellence and innovation in higher education through the use of ICT and to prepare universities to take advantage of new teaching methods. In a concerted effort to convince governments, universities, and QA agencies of the need for a QA approach to online education, EADTU has joined forces with ENQA for introducing a variety of quality models.

The SEQUENT handbook was the main outcome of this project (Williams et al., 2015). The core of the handbook used the ENQA European Standards and Guidelines (ESG) for internal quality assurance, determining the broad context for institutional approaches to quality assurance for e-learning. The handbook was based on the project partners' experiences with the tools E-xcellence, UniQue, and ECB Check. It illustrates how quality assurance dimensions of online education can operationalize the ESG standards and how the quality of European higher education can be made more future-proof through the use of technology enhanced learning.

The handbook was further illustrated by numerous showcases of universities using QA in online education instruments of E-xcellence and UniQue (Bacsich, 2015). Interesting about these showcases was the integration of the QA tools into the QA systems. All cases explain, among other things:

- How they implemented the self-assessments as part of the QA in e-learning approach
- How their institution's QA system addressed blended or online distance learning

- What impact the QA system had for the use of e-learning and how it improved the overall educational offer of the institution

### **ENQA Considerations for QA of E-Learning Provision**

Next to EADTU, ENQA has started early in addressing the challenges for universities when adopting new teaching methods. In October 2009, ENQA held a workshop on quality assurance in e-learning, which showed that the European Standards and Guidelines for Quality Assurance in the European Higher Education Area (ESG) – if correctly interpreted – can be used as a backbone for quality assurance processes, including those for e-learning (Grifoll et al., 2010). The ESG has since been revised (ESG, 2015), not specifically aimed at e-learning but certainly equally applicable to all forms of teaching and learning. However, the need for an appropriate interpretation for its use remained.

EUA's 2014 e-learning survey already indicated that 91% of 249 surveyed institutions have integrated e-learning into their education (Gaebel, Kupriyaova, Morais, & Colucci, 2014). Eighty-two percent reported to offer online learning courses. In contrast, much less attention has been paid to the quality assurance of such provisions. The authors suggested there was a clear shortcoming, citing the fact that only 23% of national QA agencies paid special attention to e-learning.

To further investigate whether QA agencies needed more support and expertise to keep up with new developments and innovations in education, ENQA launched the ENQA Working Group on Quality Assurance and E-learning in 2016. The main aim was to address the challenges associated with the alternative learning and teaching methods that ICT has created.

Recognizing that recommendations for quality assurance and e-learning had already been written, the Working Group decided to create a new focus, systematically examining both the applicability and relevance of the standards as defined in the ESG 2015 and using existing papers and publications. While each standard appeared to be fully applicable to e-learning, some seemed to require special guidelines on how to apply them. As a result of an intensive discussion process both in the Working Group and with relevant e-learning stakeholders in Europe, the Working Group came up with guidelines to use the ESG for e-learning offers, published in the “Considerations for Quality Assurance of E-learning Provisions” report (Huertas et al., 2018).

### **Peer Learning Activity on Quality Assurance in Online Education**

EADTU further conducted a survey on quality assurance and accreditation of online education. The study compared national frameworks and regulations, institutional developments at universities, and current practices of external quality assurance for online and distance learning in 15 countries. The results of this research were presented in a collaborative peer learning activity between EADTU and ENQA with the aim of identifying the next steps in the development of a quality blended degree and online continuing education in a dialog with universities, governments,

QA agencies, and students (Grifoll et al., 2010). This resulted in stakeholder-specific recommendations for QA agencies, national governments, the European Commission, and universities.

In summary, the recommendations proposed a dialog on innovation and quality assurance between higher education institutions, quality assurance agencies, and governments to support innovations in higher education and promote appropriate quality assurance policies:

- Institutions that develop and implement policies and strategies for digital education, taking into account an internal quality framework and a maturity model for blended and online degree, continuing, and open education.
- Quality assurance agencies that adapt and refine criteria/indicators and guidelines for digital modes of teaching and learning and share good practices of internal and external quality assurance.
- Governments developing drivers and reviewing regulatory frameworks for quality assurance and accreditation in higher education, encouraging and accelerating innovation. A vision of change must be expressed through national strategies.

This dialog should lead to concerted actions to support innovation in higher education and to apply appropriate quality assurance measures.

## **The European Maturity Model for Blended Education (EMBED)**

Very closely linked to quality in open, distance, and digital education is the European Maturity Model for Blended Education or the EMBED approach (2017–2020) with the aim of empowering European higher education to achieve high-quality blended education programs and courses (Goeman & Dijkstra, 2019a).

The degree to which these decision-making processes are embedded in a course or program or in institutional conditions and strategies determines the maturity level of blended education. This allows teaching staff and course designers to continuously improve blended practices in an iterative manner. Maturity therefore does not equate to quality, but on the other hand it can contribute to quality improvement and a continuous delivery of quality.

The EMBED maturity dimensions are based on most recent literature research (Goeman, Poelmans, & Van Rompaey, 2018), on the evaluation of best blended course development practices and institutional strategies, and on a Delphi research on the results of these investigations (Goeman, Dijkstra, Poelmans, Vemuri, & Van Valkenburg, 2021). Criteria and instruments are developed to assess and map the degree of maturity of blended education for each of these maturity dimensions. For each dimension, a high, medium, or low maturity level can be represented in a spider diagram.

The EMBED model uses a multilevel and multi-stakeholder approach:

- At the course level, the maturity is assessed for course and curriculum design according to six dimensions: the selection and sequencing of learning activities,

the selection of blended learning tools, course flexibility, course interaction, the student learning experience, and study load and inclusiveness.

- At the program level, the maturity level is assessed according to six dimensions: program coherence, alignment and coherence of blended learning tools, program flexibility, the student learning experience, study load, and inclusiveness.
- At the institutional level, the maturity level is assessed according to eight dimensions: institutional strategy, institutional support, sharing and openness, institutional development, quality assurance, governance, finance, and facilities.
- At the policy level, recommendations are developed for policy makers.

For each dimension, guidelines are developed to optimize processes leading to systemic decision-making (Goeman & Dijkstra, 2019b).

### **ICDE Quality Models in Online and Open Education Around the Globe: State of the Art and Recommendations (2015)**

Main player at the global level is the International Council for Distance Education (ICDE). In 2015, under coordination of EADTU, ICDE delivered a report on “Quality Models in Online and Open Education Around the Globe” (Ossiannilsson et al., 2015).

This report provides the first global overview of quality models in online and open education. It illustrates that quality in online learning is a complex matter and addresses new needs such as quality in MOOCs and Open Educational Resources. The diversity of instruments used globally at that time was developed independently.

The report delivers insight into the quality concept and the quality dimensions and describes a selected number of models in relation to certification, benchmarking, accreditation, and advisory frameworks. An important message from this global report is that while its findings on the one hand show there is no need for new quality schemes as such, it reveals a huge gap and need for knowledge sharing and capacity building and for coordination among stakeholders.

ICDE has given follow-up on this message by establishing QA focal points under the ICDE Quality Network. In November 2016, regional Focal Points on Quality were established by the ICDE Executive Board, in which EADTU represents Europe. The quality network gives advice and collects knowledge on the latest developments on quality related to open, flexible, and distance education within the institutions and regions (Mathes, 2018).

---

### **Challenges and Directions for the Future**

The corona crisis seems to give rise to a new phase of developing a digital education. Universities are now consolidating digital pedagogies for mainstream degree education while rethinking and expanding continuing education and professional development and open education provisions.

These developments are substantially supported by the EU and national governments.

## University-Level Developments

### Post-corona Pedagogies in Degree Education

With the corona crisis, universities had to move quickly to digital education and completely reorganize their campus. Emergency decisions were taken at all levels. European Commission surveys of May 2020 found that 95.1% of universities organized online distance learning during the lockdown period and even 82.7% organized online examinations. All had to create massive institutional support for organizing digital education.

Three main approaches were observed and appear to be continuing (Pieters, Oudehand, & Sangra, 2021):

- Synchronous hybrid learning: based on course design that has in common that both on-site or “here” students and remote or “there” students are included simultaneously (synchronous hybrid learning (Raes et al., 2020a, b)
- Blended learning: based on a course design with a conscious combination of online and offline learning activities (Garrison & Kanuka, 2004; Garrison & Vaughan, 2013; Goeman et al., 2018; Laurillard, 2012, 2015)
- Online distance learning: based on a course design with a continuous physical separation between teacher and student, synchronous and asynchronous (Martin, Ting & Westin, 2019)

These emergency practices have led to a better understanding of digital education opportunities by university leaders, teaching staff, and learners. Higher education institutions in all countries are becoming aware that this unprecedented situation will lead to a paradigm shift in the coming years.

New paradigms will change teaching and learning processes and require continuous professional development of staff, team teaching, and educational and ICT support of staff. In all three approaches, specific benchmarks are to be developed, for example, related to course design, teacher and student interaction, the learning experience, and e-assessment (TESLA, 2019). Also, universities will be challenged by new educational technologies with applications of artificial intelligence.

This will need change management at all levels of an institution and at the governmental level.

### Rethinking and Upscaling Continuing Education and Professional Development

Due to the needs in the economy and society, universities will rethink continuing education and professional development (CEPD) offerings and develop appropriate organizational models for this area. The permanent interaction with economy and

society adds a dimension to the design, delivery, and organization of CEPD (the quadruple helix).

To make CEPD scalable, accessible, and inclusive, universities have to use the full potential of digital education. To adapt offerings to the needs of learners, shorter types of programs and qualifications will be developed such as microcredentials and microdegrees. Extension schools or similar structures will coordinate and support the CEPD activities of an institution and function as an educational interface with public and private enterprises.

However, at most European universities, continuing education and professional development is still in an exploratory phase. Institutional developments are not yet adapted to the scale of the needs in the labor market and in society.

Quality benchmarks of digital continuing education are related to dimensions such as the level of flexibility for adult learners, the integration of academic and professional competency development, the learning experience of mature learners in a professional context, and the design of courses in co-creation with enterprises and sectors.

### **MOOCs and MOOC-Based Microcredentials**

Since 2013, MOOC platforms have been offering massive open online courses in collaboration with universities. Recently, MOOC platforms and universities have started developing MOOC pathways for CEPD, consisting of a coherent set of MOOCs. These pathways are often developed in co-creation with sectors and companies.

To valorize these trajectories, the European MOOC Consortium, consisting of main European platforms (Futurelearn, FUN MOOC, EduOpen, Miriadax, iMooX, EduOpen), has developed the Common Microcredential Framework (CMF) (EMC, 2018), which rewards MOOC trajectories with a microcredential qualification after assessment. The microcredential awarded by CMF is an academic qualification with a professional orientation. Microcredentials possibly can be stacked into a broader certified program or academic degree (bachelor, master).

To better serve the labor market, MOOC platforms have established partnerships with professional organizations and companies in both the private and public sectors, for example, in food, IT, teacher education, healthcare, and the environment.

Herewith, MOOC platforms increasingly function as an interface between universities and labor market organizations (Henderikx, Ubachs, Ferguson, Hodges, & Antonaci, 2020; Habib & Sanzgeri, 2020). Collaborations have different organizational forms: specific business spaces, corporate platforms where universities show courses for the labor market, and white label platforms for sectors and public or private enterprises. They work together to investigate needs, organize workplace learning, or even co-create content. In other cases, university courses are endorsed by industry or professional partners who have previously assessed and recognized the course for professional development or professional accreditation.

Internal quality assurance by institutions looks into the educational design of the MOOCs and MOOC pathways, the qualifications awarded, the interaction with

enterprises and sectors for combining an academic and professional orientation, and the stackability of courses.

## Policy Developments

The European Commission and national governments develop actions to support the development of digital higher education in a lifelong learning perspective.

### The Digital Education Action Plan (DEAP)

Already in 2018, the revised European Commission's Digital Education Action Plan (2021–2027) (European Commission, 2018b) sets out measures for high-quality and inclusive digital education and training in Europe at all levels. Digital technology should “facilitate the provision of flexible, accessible learning opportunities, including for adult learners and professionals, helping them to re-skill, upskill, or change careers,” which can be supported “through microcredentials which capture the learning outcomes of short-term learning.”

### The European Education Area

In 2020, the Commission launched its communication “Towards the European Education Area by 2025” (European Commission, 2020a), in which the development of a European approach to microcredentials in higher education is a key priority. It announced a proposal to the Ministers of Education Recommendation by 2021 and a plan at having all the necessary steps in place by 2025 for the wider use, portability, and recognition of microcredentials. With these steps, the European Commission frames national microcredential offers to make them comparable and responding to the same standards.

To prepare this, the European Commission established the “Microcredentials in Higher Education Consultation Group” (European Commission, 2021). This defined a microcredential as “a proof of the learning outcomes that a learner has acquired following a short learning experience.” They are “underpinned by quality assurance following agreed standards.” In terms of volume for a microcredential, the group left flexibility for innovation and experimentation: from one ECTS to less than a full degree (European Commission, 2020b).

Almost simultaneously, a European project with national ministries of education and European networks launched a complementary definition of microcredentials (Cirlan & Loukkola, 2020): “a microcredential is a certified short learning experience designed to provide the learner with specific knowledge/skills/competences that respond to societal, personal, cultural, or employability needs. Microcredentials are subjected to a quality assurance assessment in line with the ESG.”

In order to develop a microcredential policy, higher education institutions will work as central actors among external stakeholders to realize the “knowledge square”: education, research, innovation, and service to society. This is a new concept for higher education institutions, and quality assurance guidelines should

take into account new organizational models and types of course design for CEPD, involving external stakeholders at all levels.

### **The European Universities Initiatives (EUIs)**

Since 2021, 279 universities have been involved in 41 European Universities Initiatives or EUIs (European Commission, 2018a). The European Commission considers these alliances as a priority and a spearhead for innovation to be supported by digital education. They organize an integrated European campus, e.g., through joint courses and programs and embedded mobility for students and staff. In line with the delivery mode of programs, mobility can be physical, virtual, or blended (Henderikx & Ubachs, 2019). The target is 50% short-term or long-term mobility, depending on the curriculum goals and personal preferences of the students.

The corona crisis was an emergency test for the alliances for organizing this as planned. Digital teaching and learning methods enabled them to realize the goals they are committed to. To this end, they brought together the best expertise in the field of digital education at their partner institutions. Now, they see the need for changing emergency approaches in sustainable pedagogies for international education.

This is an important challenge for quality assurance. To some extent, the alliances can fall back on the already existing European approach to quality assurance of joint programs (EQAR, 2015). However, EUIs have a broader mission as their activities span multiple campuses and therefore many national quality assurance bodies would need to be addressed. The ongoing EUniQ project focuses on the special features of multicampus quality assurance and expanded missions of the new alliances, “allowing to replace multiple national QA procedures that are not appropriate to assess the quality of these European alliances” (EUniQ, 2021).

---

## **Conclusions**

### **More Complexity in Digital Higher Education**

After the corona crisis, digital higher education practices are growing in quantity and permeating mainstream degree education. They have also become more complex as various pedagogies are used in courses and programs, such as synchronous hybrid, blended, and online education and distance learning.

Universities also organize a broader range of education. In addition to degree education, they offer online programs for continuing education, microcredential courses, and open education through MOOCs, all based on their mission.

The international dimension has also become important in all these areas. Universities organize joint curricula and mobility schemes. This development has even been bolstered by the European Commission’s European Universities Initiatives (EUIs), creating alliances across Europe.

Digital education plays an essential role in creating a new pedagogical landscape.

## Quality Assurance in Digital Education

The quality assessment of digital education is typically process-oriented, e.g., related to course and curriculum design, including digital resources; interactive facilities in the learning environment for developing and delivering digital education; the support of course teams by teaching and learning and ICT services; and wider institutional strategies for digital education and innovation. At the macro-level, governments are pushing digitalization to succeed in the Commission's Transformation Agenda of the European University for 2030.

Universities and quality assurance agencies are aware that quality assurance should take into account the perspectives of the various internal and external stakeholders at different levels in the university ecosystem. Change processes affect stakeholders at micro-, meso-, and macro-levels who all need to engage in dialog with each other.

## Quality Instruments

Quality criteria for digital higher education are based on agreed principles or frames of reference. These criteria are used for benchmarking, identifying internal improvement opportunities. The widely used E-xcellence instrument refers to benchmarks related to curriculum and course design, course delivery, student support, staff support, and strategic management for digital education. The E-xcellence label recognizes a continuous cycle of e-learning improvement by the university.

For internal and external quality assurance, it is estimated that the Standards and Guidelines for Quality Assurance in the European Higher Education Area (ESG, 2015) apply to digital education as it is to traditional forms of education. However, when applying the ESG guidelines, specific extensions have been developed for digital education.

Recently, a maturity model has been developed to assess institutional decision-making about digital education at all levels, based on dimensions in the most recent research (van Valkenburg et al., 2020 ipv EMBED).

A global report on quality assurance in digital higher education shows that there is no need for new quality schemes as such but that there was a huge gap and need for global knowledge sharing, capacity building, and coordination.

## Challenges

Specific challenges for the future relate to the areas of degree, continuing education, and professional development (CEPD) and international education and virtual mobility.

## Degree Education

After of the corona crisis, universities are now consolidating digital pedagogies for on campus degree education, in particular synchronous hybrid, blended, and online

distance education. While upscaling these approaches, specific benchmarks are to be developed. Also, universities will be challenged by new educational technologies with applications of artificial intelligence.

### **Continuing Education**

Due to the needs in the economy and society, universities will rethink CEPD offerings and develop appropriate organizational models for this area. The European Commission is promoting microcredentials for continuing education. Governments and universities have already started with this new development. The permanent interaction with economy and society adds a dimension to the design, delivery, and organization of CEPD.

Quality benchmarks in this area are related to dimensions such as the level of flexibility for adult learners, the integration of academic and professional competency development, the design of courses in interaction with enterprises and sectors, the recognition of qualifications for microcredentials, and the stackability of courses.

### **Collaborations and Mobility that Transcend the Individual University**

International collaboration and digital mobility within EUI alliances are an important issue for quality assurance. EUIs span multiple campuses, and therefore many national quality assurance bodies would need to be addressed. Ways forward have to be developed for multicampus quality assurance and expanded missions of the new alliances, replacing multiple national quality assurance procedures that are not appropriate to assess the quality of these European alliances.

### **National Governments and Universities: Bottom-Up and Top-Down Processes**

The European policy agenda is shared by national governments through the Council of Ministers, where bottom-up and top-down processes meet. In the coming years, these will include the full range of quality assurance issues such as the digitization of higher education practices in university alliances, microcredentials, joint programs, and various forms of virtual mobility. National governments and institutions are already anticipating these developments. It will impact on internal and external quality assurance processes (Raes, 2020a, Raes 2020b, Detienne, Windey, & Depaep, 2020)

## Abstract

Open, Distance, and Digital Education (ODDE) has potential to help educational institutions address the various challenges which usually result in the disruptions of the learning process. This system of education is flexible, agile, and resilient enough to adjust to the different contexts and also enables the academic institution to respond to some expectations like making available lifelong learning opportunities to all types of learners. There is, however, a lingering perception that ODDE is of lower quality compared to the conventional mode of education despite results of research showing otherwise which can prevent the realization of the full potential of this system of instruction.

Through an intensive review of literature, this chapter looked at how quality in ODDE was and is being articulated with respect to curricular programs and

courses and how they are evaluated for quality with the goal of determining if there are gaps which need to be addressed to help dispel that perception of lower quality. Eleven Quality Assurance (QA) Frameworks developed by various organizations from different parts of the world during the last 20 years (2000–2019) were evaluated for a more focused review process. Results showed that there is a general agreement as to what constitutes quality in this system of education. For the methodologies for program and course evaluation, some improvements and innovations can be done as informed by the QA Frameworks and tapping on what information can the technology provide as in the case of learning analytics which served as basis for the recommendations made.

**Introduction**

Open, Distance, and Digital Education (ODDE) is a mechanism to address the various challenges being faced by the education sector. The need for a flexible, agile, and resilient education system became more evident when the COVID-19 pandemic affected the whole world and forced all educational institutions to immediately shift to remote instruction just to ensure that learning would continue for their students.

The disruptions in education, however, are not a new challenge for the education sector. Discontinuance of learning also happens when students and teachers are prevented from going to school because of natural calamities like typhoons and floods, disasters like earthquake and volcanic eruptions, and even man-caused circumstances like the disruption in the peace and order situation in the area.

ODDE is also a viable strategy which can position higher education institutions to respond effectively to the projected demand for higher education estimated to reach over 414 million in 2030 (ICDE, 2015) as well as contribute to the goal of making available inclusive lifelong learning opportunities as demanded by the fast-changing world of work. The full adoption of ODDE as a system or a component of the system of learning, however, can be hindered by the still lingering perception that this form of education is of lower quality compared with the residential or conventional education despite research results showing otherwise. Asare (2014), for instance, argued that the focus should not be the mode of delivery but rather how learners are equipped with relevant knowledge and skills to become functional citizens which can be achieved even in the distance mode of education. Also, a publication released by the US Department of Education (2010) presenting the results of a systematic review of literature from 1996–2008 showed that “*students who took all or part of their course online performed better, on average, than those taking the same course through traditional face-to-face instruction*” (p. x1v). Shachar and Neumann (2010)

also validated this finding in their research which also showed that “*that DL [distance learning] students outperformed their traditional counterparts*” (p. 322).

This perception of lower quality can be traced to as far back as the pioneering days of distance education or the correspondence system of learning which can be due to the lack of social education usually associated with what students can get when studying on campus (Tait, 2008). Citing de Salvo (2002), Tait (2008) further explained that a student’s university career is “more than the acquisition of knowledge” (p. 86) but being a “man among men” (p. 86) which can result from joining university extracurricular activities like debating society, football, and the likes.

Over the years, the implementation of distance education has evolved as influenced by the rapid advancement in the information and communications technologies (ICT). Most universities engaged in this mode of delivering instruction resorting to online learning or technology-enabled teaching and learning which was also seen to address the concern about the social education of the learners. The potential of ODDE was also implied by the Council on Higher Education (CHE), Pretoria (2014), that “there seems to be a widespread assumption that education mediated by means of ICT-supported methods can improve the quality of educational provision in developing countries, not least in institutions of higher learning” (p. 1).

The stigma of being of lower quality attached to online learning (Hodges, Moore, Lockee, Trust, & Bond, 2020) could be attributed to that observation that “students in online environments tend to feel more confused, isolated, and frustrated, and as a result their learning effectiveness and satisfaction can be reduced” (Markova, Glazkova, & Zaborova, 2017). Despite many research that aimed to address this issue of quality in ODDE and while results of these studies showed that the physical separation between the teacher and the students is not a major factor that determines quality education, the perception remains.

Two questions are forthcoming: Where are the possible gaps? And what are they?

Sloan Consortium (2002) observed that “despite research from respectable educators that points toward the positive effects of online learning, many still say that more sound studies still need to be conducted to measure and document the most effective kinds of online teaching” (p. 4) which points to the type of research that were conducted to address the concern. Markova et al. (2017), on the other hand, pushed for certain quality indicators to “be established to ensure high quality standards in distance tertiary education” (p. 686). Chao, Saj, and Tessier (2006) pointed to the methodology being used and forwarded the following observation:

*Despite efforts in defining and examining quality issues concerning online courses, a systematic, formative methodology to measure and ensure quality is lacking. The most common tools for gauging quality are surveys and course evaluations in which instructors, learners, or sometimes administrators provide their perceptions, opinions, or experiences. Data collected from surveys or course evaluations only touch on some aspects of a course’s quality—mostly issues related to teaching and learning, such as how an instructor performs in class or how the learning experience affected learners. Often, aspects not obvious to faculty or learners are ignored. . . (p. 33)*

The need to reframe how the quality of open distance and digital education is evaluated was also implied by Chao et al. (2006, p. 33) in terms of requiring “a comprehensive framework and appropriate guidelines as well as devise an instrument and method for measuring the hidden aspects of quality.” Council on Higher Education (CHE) (2014) is also of the perspective that “the question of the quality of educational delivery and support using ICTs requires much deeper analysis” (p. 2).

This chapter aims to address these implied quality determination and evaluation gaps in ODDE with the hope of contributing toward strengthening its position as the foundation of a resilient and sustainable education system.

---

## The QA Frameworks for ODDE: The Domains That Matter

Just like in the conventional mode of instruction, there are already many frameworks for QA in ODDE. Many of these QA Frameworks were developed by different organizations during the last 20 years which can be attributed to the rise of open and digital education as a result of continuous and increasing level of integration of modern ICTs, specifically the Internet, into the teaching and learning process during this time span. An evaluation of ten QA Frameworks developed by various organizations from different parts of the world from 2000 to 2019 shows the different domains or benchmarks of quality for ODDE (Table 1). Information presented in Table 1 is from multiple sources. The selection of the QA Frameworks evaluated in this chapter was based on the following criteria: (1) It was developed by an organization/agency involved with ODDE and is not a result of a study by a researcher or developed by a specific university for its use (adopted from Pedro & Kumar, 2020); (2) it was developed during the last 20 years to determine the trend; and (3) it can represent areas/geographical locations from different parts of the world.

In general, there are some agreements as to what constitutes quality in ODDE as evidenced by the similarity of the domains identified across the frameworks. Most of the frameworks studied were supposed to guide the development of ODDE programs and courses as well as the evaluation for quality which could be the reason why the domains identified were more of the inputs by the academic institutions offering ODDE which include among others institutional mission, vision, policies, planning, infrastructure, the faculty and staff credentials and continuous development, and the learner support system. Further, the QA Frameworks for ODDE during the last 20 years showed consistency in the inclusion of domains pertaining to programs and courses as these represent the products and services offered by ODDE institutions, as appropriately described by the Canadian Association for Community Education (CACE, 2002) in the way they framed their QA Framework. Some QA Frameworks are specific in identifying programs (or academic programs, for that matter), and the specific aspect that is being looked into in the framework like program design (CHE, 2014), curriculum design (Asia-Pacific Economic Cooperation (APEC), 2019; EADTU, 2016), program design and curriculum development

**Table 1** Different QA frameworks in ODDE (2000–2019)

Year	The QA Framework	Organization who developed	Country/region	Domains/benchmarks of quality
2000	Quality on the Line	Institution for Higher Education Policy (IHEP)	USA	7 quality benchmarks: Institutional support Course development Teaching and learning Course structure Student support Faculty support Evaluation and assessment
Barker, 2002	Canadian Recommended E-learning Guidelines	FuturEd and Canadian Association for Community Education (CACE)	Canada	3 major e-learning quality guidelines: Quality outcomes from e-Learning products and services Quality processes and practices and practices in e-Learning products and services Quality inputs and resources for e-Learning products and services
Inside Higher Education, 2005	Sloan Consortium Quality Framework	Sloan Consortium (which was renamed into Online Learning Consortium)	USA	5 quality principles: Learning effectiveness Cost effectiveness and institutional commitment Access Faculty (employee) satisfaction Student (customer satisfaction)
ACODE, 2014	Distance Higher Education Programs in a Digital Era: Good Practice Guide	Council on Higher Education (CHE) by South African Institute for Distance Education (SAIDE)	South Africa	19 criteria for evaluation for accreditation: Program design Student recruitment, admission, and selection Staffing Teaching and learning strategy Student assessment Library services Program administrative services Postgraduate policies, procedures, and regulations Program coordination Academic development Teaching and learning interactions Student assessment practices Assessment system Coordination of work-based learning (where applicable) Delivery of postgraduate programs Student retention and throughput Employability and recognition/program evaluation

**Table 1** (continued)

Year	The QA Framework	Organization who developed	Country/region	Domains/benchmarks of quality
	ACODE Benchmarks for Technology Enhanced Learning (TEL)	ACODE (Australian Council on Open, Distance and e-learning)	Australia	8 benchmarks: Institution-wide policy and governance for technology-enhanced learning Planning for institution-wide quality improvement of technology-enhanced learning Information technology systems, services, and support for technology-enhanced learning. The application of technology-enhanced learning services Staff professional development for the effective use of technology-enhanced learning Staff support for the use of technology-enhanced learning Student training for the effective use of technology-enhanced learning Student support for the use of technology-enhanced learning
2016	Quality Assessment for E-learning; a Benchmarking Approach (E-xcellence) Manual (3rd Edition)	European Association of Distance Teaching Universities (EADTU)	EU	6 benchmarks: Strategic management Curriculum design Course design Course delivery Staff support Student support
2017	A Benchmarking Approach – Excellence (3rd Ed.)	Online Learning Consortium (OLC) (formerly Sloan Consortium)	US	9 key areas for the quality scorecard Institutional support Technology support Course Development/instructional design Course structure Teaching and learning Social and student engagement Faculty support Student support Evaluation and assessment
2019	Quality Assurance of Online Learning Toolkit	Asia-Pacific Economic Cooperation (APEC)	Asia Pacific	9 domains of quality Leadership and management Staffing and professional Development Review and improvement Resources Student information and support Student experience Learning outcomes

(continued)

**Table 1** (continued)

Year	The QA Framework	Organization who developed	Country/region	Domains/benchmarks of quality
				Assessment and integrity Curriculum design
	Quality Assurance Framework	Asian Association of Open Universities (AAOU)	Asia	10 domains: Policy and planning Internal management Learners and learners' profile Infrastructure, media, and learning resources Learner assessment and evaluation Research and community services Human resources Learner support Program design and curriculum development Course design and development
	The Regional Community of Practice (CoP) QA Guidelines in Open and Distance Learning	Commonwealth of Learning (COL)	Southern Africa	7 standards: Program standard Learner support systems Materials development Student assessment Infrastructure and facilities Staffing Open and distance education systems and structures

(AAOU, 2019), and program standards (Commonwealth of Learning, 2019). CHE (2014) also included administrative services, coordination, delivery, and evaluation as additional aspects for evaluating programs for quality. Other QA Frameworks subsumed the program/curriculum component in the other domains as in the cases of IHEP (International Higher Education Policy, 2000), CHE (2014), and EADTU (2016). In the IHEP Framework, evaluation and assessment benchmarks include program effectiveness assessment through the following: enrollment data; costs and successful/innovative uses of technology; and regular review of the intended learning outcomes to ensure clarity, utility, and appropriateness of the ICT use. CHE, on the other hand, has a recommended framework for curriculum development and evaluation which can serve as a standard for evaluating for quality while EADTU focused on curriculum design which was articulated in terms of flexibility, academic community involvement, knowledge and skills, and assessment procedures.

For the course quality domain, some observations which can be drawn from the ten QA Frameworks studied are the following.

### Course Development

There is a consistent inclusion of the course component in all the frameworks studied which implies the common perspective that this aspect is important in determining

the quality of ODDE. Course is a main quality domain in IHEP (2000), EADTU (2016), Online Learning Consortium (2017), and AAOU (2019) frameworks and is subsumed or implied in other domains based on the domain descriptions and in the indicators or evidence of quality.

Different terms or nomenclature and descriptions were used to refer to the course domain for quality like course design (EADTU), course delivery (EADTU), course development (IHEP, 2000), teaching and instructional practices (OLC), learning effectiveness (SLOAN), and student satisfaction (SLOAN). The CACE Framework included the course component in the evaluation of process (approaches to learning; instructional strategies; and assessment of learning) and inputs and resources (intended learning outcomes; curriculum content; teaching and learning materials; learning technologies; and technical design of the LMS).

A more comprehensive description was forwarded by EADTU (2016) for course evaluation which starts at looking at the rational progression from one course to the next; the relationship of the course with the curriculum and the overall program learning outcomes, the course content design and the student interaction with the course material, the detailed development of the course materials, and assessment; and course evaluation and the process of course approval. For OLC (2017), course design covers course overview and information, course technology and tools, design and layout, content and activities, interaction, assessment, and feedback (<https://onlinelearningconsortium.org/consult/oscqr-course-design-review/>). IHEP (2000) has a domain for course structure which focuses on the different stages of the course delivery, e.g., orientation about the course and technology requirements before starting the online program, learning outcomes, library resources, assignments, and faculty response. IHEP also has course development benchmark to cover design and delivery, as well as determining the technology to be used based on the learning outcomes.

COL (2019) has a specific domain for course materials development which looks at the desired characteristics of the learning materials to include the following: presentation in appropriate formats that allow easy access by learners; and coherence between learning materials and learning outcomes and course content and assessment. Learning materials should teach in a coherent way, engage learners, and promote development of problem-solving and critical thinking skills. Learning materials should also be evaluated and updated on a regular basis. The CACE QA Framework (2002) also included teaching and learning materials as one aspect under inputs and resources.

Course delivery was also articulated in the different QA Frameworks focusing on different aspects of this quality domain. OLC (2017) includes teaching and instructional practices domain which covers the digital classroom experience, course fundamentals (course design, accessibility, and continuous improvement), learning foundations (course learning outcomes, course content, and assignments), faculty engagement (the instructor role like providing effective feedback, use of tools within the LMS to facilitate the learning experience in an effective manner), and student engagement (how the course was designed to facilitate class discussion engagement, building community, and communication). IHEP (2000) covers teaching and learning quality domain which pertains to student-teacher and student-student

interactions as facilitated by various technologies, and providing constructive and timely feedback to students' submissions. CACE (2002) has approaches to learning, instructional strategies, and assessment of learning as components of the process domain. For EADTU (2016), the specific domain for course delivery includes the Virtual Learning Environment, the personal learning environments, and the other channels, such as social media, through which students receive their course materials or communicate with fellow learners and staff. The selected systems should be driven by both educational and technical requirements. The educational requirements include delivery of learning resources, facilities for online communication, and tools for assessment while the technical requirements refer to the reliability and security standards. EADTU also emphasized that the delivery system should be reviewed and monitored to ensure that it continues to meet the educational and technical requirements.

The COL QA Framework (2019), on the other hand, puts emphasis on student assessment, which can also be considered as part of course delivery. According to COL, assessment strategies should be effective, valid, and reliable, and with appropriate security and QA measures to ensure the integrity of the assessment process. COL also included the presence of a policy for student appeals on assessment results and that the turn-around times for such appeals should be clearly defined in the policy.

In some QA Frameworks, the course domain is also implied in the student experience or journey while taking the course which can also be a result of the convergence of other quality domains like learner support services, infrastructure, credentials and qualifications of faculty and staff, and institutional policies.

In general, the different QA frameworks studied presented the course domain to cover the life cycle of the course which starts from its identification as a component of the curricular program, the development and design of the course/course materials, how the course is delivered to the learners, and the evaluation for subsequent revision and further improvement.

## **Educational Technology**

There is emphasis on the selection and use of appropriate teaching and learning technologies vis-a-vis the intended learning outcomes when evaluating courses in the ODDE system. EADTU, for instance, described the whole course delivery process to include the different technologies used like the virtual learning environment where the learners receive the instructional materials, communicate, or facilitate the different interactions that are critical to the learning process and the tools for assessment and other learning activities.

## **Program and Course Evaluation**

Program and course evaluation is a domain of quality itself. There are QA Frameworks which specifically include program and course evaluation as

domains of quality such as EADTU, CACE, and COL. SLOAN Consortium (2005) also included learning effectiveness with the following indicators: new knowledge generated; theories applied to the workplace, continuous feedback from different stakeholders; and student satisfaction and loyalty. CACE has a specific domain for quality outcomes which can be determined by the relevance to employment of the content skills and knowledge acquired from the course/program, and the recognition of the course credits and program credentials by other education institutions and employers locally and internationally. For student satisfaction, CACE proposed that this be derived from the following: course effectiveness or the achievement of personal learning goals; course efficiency or the best use of student finances, time and energy; student satisfaction with processes and practices; and adequacy of inputs/resources provided to the students.

---

## **Program and Course Evaluation in ODDE: Perspectives and Practices**

The perspectives expressed by various authors imply a comprehensive view which can be adopted when it comes to program and course evaluation. While there was a general agreement that program and course evaluation principles in conventional instruction and distance education are generally similar, many authors were also quick to point the major differences which can be attributed to the basic attributes of ODDE: the openness to provide access to education opportunities to the nontraditional learners; the separation in time and space of the learners from the teachers and fellow learners; and the higher integration of ICT into the teaching and learning process to bridge the physical separation. These attributes also make program and course evaluation in ODDE more complex compared to conventional instruction.

The Kirkpatrick (1975) model of ODDE program and course evaluation looks at four levels: (1) reaction and planned action which gauge the participants' satisfaction and studying how they intend to apply what has been learned during the course; (2) learning which shows what the participant has learned from the course; (3) workplace application which pertains to whether and how the participants apply what they have learned to their respective jobs; and (4) business results which look at the benefits gained by the organization in offering ODDE programs and courses and can be in economic terms and/or customer satisfaction.

Different authors are in agreement that evaluation of ODDE programs and courses is more complicated because of the basic characteristics and attributes of this system of instruction, which include the usually big number of enrollment in the programs and courses, the geographically and widely dispersed student body (CHE-South Africa, 2014), and the diversity in the students' profile which may have implications in quality outcomes and students' satisfaction.

Further, given the major role that modern ICTs play in the ODDE system, there may be that tendency to just focus on the technology per se instead of its impact on the teaching and learning (CHE, 2014).

CHE (2014) further emphasized that in evaluating ODDE programs and courses, the focus should not be the technology per se but the effect on teaching and learning as explained below:

*The question of the quality of educational delivery and support using ICTs requires much deeper analysis. Simply throwing computers at higher education institutions is in no way a responsible manner in which to begin to address quality improvement. While the provision of ICT hardware and related supporting network infrastructure, improvement in the provision and reliability of Internet access and connectivity, and implementation of relevant software applications are clearly important, it is only when the improvement of teaching and learning is addressed that claims made for the educational potential of supporting ICTs can be confirmed or refuted. (p. 2)*

## The Openness Attribute

Being open in widening access and participation while providing reasonable care to ensure success (Zawacki-Richter et al., 2020), ODDE programs and courses would affect the structure, the aspects to be evaluated, success definition, indicators, and criteria, as well as the evaluators who will participate in the evaluation for quality process. The openness attribute implies the wide variation in the profile of the learners and the geographical distribution which impact on the learning design and authentic learning. Questions like what examples to use, what resources to refer to, the language to use (CHE, 2014), and developing collaborative learning activities and the subsequent grouping of learners to maximize the learner-learner interaction need to be carefully considered.

Alturkistani et al. (2020) also emphasized the need for a separate evaluation system for open education as in the case of MOOCs, which are ideal representations of ODDE because teaching and learning in MOOCs is very different from the conventional mode of instruction and even in an online course which is not open. The current practices in evaluating MOOCs for quality center on three aspects: learner; teaching; and the MOOC itself. For the learner, aspects of engagement, completion rate, satisfaction, peer interaction, learning outcomes and experience, and knowledge retention were the parameters being looked into. For the teaching aspect, the pedagogical practice of teaching in massive enrollment was given importance. And for the MOOC itself, comparison with other learning platforms, content and structure, implementation, and sustainability are considered as indicators of quality (Alturkistani et al., 2020). It should also be noted that the current evaluation methods for MOOCs consist of surveys, interviews (email and online focused group discussion), pretest/posttest, and the data gathered from the Learning Management System which can include attendance rate; completion of the different MOOCs components; quiz or assignment scores; learner activity; and discussion posts.

## The Mode of Instructional Delivery

Because of the nature of ODDE, the programs and courses can accommodate various types of learners and learning contexts. ODDE programs should be structured in such a way that it can accommodate and be responsive to the needs of various learners and as such implies the involvement of a multidisciplinary team to design the learning experience appropriate to these learners. The mode of instructional delivery highlighting separation between the teacher and the learners also assumes the exacerbation of the transactional distance (Hodges et al., 2020). This implies that course evaluation for quality should look at teaching strategies or instructional practices which are considered to be critical to learning like the instructional dialogue. Instructional dialogue is the interaction between the teacher and the students facilitated by the ICTs. The consideration for evaluation is whether opportunities for such dialogue are built into the design of the courses.

## The ICT Integration

ICT integration into the ODDE programs and courses is not simply “transferring face-to-face education materials on the virtual setting” (Tonbuloglu & Gürol, 2016). Enabling or enhancing the teaching and learning process through technology integration can result in different learning design strategies and possible increase in the variables and indicators which should be considered when evaluating for quality (Benigno & Trentin, 2000). As articulated by various authors, technology contributes to the enrichment of the learning environment as it facilitates interactivity and asynchronicity (Benigno & Trentin, 2000), encourages cognitive and psychosocial development (Kerr & Hiltz, 1982, as cited by Benigno & Trentin, 2000), and helps develop metacognitive skills and organized thinking process (Henri, 1992 as cited by Benigno & Trentin, 2000).

Designing learning for ODDE often considers the integration of the various types of interactions: learner-learner; learner-teacher; learner-content; and learner-community of practice which has been recognized to promote authentic learning. The asynchronous component of most online courses provides space as well as opportunity for the learner to digest course content and engage in self-reflections which can be building blocks of the learning process. The asynchronous online discussions also allow learners to consider and appreciate the diverse perspectives about the lesson, and organize the information gathered to build their own learnings.

## Recommendations for ODDE Program and Course Evaluation

Various authors forwarded some recommendations for effective program and course evaluation in ODDE.

Alturkistani et al. (2020) recommended the use of the design thinking approach for better quality and precision of data that will be gathered and at the same time

provide general guidance especially in terms of performance indicators which should be considered in the evaluation process. Burns (2018), on the other hand, suggested the adoption of the instructional design process which “begins with the end in mind” (p. 150) or a “backward mapping evaluation” (p. 254) and which consists of three steps or answering three questions: Who is the audience of the evaluation and for what purpose would the evaluation results be used? What do they want to know? How the information will be gathered or collected? (<https://elearningindustry.com/evaluating-your-online-learning-program-part-1>). The same design for evaluation was also suggested by the US Department of Education (2008), who aside from recommending both formative and summative program and course evaluations also recommended that the process should begin “with a clear vision for the evaluation” (p. 49) which determines the following: “what you want the evaluation to accomplish and what questions you hope to answer, the most appropriate evaluation methods for meeting your goals and the budget to meet evaluation needs.”

The recommendations on the process of evaluation include the shift from formal evaluation of learning to gauging the students’ participation in group and learning activities (Benigno & Trentin, 2000), peer evaluation (Stewart & Kogan, 2015), and for the process to be continuing instead of being “episodic” (University of Toronto Center for Teaching Support and Innovation, <https://teaching.utoronto.ca/teaching-support/curriculum-renewal/program-assessment/>).

In terms of evaluation data, the University of Toronto’s Center for Teaching Support and Innovation (<https://teaching.utoronto.ca/teaching-support/curriculum-renewal/program-assessment/>) recommended the inclusion of direct, indirect, and supportive evidence. Direct evidence, which can be the student artifacts from course work like exams, capstone projects, and portfolios, can provide information on what the students know and can do and as such implies the achievement of the learning outcomes. Perceptions of students, alumni, employers, and other stakeholders comprised the indirect evidence for inclusion in the program and course evaluation. One example cited in the University of Toronto material is asking alumni the extent to which the program that they had completed at the university prepared them for their current position. Note that answers to this question can provide information as to the continuing relevance of the program in addition to the perception of the alumni. The supportive evidence are aspects connected to student learning like graduation rates, job placements data, faculty-to-student ratio, and program promotional materials, among others.

The nine principles of good practice in ODDE by Stewart and Kogan (2015) can also provide some insights on what should be looked into in program and course evaluation. The nine principles are student-faculty contact, cooperation among students, active learning, prompt feedback, time on task, the communication of high expectations, respect for diverse talents and ways of learning, the establishment of (clear) course procedures, and the effective use of technology. Likewise, the evaluation questions forwarded by Burns (2018) can help in determining the data-gathering mechanisms which can ensure the technical soundness and rigor of the evaluation process. For instance, the “what” questions usually require

quantitative designs while the “how” and “why” questions which usually look at the process imply qualitative designs. Mixed method designs can also be considered depending on the type of data or question being asked as part of the evaluation process.

While the foregoing recommendations may present a comprehensive perspective for course and program evaluation, one can also look at the traditional role of education in terms of its contribution to national and global concerns like sustainable development and inclusion in education as other relevant components. Specifically on inclusive education, the higher level of modern ICT integration in ODDE may put this system of education to a better position to provide inclusive learning opportunities targeting the inclusion of nontraditional learners who cannot be part of the conventional education system. It should also be noted that the essence of our basic guiding principle in the ODDE system is inclusion, hence, the extent by which this purpose is achieved should be a major component of the evaluation framework.

---

## **Innovating on the Program and Course Evaluation: The Role of Technology**

The emerging trends in education which provide the scenario into the future of learning imply the need for an innovative approach to program and course evaluation especially in the ODDE system where such innovations may happen sooner compared to the conventional mode of instruction. These trends which include the digitization of textbooks, deployment of immersive technologies like the Virtual Reality into the teaching environment, more mobile learning practices (Gajura, 2020), and the move toward more digital learner-learner, learner-teacher, and learner-content interactions imply the need to consider the data that can be extracted from the virtual learning environment. Benigno and Trentin (2000) suggested the analysis of course messages in terms of number and content and the activity logs or records of the activities of the students which are automatically recorded in the virtual learning environment or Learning Management System. Other emerging trends, like microcredentialing which can be concretized through the offering of MOOCs, stackable credits or unbundling of the traditional degree programs, and AI-driven teaching and learning processes like e-tutoring and automated assessments, also require innovative perspectives on program and course evaluation vis-a-vis the needs and gaps that they are trying to address in the overall scheme of manpower and economic developments. Given that these trends are anchored on digital tools and platforms, a data analytics-driven process is a logical direction for program and course evaluation. It should be noted that the use of data analytics is already a common practice in business but is still at its infancy when it comes to higher education (Dziuban, Moskal, Cavanagh, & Watts, 2012). This potential, however, had already been

recognized by software developers who are now offering digital solutions for a fully automated course evaluation process, analysis of data, and distribution of results (<https://explorance.com/solutions/course-evaluations/>).

---

## Conclusion

The existing QA Frameworks for ODDE can provide a perspective on what should be considered when evaluating ODDE programs and courses. However, there are no standardized terms, parameters, and indicators as the different frameworks use different terms to refer to the same thing (e.g., program and curriculum) or use the same term (e.g., course) to refer to different aspects which can cover course design, course materials development, and course delivery. This may have resulted in the lack of a generally accepted understanding of quality when it comes to ODDE but, at the same time, points to the complexity of the evaluation process in this system of education. This further emphasizes the need for a standard program and course evaluation framework for ODDE as recognized and recommended by the various authors. The aspect of program openness and inclusion, which resulted in the diverse profile of the learners and which, in turn, impact on course design and delivery, was not given enough emphasis in the articulations of quality in the QA Frameworks studied.

While the existing QA Frameworks can serve as a very good starting point toward the development of the standardized program and course evaluation since they already provided an extensive articulation as to what should be the indicators of quality in this system of instruction, the emerging and projected trends in the higher education system like microcredentialing, stackable credits, the use of blockchain technology, and the likes will have an impact on the process, the data, and the indicators or parameters for program and course evaluation. Data which reflect the different teaching and learning processes and which are automatically captured in the virtual environments or digital platforms where such processes take place will definitely change the framework, and possibly the focus, of program and course evaluation in ODDE. This also implies the need to employ advanced research methodologies for ODDE institutions to be better prepared for new challenges emerged from the future learning environment.

**Abstract**

The lack of transparency of the quality of Open Educational Resources (OER) is often seen as a barrier to the wider adoption, use, sharing, and further development of OER in the practice of teaching and learning in ODDE. Following the UNESCO Recommendation on OER, this chapter starts providing an overview of quality assurance systems from an international perspective, and the perceptions of faculty members on OER quality. Then, based on an empirical study, a quality framework and validated instrument for the evaluation and quality assessment of OER is presented – the Instrument for Quality Assurance of OER (IQOER). The second part of the chapter looks at how such an instrument can be integrated into a quality assurance process that takes into account the different goals, roles, and functions of the stakeholders involved. It becomes clear that a cultural change toward Open Educational Practice (OEP) is also needed to reach a wider acceptance of OER.

**Introduction**

“Open” is *en vogue*. In the course of the general digital transformation and the digitalization of learning and teaching, the open education movement has developed dynamically in recent years (Kerres, 2019) – not only because of the recent Covid-19 pandemic and ad hoc shift toward online learning. However, the idea of “open education” goes back further and is linked in particular to the appearance of open education (“open learning”) in the 1960s to reach so-called nontraditional target groups. This has also been the *raison d’être* of Open Universities, which have always used media because distance learning and teaching are made possible by them in the first place (Tait, 2008; Xiao, 2018).

Open Educational Resources (OER) are a central element of open education practices (Zawacki-Richter et al., 2020). The term OER was mentioned for the first time in the UNESCO Declaration (2002), referring to “the open provision of educational resources, enabled by information and communication technologies, for consultation, use and adaptation by a community of users for non-commercial purposes” (p. 24). Around 2006/2007, a definition of OER was still being negotiated. In their report on the OER movement to the William and Flora Hewlett Foundation Atkins, Brown and Hammond (2007) provided a widely received definition:

OER are teaching, learning, and research resources that reside in the public domain or have been released under an intellectual property license that permits their free use or re-purposing by others. Open educational resources include full courses, course materials, modules, textbooks, streaming videos, tests, software, and any other tools, materials, or techniques used to support access to knowledge. (p. 4)

In the UNESCO (2019) Recommendation, OER is defined as “learning, teaching and research materials in any format and medium that reside in the public domain or are under the copyright that have been released under an open license, that permit no-cost access, re-use, re-purpose, adaptation and redistribution by others” (see Section I, No. 1). These definitions show the wide scope of OER. Jung, Sasaki, and Latchem (2016) speak in this context of the “granularity” of learning materials: “OER range from entire courses and massive open online courses to small-scale learning materials, games, simulations, quizzes and other digital resources” (p. 10). Essentially, OER are about making teaching and learning materials available for unrestricted use. Digital materials are particularly suitable for this because they can be copied, shared, and changed as often as desired, without loss and with virtually no spatial restrictions. In his blog, Wiley (2013) describes this openness of use with five Rs: the right to retain, reuse, revise, remix, and redistribute open content. Therefore, OER might have the potential to facilitate the development of collaborative and participatory learning arrangements (Otto, 2020).

The development and distribution of OER are seen as an important element in the UNESCO (2019) Recommendation toward open and inclusive knowledge societies and the achievement of the UN 2030 Agenda. The implementation of OER contributes especially to the achievement of the Sustainable Development Goal (SDG) 4, quality education. However, despite the many initiatives to develop and sustain OER materials and repositories, Jung et al. (2016) conclude that “the take-up of OER has fallen short of expectations” (p. 1). The reason for the low adoption rate is due to the potential users’ uncertainty over the quality and appropriateness of the content. The report of the Open Educational Quality Initiative (OPAL, 2011) already identified the “lack of quality or fitness of OER” (p. 8) as an important barrier to the use of OER. Since then, after a review of international approaches to the evaluation of learning materials, Zawacki-Richter and Mayerberger (2017) conclude that no quality assurance procedure or instrument has become widely accepted and used.

The UNESCO (2019) Recommendation on OER also refers to the importance of quality assurance. Member states are encouraged “to develop and integrate a quality assurance mechanism for OER into the existing quality assurance strategies for teaching and learning materials” (Areas of Action, ii Developing supportive policy) and consider “developing and adapting existing evidence-based standards, benchmarks and related criteria for the quality assurance of OER” (Areas of Action, iii Encouraging effective, inclusive and equitable access to quality OER). The great importance of quality assurance of OER is largely undisputed. For example, Camilleri, Ehlers, and Pawlowski (2014) state that “The need for quality assurance mechanisms to support the development and sustainable use of Open Educational Resources (OER) is being raised in the literature and in European and national policy documents as a major challenge and opportunity” (p. 6).

Therefore, the aim of this chapter is to explore potential quality dimensions of digital learning materials and to propose a model and an instrument for the evaluation and quality assessment of OER. We will begin with an overview of international approaches to quality assurance systems for OER in which such an instrument could be applied.

## An International Perspective on Quality Assurance Systems for OER

An international comparison between OER digital infrastructures in higher education was conducted within the German research project “Digital educational architectures – Open learning (educational) resources in disseminated learning infrastructures” (EduArc; <https://uol.de/coer/research-projects/projects/educarc>). This international comparison covered the macro (national and regional context), meso (institutional context), and micro levels (teaching and learning) across ten countries (Australia, Canada, China, Germany, Japan, South Africa, South Korea, Spain, Turkey, and the United States). One of the main issues addressed in this comparative case study was the quality of OER, especially referring to national standards for the creation, dissemination, and quality assurance of OER at the macro level (Marín et al., 2020). In the meso level, the aim was to observe the development of institutional measures for the creation, dissemination, and quality assurance of OER across countries (Marín et al., *under review*). Finally, the micro level addressed the level of awareness of faculty members with regard to institutional procedures related to OER quality assurance and to the responsible people of these procedures across countries (Marín et al., 2022). In this section, a synthesis of the three levels studied in the context of the EduArc project (higher education) is presented, along with some insights into other educational stages.

### National and Regional Guidelines and Actors

Marín et al. (2020) addressed the influence of country-specific contexts on the development of national standards for the creation, dissemination, and quality assurance of OER in higher education and provided an overview of the different countries involved in the case study. The authors showed through their description that the level of political structure centralization had some effects on the quality issue for OER and their repositories across countries, but not in a uniform way across all of them.

For instance, the case of China, with a highly centralized political structure, shows this influence on OER quality. The Ministry of Education issued Technical Specifications for Modern Distance Education Resources Construction in May 2000. As the authors highlight, “this non-mandatory standard focuses on the guidelines for resource developers, production requirements, and functions of the management system” (Marín et al., 2020, p. 250). In addition, the Chinese e-Learning Technology Standardization Committee has already developed several national and association standards related to educational digitalization, including the consideration of OER.

On the other hand, most of the countries investigated in the EduArc project did not experience a relevant impact connected to the political structure centralization. These other countries did not have any official national quality frameworks or standards linked concretely to OER. Overall, quality assurance of OER has been more connected to the meso level, to the higher education institutions (e.g., South Africa) or, even more often, to individual faculty members (e.g., Japan). What

can be highlighted at the national and regional levels is the existence of checklists or evaluation guides related to OER in some of the countries studied. This is the case in Spain, where a working group on institutional repositories (including OER repositories) within the Network of Spanish University Libraries (REBIUN) actively develops different documentation to evaluate the status of Spanish OER repositories and guide their evaluation. Also, the South Korean governmental organizations connected to the development of Korean Open Course Ware (KOCW) and K-MOOCs have developed different documents to, on one side, ensure a good quality of OER and provide best practices and, on the other side, to help guide KOCW and K-MOOC development. A third example is Australia, where different OER guidelines have been developed to assist higher education institutions in making informed decisions for OER adoption, for instance, the Feasibility Protocol (Bossu, Brown, & Bull, 2014a).

The actors involved in OER quality at this macro level depend on the country but usually include governments, agencies, librarians, and other working groups (Marín et al., 2020). Actors related to governments and agencies usually also cover other educational stages beyond higher education. For example, in China and South Korea, the main actors deeply involved in OER quality are public agencies. In contrast, in Spain, apart from the working group mentioned above for higher education, an association for standardization endorsed by the Spanish government has developed some standards for digital educational resources across educational stages through the Learning Object Metadata-LOM-ES and quality dimensions: technological effectiveness, effectiveness regarding accessibility, and pedagogical effectiveness (INTEF, red.es, & Spanish Autonomous Communities, 2010; Fernández-Pampillón Cesteros, 2017). On the other hand, the United States is a unique case, “since many digital education organisations are involved in defining quality for (O)ER, such as Quality Matters or the Online Learning Consortium, Educause, the Association for the Advancement of Computing in Education and the Association for Educational Communications and Technology” (Marín et al., 2020, p. 250).

## **Institutional Guidelines and Actors**

As regards quality assurance of OER at the institutional level, three different models could be distinguished (Marín et al., [under review](#), pp. 5–6):

- a) Institutional cases in countries with (binding) top-down institutional quality assurance mechanisms for OER, derived from national regulations (China, South Korea, and Turkey). For instance, all inter-institutional platforms in China have their quality assurance mechanisms that derive from rules and regulations of the Ministry of Education, which supervises the quality assurance of the “top-quality courses” projects. Similarly, South Korea follows a top-down approach, where the Center for Teaching and Learning of each university is responsible for ensuring OER quality at the institutional level and for following

national guidelines. Turkey also adopted a top-down approach: the top management of the higher education institutions is responsible for institutional OER quality assurance, according to national policies.

- b) Institutional cases with their own independent institutional guidelines for OER quality assurance mechanisms (Canada, Japan, Spain). For instance, University H's (anonymized large public university in Japan) Center for Open Education uses a set of key performance indicators related to well-established instructional design strategies for online courses for creating and implementing OCW and other OER. In Spain, higher education institutions supporting the development of OER have institutional quality assurance mechanisms and guides to support faculty in this endeavor (e.g., the Universidad Carlos III of Madrid).
- c) Institutional cases with basically no institutional OER quality assurance processes, which are left up to the individuals (Australia, Germany, South Africa; bottom-up approach). For example, in Australia, there are no quality assurance processes or frameworks related to OER in higher education institutions (Stagg et al., 2018); quality assurance of OER is mostly up to individual members of faculty (academic self-assurance). Similarly, South Africa has no institutional quality assurance processes for OER, and the responsibility also lies with the academic author, following the "pride-of-authorship" model (Hodgkinson-Williams et al., 2013). In Germany, quality assurance of OER in higher education most often does not rely on institutional guidelines; however, an exception is the province-based platform Hamburg Open Online University, which has quality assurance in place for offerings under its auspices (top-down approach).

## Faculty Perceptions About OER Quality Assurance for Teaching and Learning

Marín et al. (2022, pp. 11–12) explored academics' awareness and perceptions of quality of OER, and of the institutional quality assurance agents involved in OER, as well as the academics' involvement as quality assurance agents in OER at the teaching and learning level in seven countries (Australia, Canada, Germany, South Africa, South Korea, Spain, and Turkey). In many of the countries, the perceptions of quality of OER referred to a common prejudice against OER as being of low quality. This is especially the case in Turkey, where openness and OER-related concepts were linked to free sources with low quality. In South Africa, lecturers were concerned about using OER by authors whose reputations are in doubt or not yet established (Madiba, 2018). The poor quality of OER available and the concerns regarding the quality of content stored in OER repositories are common challenges related to faculty perceptions in the literature (Bates, Loddington, Manuel, & Oppenheim, 2007; Bossu, Brown, & Bull, 2014b; Mtebe & Raisamo, 2014).

A low awareness along with a lack of frameworks regarding the quality of OER and their infrastructures was highlighted in most of the countries of the study, in line with previous literature (e.g., Baas, Admiraal, & van den Berg, 2019). For instance,

in South Korea, the lack of mechanisms to ensure the quality of OCW is a challenge for the active adoption of OCW (Lee & Kim, 2015).

In terms of academics' awareness regarding agents responsible for OER quality assurance, the outlook is also rather bleak but provides some insights into common actors. For instance, in Spain and Germany, faculty awareness about this issue was low, but the influence of IT services for the institutional learning management system (LMS) was perceived by faculty members as relevant in Germany. In the universities of both countries, academic staff who used OER were the key actors in defining the quality of OER, of OER metadata, and of OER repositories. This faculty involvement and responsibility of OER quality was present in other countries too (e.g., Japan, Turkey). In other countries' institutions (e.g., at the Australian Queensland University of Technology), the library played a key role in OER development through an optional stage of Quality Assurance (QA; Stevens, Bradbury, & Hutley, 2017).

---

## Toward a Quality Model and an Assessment Instrument for OER

The results of the international comparison study described above imply that the perceived low or unclear quality might be a major barrier to the uptake and wide adoption of OER by teachers and faculty members. An abundance of learning materials is freely available on various platforms and repositories, but the selection of high-quality materials remains a challenge.

Against this background, during the development of the Hamburg Open Online University (HOOU, <https://www.houu.de>) portal, a study was commissioned to collect an international inventory of instruments and quality criteria for learning materials and OER and to develop a model and an instrument for quality assurance of OER. The model was informed by Almendro and Silveira (2018) who noted that the quality of OER has pedagogical, content, and technical dimensions.

### OER Quality Model

The first step in the research project for the HOOU was a search for evaluation instruments for the assessment of OER (Zawacki-Richter & Mayrberger, 2017). Eight different instruments or rubrics with 161 quality criteria were identified. Based on a qualitative analysis of the quality dimensions and criteria, a framework of OER quality was proposed by Mayrberger, Zawacki-Richter, and Müskens (2018) with two broad quality dimensions – the pedagogical and technical dimension, and four subdimensions, i.e., content, instructional design, accessibility, and usability, covering a set of 15 quality criteria (see Fig. 1). In contrast to Almendro and Silveira (2018), the content dimension was integrated into the pedagogical dimension on the same level with instructional design as both subdimensions depend on each other.

Table 1 provides an overview of the 15 quality criteria in the OER quality model.

**Fig. 1** OER quality model proposed by Mayrberger et al. (2018, p. 29)

**Table 1** Quality criteria in the OER quality model (Mayrberger et al., 2018)

Quality criteria	Description
Content/academic foundation	The contents are scientifically correct. The origin of models, methods, and approaches is referenced
Content/target group orientation	The target group for the material is clearly stated. All necessary prior knowledge or skills are made explicit. The material fully corresponds to the level indicated
Content/reusability of content	The contents are presented in such a generic way that they can be used in other contexts (e.g., in a similar module in another program) without much effort
Instructional design/alignment	The intended learning outcomes are made clear to the learners. The content, learning activities, tasks, and assessment presented are consistent with these learning outcomes. The assessment is suitable to measure the desired level of learning outcomes
Instructional design/collaboration and interaction	The material contains activities or assignments that systematically stimulate interaction and collaboration among learners. The learners work together as a team in a goal-oriented way
Instructional design/applicability	Learning activities or tasks prompt learners to transfer the learning content to new types of problem situations or their (professional) practice and to cope with authentic tasks and situations
Instructional design/student support	The material offers help and support, both for navigation through the learning content and for the learning content itself. Contact options are given for technical and content-related questions
Instructional design/assessment	Assessment consists of a variety of tasks or exercises that correspond to the intended learning outcomes. It records the level of competence at the beginning and at the end of the learning process and provides feedback to learners within the learning process on the level of knowledge they have achieved
Accessibility/CC-license	The learning material has been published under a license that allows anyone to access the learning material and to use, modify, and share it with others. The resource has been published under CC 0 (“Public Domain”) or a comparable license
Accessibility/accessibility for students with disabilities	A variety of measures have been taken to ensure that people with disabilities can also use the material as far as possible. The recommendations of the Web Content Accessibility Guidelines (WCAG) are consistently implemented
Accessibility/reliability and compatibility	The learning object runs technically robust and error-free on all specified devices and operating systems. The use does not require any additional software
Accessibility/technical reusability	The learning object can be used in different contexts and be integrated into other applications. This is supported by the use of international metadata standards and documentation
Usability/structure, navigation, and orientation	The structure is simple and clear. Learners can stop the learning sequence at any time. All learning content (previously presented) can be accessed at any time

(continued)

**Table 1** (continued)

Quality criteria	Description
Usability/design and readability	The learning material has a consistent design appropriate to the content. All texts and graphics are easy to read. The interface always responds quickly to learner input
Usability/interactivity	The material contains interactive elements that can be used by the learners to independently perform constructive or manipulative actions. The design possibilities of the learners go beyond pure data input

## The Instrument for Quality Assurance of OER (IQOER)

The study by Zawacki-Richter and Mayrberger (2017) showed that existing OER quality assessment instruments differ in complexity and depth of detail. Little is known about the reliability and validity of the instruments. Some instruments are based on a quality model with several quality dimensions to which a number of quality criteria are assigned; others consist only of lists of criteria. Some instruments involve a detailed scoring guide for the operationalization of the rating scales (e.g., the LORI instrument by Nesbit, Belfer, & Leacock, 2007), while others consist of simple checklists (see also Yuan & Recker, 2015). It is also worth mentioning the Learning Evaluation Object Platform (LOEP), developed as an integrated platform for learning object evaluation, which facilitates the collaborative evaluation of educational resources (Gordillo, Barra, & Quemada, 2015).

Responding to this need of a validated and reliable quality assessment instrument for OER, such an instrument was developed in the EducArc project (see above) based on the OER quality model by Mayrberger et al. (2018), namely, the Instrument for Quality Assurance of OER (IQOER). The IQOER has two versions: a shorter one using classification scales and a longer version using mean scales based on individual items.

For the short version, a five-level classification scale was operationalized for each of the 15 quality criteria. Table 2 shows the rating scale for “academic foundation” of OER content. The classification scale allows the ranking on one of five levels, which are marked with colors from red (lowest level) to dark green (highest level). The red, light green, and dark green levels of the rating scales are all described by several statements (descriptors). The intermediate second and fourth levels are not described, so it is up to the raters to interpolate the content of these levels from the other levels.

The assessment of quality criteria using this kind of classification scale is associated with two problems from the point of view of measurement theory. First, if a characteristic is only determined using a single rating, split-half reliability or internal consistency cannot be determined because there is no other measure to correlate with. Secondly, and more importantly, a classification scale forces a joint evaluation of possibly incompatible statements. Each classification scale (Table 2) consists of several statements that do not necessarily have to be equally true for a

**Table 2** Classification scale “academic foundation” of OER content

	The contents are presented in a scientifically correct and balanced manner. Bibliographic literature sources that meet the standards of the discipline are cited throughout. The reasoning is coherent (5)
	(4)
	The contents are scientifically correct and relevant. The origins of models, methods, and approaches are mostly named (3)
	(2)
	The contents contradict the current state of research in the respective discipline or focus unilaterally on certain providers, products, or models. The underlying methods or approaches are either not presented at all or presented without reference (1)

particular learning material. For example, a material may well have cited bibliographic sources, but the reasoning within the resource may not be coherent. In such a case, the rater in the example from Table 2 is faced with the difficulty of deciding whether the dark green alternative is true. Ultimately, the rater is forced to weigh the different statements arbitrarily and make a rating accordingly.

An alternative to classification scales is to average across scores from different individual items. Such items consist of a single statement for which the rater expresses agreement or disagreement on a multipoint Likert scale. Such ratings using Likert scales require raters to make only simple judgments of clear statements about an OER. The long version of the IQOER consists of mean scales, each aggregating five to six individual items. Table 3 shows the scale “academic foundation” of the long version of the IQOERs. In this case, the scale is formed by the mean of the item ratings. The alternative “does not apply at all” is coded as 1 and “fully applies” as 5, and the alternatives in between are coded as 2–4. Items with opposing content (e.g., item 2 in Table 3) are recoded.

However, the best and most robust quality assessment instrument will not lead to higher acceptance and wider dissemination of OER if it is not integrated into a systematic quality assurance process. These aspects are addressed in the following section.

---

## Implementing a Process of Quality Assurance for OER

A functioning quality assurance requires not only quality models and instruments for quality assessment but also the development of a quality assurance process. For example the UNESCO and Commonwealth of Learning (2011) demand: “Recognize the important role of educational resources within internal quality assurance

**Table 3** “Academic foundation” scale using individual items based on Mayrberger et al. (2018, p. 35)

#	Item	1	2	3	4	5
1	The OER contains references to subject-specific literature or research findings					
2	The content of the material focuses unilaterally on specific providers, products, or models					
3	The content is up-to-date, accurate, and relevant					
4	The reasoning in the material is coherent and comprehensible					
5	The presentation of the content is precise					

1 = does not apply at all, 2 = rather does not apply, 3 = applies somewhat, 4 = largely applies, 5 = fully applies

processes. This should include establishing and maintaining a rigorous internal process for validating the quality of educational materials prior to their publication as OER” (p. 7).

However, authors and providers of OER platforms face the challenge in how quality assurance can be designed within the process of developing OER. Even if a comprehensive quality assurance model including corresponding scales is available, the following questions arise regarding the workflow of quality assurance:

- At what point in the process of creating or using an OER should the quality assessment take place? (Time)
- What is the purpose of the quality assessment? (Objective)
- Who assesses the resources by means of the criteria or scales? (Rater)
- In what way do the quality assurance institution and the authors/developers of the OER work together? (Degree of interaction)

Approaches to quality assurance of conventional, non-free learning materials (e.g., textbooks) cannot always be easily transferred to OER. In this context, Camilleri et al. (2014) explain the differences between the quality assurance of OER and that of non-OER due to the life cycle of OERs, which also includes the possibilities of reuse and adaptation:

...the traditional lifecycle of a resource, particularly with respect to the processes of creation, editing, evaluation and use, is significantly disrupted. Whereas before these steps were traditionally distinct, consecutive and managed by various actors, the freedom granted by OER leads to a blurring of these boundaries. The involvement of many more actors in each step, therefore, means a federation of responsibility for each step, which in turn can lead to cross-over in the functions and timing of processes, as well as sub-cycles (such as several rounds of editing and evaluation). (p. 4)

## Aim of Quality Assessment

While anglophone OER platforms such as MERLOT ([www.merlot.org](http://www.merlot.org)) already contain thousands of resources, the stock of OER in other languages that are suitable

for higher education usage is currently still very limited. From the perspective of many providers of recently established OER platforms, the aim of quality assessment is therefore to support authors and developers in the creation of OER rather than to make selections of submitted resources.

A quality assessment by users after publication of the resource often helps to inform potential users. In such a crowd rating, the published OER can be continuously rated by users by means of scales. The averaged results of the ratings are constantly updated and presented. In summary, three essential goals of quality assessment can be outlined by means of standards, criteria, and scales: to support the creation and development of the resource, to select the resources or to check minimum standards, and to inform the users.

### Time of Quality Assessment

The quality assessment can occur at various moments within the following 11-step process of the OER “life-cycle” described by Camilleri et al. (2014).

1. Creation of the resource by an author/creator
2. Description of the resource by means of metadata
3. Approval by the commissioning body of the resource
4. Publication of the resource, making it available to the wider public
5. Discovery, the process by which a user finds the published resource
6. Evaluation or checking of the fitness for purpose of the discovered resource
7. Resolution, where a handle is used as a precursor to obtaining it
8. Obtaining the resource usually by downloading it or streaming
9. Re-purpose and re-use: the resource may be edited and/or changed by the tutor using the resource
10. Integration, which describes the process of including it into a larger learning experience (such as a course), or as part of a technical tool such as a virtual learning environment
11. Use, which describes the actual utilization of the resource to enable a learning experience by the end user/student (p. 15)

Quality assessment by means of criteria, standards, or scales can take place at various points within this process:

- Content-related criteria can be applied even before the resource is created, for example, when concepts are evaluated by experts within the scope of project funding.
- During the development process, the standards and criteria can support the authors and developers in aligning their work with the development goals. Formative evaluation can be used to check the level of progress achieved and to define work steps that still need to be done.
- Immediately before publication, a peer review process can ensure the quality of the content of the resource. Instructional designers and technical experts can check compliance with minimum standards.

- After publication in repositories, the resources can be assessed by users toward the standards, criteria, or scales. A distinction should be made between evaluation by lecturers as indirect users and by learners as end users.

## Raters

Depending on the aim and time of the quality assessment, different groups of people can be considered as raters (i.e., for carrying out the assessment):

- The authors or creators themselves can use standards, criteria, or scales during the development of the OER to identify remaining work steps (self-evaluation).
- In a summative evaluation, subject matter experts can assess the content quality of the resources in a peer review (cf. UNESCO and Commonwealth of Learning, 2011). The assessment can be done either before publication on a platform or with regard to a concept outline before the development starts.
- Specialists from the fields of instructional design or technology can check compliance with minimum technical or pedagogical standards before publishing an OER. However, the development can also be monitored and supported by a formative evaluation regarding these standards.
- An evaluation by users usually takes place after publication of the resource. The use of more subjective rating scales (e.g., how motivating or interesting the resource is perceived) can provide other users with usage information that goes beyond objective assessment standards. Camilleri et al. (2014) call this form of evaluation by users “social ranking” (p. 24).

## Level of Interaction

There are usually two parties involved in an OER quality assessment: the institution that initiates the quality assessment (QA agency, often the provider of an OER portal) and those who create or develop the resource. The level of interaction between these two parties can vary greatly.

- Level 0: No interaction: The QA agency assesses OER without knowledge of the authors or creators or does not provide information on the standards, criteria, or scales used.
- Level 1: Information: The QA agency provides information about the criteria, standards, or scales without concrete advice on how to achieve these criteria.
- Level 2: Instruction: The QA facility gives concrete instructions on how to achieve the criteria/standards or how to optimize the quality of the resources. The instructions are of a general nature, so they can be applied to a wide range of resources.

- Level 3: Counselling: The QA organization provides individual counselling to the authors or creators before and/or during the creation of the resource on appropriate ways and activities to optimize the quality of the resource.
- Level 4: Cooperation: The QA agency provides templates, tools, etc. that facilitate the creation of quality-assured resources or is actively involved in the technical development of the resource itself.

Standards, criteria, or scales are used for all different levels of interaction. While these are only used as an assessment tool in the “no interaction” and “information” scenarios, they form the basis for the “instruction” and “counselling” scenarios. In the “cooperation” scenario, the quality assurance agency develops templates and tools itself based on the standards, criteria, and scales, which are used in the creation of the resources.

## OER and OEP

For educational institutions, the use of OER is often only one element on their way to adopting Open Educational Practices (OEP), and an open learning architecture (cf. Camilleri et al., 2014). Ehlers (2011) describes OEP as the following process: “[Using OEP] builds on OER and moves on to the development of concepts of how OER can be used, reused, shared, and adapted [, and] goes beyond access into open learning architectures, and seeks ways to use OER to transform learning” (p. 3). Tillinghast (2020), who speaks of “OER-enabled pedagogy” (p. 168), describes the example of a teacher who creates a chapter of an OER textbook for a course that she thinks is missing. Another example would be the creation of OERs by the learners themselves.

In OEP, in addition to the quality of OER, the quality of the courses in which OER are used, or the quality of the open learning architecture as a whole, moves into focus. Here, quality assurance focuses more on the OEPs and less on the OERs used. Thus, Brückner (2018, p. 60) calls for an “alternative perspective on quality of OER.” She advocates for an enhanced understanding of quality that also takes special features of OERs such as their free accessibility and changeability into account. An essential aspect here is to involve the stakeholders involved in quality assurance at every stage of the development process and use of OERs.

## Quality Standards and Quality Culture

In summary, the use of standards, criteria, and scales to capture the quality of OERs is by no means a one-time measurement of quality. Rather, standards, criteria, and scales represent the starting points for a complex development and revision process involving different actors and stakeholders. In this process, the quality-assuring agency is often not an independent observer but rather an active co-creator of quality. Also, the

selection of resources fulfilling minimum standards is often not in the foreground of this process but rather the active accompaniment and support of the development of OER and the achievement of the highest possible quality under the given conditions.

Eventually, the aim of such a quality assurance process is to establish a “quality culture” (UNESCO and Commonwealth of Learning, 2011) for teaching and learning with OER.

---

## Conclusion

OER can promote wider access to and collaboration on educational materials and thus contribute to the UN Agenda for Quality Education (SDG 4). However, it should be noted that worldwide dissemination and application in the practice of teaching and learning is still limited, even though there are many countrywide initiatives to support the creation of OER and build corresponding infrastructures. These depend strongly on the nature of the respective education system.

The low usage rate of OER is often linked to the question of quality. There is an unmanageable variety of OER materials and repositories, so that teachers are confused when choosing materials. Interestingly, there has been no widely used instrument for evaluating OER that has been systematically developed and meets scientific quality criteria. This was the starting point for the IQOER instrument described here.

However, the mere existence of such an instrument is not enough. It must be integrated into a quality assurance process agreed with all stakeholders. When implementing a quality assessment instrument in a quality assurance system, the process must be designed and communicated in such a way that it meets with the greatest possible acceptance on the part of the teachers and faculty members.

Finally, the culture of teaching and learning must change toward an Open Educational Practice in which it becomes a matter of course that high-quality learning materials are created, shared, and further developed together. Only then can we expect OER to be widely disseminated, even beyond the Anglo-American sphere. This would be very desirable, because the need for free learning materials is great in many countries. Especially during the Covid-19 pandemic, many teachers created digital learning materials with great effort in so-called emergency remote teaching and in the period thereafter. It would be a pity if these materials would not be shared and developed further in the future.

## Abstract

The recognition of prior learning (RPL) can, and does, play an important role in the accreditation of higher institutional learning, thereby benefitting students, employers, and society. Using rigorous tools that permit learners to bring forward for assessment their experiential learning from various life experiences, RPL can contribute to a fuller and equally valid expression of learners' knowledge than does traditional assessment. Additionally, RPL contributes to mitigating issues of equity, diversity, and inclusion in education by acknowledging and valuing a variety of learning opportunities. RPL also raises difficult epistemological issues

and the question of knowledge ownership, thus making it a contentious and challenging academic concern. This chapter reviews the process and pedagogy of RPL practice within the evolving context of accreditation, both at present and in the future, a future which includes innovations such as open educational practice, MOOCs, and micro-credentialling, all of which create opportunities for traditional modes of accreditation and assessment to re-examine their purpose and process.

## Introduction

The hallmark of formal higher education is accreditation. Learners seek, via accreditation, acknowledgment of the learning that they have acquired from their institutions, be it the acquisition of degrees – post-graduate, graduate, or undergraduate – or perhaps a diploma requiring 2 or 3 years of study. Accreditation is an important – the most important? – goal for most higher education learners.

Accreditation of an institution, however, is equally important, involving many stakeholders. Students seek a viable institution with proven quality and a proven history; the labor market seeks assurance that graduates are appropriately knowledgeable, skilled, or certified. National and international agencies manage institutional accreditation processes in order to ensure and assess institutional quality in all its aspects: research, teaching, programs, assessment protocols, accountability.

Nevertheless, all accreditation is fraught with difficulties. Carey, from New America Foundation, says that “No one really likes accreditation but no one knows what else to do” (uPlanner, 2016). In determining “what to do,” in matters of accreditation, institutions face many challenges, both internal and external. This chapter examines the relationship between the accreditation of students’ learning and the process of recognizing prior learning (RPL) – a process internal to the institution. In so doing, this chapter discusses the underlying foundational principles of RPL, thereby establishing its educational philosophical ballast, and further topics of related concern: society, hegemony, epistemology, pedagogy, and the future. It will describe its process; it will outline RPL’s current role in higher education; and it will offer strategies to further engage institutions and learners in a valuable process that can expedite their studies, allow them to move more quickly and efficiently into the workplace, or to advance appropriately in their current positions. As the president of Capella University recently stated: “Improving the effectiveness of practices such as [RPL] is one way that institutions can reduce barriers to access and affordability and offer educational experiences that are tightly coupled with the needs of the students we serve” (Kelly, 2021). An academically rigorous RPL assessment process contributes to a sound accreditation process.

## The Recognition of Prior Learning

The Recognition of Prior Learning (RPL), also called Prior Learning Assessment and Recognition (PLAR), among other labels, is a practice in higher education whereby learners' previous and existing knowledge and skills are assessed by an institution's content experts. Credit is then granted (or not) toward the learner's program of study. This chapter uses the acronym RPL to appeal to the largest global readership.

RPL is not a new process; it rests philosophically not only on the work of John Dewey (1938) who proclaimed that the "beginning of instruction shall be made with the experience learners already have . . . this experience and the capacities that have been developed during its course provide the starting point for all further learning" (p. 74) but harks back to Aristotle and, more recently, to noted educators Knowles (1970), Vygotsky (1978), Kolb (1984), and Brookfield (1986).

Given its objective to facilitate faster and more accessible credentialization for deserving learners, what process could be more relevant today in the "age of open," an era now, in the twenty-first century, that promises and celebrates the lowering and abolishment of many of the barriers that have traditionally stood in the way of learners for decades? Even more dramatically and specifically, what could be more helpful now at the time of a global pandemic – and those that are projected to follow – than a path to higher education with fewer barriers and constraints?

### RPL: What It Is, What It Is Not

Speaking broadly, the recognition of prior learning offers a "process-oriented approach for recognising and valuing what people have learned in their lives and linking that – through personalised lifelong learning – to further development steps" (Duvekot, 2014, p. 65). *Personalized lifelong learning* refers to, or includes, the recognition of prior learning, which permits learners to bring forth for assessment their *own* learning journeys and the results of that learning, whether it be formal or informal and experiential (whereas RPL generally attends to informal learning that learners have acquired experientially, formal learning is also often considered in the RPL process if that formal learning has not already been credited to the learner's transcript in the credit transfer process).

Defining what RPL is *not* offering a narrower path to defining what it is. The RPL process is not credit transfer nor credit equivalency. However, some institutions' categorization of RPL lump it into the classification of transfer, along with advanced standing and block transfer, thus further confusing the issue (see, for example, Sheridan College in Canada).

**Credit transfer (CT).** On many occasions and in many institutions, RPL is often confused with credit transfer (CT). Credit transfer offers learners another portal to advanced standing via the transfer process where credits earned formally at a previously attended formal institution are assessed for value by the host/receiving institution and subsequently awarded to learners following their successful application for transfer. "It is important for reasons of social equity and educational

effectiveness for all institutions to develop reasonable and definitive policies and procedures for acceptance of such learning experiences” (Distance Education Accrediting Commission [DEAC], 2021). As such, most institutions have developed, in cooperation with other similar institutions, such agreements.

The evaluation of already-recognized credits – or a completed credential – from a recognized institution to another institution is quite different from RPL, where it is the learner’s experiential, nonformal, or informal learning that is assessed. In considering the effects of the Covid-19 pandemic on higher education, a recent article by Commonwealth of Learning personnel presented transfer credit as part of a “new model for a new normal” (Kanwar & Carr, 2020), a model that focuses on accessibility and mobility, thus permitting learners additional flexibility as they work toward a credential. While it is true that increased credit transfer processes will indeed serve learners, so too would the increased use of RPL. Transfer credit recognizes formalized learning; RPL recognizes nonformalized learning.

**Credit equivalency (EQ).** Some institutions (see, for example, Recognition of Prior Learning Service at NBCC in Canada) equate life experience and life’s experiential learning (volunteering, military service, workshops, seminars, training, self-directed study, faith study) to the outcomes or competencies required in a formal course, unit, or module. In these cases, documents are submitted to indicate the scope of learning and the “match” of the applicant’s experiential learning with the institution’s offering. The defining difference between EQ and RPL is the dependence on the externally evidenced fit of one to the other. EQ requires little of the applicant but to fill in the logistical details of his or her experience. “Samples of work . . . which demonstrate specified learning, such as portfolios, product, models, written reports, visual presentations, published articles, or project plans” (NBCC, 2021) are accepted as evidence of learning; whereas in a rigorous RPL process, these items only serve as documentation.

In sum, credit transfer and credit equivalency can be fairly straightforward, following a close vetting of course curriculum and the acceptance of stated curricular levels, intended outcomes or objectives, and assessment protocols; RPL is usually, and *should be*, a more detailed and personalized demonstration and examination of an individual’s learning in a clear fashion as demanded by the receiving institution. The components of such a process are outlined below.

While RPL-offering institutions will each have their own process, there are several important foundational concepts that form the basis of those processes. Following are those concepts as presented by the Open University of the Netherlands (EUCEN, n.d.): the process must be learner-centered; clear guidance and instruction must be provided to learners; learners must provide evidence of their learning; evidence of learning must be supported by documentation; and RPL credit awarded must be of equal value to the similar credit earned through program study.

---

## The Philosophy and Practice of RPL

Issues around knowledge are key to the understanding and implementation of RPL practice. Although scholars approach the understanding of knowledge from various perspectives, a key question problematizes the central issue: how do experiential and

academic learning articulate with each other (Osman, Shalem, Castle, & Attwood (2000, p. 12)? Discussion around this issue raises the question of knowledge boundaries: What are they? Are different forms of knowledge separated by *soft boundaries* that permit the transfer of knowledge across contexts or *hard boundaries*, where informal learning may produce a different knowledge than that acquired in a formal context (Harris, 2006)?

Harris (2006), citing Bernstein (1999), raises another fundamental epistemological issue, that of vertical or horizontal discourses and their associated knowledge structures which impact ways of learning, curricular context, and the suitability of RPL assessment protocols (see Harris (2006) and Bernstein (1999)). While a full discussion on the manifestations of philosophical differences regarding knowledge is outside the scope of this chapter, despite these differences, however, a process has emerged as a viable approach to determining the validity and usefulness of prior knowledge in formal institutions' credentialing protocols where RPL applicants are required to align their prior knowledge to institutional requirements that are usually expressed in course/module/unit or program outcomes.

The varying and often discordant discourses attempting to define RPL protocols indicate that, as with any and all facets of higher education, recognizing prior learning is a philosophically based and often contested academic process. As such, learning must be positioned at the heart of RPL. Citing Kolb (1984) and Boud, Keogh, and Walker (1985), Shalem and Steinberg (2006) hold that "Much current research and policy of RPL is premised on the notion that 'experiential learning' . . . that is, learning from experience, can be made equivalent to a disciplined academic way of learning" (p. 98). While the pedagogical complexity of such a process is not disputed, three pillars of RPL are widely recognized as essential factors in an academically rigorous process: clear learning outcomes that serve as a blueprint for learners' guidance, the creation of a portfolio that serves as the vessel for the presentation of learners' knowledge, and qualified assessors who serve as evaluators of learners' work.

#### **Learning outcomes, providing direction and guidelines for RPL applicants.**

How do learners identify, construct, and display their experiential knowledge? Ironically, as Michelson (2006) points out, while purporting to honor the individual learning of each applicant, most RPL processes ask learners to conform to "universalised academic norms" (p. 148) that meet institutional standards, thereby articulating their knowledge in recognizable academic language. To do so, applicants must be mentored or coached in that language, assistance that is usually offered by RPL personnel. Even with such help, framing their knowledge in the appropriate lexicon is challenging for learners.

**The learning portfolio, providing a vehicle for presentation.** The RPL portfolio is a learning portfolio rather than a performance or showcase portfolio; as such, its task is to provide the vehicle for learners to clearly demonstrate their experiential knowledge in the format adopted by the institution. Developing an RPL portfolio comprises both product and process: in today's world, the product is usually an electronic portfolio mounted on a platform such as Mahara; the process is one of deep thinking and reflection of one's learning, situated in the institution's academic context of outcomes and language.

The portfolio is a daunting document that is often criticized for constraining learners' perceived experiential learning. Realistically, however, in this sense, portfolios do not differ from any assessment instrument used in education. Critical thought recognizes that *all* assessment is flawed in some ways and to some degree (Conrad & Openo, 2018). All assessment privileges one audience over another. All assessment depends on someone's epistemological stance.

However imperfect assessment processes are, they remain integral to higher education. In the case of portfolio assessment, compared, for example, to examinations, candidates are given the opportunity to build on and develop their understanding of their own relevant knowledge, usually with the assistance of mentors or coaches. The portfolio development process involves several stages of reflective inquiry by learners to identify the acquired experiential knowledge from any number of locales or sources, formal or informal – work environments, past informal or non-credentialed study, volunteer work, faith life, domestic experience. RPL tools exist for this preliminary step of the process (Sansregret, 1993). That recalled knowledge is then situated – one could say massaged – to align with institution-provided learning goals or outcomes.

Criticism notwithstanding, the reflection required for this step of RPL is praised by successful RPL candidates who are exposed to and educated in this skill often for the first time. The discovery by learners of their tacit, hidden, or unidentified learning from past experiences is rewarding and creates a new – and triumphant – sense of self-esteem which is considered by RPL practitioners to be one of the most important aspects of the process, both for learners and for those who assist learners through the process. Assessors, too, often comment on the visible evidence of meaningful reflection present in portfolios. A short, autobiographical piece of writing usually required in the portfolio provides the opportunity for learners to reflectively position their learning within their life stories.

A final task for portfolio applicants requires the inclusion of documentation attesting to the experiences that they have named as knowledge sources. Such documentation can take many forms including letters from those who are or have been in positions of observation or evaluation of the learners' performance in whatever venue. Locating such documentation, while often tedious and laborious for learners, is regarded as a checks-and-balance mechanism to assure authenticity and rigor. That said, the heart of the portfolio remains the learners' expression of knowledge, with documentation serving a supporting role.

**Assessors, providing quality and informed evaluation.** If learners' learning comprises the heart of the RPL portfolio, then those who assess learners' work provide the lifeblood that feeds the process. As qualified and engaged teachers are deemed to be the appropriate assessors of students' work in higher education institutions, so too are RPL assessors tasked with that moral and academic authority. That said, the selection and training of assessors is a critical aspect of the process. Assessors must be intimately familiar with the intended outcomes of the program, module, or course with which they are RPL-associated. However, more than that, they must appreciate the spirit of prior learning assessment. They must accept the notion that not all valid knowledge comes from textbooks. Not all knowledge can be

broken up neatly into a course or module-sized box. As Michelson (2006) explains, if all knowledge is:

...situated knowledge, then similarity to academic knowledge cannot be the sole criterion for assessment; there will be times at which a path of inquiry with compelling explanatory power will lead to knowledge that is not congruent with academic forms of truth. (p. 156)

This discussion leads directly back to issues of power and politics within academia: Whose knowledge counts? Whose knowledge should be credentialled? This foundational discussion cannot be avoided and likely will not ever be satisfactorily or quietly resolved. However, as Michelson (2006) concludes, “by substituting dialogue and mutual recognition for what was unidirectional judgment, we destabilise the basis on which validation is given and invite a sharing of epistemological authority” (p. 157) – whether welcomed within the institution or not.

---

## RPL Benefits Learners

Ample evidence from the field indicates that recognizing prior learning serves students well. Becky Klein-Collins, Vice-President of the US-based Council for Adult and Experiential Learning (CAEL), reported these statistics in a Lumina-hosted session:

- The average number of PLA credits earned by students is 15.
- Cost savings for adult students range from \$1,500 to \$10,200.
- Time savings for adult students’ completions with PLA credits range from nine to 14 months.
- “Tipping point” analysis for PLA completers’ data indicate that adult students see increased effects with 15 or more PLA credits. (2020)

The benefits of RPL to learners’ higher education experience and progress are many. Successful RPL completers will achieve their educational goals more quickly, save tuition costs by earning RPL credits toward their program of study, benefit from an individualized RPL process that allows them to tailor their program of study around their prior experience, benefit from cognitive development resulting from rigorous RPL demands, experience personal growth from reflective activities contained with RPL processes, recognize the integration of their prior (and present) learning with past experience, and experience increased self-esteem and confidence following the formal recognition of their prior learning.

---

## Institutional Infrastructure and Process for RPL

A major stumbling block for many institutions that express an interest in implementing an RPL process is the institutionally complex nature of the task. Unlike many higher educational processes which operate within programs or units

or faculties – for example, an arts faculty or a science faculty, where most day-to-day decisions can be made by the top-ranked administrator – the RPL process must span the entire institution; it must encompass, equitably, all programs. In fairness, it must offer the same opportunities to all learners.

In some cases, institutions will initiate an RPL in one program area as a pilot study in order to determine the efficacy of their process before expanding that process to the institution at large. The Open University of the Netherlands, as an aid to the implementation process, has developed a task chart that outlines the various responsibilities and actions that comprise an RPL process. In it, they categorize task, its implications, and, importantly, *wider* institutional implications (EUCEN, n.d.)

To best successfully position the RPL process within an institution, the creation of an independent unit or center is advised (Conrad, 2008). This center should stand alone, detached from academic units, in order that its decisions can be perceived to be fair and not influenced by faculty or program personnel. Ideally, this independent center or unit will be led by an experienced academic who is knowledgeable in epistemology and assessment. Because the RPL process will span the institution, the RPL champion – for the RPL leader *must* be a champion for the process, given the probable pushback and/or misunderstanding of the process by colleagues within the institution (Osman, 2006; Van Kleef, 2014) – will require skills in communication as well as a broad knowledge of institutional academic structure and requirements. An RPL leader should be invited to engage in pan-institutional meetings, both academic and administrative, to initiate, present, explain, and even defend RPL processes as they pertain to learners' engagement with the process and the integration of their RPL-earned credit into their academic status.

Although the establishment of such a unit or center is key to RPL success within an institution, such hubs have historically not been perceived as necessary or fiscally possible by institutional administrators. In an ideal situation, RPL personnel will minister to the needs of learners both academically, via an assessment process, and administratively, in collaboration with administrative personnel. However, in many cases, RPL practitioners find themselves working alone, shouldering not only the responsibility for many learners' academic assessment but also the subsequent administrative tasks.

---

## **New Patterns of Accreditation of Students' Learning**

The prior discussion of RPL rests within – and takes its function and importance from – the larger discussion of accrediting students' learning. To that end, prior learning and recognition advocates have long recognized that the learning obtained by students enrolled in higher education programs of study forms only a partial representation of an individual's acquired knowledge. Accordingly, RPL processes have provided pathways for learners to bring forward and capitalize on their prior or experiential learning.

However, as outlined earlier, these pathways have not been without hurdles and bumps. Also, with a nod to technology and education's current advances in media, Pittinsky declared in 2015 that higher education "must find ways to credential better – with more information and in more accessible ways – using the transformative technology we now have available." Pittinsky unapologetically acknowledged that our society – he referred specifically to the United States – is a credentialing society and that higher education institutions are the "gatekeepers of many of those credentials" (2015).

The societal and economic push for credentials is not germane to this discussion save to say that they exist, have always existed in the modern world, and will no doubt continue to exist. However, Pittinsky (2015) raises the issues of access and scalable logistics to question the reasonableness of current credentialing protocols. He suggests that there are innovative trends that can contribute to better meeting societal and labor market needs and expectations of higher education graduates. Of interest to this RPL-centered discussion are open education, massive open online courses (MOOCs), and micro-credentialing.

As Pittinsky points out, innovative processes have been developed to meet evolving societal needs. The broadest category of innovation, open education is, as leading scholar Laura Czerniewicz (2020) points out, neither a simple nor single-faceted concept. However, attempts to open education have proliferated around the world, at all levels of education, contesting traditional views of access, equity, and diversity (Conrad & Prinsloo, 2020). MOOCs, a type of openness, implemented in 2008, provide opportunities for access to higher learning *en masse* with some provision for accreditation. Currently, however, micro-credentialing offers perhaps the most concrete innovation toward accreditation for learners at many levels, including higher education.

It should be noted that innovation and variations in the credentialing of students' learning directly affects the long-regarded bibles of student achievement – the transcript. That logistical discussion is not a part of this chapter.

## Micro-credentialing in Higher Education

Micro-credentialing is defined as a "representation of learning, awarded for completion of a short program that is focused on a discrete set of competencies (i.e., skills, knowledge, attributes), and is sometimes related to other credentials" (HEQCO, n.d.). The recent move to micro-credentials is closely linked to workplace recovery plans that will necessarily follow the Covid-19 pandemic which has affected global systems from 2019 into the foreseeable future (Marcus, 2020). The pandemic has shifted priorities and protocols, in education as well as in most other major societal-life areas. Educational research on the effects and outcomes of the changes wrought in education has resulted in new data on related topics that examine not only the effects of the "pivot" to what has been termed *emergency remote learning* but also on prospective and future avenues to credentialing and student success. Educators continue to look to the future of higher education to determine the long-term effects of Covid's enormous impact on educational systems.

Among other studies, Marcus (2020) reports that “stackable” bachelor’s programs in the U.S.A – those that permit the accumulation of degree credits via a series of short courses – at Western Governors University has doubled in size during Covid-19. Similarly, MIT and Harvard’s online provider, edX, has experienced a 14-fold rise in enrollment during approximately the same timeframe. The University System of Georgia has initiated a “nexus degree” which comprises certifications that add up to associate degrees initially and then bachelor’s degrees.

In the UK, the Open University has partnered with FutureLearn to offer a range of micro-credentials as have the University of Glasgow and Coventry University, among others. In Europe, the challenges and opportunities for micro-credentials in higher education were addressed in a report coordinated by Italy and Germany that included participants from Finland and the European Distance Education Network (EDEN). The report noted that students approved of micro-credentials, and the demand for such learning was acknowledged, but “certification is perceived as optional” (Uggeri & Hudak, 2019, p. 37). In conclusion, the report recognized the need and potential usefulness of micro-credentials but noted bureaucratic concerns around the development of such and of a related “digital passport for education” (p. 37).

The American National Student Clearinghouse Research Center that tracks the process of bachelor degree candidates reports that more than 40 percent of those learners will not complete within six years (Marcus, 2020). Creating micro-credentialling paths toward degrees is seen as a solution to such a high attrition rate. The president of Brigham-Young University’s online arm, BYU Pathway Worldwide, praised micro-credentialling in this way: “If you were design [college] from scratch, this is how you’d do it” (Marcus, 2020).

Tooley and Hood (2021) speculate that micro-credentials can serve teachers well as they seek new and immediate new skills with which to adapt their practice to Covid-19 realities:

High-quality micro-credentials verify a small, discrete, and evidence-based competency that a teacher demonstrates by submitting evidence of application from their practice (as assessed by a validated rubric). The associated resources and assessment are offered digitally in an asynchronous, self-paced format, which is crucial for schools forced into remote learning.

Professional and continuing education providers have traditionally been more nimble as regards meeting workplace and employer needs; therefore, it is not surprising that continuing teacher education, for example, has realized the value of micro-credentials. Traditional, credentialled higher education, on the other hand, has historically been slow to adapt to change given its need to adhere to strict oversight and rigorous academic vetting of new protocols.

Leveraging micro-credentials into students’ credentialling options begins to meet the needs of fast-changing economies and societies by focusing on an individual’s competencies, skills, and knowledge. In this way, the gap between learning and work is lessened; access to learning is increased; and individualism is valued. From these changes result increased equity among learners and the lessening of the negative

effects of social and economic diversity among learners. The recognition of prior learning can be key to these changes.

Klein-Collins and Travers (2020) note accurately that the recognition of prior learning has not changed much in many decades; they ask, subsequently, how the practice can be thought of differently so as to meet future learning needs. They note, however, that higher education has experienced some shifts in “how learning is defined, valued, delivered, credentialled, and supported” (p. 2). New types of credentialling include the emergence of “short-term, competency-based, and stackable” (p. 2) micro-credentials as well as the recognition of less-formal modes of learning such as that offered by open programs and MOOCs, described above.

---

### **RPL and Assessment in the Larger Picture: Issues of Equity, Access, and Inclusion**

Issues of equity, diversity, and inclusion have received more prominence in recent years. Injustices of the past in many parts of the world – slavery and colonialism, for example – are being revisited, often accompanied by attempts to right those historical wrongs. In the field of higher education, the turns toward open education, open educational resources (OER), and open education practices (OEP) have touted access and equity as primary concerns. However, additionally, cultural responsiveness has been deemed an important aspect of equitable education and training. The complementary states of educational openness and global “village-ness” have awakened educators to the importance and complexity of culture. Also, from outside the field of higher education itself, employers and the workforce have been calling for not only more highly skilled workers but also more cognitively prepared graduates from institutions of higher learning.

Recently, the pandemic-induced sudden and dramatic pivot to emergency remote learning has increased even further the attention to culture, inclusion, equity, and access in education. Taken together, these facets raise the profile of socially just assessment (Montenegro & Jankowski, 2020). As regards the interest of this chapter, new calls for equity and social justice in assessment resonate with the mandate and vision of RPL, which has been articulated above.

Equity and social justice rail against the many long-entrenched imbalances and inequities in education described here:

**The dynamics of power and oppression.** Traditional educational philosophies and teaching approaches have supported positivist and didactic approaches to learning both in presentation style and assessment techniques (Conrad & Openo, 2018). Classrooms have been teacher-centric from primary school to university classrooms. However, these strategies and approaches have been changing for several years as learning philosophies have shifted from sage-on-the-stage to constructivist, learner-centered approaches which value learners’ prior experience and recognize the potential and importance of guiding learners toward an authentic understanding of knowledge, one that resonates with them meaningfully rather

than one that is forced upon them and construed in someone else's language or experience.

Thus, formerly, there was no question of whose knowledge was important and whose knowledge was disseminated; it was the knowledge of the teacher and the textbook which, in many countries, was the knowledge of the dominant culture. These "systems of power and oppressions influence[d] how students experience [d] college, engage[d] with the learning process, and [built] knowledge" (Montenegro & Jankowski, 2020, p. 7).

**An uneven playing field.** Neither education nor any aspect of society has ever provided equal access or opportunity to learners. Similarly, assessment protocols inevitably privilege some learners above others. For example, why does a pre-kindergarten child taking the Denver Developmental Screening Test not know what a hedge is when asked. Why does he not know? He does not know about hedges because he lives on a farm and has never seen a hedge or heard one being discussed around the farm kitchen table. Therefore, he is marked as deficient on this question. (The Denver test was revised in 1992 to address the difference in norms in, for example, ethnic groups.) "It takes a conscious, intentional approach to make [social equity] happen, alongside potentially hard conversations" (Montenegro & Jankowski, 2020, p. 8).

**Subjectivity and the lack of critical consciousness.** A critical consciousness is necessary to recognize our own subjectivity and subsequently, to recognize our own biases and stances on power and privilege. A popular expression, "don't ask a fish about water," refers to the fact that we cannot easily see beyond or outside of our own fishbowl existence (Don't ask the fish, n.d.). Stepping out of our own fishbowl, or our own comfort zone, however, requires conscious effort, attention, and reflection (Rose, 2013).

**Institutional culture, language, and the will to change.** Teachers' individual willingness to adapt to cultural, access, or equity challenges may be thwarted by an oppressive or tone-deaf institutional administration or culture that does not or will not provide or foster a climate that is receptive to change. In some cases, new language is required in order to even begin the discussion. In a similar discussion, Spence (2020) criticizes our current language as old and faltering; it cannot meet the needs of a changing society. At the very least, a leader is needed – a champion. However, educators are busy, multitasking professionals, already dealing with myriad issues and personalities; the advent of Covid in 2019 has only increased and complicated demands on their time. Who will take on the mantle of change-agent? "No one wants to waste their time or, worse, share their thoughts and see no action taken in response; thus adding to feelings of being unheard or unseen" or overworked (Montenegro & Jankowski, 2020, p. 15).

## RPL and Social Justice

Social justice, long an important item on global agendas for change, forms a fundamental pillar to RPL's *raison d'être*, although its attention to this cause may

not be obvious to those benefitting from the process – the learners. Learners perceive their own set of welcome benefits at the microlevel: they save money and time. The recognition of their prior learning permits them to complete a degree program more quickly and cheaply.

However, to those in positions to shape educational policy and programs, the awareness of RPL's contribution to social justice – equity and inclusion – is paramount (Wong, 2014). For while RPL provides a logistical framework for assessing prior knowledge, it does not answer the fundamental epistemological questions of knowledge that remains: Whose knowledge is valued, whose is not valued? Whose experiential learning is included, whose is excluded? The acknowledgment of valued knowledge is key to equity and inclusion. Many global RPL initiatives – in South Africa, Scotland, Australia, and Europe – have emphasized social justice in their platforms (see, for example, Cameron & Miller, 2004; Guimarães & Mikulec, 2020).

## Future Potential and Challenges for RPL

The recognition of prior learning has, over the years, been “represented as an emancipatory strategy to facilitate access to higher education” (Peters, 2006) for those for whom access has been difficult or denied. However, despite these high ideals, the path has not been smooth. Although scholars such as Felder looked forward in 2017 to “continued reflection by assessment professionals on the ways that current assessment efforts either centralize issues of equity or serve to perpetuate them . . . pushing the scholarly conversation forward towards wider understanding and action,” progress has been slow.

Ten “sketches of innovative pedagogies” for 2021, recently featured in Canada’s Contact North/Contact Nord biweekly online newsletter (2021), were drawn from scholarship from the UK’s Open University; they include the following:

1. Best learning moments
2. Enriched realities
3. Gratitude as a pedagogy
4. Equity-oriented pedagogy
5. Using chatbots in learning
6. Hip-hop education
7. Student co-created teaching and learning
8. Telecollaboration for language learning
9. Evidence-based teaching
10. Corpus-based pedagogy

While some of these innovations may seem more easily understandable and accessible to the reader than others, the notable point is that none of them mentions anything specific about assessment, prior learning, or inclusion. Indeed, while equity-oriented pedagogy may hint at innovation leading to increased openness or access to learning – a move that might rely on RPL – it does not explore this notion.

This author, while considering the future of RPL and assessment several years ago, wrote:

Re-examining assessment strategies, however, has emerged as the hallmark pedagogical issue linking traditional higher education practice to the innovations that attempt to challenge it. Finding the assessment ‘fit’ to legitimise open learning is somewhat akin to finding the Northwest Passage to claim the treasures of the East. Within the quest, RPL’s potential seems, to its champions at least, to offer an accessible and proven solution. (Conrad, 2014, p. 331)

At the time of writing, one might ask, what has changed? At 2020’s European Higher Education Bologna Process Implementation Report gathering, a presentation examining the current status of RPL in Europe concluded that little progress had been made even though accommodating legal frameworks have been created (Crozier, 2021). In spite of this provision, higher education lags behind adult education, vocational education, and the labor market in making use of RPL. Among the reasons given for this lag are these: there is little political advantage connected to individuals benefitting from RPL, and societal benefit is not well understood by governments; higher education is perceived to be sufficiently inclusive already; higher education has not championed or lobbied for increased implementation of RPL. Potential RPL applicants are also deemed to be unaware of its potential benefits to them.

In Canada, the Canadian Association for Prior Learning Assessment (CAPLA) continues, at the time of writing, to offer training in RPL processes; its focus includes college and university level study as well as private and labor enterprises. In considering the future of RPL in Canada, CAPLA looks to micro-credentialling as potentially providing a boost to RPL’s momentum. Luff, Travers, and Piedra (2021) highlighted Canada’s 2020 Future Skills Council Report which directly called for the expansion of RPL for broader employer use. Their call is reinforced by UNESCO’s Institute for Lifelong Learning that asserts that RPL implementation meets the growing need of citizens for opportunities for continued and lifelong learning.

Beyond higher education, private institutions promote RPL processes via online training. The International Training Centre’s (ITC) “E-Learning Course on Recognition of Prior Learning,” offered in the spring of 2021, sought to attract policy-makers, managers in employment sectors and human resources, and stakeholders in NGOs and others in the fields of skills development. A Certificate of Completion was offered.

---

## Final Words

This chapter aimed to elucidate the recognition of students’ prior learning within the larger context of accrediting that learning. Both topics point to important issues around learning: quality, access, and equity. Accrediting higher education learning is an historic and usually traditional process that is carefully managed by institutions;

RPL provides one facet of that total picture. Unfortunately, it is a facet not often fully understood, and therefore its affordances – for learners, employers, and society – are unappreciated, its process unimplemented or, perhaps, implemented badly.

Higher education institutions worldwide have adapted to and welcomed the concepts of open learning and micro-credentialling to varying degrees in order to hasten students' academic progress and provide greater and more equitable access to students. RPL's long history has proven it a worthy piece in the puzzle of accrediting learning. As education's responses to the still-current pandemic evolve, will RPL take its place among other solutions? While this writer is dubious, the hope remains.

**Abstract**

This chapter is anchored on *Collaboration* being a new construct in the Digital Library Reference Model proposed by the DELOS Network of Excellence on Digital Libraries. The chapter argues that distance learning library services will be significantly enhanced with a collaboratively implemented digital library service taking into cognizance the role of collaboration in strategic planning and policy development, provision of digital collections and information services, and technological infrastructure and skills development in the distance education context. The study concludes that the collaborative model for implementing digital libraries in open, distance, and digital education (ODDE) can ensure that digital libraries are collaboratively designed leading to wider acceptance and use in ODDE.

**Introduction**

Reference Models have been appropriated to support the development and implementation of user-centred digital libraries (Candela et al., 2007). For instance, the Digital Library Reference Model, the brainchild of the DELOS Network of Excellence on Digital Libraries, supports the development and implementation of collaborative learning models such as open education and other post-distance education models (Tammaro, Ciancio, De Rosa, Pantò, & Nascimbeni, 2017). Digital libraries facilitate collaboration in these types of learning in two ways: as learning objects integrated into open educational delivery platforms and virtual learning environment platforms serving as qualified educational infrastructure in their own right (Owusu-Ansah, Rodrigues, & van der Walt, 2019; Tammaro et al., 2017). These pathways to collaboration, notwithstanding, there remains a chasm between digital library teams at the organisational level and the distance education community (Courtney & Wilhoite-Mathews, 2015; Zhang, Liu, & Mathews, 2015). This results in the need for more suitable models for integrating digital libraries into open, distance education, and digital education (ODDE) (Owusu-Ansah et al., 2019).

This chapter explores the potential of the Digital Library Reference Model for developing a collaborative model for integrating digital libraries. According to Candela et al. (2007), the Reference Model provides the framework for developing all the components of an educational digital library. These components are as follows:

1. The appropriate policies to guide the implementation of the digital library
2. A definition of digital library users and their rights and responsibilities
3. The nature of the digital collections and services
4. The acquisition of the right ICT resources to enable the digital library and ensure access to it

The Digital Library Reference Model (Candela et al., 2007) is one of the most useful frameworks for the development and implementation of digital libraries to support practice in several professional fields including the digital humanities (Zhang et al., 2015). The model is aimed at providing a simplified theoretical foundation for the development and implementation of complex systems (Candela et al., 2007). As a reference model, it embodies “a minimal set of unifying concepts, axioms and relationships within a particular problem domain, and is independent of specific standards, technologies, implementations, or other concrete details” (Candela et al., 2007, p. 25). Proposed by the DELOS Network of Excellence on Digital Libraries, the Model is part of the Digital Library Manifesto, and it is expected to bridge the gap existing within current theoretical approaches and ensure a “common basis for communication within the digital library community, and to help focus further advancement” (Candela et al., 2007, p. 25).

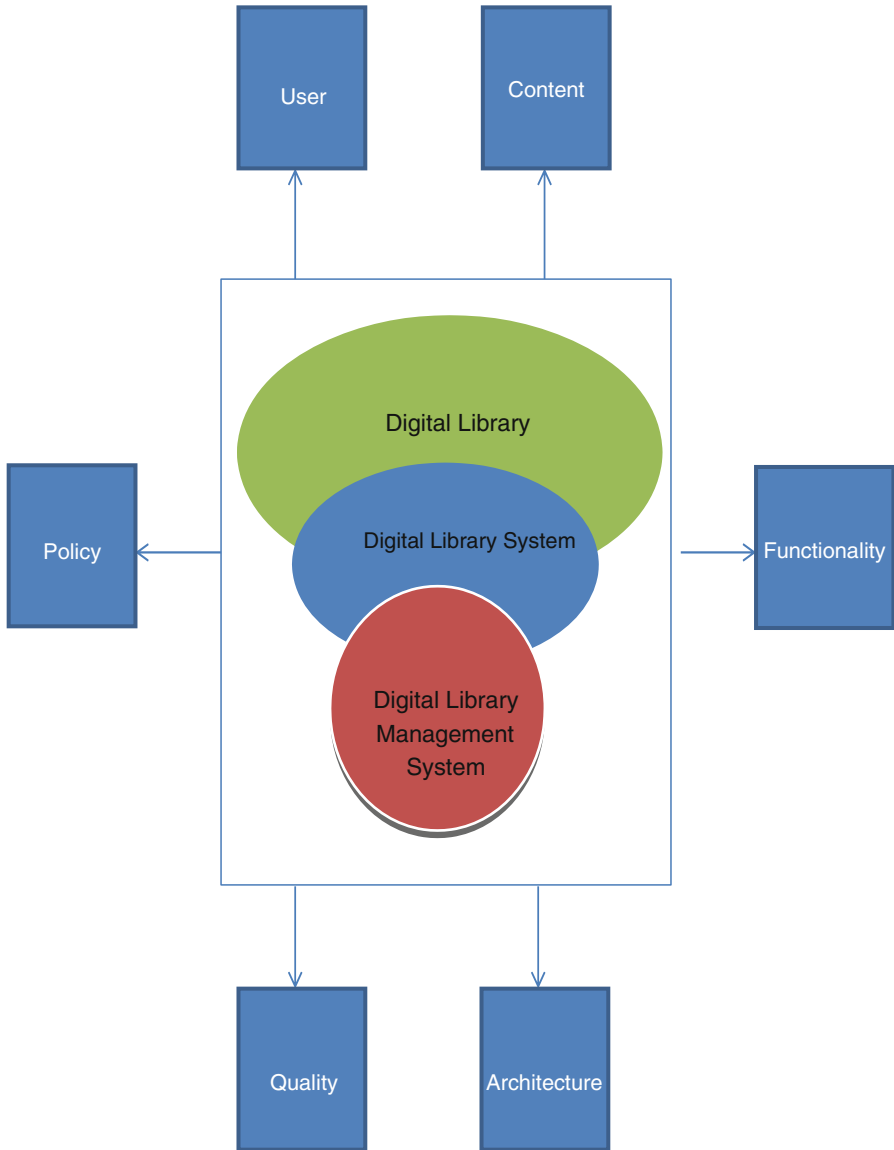

Although other models such as the 5S framework by Fox, Gonçalves, and Shen (2012) and Soergel’s Framework for Digital Library Research (Soergel, 2002) and other models of digital libraries were considered equally relevant in developing educational digital libraries, the Digital Library Reference Model was seen as more appropriate for this chapter due to its relative comprehensiveness and practical orientation. For instance, Soergel (2002) conceptualized that for digital libraries to be sustainable and be useful, digital libraries must support professional practice such as teacher education or medicine; provide innovative methods of intellectual work; and enhance collaboration in professional communities. He represents these ideas in 11 themes insisting that digital library researchers address all the concerns raised therein. Soergel’s Model represents a comprehensive research vision for the development of digital libraries. A basic practice-oriented framework in the form of the Digital Library Reference Model, however, was considered more appropriate for this handbook.

According to Owusu-Ansah (2020), conceptions of digital libraries have evolved over the years from a content-centered system that supports specific information provision to one that “delivers innovative, evolving, and personalised services to users” (p. 237). This has led to the development of a new definition for digital libraries as “a virtual organisation that comprehensively collects, manages, and preserves for the long-term rich digital content, and offers to its user communities specialised functionality on that content, of measurable quality and according to codified policies” (Candela et al., 2007, p. 157).

---

## Background of the Digital Library Reference Model

The Model (Fig. 1) describes the digital library as a three-tier construct with each representing three notions of conceptions in the digital library universe (Candela et al., 2007). The most important component is the digital library management system (DLMS), which may often be proprietary or commercial product (or set of components), a generic piece of software providing basic functionality required by the particular digital library (Werla & Mazurek, 2011). The second tier is the digital

**Fig. 1** DL, DLS, and DLMS: a three-tier construct with six DL concepts. (Source: Werla & Mazurek, 2011, p. 2)

library system (DLS) which enriches the digital library management system with the specific functionality and/or configuration required by the digital library (Werla & Mazurek, 2011). Lastly, the third layer is the digital library (DL) consisting of the organization (institution) collecting and preserving digital content and providing access to it.

## Composition of the Digital Library System

The digital library system is composed of six core elements, namely, user, content, policy, functionality, architecture, and quality (Candela et al., 2007). All these concepts, according to the authors, impact the performance of digital libraries. These components are basic to every digital library and are explained further in the next sections.

### User

Candela et al. (2007) refer to users as actors that interact with the digital library. These actors may be human or machine agents. Users include the end-users, who further comprise information creators, consumers, and librarians; the designers who use the knowledge to define, customize, and maintain the digital library for functionality to immediate and potential users; the administrators who determine the software needed to construct the digital library based on the end-users' expectations; and the application developers who develop the software needed to ensure appropriate digital library deployment (Anunobi & Ezeani, 2011). In ODDE, users consist of distance learners, their instructors, educational administrators, and librarians. All of these groups of users play critical roles in the distance education field and may exploit digital library services to support teaching and learning through effective collaboration (Tammaro et al., 2017; Zhang et al., 2015).

User is also a notion for the rights of these actors while exploring the digital library. In ODDE, the rights of users while accessing the digital library include the provision of remote access to digital collections, a right that may be secured through the implementation of favorable user policies for distance learners (Calhoun, 2014, p. 127). Furthermore, it may also include the profile of users as individuals or as a group. The profile of distance learners may be seen in the context of the digital divide in terms of access to relevant technologies, information literacy, and technology skills (Courtney & Wilhoite-Mathews, 2015). To meet the dynamic information needs of ODDE students (Oladokun, 2014), it is important to understand their ICT and information competencies as this is a requirement for effective utilization of digital resources for academic purposes (Liebenberg, Chetty & Prinsloo, 2012). Furthermore, Owusu-Ansah, Rodrigues, and Van Der Walt (2018a, 2021) advocated for the development of appropriate user policies and rights and deliberate instructional practices favorable to distance education to assure the knowledge, skills, and positive attitudes in and towards digital libraries.

### Content

The content constitutes manipulated data and information that is made available to users, and these include primary objects, annotations, and metadata (Candela et al., 2007). Furthermore, Witten et al. (2010, p. 39) describe the content in terms of the

document format, and these may include texts, multimedia, or image. According to Candela et al. (2007), content is an umbrella term for all sorts of information objects that are found, managed, and supplied by digital libraries. According to the Association of College and Research Libraries (ACRL) Standards for Distance Learning Library Services (2008), resources for distance education should, among others:

- Meet all students' needs in fulfilling course assignments
- Enrich the academic programs
- Meet teaching and research needs
- Support curricular needs
- Facilitate the acquisition of lifelong learning skills
- Accommodate students with varying levels of technological access (i.e., low bandwidth)

Consequently, digital library collections for distance learners must be capable of supporting these goals in ODDE.

## Policies

These consist of the conditions, rules, terms, and regulations governing the digital library and its users (Candela et al., 2007). Policies guide how digital libraries will be used and how their applications will evolve, and these may include content guidelines, access policies, and preservation policies (Riddle, 2015). Policies are designed by people such as digital library managers, managers, and stakeholders (Innocenti, Vullo & Ross, 2010). Gallagher, McMenemy, and Poulter (2015) emphasized the need to inform users of acceptable or non-acceptable behavior while using the public digital library facilities. Instances of specific policies include acceptable user behavior (Robinson, 2019), digital rights management (Mwanzu, 2021), privacy and confidentiality (Avuglah, Owusu-Ansah, Tachie-Donkor, & Yeboah, 2021), charges to users (Rousmaniere, Ciarkowski, & Guild, 2020), and collection delivery (Candela et al., 2007). In ODDE institutions and their libraries, policies originate from the institutional strategic plan (Owusu-Ansah et al., 2018a). In this chapter, therefore, policies are discussed as components to be factored into a strategic plan. The ACRL Standards (2008) espouse the development of strategic plans for the provision of distance learning library services. This must be an iterative process that includes evaluation, updating, and refinement. Furthermore, strategic planning for any distance learning library service such as a digital library must be factored into the library-wide mission statement and goals and in consonance with that of the institution (ACRL, 2008).

## Functionality

The functionality concept refers to the services offered by the digital library to its users. According to Candela et al. (2007), the most common of these services include

registration of new information objects, search, and browse. Anunobi and Ezeani (2011) note that these services support the management of the collections, provide replication and reliable storage, aid in query formation and execution, and help in name resolution and location. The functions of the digital library must reflect the particular needs of the digital library community and/or the specific requirements relating to the information resources it contains (Candela et al., 2007). For distance learners, the provision of discovery systems that enable seamless access to distributed information sources is very critical (Calhoun, 2014, pp. 66–67). Again to enhance access and use of digital content and services, distance learners must be provided with a wide range of informational, instructional, and user services in the form of digital reference services (ACRL, 2008). Also, the integration of open access models of digital library resources can considerably enhance the functionality of digital libraries in respect to the discoverability, interoperability, and usability of digital content, resources, and services (Liebenberg, Chetty, & Prinsloo, 2012; Toledo, 2017).

## Architecture

The architecture involves the enabling technology which ensures that the services and content offered by the digital library are well integrated into hardware and software components (Anunobi & Ezeani, 2011). According to Candela et al. (2007), the architecture component provides a clear framework with which to address the issue of complexity in digital libraries and interoperability across different digital library systems. To enhance the acceptability of digital libraries, they must be accessible, and the architecture component makes this possible. Distance learners require access to ICT as an enabler. Academic libraries must, therefore, provide the relevant technological infrastructure to facilitate access to online and digital resources for distance learners (Maddison, 2013). In distance education, enabling technologies for digital library services include computers and networking facilities, assistive technology, and remote access technology, among others (Omotayo & Haliru, 2020).

## Quality

This concept represents the platform for determining the characteristics and for evaluating the content and behavior of the digital library (Anunobi & Ezeani, 2011). Quality consists of parameters that can be used in measuring not just the content but also the specific information of objects or services associated with them (Candela et al., 2007). According to Soergel (2002), evaluation of digital library quality may be completed with either a qualitative or quantitative approach. Objective measures may be evaluated for quality using quantitative methods, whereas subjective parameters are better evaluated with qualitative approaches. Several authors such as Saracevic (2000), however, report that evaluation of digital library

services has been lacking in practice due to factors such as the complexity of digital libraries, lack of comprehensive knowledge of the nature of digital libraries, low level of interest among digital library developers for evaluation of their services, and lack of funding for evaluation activities, among others. The situation has improved over the past decade with numerous studies reporting successful evaluation of digital libraries (Alzahrani, Mahmud, Ramayah, Alfarraj, & Alalwan, 2019; Heradio, Fernández-Amorós, Cabrerizo, & Herrera-Viedma, 2012; Shen, Gonçalves, & Fox, 2013; Xie, Joo, & Matusiak, 2018), albeit on the user perspective. Alzahrani, Mahmud, Ramayah, Alfarraj, and Alalwan (2019) examined the critical success factors of digital libraries using the DeLone and McLean (2003) information system success model. Two dimensions of digital library quality were identified, namely, system and information quality. The system quality dimensions in their study referred to the extent to which a digital library was “user-friendly” and remained responsive and useful without difficulties to the user. On the other hand, information quality involves a user’s perspective of the value of a digital library. The dimensions of information quality include timeliness, the accuracy of content, completeness, relevance, and consistency of the digital library service. Furthermore, Xu and Du (2018) alluded to service quality as being responsible primarily for user satisfaction. In the same vein, user satisfaction results in further use of the digital library system (Alzahrani et al., 2019). Xie, Joo, and Matusiak (2018) examined a set of evaluation criteria of digital libraries from the perspective of academic stakeholders. The ten dimensions of quality were collections, information organization, interface design, system and technology, effects on users, services, preservation, administration, user engagement, and context. Despite the crucial role of evaluation in digital library projects, they are often not factored into the digital library development cycle (Chowdhury, 2016). Xie et al. (2018) noted the critical place of evaluation in digital library implementation pointing out that evaluation involves “the process of determining merit, worth or valuation of [the digital library], or the product of that process” (p. 854). It does appear, however, that evaluations of digital libraries focus more on the user perspective rather than the detriment of developers’ perspective (Rahimi, Soleymani, Hashemian, Hashemian, & Daei, 2018).

---

## Other Actors in the Digital Library Universe

In addition to the core concepts discussed above, Candela et al. (2007) describe the roles of four main actors within the digital library universe who variously interact with the three-tier framework and the core concepts. These are digital library end-users, digital library designers, digital library system administrators, and digital library application developers.

**Digital library end-users** are the ultimate clients of the digital library as they exploit the digital library functionality for providing, using, and managing the digital library content as well as some of its other constituents. The digital library is a full entity that serves the functional needs of end-users. Furthermore, digital library end-users comprise content creators, content consumers, and librarians.

**Digital library designers** comprise the organizers and initiators of the digital library from the application point of view. They exploit their knowledge of the application semantic domain to define, customize, and maintain the digital library so that it is aligned with the information and functional needs of its end-users. To perform this task, they interact with the digital library management system to provide functional and content configuration parameters.

**Digital library system administrators**, on the other hand, ensure the successful implementation of the digital library from the physical point of view. They select the software components necessary to create the digital library system needed to serve the required digital library and decide where and how to deploy them. They interact with the digital library management system by providing architectural configuration parameters, such as the selected software components, the hosting nodes, and the allocation of the components.

**Digital library application developers** are the implementers of the software parts needed to realize the digital library. They develop the software components of the digital library management system and digital library system, to achieve the necessary functionality (Candela et al., 2007).

## Initial Framework for Developing Digital Libraries for ODDE

This chapter adapts the Digital Library Reference Model and proposes a new model for developing and implementing digital libraries for ODDE. This has become necessary as the existing model does not meet the emerging challenges of the ODDE information environment (Arthur-Nyarko, Agyei, & Armah, 2020; Chou, 2018). Some of these challenges include new barriers of information access relating to the cost of subscription (Joachim Schöpfel & Claire Leduc, 2012), unfair policies relating to information provision in ODDE (Owusu-Ansah et al., 2018a), and unequal access to technology in ODDE (Lusigi, 2019).

In the new model, three core concepts, namely, policy, content, and architecture, are considered critical success factors for implementing digital libraries in ODDE. The necessity for a simplified construct has never been so important to enhance the implementation of a collaborative digital library in ODDE. They are adapted here as strategic planning and policy development, digital content and information services, and technological infrastructure and skills development. Furthermore, the two other concepts, the user and functionality, are subsumed under the three critical concepts. For instance, users may consist of underqualified teachers upgrading their skills through ODDE whose information needs must determine what manner of content the digital library is populated with. As a result, the user component is considered inseparable from the content component. Similarly, functionality, which represents the range of services the digital library provides, is also seen as an aspect of the content. Consequently, the user, content, and functionality are intertwined and discussed as aspects of distance learners' information needs. The new model is, therefore, portrayed in Fig. 2 and explained thereafter.

**Fig. 2** The initial construct of the digital library framework in ODDE. (Source: Author construct, 2020)

## Strategic Planning and Policy Development

The success of every digital library project depends on the availability of policies and strategies in terms of the sustainability of its services and resources. Plans and policies on the digital library must include endorsed documents such as strategic plans, policy documents, and action statements. Strategic planning in digital libraries must take into consideration the economic, social, and ethical aspects of sustainability (Calhoun, 2014, p. 83).

From the economic point of view, there must be ongoing funding and a successful business model for recovering investments, and actions towards this goal may include ongoing business planning, determining user needs and providing satisfactory services, and being accountable. According to Chou (2018), the absence of a long-term plan funding policy can negatively impact the resourcefulness and functionalities of a digital library. ODDE stakeholders, like other members of the academe, are confronted with several financial challenges in respect to access to quality information for their academic work (Fyfe et al., 2017). Among these include the high cost of subscription access and unsustainable models of information delivery in the electronic information realm. Increasingly, library information is held behind paywalls, a phenomenon of “pay to read” or “pay to download” (Björk, 2017). This is also referred to as the subscription access model, as opposed to the open access model which rather requires, in some cases, the authors to pay for the cost of the publication, so that the public can have free access to the content of the article on the Internet. The paywall model, so-called because one cannot access an article because there is a “wall,” that is the subscription charges, has become a major barrier to access to library resources in the ODDE community especially in the Global South (Collyer, 2018). Libraries in ODDE in these emerging regions of the world can eliminate this barrier by fashioning out collaborative policies in the form

of library consortia and collaborative information-sharing schemes (Mohd, Yusof, & Umar, 2014; Sachin, 2018). Fyfe et al. (2017) view the idea of consortial access to digital library scholarly content in ODDE as akin to the strategies adopted by large commercial publishers manifested in mergers and acquisitions to consolidate their “oligopolistic” economic gains (p. 10). In the same vein, ODDE institutions and their planners stand to gain by forging “mergers” in the form of library consortia to acquire licensed digital content while benefitting from the shared experiences of each institution. Sachin (2018) argues that consortia agreements have a number of advantages including, among others, ensuring that the information needs of a larger population of users are met while also catering for the technical capacity of the personnel responsible for the implementation and operation of the digital library.

From the social perspective, libraries implementing digital libraries must have policies and strategies geared at providing long-term access to resources (Adjei, Mensah, & Amoafu, 2019; Baro, 2016); maintaining visibility and community awareness (Gireesh Kumar, 2020); and providing ongoing access to content and services that are valuable to the users (Siyao, Whong, Martin-Yeboah, & Namamonde, 2017). Finally, from the ethical point of view, a digital library may be sustainable if it has in place policies and strategies to provide equitable services to marginalized users such as distance learners by providing remote access to its content and resources (Chou, 2018) and at the same time upholding the rights of content producers and creators through policies and plans (Mwanzu, 2021; Calhoun, 2014, p. 83). At the same time, policies are used to manage access to digital resources (Arms, 1998). Chou (2018) maintains that there is a need for enduring funding and maintenance plans to ensure the financial sustainability of the digital library as it seeks to avoid losing the trust and credibility of its users.

## Digital Collections and Information Services

Lesk (2005, p. 2) argues that the most important thing for digital library developers to consider is the content to meet user needs. Candela et al. (2007) asserted that content comprises “managed information” elements such as primary objects, annotations, and metadata. They argue that these may come in the form of special collections, maps, schematic data, or computer-generated graphics; copyright-free materials; and collections. Tedd and Large (2005, pp. 51–60) classify digital library resources into full-text materials, metadata sources, multimedia materials, and general websites. Many experts (Simamora & Gunawan, 2001; Ferguson et al., 2002; Perrault, 2007; Bower & Mee, 2010) are of the view that digital library resources provide essential remote support to meet distance learners’ information needs. Distance learners require digital content in various formats and from different sources for a variety of purposes such as completing assignments, writing dissertations, and supplementing tutorial lessons. In the context of ODDE, the effective use of digital library content requires opening access to digital resources. The need for opening access to research has never been greater in the twenty-first century. Simply, open access involves making the results of research freely available to everyone

(Björk, 2017). In the age of high-speed Internet and computer infrastructure vis-à-vis pressing global, regional, and national challenges and emergencies such as the COVID-19 Pandemic and terrorism, several global bodies including the European Research Council are advocating immediate access to research results within their jurisdictions (Abdelrahman, 2020). This and other global efforts towards knowledge-sharing have given further impetus to the concept of open access publishing.

According to Abdelrahman (2020), there are three basic types of open access publishing. These are Gold, Hybrid, and Green Open Access. Gold and to some extent Hybrid publishing involve funding the cost of publications through article publication charges, government funds, or society grants. However, sometimes the inordinately high cost burden on authors from the Global South does not enable the widespread adoption and promotion of publishers of Gold and Hybrid journals in libraries from the Global South. Conversely, many institutions and libraries in emerging countries value the green road, representing modern models of sustainability. The green road, also known as Green Open Access involves the use of repositories for publishing scholarship. Consequently, academic libraries implementing digital libraries are focusing their lean resources on promoting green publishing through institutional and subject repositories (Kakai, Musoke, & Okello-Obura, 2018; Toledo, 2017). The infrastructure of these repositories is such that they promote collaboration and sharing of resources through the adoption and implementation of licensing regimes that enhance sharing, discoverability, and interoperability in ODDE (Ntim & Fombad, 2020).

## Technological Infrastructure and Skills Development

Technological infrastructure ensures that the services and contents offered by the digital library are well integrated into hardware and software components (Anunobi & Ezeani, 2011). The infrastructure consists of the appropriate technical infrastructure and resources that ensure access to relevant information to digital library users. Furthermore, these include software and hardware, programs, and standards to ensure seamless access to information. The different components of technology enable networking and interoperability of different information technologies and tools. In this chapter, the following are considered critical to the deployment of digital library services in distance education: ICT infrastructure (computers, networking, connectivity, etc.); interoperability of different information systems (the seamless provision of distributed information services); and the use of appropriate software in the provision of digital library services for distance education. In ODDE, the significant challenge posed by lack of stable Internet connectivity and computing infrastructure has been noted to impact the uptake of new information models such as OERs and MOOCs (King, Pegrum, & Forsey, 2018).

Similarly, without the right mix of information and technology skills, distance learners may not be able to exploit the opportunities offered by the digital library. From the perspective of the ODDE community, in particular, some of the issues

discussed in respect of technological and information skills include the level of computer experience, types of computer skills, availability of training programs, methods of training, the general perception of ICT skills, and challenges to digital library usage (Besseah, Achiro, Mhando, & Salau, 2017; Brewer, Rick, & Grondin, 2017; Saikkonen & Kaarakainen, 2021; Yu, 2017).

## **The Collaborative Model for Implementing Digital Libraries in ODDE**

Previous findings (Owusu-Ansah et al., 2018a, 2018b) justify the use of the Digital Library Reference Model proposed by the DELOS Network of Excellence on Digital Libraries in developing and implementing an educational digital library for ODDE. In this chapter, three main variables adapted from the model, namely, strategic planning and policy development, digital collections, and information services, technological infrastructure, and skills development, were considered to be critical success factors.

From the literature (Owusu-Ansah et al., 2018a), it has emerged that strategic planning and policy development is the basis for the integration of digital libraries into distance education, and this involves establishing a formal need for using digital libraries in distance education as captured in the organizational mission, developing specific policies and rules for developing appropriate digital content and services, and obtaining the funding needed to sustain these services. All these constitute efforts at ensuring the sustainability of the digital library (Chowdhury, 2016). Digital collections and information services also involve the provision of appropriate digital library services and creating awareness and use of these resources in distance education (Okoroma, 2018). The technological infrastructure consists of technical infrastructure and networking resources required for digital libraries, while skills consist of technology and information literacy skills needed by distance learners for the effective use of digital library resources, respectively (Aheto & Cronje, 2018; Baro, Obaro, & Aduba, 2019; Deal, 2016; Pratama & Scarlatos, 2020).

Again, previous studies (Owusu-Ansah et al., 2018a, 2018b, 2019) buttressed the need to consider integrating factors such as the need for librarians to understand their role in distance education and embrace collaboration with distance education stakeholders as these actions constitute the most effective approaches to integrating digital libraries into distance education (Owusu-Ansah et al., 2019). Through collaboration with distance education instructors (faculty) and coordinators (administrators), librarians are enabled to implement critical services such as information literacy and (digital) reference services in distance education. Furthermore, Tamaro et al. (2017) pointed out the need to make changes to how teaching and learning are done in distance education to enhance the usability of digital library resources in distance education. These changes can be made possible through collaboration between library staff and distance education instructors on the one hand and with distance education administrators on the other (Zhang et al., 2015). Furthermore, the collaboration between librarians in different ODDE institutions can result in, among others, the following:

## Enhancing Seamless Information Access in ODDE Through Inter-library Cooperation

The development of inter-library cooperation may be a viable response to the high and unsustainable cost of digital library resources for the ODDE community (Mazurek & Werla, 2011; Olesova & Melville, 2017). This may manifest as the use of sustainable information models for providing access to information for ODDE stakeholders. There is a need for policies to mitigate the effect of the paywall phenomenon (Björk, 2017; Chou, 2018). One of such economic policies is the idea of a library consortium. Since the ODDE community pervades one academic community, it makes sound economic sense for institutions implementing this type of education to resort to collaborative digital library service in the form of a library consortium to serve not just the needs of the ODDE community but their on-campus communities as well. The uniqueness of a collaborative digital library effort in respect to the economic factor is the fact that members may benefit from learning new skills, obtaining a stronger voice, optimizing resources, and eliminating operational flaws while empowering the users of the digital library (Pereira & Franco, 2020).

Furthermore, within each ODDE community, librarians must collaborate actively with ODDE stakeholders through a collaboration policy or an explicit statement on collaboration in a strategic document for supporting the implementation of digital library services in ODDE (Owusu-Ansah et al., 2018a). In his editorial on collaboration in the academic library sector, Atkinson (2019) pointed out the need for a documented policy on the scope, goals, and objectives as well as outcomes and outputs among participants during collaborative initiatives involving academic libraries and other partners. Such a policy must also detail roles, accountability, and procedures for getting things done. Eventually, these will culminate in strategic guidelines and standard operating procedures for the members of the team (Atkinson, 2019).

## Embedded Library Services as an Anchor of Collaboration

The implementation of digital libraries in distance education stands to benefit tremendously through the development of embedded library services which can appreciably raise the visibility and usability of digital library resources in distance education (Woodward, 2015). Several goals of embeddedness have been discussed in the literature including course design (Olesova & Melville, 2017; Skarl & Bosque, 2019), research support (Besseah et al., 2017; Brewer et al., 2017), open educational resources (Goodsett, Loomis, & Miles, 2016), and information literacy (Scheidt et al., 2016; Scheurer & Nadir, 2018; Schwenger, 2016).

In the distance education context, embeddedness requires librarians to seek collaboration with faculty counterparts in the development of online courses to enhance student learning. Olesova and Melville (2017) opined that embedded

librarian collaboration with an online course faculty requires librarians to be involved in setting learners up, designing for content organization, developing instructional strategies, and addressing learning management issues. On the other hand, the impetus for a collaboration such as this may be, among others, the creation of dedicated distance library services with dedicated staffing equipped to perform both systemic and snap tasks to integrate library resources within the distance learning curriculum (Owusu-Ansah, Rodrigues, & Van Der Walt, 2018a). For instance, a long-term, systemic task may involve the embedded librarian creating a distance education Web page on the library website with a link to the distance education website where most or all relevant digital library resources are explicitly linked to academic tasks. Again, embedding may involve simple, snappy, tasks such as taking a snapshot of Online Public Access Catalogue results containing relevant books on a particular topic in a course and posting simple information on how to borrow a book. These outcomes of the embedded digital libraries were re-echoed by the European Library Automation Group when they explored the potential for cooperation between libraries and the academic community (Tammaro et al., 2017). These efforts are poised to elevate library service provision in open distance education from beyond cooperation to collaboration (Olesova & Melville, 2017).

## **A Framework for the Collaborative Digital Library Model in ODDE**

In view of the overwhelming need for collaboration between librarians and distance education stakeholders to ensure integration of digital library resources into distance education (Owusu-Ansah et al., 2018a, 2018b, 2019), this study readjusts the initial proposed theoretical framework to include an integrating factor of collaboration between librarians and distance education stakeholders as shown in Fig. 3.

Figure 3 represents the development of an educational digital library for ODDE with the collaborative digital library framework. This framework, however, proposes another component in the ODDE context, *collaboration*. Collaboration was recognized as a key factor for the successful integration of digital library resources into distance education. Collaboration is critical in the areas of strategic planning and policy development, services and technology, marketing, training, and innovating teaching and learning in distance education with digital library resources.

The significance of the framework is outlined as the following:

1. It presents a simplified theoretical foundation for the development and implementation of digital libraries in ODDE.
2. With the collaboration component, the framework isolates some important challenges distance education stakeholders and librarians are likely to encounter in using digital libraries. Some of these challenges include lack of strategic plans and policies for digital library use in distance education, poor technological infrastructure and information skills, lack of awareness of digital resources, and

**Fig. 3** Collaborative model for digital libraries in ODDE

lack of integration of library resources into distance teaching and learning. Some experts are of the view that lack of collaboration in information literacy instruction can impact negatively digital library use (Buck, Islam, & Syrkin, 2006; Figa, Bone, & Macpherson, 2009).

3. Lastly, the collaboration component will enhance librarians’ and ODDE stakeholders’ awareness of the barriers to put in control mechanisms at every stage of the integration.

---

## Conclusion

For successful implementation of digital libraries in ODDE, this chapter proposed *collaboration* as an independent component of the original digital library framework developed by the DELOS Framework on Digital Libraries. Collaboration is considered a critical success factor for digital library implementation. The updated framework holds the potential to deepen efforts aimed at integrating digital libraries into the curriculum of distance learners. The thrust of the model is that there is a need for collaboration between librarians and ODDE stakeholders, on the one hand, and with librarians in other ODDE institutions, on the other, in the areas of planning, designing services, selecting software, marketing, training, and transforming teaching and learning in ODDE with digital library resources.

### Abstract

With changing scenarios in globalization, technologization, and conception of twenty-first-century learners and learning, distance teaching institutions are also gradually changing their delivery strategies and learner support systems. This is more visible in the following: from separation of course design and learner support to both forming an integral part of blended teaching-learning; from physical and geography-based operation to more technology-enabled networked operation; from largely behaviorist model to more of constructivist and connectivist models of course design and learner support; and from a humanistic support system to more of strategic support system. In these changing scenarios,

S. Panda (✉)  
Indira Gandhi National Open University, New Delhi, India

however, the changes in academic practices have not kept pace with technology changes; and technology and market, rather than the scholarship of teaching and support, dominate the support discourse and practice. These developments raise various research questions which need to be investigated further. The analysis in the chapter shows that the future of distance and online learning vis-à-vis learner support is poised to shift from the “course material-tutoring” system to the “networked-interactive-intelligent” system, though both will continue for quite some time to come. Institutional leaders, faculty, and other stakeholders need to engage with further articulation and reflection toward evolving a quality, productive, pedagogy-led, and learner-friendly support system.

**Introduction**

What Rumble (2001) had underlined some two decades back about the changing global-societal scenario holds good even today – that there is massive population growth and consequent demand for quality mass education, fast moving globalization and neoliberalism, decline of state power and increase in privatization, changing employment and living, and rise in information technology and knowledge economy. To these, we could add some of today’s changing scenarios: increasing global free trade and mobility; changing twenty-first-century learners and learning; decreasing “education” and increasing “learning” and vocationalization; increase in the use of flexible, collaborative, and personalized social technologies and social networks; and not the least, the prolonged pandemic and consequent long-term impact on the entire lifestyle, including education. Add to these what Salmon (2019) describes as coming up of, alongside industrial revolution 4, the Web 4.1 (i.e., the symbiotic web) leading the Education 4.0 (Bonfield, Salter, Longmuir, Benson, & Adachi, 2020), alongside Globalization 4.0 (Samans, 2019).

In these changing scenarios, where new digital technologies (including artificial intelligence, chatbots, machine learning, big data, immersive technologies, learning analytics, and Internet of Things) are brought to the center stage of teaching-learning, distance teaching institutions (and more specifically, the open universities) have been at the forefront of constant changes in especially three aspects – (i) changing and flexible methods of delivery, (ii) use of new and changing media and technology, and (iii) increase in open and flexible educational practices. Historically, starting from the erstwhile correspondence education, the out-of-classroom education has evolved through distance education, open (university) education, digital and online learning, and blended learning. Alongside this development, the learner/learning support system has also undergone significant changes. The first attempt to scientifically explain distance education within a

theoretical framework of “transactional distance,” i.e., the interaction of dialogue, structure, and autonomy, along with the required learner support system for independent study was made in as early as 1972 (Moore, 1972, 1993), and a comprehensive theoretical framework for “dialogue” in the distance education instructional system was given by Gorsky and Caspi (2005), with actual discursive practices, learning outcomes, and support systems. Subsequent transformation from distance to online education/learning brought to the fore the inquiry-based theoretical discourses relating to cognitive presence, teacher presence, and social presence, and the required support systems for especially asynchronous learning (Garrison & Anderson, 2003).

Out-of-class educational delivery has taken many shapes, including the largest number of dual-mode universities, above 60 single-mode (open) universities, and significant number of virtual universities around the world (Tait, 2018). Depending on the nature of program design and instructional design and delivery, the learner support systems for these institutional types vary across pedagogic, technological, administrative/managerial strands. While there is a large chunk of learners who prefer a traditional print-based and study center-attended model, there are others who prefer an independent and seamless online learning, with built-in collaboration. During the past two decades of this century, most institutions have gradually moved to blended teaching-learning (including remote-teaching during Covid-19 notwithstanding) which did not require drastic structural as well as infrastructural changes. However, academic organization and administrative management of such blended design and delivery requires added understanding, training, and capacity building. More or less, each delivery strategy has included one or the other form of technology-enabled learning, and national strategies have invariably adopted a policy-technology-capacity building change management model (Mishra & Panda, 2020), especially in the Commonwealth.

Irrespective of the type of distance teaching institution, access, flexibility, and openness have been the major considerations in educational delivery, including learner support. While the traditional open universities have largely depended on home delivery and study center-based support, dual-mode universities have had a judicious mix of distance teaching-learning and on-campus library access and access to labs and practicum. Though the British vision and model of single-model open universities will still attract the developing countries grappling with mass higher education, the dual-mode (or even multimode) university-blended learning continues to be the focus and the future in many developed as well as progressive systems. Nonetheless, it may be underlined here that, irrespective of the system, the contours and trajectories of learner support system shall be different for largely “fresh full-time entrants” in dual-mode universities, and for largely “employed continuing education students” of open universities. In such diversified delivery contexts, the staffing, management, and development of the faculty and staff (so crucial to learner support) would also vary (Panda, 2004). Tait (2010) commented that: “. . .One of the tipping points we balance on is whether educational institutions can skill themselves quickly enough in the organization and management of online learning experiences to be able to satisfy their learners. . .” (pp. x–xi).

In the earlier formulation of distance education as industrialized system of education (Peters, 1983), the major concern was access to mass education, rather than organization of individualized student learning experiences. Issues like attrition, persistence, and dropout came up to the fore, and attempts were made to address these through learner support services including tutoring, counseling, academic advising, and regional and study center support services. Concerns for a humanistic approach to one-to-one learner support in the context of mass higher education were raised by Sewart (1993), and subsequently Rumble (2000) argued for the distance education community to be driven by the concern for planning “customer care and support” (in comparison to the campus-based counterparts) and prepare toward that.

With the advent of the World Wide Web (WWW), and especially the semantic web, the learning design, learner support, and institutional organization and management have undergone considerable changes (Panda, 2009). The emergent and contemporarily dominant blended learning model has also traversed beyond the judicious combination of F2F and online learning delivery, to include blending at every stage of design, development, delivery, and evaluation, and especially with due consideration to distance teacher/online instructor to be at the center stage of teaching and learner support (Garrison & Vaughan, 2008; Vaughan, Cleveland-Innes, & Garrison, 2013). In such a situation, the web provides for significant opportunities for learners to interact, collaborate, and engage among themselves as also with the teacher (which was less possible in traditional distance education). Both synchronous and asynchronous communication facilities enhance such collaboration, engagement, and the possibility of “reflection.”

As we moved toward online learning, the nature of learner support did undergo considerable changes. Analyzing the types and nature of interaction in learner-learner, learner-content, and learner-instructor interaction, Anderson (2003) emphasized that while the issues of availability and access to technology as also faculty time need to be addressed, learner support is required to be designed for all three types of interaction in online learning (synchronous as well as asynchronous). Since in online learning there is possibility of simultaneous cocreation of content by students and instructors, learner support cuts across learning resources and learning support; needs to be conceptualized in an individualized, interactive, and cross-functional framework; and should be organized before, during, and after the learning process (Thorpe, 2003).

This introductory analysis clearly brings up three trends: (i) that with changing technology-enabled distance learning and the nature of learners, learner support has also undergone significant changes, (ii) that the established notion and practice of learner support as a separate activity from course design and development has undergone changes to include learner support as an integral part of course design/ learning design, and (iii) that learner support in the twenty-first century distance/ online/ blended learning is considered to be more individualized, network-based, and operates within a system of flexible open educational practices.

## Learner Support Variables and Frameworks

### Support Variables

Though there is no standardized conception on learner support, within a comprehensive coverage of open, distance, and online learning, Brindley, Walti, and Zawacki-Richter (2008) remarked that: “Learner support is most often used as a term subsuming all interaction between institutional personnel and students (prospective and registered) intended to assist them in meeting their objectives from point of first inquiry through graduation and beyond, often for a life time” (p.1).

In the traditional context of industrialized system of distance education, where the process of learning was largely depersonalized and students were treated as part of a production line, there was a felt need to personalize learning and provide for counseling and especially mentoring (Panda & Jena, 2001; Sewart, 1993). In the 1990s, lots of debate took place on “independence/autonomy” versus “interaction,” and the right balance that the distance teaching institution and the distance teacher could maintain (Daniel & Marquis, 1979). These considerations notwithstanding, in reality, the offer of student support largely depended on the market, the package, the delivery system, the organizational image, and the organizational culture.

Though analyzed in the context of open university education, learner support was conceived of achieving three functions (Tait, 2000) – cognitive, affective, and systemic.

- Cognitive: This support is extended through the facilitation of learning within the standardized self-learning materials, and through tutoring/academic counseling.
- Affective: This support is provided through organization of communities of learners toward facilitative environment and increase in self-esteem.
- Systemic: Provision of transparent and student-friendly administrative processes and information management systems.

All the three need to work in tandem with the goal of making students comfortable, valued, and to effectively manage their studies.

In a detailed work, though based on the experiences of the UK Open University, Macdonald (2008) discussed the types of support that could be organized by an institution (Table 1) as also various tutor variables, the value they entail for students, and what more can be done to enhance the quality of learner support (Table 2).

**Table 1** Types of support across individuals, groups, and peers

Types	Individual	Group	Peers
Formal	Assignment	Tutorials, practical	Collaborative projects
Informal	Individual needs	Group networks	Social networks

Source: Macdonald, 2008, p.18

**Table 2** Tutor interventions/variables

Affective:	To build confidence in students
Dialogic:	To address individual student needs
Focusing:	To facilitate development of study skills
Reflective:	To provide for reflective tasks
Time management:	Student management of time, and management of assignment turn-around time

Source: Macdonald, 2008, p.22

**Table 3** Learner support system variables

Institutional variables	Technology variables	Learner variables	Academic/pedagogic variables
Organizing development of learning resources (print, audio, video, and multimedia) Course delivery Support systems (pre, on-course, and poststudy) Support networks Learning analytics Learning space. Online redressal mechanism Physical facilities and personnel Reliable and valid service Cost-effectiveness and cost-efficiency Administration and logistic support; information management system	Media channels, and conferencing facilities LMS/online platform Online tools Social media and networks Assistive technologies Servers and data privacy	Needs and preferences Readiness, motivation Satisfaction Study skills (and learning to learn skills) Self-regulated learning, and metacognitive skills Media choice	Learning resources Teaching processes Interaction, collaboration, and engagement Culture and learning Gender and learning Education and support for the disabled Tutoring, counseling, and mentoring Independence versus interaction Teacher/ tutor roles, competencies, training, and development

Academic support in the formal institutional study could be individual-based (e.g., through assignment comments and grades), group-based (e.g., in the study center tutorials and practical labs), and peer-based (e.g., through group collaborative project work). Besides, informal channel is also open to address individual and group needs through institutional and/or professional networks.

From a functional point of view, a tutor’s responsibility was much beyond dissemination and explanation of information to include more of humanistic dimensions of fostering confidence, development of skills of self-regulation and metacognition, and enhancing the ability to reflect.

Irrespective of modes of educational delivery, the variables of learner support system could be summarized to include and address a combination of or almost all the four types of variables listed in Table 3.

These institutional, technology, learner, and academic variables may vary across institutions (and, at the micro level, can be expanded to micro/contextual variables) but need to work in tandem within a macro institutional policy and system of learner support.

## Support Frameworks

In a recent survey of institutional leaders, Tait (2018) reported that while some open universities have got into learning analytics, OERs and MOOCs, many others have been constrained to gradually close down their well-established physical study/learner support centers. On the other hand, most have been lobbying with governments to establish national gateways/networks, along with Wi-Fi hotspots, e-learning platforms, related ICT infrastructure, and nationalized (and standardized) online examinations and automated learner feedback systems. For them, the change from the study center-based to network-based support (as also convenient mix of the two) could be traced through examination of a few frameworks as practiced by select distance teaching institutions.

Tait (2014) presented the evolution of the learner support framework at the UKOU over a period of time, starting with 1971:

- 1971–1976: local counselor, local module-tutor, regional center support, and 1-week residential schools
- 1976–2000: tutor counselor (initial tutoring and subsequent counseling), support of regional center, and residential schools
- 2000-present: module-based subject tutor, support of regional center with additional educational guidance team, and decline of residential schools
- 2014 onward: local based module tutor, program-wise national student support teams offering integrated subject-qualification-guidance support through phone and email (moving away from geography as the factor of learner support organization to subject and qualification-based support); end of student support as separate from course design, taken over through ICT

In case of the Indira Gandhi National Open University (IGNOU, India), which has the second largest distance education system in the world, and which was designed on the pattern of UKOU (i.e., headquarters-regional centers-study centers), learner support has undergone considerable changes, since its functional operation in 1987, in three distinct phases:

- Phase 1 (1987–1996): The regional support and other academic support units at the headquarters operated through regional centers in each state, which in turn operated through study centers and work centers (i.e., the contact point of students).
- Phase 2 (1996–2016): Besides the HQ-RC-SC model, the media center (with state-of-the-art media infrastructure and a dedicated educational satellite uplinked from the center) and the academic schools of studies also directly interacted with students for academic program-specific tasks.
- Phase 3 (2016-): Gradually, the open university centralized most administrative and organizational support at the headquarters, operated through technologies; and many study center academic and associated activities were handled by the faculty at the headquarters through the use of technologies and networks, though

the activities of academic counseling and practical continue at study centers/work centers.

In case of online learner support, in his theoretical framework, Rekkedal (2008) presented a case from NKI, Norway, comprising five stages of distance learning (along with support needs, responsibility center, and technology to address the support needs).

- Prospective phase: course choice, financial, practical aspects; generally handled by administration; with use of technologies like print, broadcast media, and Internet.
- Start-up phase: registration, material dispatch, induction, and follow-up; generally handled by administration with some faculty support; and through surface mail, phone, and email.
- Learning phase: (i) teaching, tutoring, academic support, social support, and assessment; by faculty; through phone, email discussion forums; (ii) practical support, technical support, resource library, learning groups, and local support; by administration and local faculty; and through F2F, phone, and email.
- Graduation: diploma accreditation; by administration; F2F.
- After graduation: further study, job opportunities, and alumni services; generally handled by administration; mix of print, F2F, Internet, and forums.

In case of online learning, Contact North-Contact Nord, Canada, outlined an eight-characteristics framework from online students' perspective (CN-CN, n.d.), which should be useful to other institutions and their faculty:

- Purposeful: learner support as integral part of institutional mission and strategic objectives
- Transparent: clear nodes and standards
- Accessible: seamless and 24 × 7
- Responsive: individual need-based, with definite turnaround time
- Interactive: interaction with institution, faculty, staff, and content
- Self-directed: independent skills and management
- Integrated: integrated across functions
- Open to change: prone to updating by new cohorts and by new changes

Based on the ARCS (affective-reflective-cognitive-systemic) model, a comprehensive analysis of various learner support frameworks in Asian distance education was undertaken by Jung and Hong (2014). In their revised model, and especially in relation to gender, the researchers located a five-variable support framework with associated subvariables (and which needs to be seen in relation to Tait, 2000):

- Affective: social, political, and emotional
- Cognitive: content, tutoring, assessment, and self-learning strategies
- Reflective: assistive guidance, developmental guidance

- Systemic: policy support, customized support
- Gender: life skill development, confidence building, and policy and learning environment

Given these and many institutional frameworks and subsequent changes in learner support systems due especially to technology sophistication, the traditional roles and competencies of distance teachers and tutors have also undergone significant changes. A tutor or online instructor undertakes all or most of these roles: designer, technologist, content expert, instructor, assessor, researcher, mentor, facilitator, adviser, colearner, and manager (Panda, 2019); therefore, continuous training and professional development inputs are essential to sustaining an effective support system.

## Technology and Learner Support

As discussed above, the traditional distance education learner support system was based on the tasks of tutoring (F2F or technology-mediated), counseling (F2F or synchronous), organization of study center activities, and interaction through conferencing and interactive radio/TV. This model has undergone considerable changes in the past decade at the behest of the semantic web, availability of synchronous and asynchronous technologies, and related research on online and offline interaction (Table 4).

Across various synchronous technologies (including telephone, conferencing, and chats) and asynchronous technologies (including SMS, email, among others), the following four powerful technologies have been proved effective in facilitating reflective and inquiry-based learning.

- Blog: for *individual* articulation and reflection (Jimoyiannis, Schiza, & Tsiotakis, 2018; van Wyk, 2018)
- Wiki: for *collaborative* projects and collective/community reflection (Biasutti & EL-Deghaidy, 2015; Huang, 2019; Kim & Kim, 2020)
- Discussion forum: for *critical* discussion and inquiry-based *reflection* (Chaka, Nkhobo, & Lephalala, 2020; McDougall, 2015; Wu, 2021)
- E-Portfolio: for *self-critical reflection* and *self-management* (Chaudhuri & Cabau, 2017; Jenson & Treuer, 2014)

**Table 4** Synchronous and asynchronous media vis-à-vis types of interaction

Interaction	Synchronous	Asynchronous
1. Learner-content	Teleconference, interactive radio, and virtual class	Interactive multimedia, web-based interaction, and facsimile
2. Learner-instructor	F2F counseling, telephone, chat, teleconferences, and interactive radio	Email, sms, discussion boards, facsimile, and online LMS
3. Learner-learner	Self-help group, chat group	Email, mail list, discussion board, facsimile, whatsapp, facebook, and online networks

It had been appropriately pointed out by Brindley et al. (2008) that, in case of traditional distance education, course production and learner support were distinctive activities which have now been blurred in the case of online and blended learning. When Tait (2000) and Simpson (2000) conceptualized and analyzed learner support at the time of the second generation distance education, various academic support and nonacademic guidance and support (including study skill development, feedback mechanisms, and graduate follow-up) were considered crucial. In the present context of Web 4.0 and changing institutional transformation, learner support has undergone considerable change. Tait (2014) revisited the reconfiguration of student support in the digital age, almost after one and half decades. Tracing the history from the earlier printed resources (didactic conversation), through the postal system and the telephone communication (synchronous conversation), and radio and television (radio wave) to the digital age (synchronous and asynchronous communication), Tait (2014) underlines that institutions have moved away from the behaviorist model to the constructivist and the connectivist, and that the earlier separation between course creation and learner support had resulted in “an integrated part of the overall curriculum design and learning and teaching system” (p.9).

It is worth noting that while there is still continuance of the traditional learner support models in a large number of distance teaching institutions, “the need for (such) reassessment is due both to the fact that while practice has moved on, scholarly analysis has not adequately done so, and secondly that practice itself in some second generation distance teaching institutions has not yet fully made the far-reaching changes that the digital revolution offers” (Tait, 2014, p.5). What has come up in the above analysis is that student success (or even dropout) is largely dependent on “effectiveness of learning design” (in which learner support is embedded), irrespective of the mode of (F2F, distance, and online) delivery. Further, the technological development of learning/learner analytics makes it easy to embed learner support with learning design, and to diagnose and facilitate student learning at every now and then, instead of waiting for periodic intervention (as in case of the traditional support model).

---

## Management of Learner Support Services

Given the policy, plan, and infrastructure for a working learner support system, it is the actual implementation that matters – and how the entire process is managed and with what motive. The traditional as also the contemporary management of mass distance education (including MOOCs) was greatly influenced by what Peters (1983) described as the industrialized system of education – where there is hierarchical model of organization with line authority, line management, specialization of tasks and skills (and division of labor), centralized authority, dominance of interests of the institution, and quality control (subsequently, assurance). Subsequent changes went beyond the analogy of the machine to the analogy of the living organism and included the following: subsystem complexities, open system in constant interaction with the environment, diverse and flexible regulatory system as per changing environment, multiple ways of achieving the stipulated outcomes, and to be open

and flexible enough to deal with the changing environmental challenges. In the distance education system, these entities operate too; there existed divisions in the traditional teaching functions including student support; and therefore there is a need that these discrete functions and changes operate in a coherent manner for effective teaching-learning, learner support, and quality of student learning.

It may be underlined that learner support in the traditional distance education (especially open university) delivery model was considered as part of institutional management. This functioned within a decentralized and distributed (and sometimes franchised) framework in which study center core activities of tutoring and counseling were *less visible*. In the case of online and blended delivery model, it forms an integral part of curriculum and assessment, with more faculty and student control, and is therefore *more visible*. Today, with more of accountability perspective and privatization dominating the institutional decision-making basket, education is being treated as a service industry and a tradable commodity, and students being treated as customers or clients. The humane and integrated personality development discourses have been considerably diluted to produce skilled knowledge workers in the knowledge economy. Distance education and the concomitant learner support have also been subjugated to this discourse. Therefore, it is not surprising that economy of scale and cost-efficiency have often dominated decision-making on how distance students should be supported. As an offshoot, the learner/learning management system (including learning center and technology management) has been more “administratively” viewed. There is therefore a need to relook at the balance between leadership and administration imperatives, on the one hand, and faculty and student voice, on the other.

---

## Issues, Challenges, and Suggestions

Stemming from the above discussions are some selective critical issues which distance educators, tutors/instructors, and institutional leaders need to address, especially in the changing context of globalization, technologization, and twenty-first century learning.

### Independence Versus Interaction

The debates on “independence versus interaction” were captured by Daniel and Marquis (1979) in their seminal article in which issues relating to pedagogic (learning), social (community), and economic (cost-efficiency) dimensions were discussed. While more interaction was to increase not only cost but also social learning and social development, more independence was to decrease not only cost but also social learning. Distance teaching institutions had to make decisions to have the right mix, balancing institutional and student interests. When the debate started, interaction and communication did exist in forms of real and simulated communication (real at study centers, and simulated through self-learning materials) (Holmberg, 1989), though Daniel and Marquis (1979) referred to “human communication.”

Both intellectual articulation and quality studies have underlined interaction as essential to “quality” learning (alongside independent study). On the other hand, distance teaching institutions struggle hard to ensure independent study (self-learning) in contexts where most learners do not have required study skills for self-learning, thereby demand for more interaction (meaning, more direct lecturing by teachers/ tutors at study centers, and through video lectures and teleconferencing sessions). This suggests that serious institutional scholarly policy decisions need to be made, on the one hand, to provide for mechanisms that facilitate independent study skills of learners, and on the other hand, ensure that interaction does not largely result in one-way communication from the peer or tutor or the mentor. At the same time, interaction also needs to be built into independent study of self-learning resources. This is clearly supported by the equivalency theory of Anderson (2003) that, given the three types of interaction (learner-content, learner-teacher, and learner-learner), “an instructional designer can substitute one type of interaction for one of the others (at the same level) with little loss in educational experiences” (p4). Even the student-teacher interaction can be minimized (with reduction in cost) and quality of learning maintained, in consideration of a variety of types and mixes of interaction that Anderson (2003) articulated.

## **Culture and Learner Support**

In any educational context, and especially in open and distance learning where it is difficult to ascertain the cultural differences in goals and attitudes of learners, it is important that, besides addressing the psychological and technical distances, more of sociocultural distance is studied and addressed to. There are differences in the goals and attitudes of learners, influenced by the goals and attitude to education of their own culture. Gunawardena (2014), while underlining that there are individual differences in the goals and needs among students, exemplifies cultural differences and expectations between the western world and the global south. While in the western world the stress is on understanding the world and achieving personal goals of excellence, in the nonwestern world generally the emphasis is given to respect for elders/teachers, moral development, and contribution to the society (and development of skills to address those). Also, while in the former, there is stress on individual excellence but in a collaborative and experience-sharing environment, in the latter, students often work individually (without much collaborative engagement), though find comfort in community values and ethos. Teaching-learning therefore needs to address the cultural and linguistic affiliation so as to remove isolation of students and increase institutional and cohort affiliation. This is more so in online learning where diversified groups of students with cultural, age, gender, language, and socioeconomic status differences interact in the same course of study. There are also other critical feminist, queer, and disability perspectives to address to. This is where learner support is intrinsically associated with curriculum design, teaching-learning, and assessment. It therefore requires clear guidelines, transparent communication, and individualized counseling support and mentoring.

## Gender and Learner Support

With more opening up of societies, gender issues are being articulated in a more transparent and just manner, more so in case of technology-enabled learning. In the context of traditional nononline form of ODL, deeper research and analyses are needed on cultural socialization, gender (across ethnic, class, educational backgrounds), and open distance learning, and the nature of support that could be appropriate and most effective. This could be extended further to the context of online learning (both synchronous and especially asynchronous) where there is more possibility of flexibility, voice, and collaborative reflection. Other areas of concern are access and gender equity, and technology-gender-online learning (Gnanadass & Sanders, 2018). Moreover, gender in distance education is also viewed not only from the perspective of access and equity, but also from the feminist perspective. A recent work on gender and distance education (Aneja, 2018) could be useful in further articulation from the points of view of: democratization from a gendered perspective, feminist pedagogical perspectives, and gender and social media in distance education (learning and support). For an elaborated model, also see Jung and Hong (2014).

## Disability and Learner Support

Almost each nation has now a legal/constitutional policy for the disabled, and their education and training. Higher education institutions have been constantly struggling to facilitate education and learning for the disabled – there are distinguished requirements for visual, hearing, and mentally impaired adults, as also for those who are physically challenged and have learning disability. There are access and assistive technologies available, and the universal design for learning (UDL) promises cognitive/academic access across peer groups and across programs of study. Quite often, the facilitation gets limited to physical access to resources (digital and otherwise), technology (enabled learning), and human assistance. There are also other disadvantaged groups who need support, which is often limited to special study centers, special provisions, and special concessions like fee waive and reservation for them. In the institutional arrangement for addressing the access needs of disadvantaged distance learners, we have almost neglected the quality of learning and support interventions, which are generally left to the students themselves to deal with, and which therefore need to be institutionalized.

## Technology-Enabled Learner Support

In spite of massive technological developments and institutional technology provisions, two practices remain as concerns, and which need to be addressed through institutional policy and leadership. First, even if many institutions have entered into (sometimes sophisticated) online learning, the traditional distinction between curriculum/ course design and learner support still persists. Second, massive technology deployment still stands as supplementary to media-mix, and media has not been “integrated” into curriculum design, course delivery, and learner support. This

represents a patchy work (and could be considered more as “market-driven”) without due consideration to support across a student’s learning trajectory (to be considered as more “pedagogy-driven”). For example, one may consider scaffolding for constructivist inquiry (McLoughlin, 2002), instructional design strategies (Schutt, 2003), factors in scaffolding at-risk students in blended learning (Hughes, 2007), activity design for online blended learning (Macdonald, 2008), alignment in authentic online learning (Parker, Maor, & Herrington, 2013), four pillars including scaffolding with technology (Babacan & Thurgood, 2021), and designing learning experiences that are personalized, interactive, immersive, framed by microlearning, and skill-based (Guralnick, 2021), among others.

## **Ethics of Learner Support**

Given that the main concern of distance education is access, equity, quality, lifelong education, and employability, there are ethical concerns relating to inclusiveness, nature of participation and support, institutional goals and support provisions, and fair decision-making. Visibility of professional ethics gets delayed in the traditional model of learning material and study center-based delivery and support, where as in seamless online distance learning, professional ethics is transparent and its visibility is immediate. Ethics embraces a larger canvas: institutional policies and plans of action, student autonomy and choice, faculty out-of-box concerns and actions on learner support (which is at times at odds with institutional plan and provision), and public/other stakeholder support for distance education (including parity of esteem). There is a need for provision of wider course baskets and media baskets to choose from; and also that the degree of openness and flexibility provided to the students forms part of ethical consideration and commitment. Tait (2000, 2003) had strongly argued for leadership and faculty introspection on issues relating to top-down/bottom-up learner support and the democratic concern of student voice. This concern for voice is much above the usual client feedback and student satisfaction surveys. Kelly and Mills (2007) talk of (ethical) conflict in “being fair to all students and being responsive to individual student needs” (p.150). The authors point to ethical underpinnings in three important areas – institutional access and admission policy, teaching and learner support, and governmental policy – and caution us about the usual uncomfortable trade-offs. Here, two issues assume considerable importance:

- First, in a competitive market, for institutions to attract students is important, but more important is to support them to ensure that they succeed. This also involves appropriate and sufficient information counseling for prospective students to make informed choices, and also to facilitate their study skills.
- Second, in case of an open admission policy, there is an ethical danger of either compromising quality or accepting high rate of dropout. Therefore, the claim to parity of esteem needs to be seen from an ethical perspective too.

## Quality and Parity of Esteem

The dual-mode universities have generally added open and distance (and online) learning to their profile in the name of access (or even increasing the gross enrollment ratio); therefore, services offered to the students are generally an add-on. It may be construed as unethical for distance teaching institutions to treat ODL as an add-on and to increase Gross Enrollment Ratio, and not able to provide for all types of support to their students that a full-time campus student gets. Conversely, it is unrealistic to ask those students to travel to mainstream campus to access those services like personal advice and counseling, career guidance, library resource support, and computer and other lab facilities (LaPadula, 2003). Will it then be fair to talk of “parity of esteem” and equivalence in quality?

---

## Research

Decision-making for learner support systems must be based on research. Considerable research studies on learner support in distance and online learning have been undertaken during the 1980s till the first decade of this century, though the subsequent research studies focused more on technology-enabled “learning” (rather than “support”). Reviews and research analyses on learning/learner support may be accessed from Robinson (1995), Salmon (2000), Simpson (2000), Lee (2003), Brindley et al. (2008), Macdonald (2008), Jung and Hong (2014), Zawacki-Richter and Naidu (2016), Sanchez-Elvira Pariagua and Simpson (2018), Kara, Erdogdu, Kokoc, and Cagiltay (2019), and special issues of *The International Review of Research in Open and Distributed Learning* (2003, 1), and *Open Praxis* (2014, 1). Robinson (1995) had long back underlined that research should focus more on theory building as also building on the existing research systematically. Besides this important consideration, review of the research studies on learner support in ODL points to the following further research questions:

- How do students learn and what contribution do a variety of interaction and tutoring make to their learning vis-à-vis their behavior, needs, motivations, and study approaches? What are the various models to effectively combine student-independent study and their (online) interaction and engagement?
- What could be the most effective learner support with social technologies and social networks? What effect does social technology-based learner support have on student-independent self-regulated learning and self-directed learning?
- What are the most appropriate and effective support strategies in course-based and MOOC-based educational programs, and how to support such learning to be more interactive and engaging? What impact does such learner support have on student study, dropout, and success?
- How do interaction and knowledge construction take place in an online and/or blended learning environment, and what support and scaffolding strategies could

be used to facilitate voicing opinions, questioning, participating in interactions, self-review, peer review, peer mentoring, inquiring and reflecting, and confidence building?

- What is the future of learner support in distance, open, online, and blended learning, and especially in the context of Covid-19 and post-Covid (when especially the teachers and tutors have had considerable experience and expertise in dealing with remote teaching)? How do the variables of culture, gender, and learner support interact for satisfaction, confidence building, and learning?
- In what different ways the new technology innovations like artificial intelligence, Internet of things, machine learning, and learning analytics could be put to practice in enriching the quality of support, personalizing support, addressing the institutional administrative-academic-support “system” in an intelligent flexible manner, and in ensuring cost-effectiveness and cost-efficiency?
- What additional and changing competencies teachers and instructors need to develop for quality learner support in the changing contexts of open education, open pedagogy/teaching, and open educational practices? What about teacher/tutor attitude, perception, and development?
- What best institutional provisions can be ensured for quality support and quality student learning – relating to access, adequacy, effectiveness, institutional culture, administration and management style, infrastructure, and networks?

---

## Conclusion

In future, distance learning organization and delivery is poised to shift from the study center-tutorial-learning materials model to more of resource based-networked-individualized and collaborative model, and a shift in the focus from “learning material” to “interactive learning and support system.” Digitalization of operation and services could ensure more transparency, efficiency, and learner-friendliness. Institutional leaders will continue to grapple between access and equity, on the one hand, and efficiency and quality, on the other. Serious introspection is needed in respect of institutional preparedness for technology-enabled learning – moving beyond adequate and effective provision to more of integration, and pedagogy-determined and learner-friendly operation. Mere provision is not enough; it needs to be operationalized and equitably distributed, and continuously grappled with. The recent experiences of remote teaching and support during Covid-19, though enriching in terms of keeping the process going, compel us to seriously relook at the organization and delivery of online and blended learning, vis-à-vis student engagement and quality of learning and learner support.

### Abstract

Administrative support provided to teachers, learners, and staff is critical for ensuring the quality of the teaching and learning experience in open, distance, and digital education (ODDE). Having been seen for a long time as a peripheral function, administrative support is now recognized as playing a decisive role in suppressing student dropout, improving teaching effectiveness, and promoting learning success. This chapter examines in detail how administrative support systems are organized and should be redesigned to efficiently assist stakeholders. This analysis is conducted in the framework of the ongoing digital transformation process of higher education institutions (HEIs). Reference models for

implementing digital learning innovation are described and analyzed. The chapter proposes that administrative student support in ODDE should not be organized as a separate autonomous structure. It is argued that in such complex and unstable innovation-driven institutional environments, the learner, faculty, and staff administrative support system should be designed as a hub of resources and services operating within an open and flexible learning ecosystem. It is suggested that multidisciplinary teams are set across the HEIs to collaboratively design, deliver, and support ODDE provision. Administrative staff professional development is also suggested to be reorganized in this innovative framework.

**Introduction**

Digital technologies have significantly transformed the way we live, work, learn, and exercise our citizenship. Mobile internet associated with an increasingly powerful and cost-effective computing and data sharing capability has made it possible to establish networks and communities, learn and develop skills, build and disseminate knowledge in an increasingly agile and autonomous way. Recognizing this fact, higher education institutions (HEIs) have been steadily moving from the traditional face-to-face classroom environment to an increasingly hybrid or fully digital territory (Teixeira & Mota, 2020; van der Zwaan, 2017). HEIs realized the future survival and expansion of their educational provision would depend largely on their ability to provide online education (Bates, 2019; Seaman, Allen, & Seaman, 2018). Many have dramatically increased their provision of fully online courses as a result of the expansion of massive open online courses (MOOCs) offering. The need to upscale access to quality higher education worldwide as well as widen participation has contributed substantially to consolidate this trend.

An ecologically friendly social and political atmosphere has favored the development of more sustainable formats of education delivery as it is the case of open, distance and digital education (ODDE). In recent years, open education has become a core component of open science which extended the principles of openness to the whole research cycle. An open knowledge ecosystem is thus being built with important implications on how the higher education, research, and innovation landscape organizes and operates (Burgelman et al., 2019; Teixeira & Mota, 2020).

The movement toward the mainstreaming of ODDE was dramatically accelerated by the global impact of the SARS-CoV-2 pandemic (Witze, 2020). However, the widespread implementation of emergency remote teaching and learning – ERT&L (Czerniewicz et al., 2020; Hodges, Moore, Lockee, Trust, & Bond, 2020) resulting

from the forced closing down of campuses has demonstrated how most HEIs were unprepared for this new scenario. Having the time and the resources to move beyond a crisis mitigation stage, they need to speed up the process of digital transformation (Dx).

In order to be successful, this transition requires HEIs not only to adjust their methodologies and procedures, but also to transform their organizational cultures (Grajek & Reinitz, 2019). This implies changes on the overall institutional governance and infrastructure as much as on how technology is integrated in educational practices. Administrative support, which has previously been seen as a peripheral function, plays a central role in HEI's organization nowadays and has become essential for meeting the new demands and assuring the success of teaching and research (Ryttberg & Geschwind, 2017).

Administrative support, once defined as the institutional assistance given to the design and delivery of quality education programs and courses, can currently be best described as the institutional capability to support the participation of all in quality research, teaching and learning experiences. It involves policies, finance, supply chain, human resources development and management, research administration, student affairs, as well as digital technologies to provide support services in an efficient, effective, and sustainable way to their stakeholders, that is, learners, faculty, and staff.

As HEIs embrace ODDE, by that changing their traditional mode of providing education, the way learner as well as teacher and staff support is offered must be transformed as well. Distance and traditional learners, for instance, each have unique support needs which should be met with differently designed services. Sánchez-Elvira Paniagua and Simpson (2018) claim that non-academic learner support in ODDE should aim particularly to developing learners organizational and affective skills. It deals therefore with the emotional stresses of study and staying motivated. Administrative learner support is usually provided in the form of funding, guidance, oversight, and other kinds of assistance (Meyer & Barefield, 2010; Ryan, Hodson-Carlton, & Ali, 2005). As such, it can include both action taken *with* a learner and action taken *for* a learner, including such diverse areas as:

- Program policies and regulations
- Student recruitment, admission and enrolment
- Academic counselling
- Financial aid, billing and payment
- IT infrastructure policies and procedures
- Human resources training and professional development
- Course materials and learning resources creation and sharing
- Libraries, archives, and repositories
- Student assessment and certification
- Student mobility and international exchange
- Student employability and further academic options
- External and internal communication
- Estates and facilities management (particularly in the case of campus-based HEI)
- Quality assurance

All these operations affect in some way the quality of the individual learning experience and consequently need to be adjusted to the specific needs and requirements of ODDE learners (Sánchez-Elvira Paniagua & Simpson, 2018; Tait, 2014; Zuhairi, Karthikeyan, & Priyadarshana, 2020; Aoki & Pogroszewski, 1998). The same applies to the respective support positions which also need to be redesigned, adjusted, and provided with timely training so that they can adequately fulfill the requirement for the services they provide in an online environment (Restauro, 2004). To facilitate this transformation, administrative support should be provided in the framework of a holistic institutional innovation strategy which promotes synergies across the HEI and involves all academic bodies and operational sectors (Teixeira, Bates, & Mota, 2019).

Also, as clearly demonstrated in the context of the pandemic, ODDE teachers feel much more engaged if they can rely on a strong infrastructure which supports their technological, economical, and emotional needs. Faculty members who perceive that they have the backing of a fully developed and well-designed support structure for ODDE, are rarely apprehensive about accepting the challenge. In cases where faculty apprehension abounds, it is usually due to a serious lack of administrative support in one or more critical areas (Meyer & Barefield, 2010). The online teaching needs of faculty often go unmet by the institutional infrastructure because administrators frequently fail to understand how technology rapidly changes the way learning must be designed and instruction must be delivered to meet learner demand. Technology also has great impact on other factors such as student admissions, registration, faculty, and staff development; and faculty workload are impacted tremendously by ODDE, yet HEIs are usually unprepared to handle the changes (McQuiggan, 2007). As demonstrated by ERT&L, distance and digital education programs are often developed in haste to meet growing demand, but without assuring a proper infrastructure, policies, and administrative support (Tallen-Runnels et al., 2006; Teixeira, Bates, & Mota, 2019). In this chapter we discuss successful models and practices for organizing and running administrative support in ODDE, focusing in particular on the main stakeholder – learners.

---

## **Applying a Holistic Approach to Institutional Change**

The first step to assure a sustainable ODDE provision is to assure strong governance support to educational innovation. Leadership across HEIs needs to focus on promoting ODDE and commits to change of educational practices, which implies that the leaders of HEIs need to develop a holistic vision which can inspire the stakeholders, be a reference for strategic planning, and engage all actors in the process.

Literature embodies many different models and strategies which describe and explain how learning innovations and educational change may be successfully introduced. Most of these models are grounded on empirical evidence. In relation to ODDE integration specifically, we can point out four main approaches: grassroots bottom-up, network-based, strategically driven, and collaborative (Laird, 2004). The first approach identified by Laird follows a grassroots inspiration and has been

prevalent in most HEIs. In this scenario, individual faculty members develop innovative educational practices in complete autonomy and in an undisruptive scenario. Their initiatives do not fall into any institutional strategy and are not supported by institutional policy. As such, faculty members have exclusive control over how their ODDE program or course is created and delivered and receive no specific contribution from administrative support. This model although providing large freedom for experimentation, but lacks capability to replicate and disseminate innovative practices.

A variant of the described model applies to when these bottom-up individual initiatives are part of networks or special interest groups. Teams of teachers support each other in conducting an innovative educational practice. They share the tasks and collaborate in disseminating the results. As each department in the institution operates independently from any other departments administrative support cannot be provided systematically. This model limits the impact, overall quality, and transferability of results.

A more successful and resilient approach is to engage the HEI in a strategically driven transformation of its educational practices. This could be organized applying a bottom-up model, in which individuals or small teams of volunteers conduct innovative educational practices with the special support of dedicated institutional R&D centers or support services. This approach is what Laird calls Distance Education model. A specialized unit or sub-department is established and operates independently from the rest of the campus, having no real connection to the traditional academic mission of the campus. In this model, administrative support is provided in a systematic way channeled through the provision of services to the specialized structures. In fact, since the 1960s, HEIs have been establishing Teacher and Learning Centers (TLCs) designed to support learning innovation. These units intend to act as hubs for educational reforms (Pérez-Sanagustín et al., 2022; Singer, 2002). However, they traditionally focused their activities as labs for the improvement of teaching skills and transfer of knowledge on student learning. This configuration is only efficient to support pockets of incremental innovation but does not escalate easily.

Recent literature (Holt, Palmer, & Challis, 2011; Pérez-Sanagustín et al., 2022) has suggested a significant shift in the TLCs design concept. It enhances the need for assuring that other major stakeholders, such as learners or managers, also participate in the activities. It emphasizes the strategic role of TLCs as the designers and sustainers of open education networks encompassing powerful forms of learning both across, and up and down the organization. This clearly represents a more holistic and transformational approach as it is based on a collaborative-based model.

Literature finds teamwork to be vital for an effective implementation of ODDE (McKenzie, Ozkan, & Layton, 2006; Restauri, 2004). The most successful way to induce disruptive educational change in the digital age lies on system integration and applying a teamwork approach where experts from each critical area of the infrastructure are intimately involved in the developmental process throughout its course (Laird, 2004). In this model, all the campus resources and services are being involved and traditional instruction is unified with online learning design and

facilitation. This generates a synergistic effect that allows technology, infrastructure, and resources to be shared by all faculty and staff. The online learning and the traditional learning infrastructure are combined and share resources equally, generating a true learning ecosystem. In such context, all sorts of administrative support (from policies to financial management and certification) are provided to relevant stakeholders according to their needs and at each stage of institutional development, in a coordinated, strategically driven, and network-based way.

Such a system approach which is particularly suited to ODDE can be used either in a stand-alone version or in the framework of an inter-institutional collaboration network which fosters organizational learning even further (Srivastava & Frankwick, 2011). This is the reference model adopted for example in the Portuguese distance higher education regulation (MCTES, 2019). In such a scenario, different and even competing HEIs form alliances to support each other, sharing know-how, infrastructure and resources, as well as jointly developing new educational provisions. External collaboration could also extend to specialized public agencies or nongovernmental organizations which can share know-how and resources for addressing specific target groups (e.g., students with special educational needs or disability – *SEND*) (Behling & Linder, 2017; Brinthaup et al., 2019).

The collaboration methodology maximizes efficient use of administrative and technological resources, minimizes redundant systems and costs, and allows faculty to provide better quality instruction in a more productive atmosphere (Paolucci & Gambescia, 2007). Administrative support services are either realigned to support ODDE or new personnel are hired to provide the specific support needed. A collaborative methodological process may seem more expensive and difficult to organize and implement at the onset, but in the long run it can save critical faculty from resigning in frustration and encourage more student enrolment (Meyer & Barefield, 2010). Evidence shows this collaboration approach to be the best for assuring sustainable disruptive change of educational practices.

---

## **Aligning Administrative Support with a New Learning Ecosystem**

It is hard to imagine a well-functioning HEI without well-functioning administrative support services. This is critical for assuring a successful experience for both learners and faculty. It should be noted though that the notion of learner support is relatively recent. It was absent in the first generation of correspondence education. As Tait (2014) explained, this idea of learner support only became an important part of ODDE theory and practice from the second generation onwards, when the pedagogical foundations of open and distance education shifted toward the recognition of the humanity of the individual student, and the identification of the affective dimensions of the learning experience, along with the cognitive and systemic dimensions (Tait, 2000). As a result, learner support became paramount and learner support systems came to be seen as critical elements for ensuring learner retention (Compura, 2003; Krauth, 1999; Aoki & Pogroszewski, 1998). The model inaugurated by the Open University (OU UK) in Europe, in the early 1970s, and soon replicated across the

world, gave the tutor the role of providing individual support to students both subject specific and supportive of progress and success. This support included assistance related to administrative and other systemic issues.

In the analogue age, support to ODDE learners meant the HEIs should be able to assure some sort of geographic proximity to learners. Inspired by the OU UK model, large-scale open and distance education universities separated the curriculum creation system from the learner support system. Consequently, they established large networks of local or regional study centers as well as examination centers spread across their territories which provided proximity support to learners. As HEIs moved online, learner support become an integrated part of the overall curriculum design and learning and teaching system, and no longer a separate subsystem in its concerns, professional sub-groupings, and scholarly literature (Tait, 2000; Compora, 2003).

Similarly, administrative support should not be seen as an independent element in the HEI system but as a hub of services that provides support to learners, faculty, and staff. As such, administrative support should cooperate closely and permanently with the learner support system, the faculties, and the technical departments. The success factor is therefore how each of the key components of an administrative support system can provide valuable support for the stakeholders (learners, faculty and staff).

In an increasing number of countries, the provision of ODDE programs and courses is regulated by specific legislation. Several strict pedagogical and technical requirements are imposed to HEIs as a condition for operating as ODDE providers. In the Portuguese case (MCTES, 2019), mentioned in the previous section, HEIs are required to have an appropriate technological infrastructure and support services as well as specially trained learner support staff amongst other conditions. It is mandatory for HEIs to develop integrated administrative management systems that ensure the dematerialized processing of all academic processes, including online communication systems for student attendance that allow for applications, enrollments, registrations, access to assessment results and other administrative documentation, and information be accessible online (MCTES, 2019: art. 9).

While the support services each HEI choose to offer may vary according to the national regulation, students' characteristics, the pedagogical approach followed, and the institutional culture, the decision-making is greatly driven by accreditation guidelines. In recent years, quality assurance agencies worldwide have been setting quality and accreditation standards for ODDE provision which share many similar elements (Ossiannilsson, Williams, Camilleri, & Brown, 2015). This establishes a good reference for the organization of administrative support systems.

## **Policies**

A cornerstone to all these set of standards is the requirement for HEIs to support the implementation of ODDE with appropriate policies, structures, and processes, which take into account all ethical and legal considerations and are embedded in the institution's organizational culture and values. This framework should provide

guidance on ODDE organization, ensure protection against academic fraud, as well as accessibility and participation for all learners, and proper and timely administrative and technical support for all users of the digital learning ecosystem.

## **Pedagogical Approach**

A successful innovation strategy must also be able to align academic and legal regulations with an institutional pedagogic model, which serves as a reference for ODDE organization and practice. Such a tool allows for an easier and coordinated adjustment of the administrative and technical structure with the concrete needs of faculty and learners. An example of this interdependence may be found in how HEI must ensure the security and fitness for purpose of the e-assessment system (Foerster et al., 2019). Certainly, one of the factors contributing to that goal is the implementation of protective measures which guarantee learner authentication and anti-plagiarism technologies which track learners' identity and work authorship. However, this must be always complemented with a code of practice which regulates the retrieval, storage, and use of learner data, and establishes for which purposes learning analytics is carried out. Such a combination of policy, technology, and a code of practice will ensure quality as well as information integrity, validity, and data protection. When external proctoring systems may be used, quality assurance procedures and security measures need also be implemented for external partners providing ODDE systems or services.

A prior condition to e-assessment practices as with other processes is that stakeholders, most especially teaching staff and learners, are informed about the methods and the criteria used for grading learners' work. This is once again partly assured by the pedagogical model, which establishes a framework for e-assessment design, and by clear communication from teachers. However, it also partly depends on how administrative support services confirm the information and apply those rules for certification and other processes. As such, an additional a code of conduct for learners must be in place. A code which includes recommendations on good practice and information on how cheating and plagiarism must be avoided and the consequences and sanctions such misconduct will lead to.

## **Learner Support**

The interdependence of factors which characterizes teaching and learning processes in such complex fully digital or hybrid environments calls for a highly integrated response from the HEI organization. This is expressed in closer and interconnected cooperation between governance, administration, and faculty. In what specifically regards learner support, this means administrative support services and technical infrastructure and support services should work in a very coordinated way and in close communication with faculty and other stakeholders. Consequently, HEI are required to implement efficient learner support policies and

strategies, which provide access to well-resourced support services for learner's counselling, orientation, tutoring, and facilitation in order to increase retention and success. As previously stated, learner support must cover not only pedagogical, but also technological and administrative-related needs, ensuring that services are timely and adequate to learners' profiles and needs, and considering the IT skills of the learners.

## Technological Infrastructure

Infrastructure support for ODDE faculty needs should be a well-organized effort with a never-ending process of improvement. At whatever state the current infrastructure is, there is always room for improvement, but the implementation of ODDE requires certain considerations not normally an issue in a campus conventional teaching environment. Meyer and Barefield (2010) distinguish different sets of priorities according to each of the three stages of ODDE implementation: foundation, development, and maintenance.

One of the most critical priorities in the foundation stage is to ensure a cooperative atmosphere between administration support and faculty (McLean, 2006), as well as to train technology support staff to be extremely supportive and responsive to the immediate needs of the learners and faculty (Jennings & Bayless, 2003). Another paramount condition to be secured is permanent connectivity to teachers and learners. Online registration, billing and payment system, online bookstore, and online library services are essential parts of the basic foundation needed to support ODDE provision. These online services should be well established in advance of implementation of ODDE programs and courses (Tallen-Runnels et al., 2006).

## Learning Resources

In the development stage, additional factors need be taken into consideration which requires administrative support to teachers and learners. These relate for instance to the production and/or distribution of learning materials to all learners. In an ODDE environment it is recommended the extensive use of open educational resources (OER), notably MOOCs. Such a decision allows for easier access to resources and the possibility for teachers and learners to contribute to its updating and improvement continuously. This calls for the dissemination of an open culture amongst faculty and other stakeholders as it has implications regarding intellectual propriety rights. The institutional adoption of open science policies, including open access to scientific publication and open licensing, is instrumental. Such an institutional strategy requires for administrative support services to adjust policies and procedures (Inamorato dos Santos, Punie, & Castaño-Muñoz, 2016). Universal accessibility to learning content and support services should also be assured and must be embraced by HEI as a major goal.

## Assessment and Certification

As fully demonstrated during the pandemic, another critical element in the development stage is to ensure e-assessment integrity and security. From a conventional perspective, stakeholders may wonder how can tests be proctored or learners be monitored while taking a test online and at a distance? An increasing number of solutions are available in the market. However, the best strategy is to redesign assessment and certification practices making full use of Ed Tech tools. This refers for example to the implementation of ePortfolios and micro-credentials.

## Communication

Accreditation standards usually require HEI to have information management systems which enable agile, complete, as well as representative collection of data and indicators derived from all aspects related to ODDE methodology, authenticity, and authorship technologies. Feedback procedures with the learning environment and the educational digital technologies used are also called for. This typically relates to the following aspects: ease of use for all learners' profiles; as well as privacy in relation to personal data, legal requirements, and ethical aspects involved. The HEI are expected to ensure as well the collection and dissemination of relevant information from stakeholders (learners, academic staff, support staff) for the effective management and enhancement of the ODDE methodology. The purpose of this is to promote improvements in the learners' learning experience.

An important additional element is that HEI must publish openly reliable, complete, and up-to-date information, accessible to learners before and after enrolment, on the ODDE practices, the pedagogical model which supports them, the minimum hardware requirements to make full use of the digital environment, the institutional learning, and technical support provided.

## Quality Assurance

Finally, at the maintenance stage, the process of continuously monitoring and evaluating new online technology assumes high importance. Updating technology only when there is value added ensures that decisions to upgrade technology are only made when it can be proven that there will be value added with the updated technology (Ryan et al., 2005). Periodically assessing and updating the quality of course content and delivery, as well as of support services, is a process that is much more critical in an online environment than with campus courses because technology and online learners demands change much more rapidly. Quality assurance plays a critical role in this context.

## From Digital Transition to Digital Transformation

The sustained expansion and further development of ODDE within an increasingly hybrid HEI landscape calls for the development of Dx. As indicated in a report by the Spanish Rector's Council, the Dx of HEI is no longer an option. Each university must therefore design, arrange, and execute a digitization plan that will allow it, depending on its reality and university model, to evolve as an organization throughout the process (Crue-TIC, 2018). Nevertheless, the most important challenge is the transformation of the organization itself as a deep change in both culture and leadership is required (Grajek, & Reinitz, 2019). HEI must evolve from the concepts of benefit/expense to vision/purpose, from hierarchy to collaboration networks, from control to trust and empowerment, from systemic planning to experimentation and acceptance of error as part of the learning process, and from opacity to transparency. The changes to be made affect the vision, culture, processes, and services (Crue-TIC, 2018).

There is growing evidence that HEI are embracing Dx, intentionally or not, as a matter of survival and a preparation for the still very uncertain future that emerges in the post-pandemic age (Reinitz, 2020). The objective is to become proficient and effective in the new digital or hybrid environment while, at the same time, keeping high academic standards. In fact, recent surveys confirm that most HEI leaders view Dx as a high priority and are committed to induce change in their institutions (Jensen, 2019). However, evidence also shows they are divided in how Dx translates into action. When asked to assess whether change is mainly being pushed top-down by the leadership and through an institutional-wide strategy or whether it is mainly developing as bottom-up, building on different opportunities and experiences across the different faculties or administration, results are not homogeneous. Although Dx seems to be part of the institutional strategic planning in most HEI around the world today, only in some cases there is reference to an actual digital roadmap or strategy in place to support its implementation (Jensen, 2019).

Reinitz (2020) identifies three stages in this transition: the 3Ds (digitization, digitalization, and Dx). The first and most basic step is digitization. The term refers to the transition from an analogue to a digital form. It can be described as a simple analogue-to-digital conversion of existing data and documents. A typical example of this stage is digitizing paper records and making them available online. In this case, neither are the processes optimized nor the document and data changed. They are simply encoded in a digital format. From learning materials to administrative documents most HEI across the world today have its information produced and shared in digital format and even openly accessible online. This has allowed for the automation of many manuals and paper-based processes which improve accessibility and work-flows. On a recent study on German universities, Gilch and others (2020) have concluded that digitization strategies are targeted at administrative support (61.8%) almost as much as at teaching and learning (69.6%). The objective most frequently associated with this is to increase the administrative services' quality and the administration's efficiency.

For administrative support, digitization involves four major operations. The first is to digitize all documents produced or used in its procedures (e.g., legislation, policies, regulations, and written procedures). The second is to assure that all administrative data is digitally retrieved, processed and managed according to established procedures protecting personal privacy and the integrity of the information. Thirdly, is to move all internal or external communication to digital media (either using email or other digital communication platforms). Finally, it implies providing online access to data and documents according to specific institutional policies. This can be done at four levels, as defined by Gilch and others (2020):

- Level 1 – Information is provided online
- Level 2 – Forms can be downloaded
- Level 3 – Forms can be completed online
- Level 4 – The process is completely digitized

Administrative managers are responsible in a top-down approach for the establishment or further development of a digital infrastructure, the optimization of the university's internal IT services and for the establishment of digital workflows in administration (Gilch et al., 2020).

The second stage in the journey toward digital transition is digitalization. This refers to the use of digital technologies and information to transform individual institutional operations. Evidence shows that most HEIs are using digital technologies and data not simply to move activities online, but to generate integrated digital environments where information is at the core. This involves, for instance, streamlining the enterprise resource planning (ERP), the invoice workflow and the travel management. As recent studies also indicate (Gilch et al., 2020), this transition may be conducted gradually. In fact, HEIs prefer to prioritize the digitalization of more critical administrative processes first, as the following:

- Application procedure
- Enrolment
- Notification of examinations and grades

Independently of the pace in which the transition is managed, digitalization implies that all other typical procedures will be handled completely digitally as well (e.g., payroll, procurement, research administration, invoice processing, application for jobs, traveling and accommodation application, and accounting).

Lastly, Reinitz (2020) distinguishes digitalization from a third and final stage, Dx. The term is used to describe a situation in which an institutional strategy to transform the strategic direction or value proposition of the HEI is in place. In some regions, notably Europe, policy is playing a critical role in promoting Dx. The new EU Digital Education Action Plan (2021–27) is most certainly a strong evidence of that. Dx represents an extra step by which all education and research-related institutional processes are disruptively changed as a result of digital technology possibilities. The organization's entire operating model including administrative

support is to shift and not just teaching practices. In order to assure the Dx journey is carried out, governance and leadership need to be focused on promoting educational innovation. There needs to be a holistic vision that inspires the institution's community, aligns strategic planning with it, and engages all relevant actors in the process.

Dx allows HEIs to develop an increased capacity to accommodate openness, complexity, and diversity. As stated in previous sections, ODDE learners are more diverse in profile, expectation, and needs than traditional ones. This results not only from the heterogeneous nature and geographical dispersion of the student population. It has been noted by literature that individual students are increasingly following more complex trajectories, moving from one HEI to another, changing between degrees and even fields of knowledge, mixing formal and nonformal learning offerings, and designing their own pathway (Haas & Hadjar, 2020). These phenomena have clear implications for administrative support. Enrolment in a degree, for example, does not represent necessarily an intention of the student to complete it. As such, the relation between enrolment and completion/dropout does not allow the identification of certain factors within the educational trajectory that may have led to one or the other outcome (Haas & Hadjar, 2020). HEI policies and administrative procedures must be adjusted in accordance. They should become highly flexible, transparent, and customizable. In addition, managers and administrative staff have to be also able to tailor them to meet personalized requirements. Moreover, interacting in a hybrid or in a fully online environment requires specific training and expertise. This implies administrative staff should be digitally competent and be recruited and trained for operating in this new context.

Another key aspect of HEI will be to develop a coherent and multifaceted educational ecosystem, one which includes both the several elements of the learning environment (the learning management system, the digital repositories, the virtual and remote labs, and the e-assessment system) and the administrative and technical support services as well. Considering that this is a cultural change process, HEI should also strive to make this ecosystem open, promoting the use, reuse, and remix of OER, and assuring universal accessibility and digital inclusion (Czerniewicz, 2018; Teixeira & Mota, 2020).

One central feature of the digital society is the way in which knowledge and information are produced and distributed in networks that often escape the control of organizations and institutions. HEI are facing an "age of super-complexity" in which knowledge claims are no longer made solely by universities, but knowledge production is increasingly built in private firms and non-academic organizations (Baltaru & Soysal, 2018). According to Wiley and Hilton (2009), universities responded to the radical changes technological innovation brought upon human society by increasing connectiveness, personalization, participation, and most especially openness, since it is a prerequisite to affordable, large-scale progress in the other areas.

Open professional collaboration and inter-institutional alliances are key in the digital age. Based on Hagel and Brown (2005), Wiley and Hilton (2009) suggest that universities will have to rely on "dynamic specialization" strategies, committing to eliminate resources and activities that no longer differentiate them and concentrating

on accelerating growth on what truly distinguishes them in society in order to be or remain successful. They identify five critical functional areas in university organization. These are: structuring and providing access to content; tutoring and learning support services; curating and providing access to research materials; acting as a hub for social activities; and assessing learning and awarding degrees. Wiley and Hilton (2009) expect HEIs focus on developing truly world-class expertise in one or two of these functions and outsource the others.

The implementation of such a model has major organizational and management implications (Teixeira, 2012). Innovative universities, as described by Christensen and Eyring (2011), will have to evolve from a closed environment to an open network one in which data and resources are openly and freely shared with fellow institutions and also with the community. This implies a major change in academia and its validation practices, as well as in many other aspects of how HEIs operate (Weller, 2014). However, even the most flexible universities are traditionally much stable organizations, not changing its basic structure and processes over the years. As such, leaders find it much more difficult to reengineer them as learning organizations (Senge et al., 2000). In fact, higher education has historically avoided competitive disruption.

By unbundling teaching and learning processes and outsourcing services, namely administrative support (Teixeira, Bates, & Mota, 2019), as well as “rebundling” them into new forms (Czerniewicz, 2018), according to different variable contexts, HEIs will gain flexibility, critical dimension, and resource capacity. This will equip these institutions to respond promptly to a rapidly changing environment, thus carrying on their mission of providing quality learning opportunities for all.

---

## **Role-Changing: Redesigning Professional Development**

Looking ahead at the digital futures of higher education, we can anticipate artificial intelligence (AI) and robots will be playing an increasingly important role in assisting teachers to teach and learners to learn more efficiently. This however does not mean classrooms will be replaced by teaching and learning machines. The purpose of Dx is not so much to automate processes, but to add data intelligence. The same principle applies to administrative support in HEI.

Although processes will be increasingly automated, HEI readiness to overcome the challenges of the new normal will depend heavily on how well their faculty and support staff will be prepared. It is urgent to rethink professional development in HEI. The pandemic crisis has highlighted the importance of teachers' digital competences (Gewerc, Persico, & Rodés-Paragarimo, 2020). However, not much attention has been given to the need for administrative support staff to develop further their digital competences as well. Similarly to faculty, these competences need to be acquired and developed in authentic contexts. This implies staff should be trained in immersive online-based settings and not in traditional in-person environments. Otherwise, they will not be properly prepared as they will lack the experience of working, communicating, and learning online. In addition, they need to train to operate in increasingly learner-centered contexts in which personalization of support services and learner participation in its management are key elements.

A healthy ODDE provision must be preceded by a healthy online development program for both faculty and staff. Staff mentoring could be very effective to help remember and put into practice what was learned in the training sessions. Training that takes place without mentoring is quickly forgotten and refresher training is required, but training that is followed by a well-organized mentoring program has proven to be very effective in helping faculty remember what was discussed in the classroom (Mandernach, Donnelly, Dailey, & Schulte, 2005). The same can be applied to administrative staff.

The administrative support staff usually view themselves as back-office actors. However, in a disruptively changing environment as Dx, they are called to shape their roles themselves and have a larger participation. This implies a certain amount of ambiguity and insecurity as they are bound to operate in a cultural environment dominated by academic norms and values which may be strange to them. Moreover, they must perform a mix of roles which are midway between administrators and academics. In fact, administrative support staff to ODDE teachers and learners may fall into the category identified by Whitchurch (2009) and confirmed by Rytberg and Geschwind (2017) of blended professionals working in a third space. In the words of Musselin (2007), most of them are project-oriented employees. In fact, they regard their tasks at hand as more important than belonging to a specific organizational unit.

Therefore, setting up an open collaboration culture supported by fluid communication and multidisciplinary teamwork is essential to disseminate educational innovation and ensure a supportive institutional environment for quality ODDE development. Accordingly, it may be instrumental to ensure professional development of administrative support staff and technical support staff is conducted in a coordinated and whenever possible integrated way with faculty.

---

## Conclusions

Spearheaded by the global impact of ERT&L, HEIs worldwide are accelerating the movement toward mainstreaming ODDE. As they move forward in this direction, it becomes critical for HEI to reorganize and adjust their existent infrastructures and services. In this context, major attention should be given to the redesign and readjustment of administrative learner support systems as their action is central to the quality of the ODDE learning experience. As literature recognizes, ODDE learners have unique support needs which should be met with services that adequately fulfill their mission in an online environment. ODDE faculty also feel much more engaged if they can rely on a strong infrastructure which supports their technological, economical, and emotional needs.

We have demonstrated in this chapter the importance of administrative learner support being provided in the framework of a holistic institutional innovation strategy involving the active participation of all stakeholders by which strong synergies are promoted across all sectors of the HEIs, academic and non-academic. Given this process leads to an institutional transformation it implies a deep change in both culture and leadership.

The possibilities of digital technology combined with the theoretical foundations of open and distance education which build upon universal accessibility and learning flexibility promote the use of collaborative pedagogical models. This leads ODDE to empower learner participation at all phases of the learning process. The introduction of learning analytics, AI, and adaptive technologies has allowed to combine scalability with personalization. An increased flexibility and customization in design, delivery, and support of ODDE programs and courses is therefore now being required by all stakeholders.

In this new emerging scenario, we have demonstrated that administrative learner support, as part of a wider administrative support hub of resources and services, should have a close collaboration and consequently participation in the integrated process of design and delivery of courses and programs. A system-wide approach is needed. We recommend therefore HEI to set up multidisciplinary teams involving faculty, learning designers, administrative, and technical staff, as well as alumni to coordinate design, delivery, and support of ODDE provision. In the same direction, we also suggest ensuring professional development of administrative support staff and technical support staff is conducted in a coordinated and whenever possible integrated way with faculty.

As HEI engage in Dx and ODDE provision expands, a new organizational model based on the principle of dynamic specialization is emerging. HEI are reorganizing as learning ecosystems and converging each other and with other non-formal learning institutions in large open networks. It is foreseeable that this new landscape will impact dramatically in the design and organization of administrative learner, faculty, and staff support systems, as each HEI may share its most efficient services with others and use other's services to replace its own less successful services. The resulting scalability will produce major gains in efficiency and a better service provided will also increase the quality of the learning experience. Moreover, this new open collaboration institutional model represents at best the affordances of open science and ODDE in higher education.

## Abstract

Open, distance, and digital education (ODDE) is meant to provide unique educational opportunities for everyone, including learners with special needs. While promising flexible and accessible learning experiences for learners with special needs, ODDE may simultaneously result in the creation of certain barriers. Supporting learners with special needs in ODDE environments, therefore, becomes a critical task for all educational institutions. This chapter focuses on the challenges that learners with special needs encounter during their learning process in ODDE, as well as those mechanisms that can be used to support them in order to overcome these challenges, such as means of increasing accessibility,

This chapter was supported by Anadolu University Scientific Research Projects Commission under grant no.: 2107E058.

recognizing Universal Design for Learning principles, using assistive technologies, providing accommodations, and adaptations in terms of pedagogical, managerial, social, and technical support. The chapter suggests that ODDE is inclusive in nature and that it should therefore further focus on empathy and care-oriented pedagogies. ODDE, inspired by openness philosophy, envisions equity, equality, and justice for every learner, including learners with special needs.

**Introduction**

Open, distance, and digital education (ODDE) is an umbrella term that is rooted in interchangeably used educational models, such as open education, distance education, online education, or digital education. As a generic broad term, the letters in ODDE abbreviation highlight, respectively, different aspects of the term. For instance, open refers to ODDE's theoretical and philosophical characteristics; distance refers to ODDE's pedagogical characteristics; and digital refers to technological characteristics, which includes online and digital tools, services, or environments. Finally, education refers to teaching and learning informed by open, distance, and digital practices.

Emphasizing that ODDE is a “notion with pluralistic and inclusive connotations, and a stance that defends widening participation” (Zawacki-Richter et al., 2020, p. 321), ODDE has always possessed a heterogeneous learner body through its welcoming of non-traditional learners (Wedemeyer, 1981) through flexible ways of delivering education and technological affordances to facilitate teaching and learning by fostering participation (Stöter, Bullen, Zawacki-Richter, & von Prümmer, 2014). The emergence of open universities has played a pivotal role (Tait, 2008) in providing learning opportunities for learners who were previously excluded from or unable to access conventional education (Bozkurt & Zawacki-Richter, 2021). In addition to traditional learners, ODDE ensures that the back door (Wedemeyer, 1981) is kept open for non-traditional learners; these include disadvantaged learners, such as those disadvantaged as a result of gender, remoteness, wealth, disability, ethnicity, language, migration, displacement, incarceration, sexual orientation, gender identity and expression, religion, and other beliefs and attitudes (UNESCO, 2020, p. 6), as well as learners with special needs.

The term learners with special needs is generally used to refer to learners that experience difficulties in learning due to their cognitive, physical, or sensory impairment; chronic illnesses; or psychosocial issues to the extent that the learner in question may require assistance in regard to their learning process (Laamanen et al., 2021). On review of the literature, it can be observed that there are also

other commonly used terms that refer to learners who require special education, such as exceptional learners, learners with disabilities, learners with special educational needs and disabilities, disabled learners, and learners with disabling conditions (Kinash, Birt, & Judd, 2019; Kirk, Gallagher, Coleman, & Anastasiow, 2009; Laamanen et al., 2021; Repetto, Cavanaugh, Wayer, & Liu, 2010). Though there is diversity among those terms that define special needs, all these terms focus on a single purpose, which is that learners in these groups require learning practices to be modified according to their specific learning needs. In this chapter, the term learners with special needs is adopted because the focal point is the special needs of learners who require adaptations in their learning process in ODDE; however other terms will also be used and retained if they are deliberately used by those authors cited herein.

---

## Learners with Special Needs in ODDE

When examining learners with special needs in a general sense, Reiser and Dempsey (2012) suggest four categories: visual involvement, auditory involvement, mobility involvement, and cognitive involvement. These four categories are the most commonly used when considering provision of support for learners with special needs in ODDE. Visual involvement includes any condition resulting in the loss of visual perception; auditory involvement includes both deaf and hard of hearing categories; mobility involvement refers to any difficulties experienced regarding the movement within the natural environment, such as arthritis, cerebral palsy, muscular dystrophy, multiple sclerosis, or traumatic brain injury; cognitive involvement includes learning disabilities, autism, traumatic brain injury, cerebral palsy, epilepsy, neurological impairments, and mental illness. Learners with special needs may experience one or more than one of these conditions, and therefore they may belong to one or more of these categories (Catalano, 2014). However, it is important to note that learners can also have temporary disabling conditions that belong to one or more of these groups, such as having a broken arm or leg or being pregnant.

According to the WHO statistics, 15% of the world's population experience disability in varying degrees and in different forms (WHO, 2011). As a result, an increase in the number of learners with special needs has been observed in all levels of education globally (Fichten et al., 2009; Kinash et al., 2019; Laamanen et al., 2021; Tesolin & Tsinakos, 2018). Repetto et al. (2010) indicate that learners with disabilities are at risk of dropping out of school due to certain reasons such as access problems, lack of support, inability to find a helpful person to connect with, fear of course failure, poor self-esteem, etc. In this sense, ODDE is considered to be a means of increasing access to equal opportunities in education, thereby eliminating the barriers of access emerging in face-to-face education (Jelfs & Richardson, 2010; Kinash, Crichton, & Kim-Rupnow, 2004).

ODDE not only offers learning opportunities in terms of spatial and temporal flexibility by allowing learners to study at their own pace, it also increases accessibility for those learners who would otherwise be unable to attend face-to-face classes (Fichten et al., 2009). Additionally, learners with special needs can experience the

advantage of increased accessibility through the use of assistive technologies and multimedia involving speech, text, and audiovisual materials (Crichton & Kinash, 2013; Erickson & Larwin, 2016). Accordingly, these learners may perform better in online courses than in face-to-face courses (Stewart, Mallery, & Choi, 2010). As noted by several other researchers, empirical evidence suggests that learners with disabilities increasingly prefer to participate in online courses at a higher rate than other learners and that they recognize the benefits of ODDE (Alamri & Tyler-Wood, 2017; Moisey & Hughes, 2008). For example, Fichten et al. (2009) identify benefits of online learning from the perspectives of learners with disabilities; the most common benefits were the availability of online course notes, the support and enrichment of the learning process, help in understanding course content, the ability to learn from home and to work at one's own pace, the availability of online course resources other than notes, help in regard to time management, the convenience of communicating with peers/professors, and availability of information at any place and time. When the achievement level of learners with special needs is examined in ODDE, it can be observed that this level may be lower than that of learners without experience of any disabling condition. In a study in which the researcher compared the outcomes of disabled and non-disabled learners who were enrolled in distance-learning courses at the Open University UK (OUUK), Richardson (2010) found that disabled learners had lower grades, lower pass rates, and poorer course completion rates than their peers. In parallel to this, Wolanin and Steele (2004) indicate that learners with disabilities often need more time than their non-disabled peers for academic tasks, resulting in learners with disabilities taking twice as long as their non-disabled peers to complete their degrees. Supporting these statements, a study conducted by Moisey (2004) at Athabasca University revealed that learners with disabilities had a completion rate of 45.9%, which was lower than the completion rate for learners without disabilities (52.5%). These findings may be due to those challenges that learners with special needs encounter in online learning environments.

---

## Challenges Encountered by Learners with Special Needs in ODDE

Moore and Kearsley (2012) describe online courses as “both a boon and a bane to disabled learners” (p. 113). Despite their affordances, many online courses may create barriers to learners with special needs (Barnard-Brak & Sulak, 2010; Edmonds, 2004; Moore & Kearsley, 2012). In this chapter, these barriers are examined according to five themes (Tesolin & Tsinakos, 2018):

*Internal and external stereotypes:* Invisibility of disability, having negative attitudes about requesting accommodations, and having negative perceptions on the ability to succeed may constitute a barrier to success among learners with special needs in ODDE. Identifying learners with hidden disabilities (e.g., learning disabilities or health-related impairments) is more difficult than identifying learners with visible disabilities (e.g., visually impaired learners, physically impaired learners) if these learners do not inform their instructors of their disability (Tandy & Meacham, 2009).

The learner's type of disability (e.g., visible or invisible) is critical because, as claimed by Barnard-Brak and Sulak (2010), learners experiencing visible disabilities tend to have more positive attitudes toward requesting accommodations in the online versus face-to-face learning environment as compared with learners who experience hidden disabilities (e.g., learning disabilities or health-related impairment).

*Lack of infrastructure:* Inadequate technical and policy frameworks can lead to failure among learners with special needs in ODL. Burghstahler (2002) mentions the digital divide – which she calls it as second digital divide – that learners with special needs experience; even if they have ostensible access to computers and the Internet, they may not have the opportunity to actually access these tools due to the inaccessible design of electronic sources or online learning environments. Additionally, a lack of policy frameworks, regulations, and guidelines and inadequate implementation of existing frameworks may also hinder learners with special needs.

*Inaccessible education platforms, websites, and resources:* Fichten et al. (2009) note that inaccessibility of websites and learning management systems (LMS) may cause a problem in terms of access for learners with learning, visual, and neuromuscular disabilities, and this problem remains even when they use screen magnification, screen reading, or dictation software. Furthermore, Fichten et al. (2009) add that visually impaired learners may encounter difficulties using certain websites when employing screen-reading technologies; additionally, fixed font size of materials or online maps and images can create problems for visually impaired learners.

According to the study conducted by Massengale and Vasquez (2016), incompatible content with screen readers, so that these readers are unable to read such content; the use of JavaScript requiring learners to be able to use a mouse; content opening in pop-up windows; and problematic links to text and tables without headers were the top five challenges encountered by learners with special needs. Comparatively, Moisey and Hughes (2008) emphasize that keyboards can be difficult or impossible to use for learners with fine motor problems or conditions such as carpal tunnel syndrome; learners with hearing impairments or communication disorders (e.g., aphasia, severe stuttering) may be unable to participate in audio-conferences; learners who experience learning disabilities or reading-comprehension problems may experience difficulties in understanding text-based materials.

*Lack of qualified educators/training:* This theme involves educators' lack of knowledge of accessibility, training needs, lack of interaction, disconnection with peers and instructors, and poor course design. Fichten et al. (2009) claim that staff who are responsible for deploying e-learning generally do not examine academic software that has already been purchased in regard to its compatibility with adaptive software such as screen readers. Additionally, they mention poor use of e-learning by some of the professors as well as these professors' lack of knowledge of working with e-learning.

*Lack of interaction and communication:* Online discussions and communication in ODDE may be cognitively demanding; for example, participating in synchronous chats can be difficult for visually impaired or dyslexic learners as it requires them to read and respond quickly (Tandy & Meacham, 2009). Additionally, inadequate

communication with peers and instructors may constitute a barrier to success (Alamri & Tyler-Wood, 2017).

In sum, various strategies are needed to support learners with special needs, whose needs can vary according to their specific disabling condition and its corresponding severity (Barnard-Brak & Sulak, 2010; Edmonds, 2004). There may even be individual differences between learners who experience the same type of disabling condition (Griful-Freixenet, Struyven, Verstichele, & Andries, 2017). Therefore, it is crucial to provide different types of support according to the type and level of a disabling condition in order to enhance success in such a heterogeneous group of learners (Laamanen et al., 2021; Moisey, 2004).

---

## Learner Support Systems in ODDE

Learner support in ODDE refers to all those activities that support learners' progress in their respective studies, which is considered as one of the key indicators of quality (Hall, 2003; Simpson, 2002). Spatial, temporal, and transactional distance between learners and instructors – which is underlined in the definition of distance education – can lead to challenges for learners when finding solutions to their problems during their learning process. Moore and Kearsley (2012) emphasize the direct relationship between learners' failure and dropping out of a program and the failure of the available learner support system. Therefore, establishing strong learner support systems plays a crucial role in learner motivation, engagement, and achievement in ODDE (Moore & Kearsley, 2012; Thorpe, 2002).

Services that support systems that are involved in an ODDE system typically involve “enquiry, admission and pre-study advisory services; tutoring; guidance and counselling services; assessment of prior learning and credit transfer; study and examination centers; residential schools; library services; individualized correspondence teaching; record keeping; information management, and other administrative systems; differentiated services for learners with special needs; materials which support the development of study skills, program planning or career development” (Tait, 2000, pp. 289–290). There are various classifications that examine support systems in the literature (Genç & Koçdar, 2020a). For example, Simpson (2012) classifies support services into two groups: those of academic and non-academic support. Support for cognitive issues related to a certain course or courses and instruction-related issues were considered under academic support, while affective and organizational aspects of learners' studies were considered under non-academic support. Berge (1995) categorized support needs into four groups: pedagogical, managerial, social, and technical. Services related to academic skills and course content can be listed under pedagogical support; services related to registration procedures, administrative acts, timetable, organization, evaluation, and procedural rules can be listed under managerial support; services related to improving human affairs, strengthening group dynamics, enhancing learner–learner or learner–instructor non-academic interaction, and minimizing the sense of isolation can be listed under the social support; and services related to the elimination of

software- and hardware-related problems encountered by distance learners can be listed under technical support. In sum, the intention behind all these activities is to support and facilitate the learning process.

---

## Supporting Learners with Special Needs in ODDE

Support systems have a critical role in the achievement of learners with special needs (Altınay, Altınay, Ossianilsson, & Aydın, 2018). For example, according to the results of the study conducted by Moisey (2004), learners with special needs at Athabasca University who received a greater number of different types of support services were found to have more success in their respective courses. On a review of the literature, it can be observed that discussions concerning supporting learners with special needs in ODDE are generally undertaken through the concepts of accessibility, Universal Design for Learning (UDL), use of assistive technologies, and accommodations or adaptations provided by educational institutions.

### Accessibility

The most commonly mentioned issues regarding accessibility in ODDE are web accessibility, LMS accessibility, and accessible course/learning design.

**Web accessibility:** The term “accessibility” is widely used in the context of web design (Cooper, 2014). The World Wide Web Consortium (W3C) is an international web standards organization, and its Web Accessibility Initiative (WAI) creates detailed guidelines. As is noted on the W3C website, web accessibility refers to “websites, tools, and technologies are designed and developed so that people with disabilities can use them”; in other words, they are able to “perceive, understand, navigate and interact with the web and contribute to the web” (W3C, 2021). In addition, implying that accessibility is a broad concept, W3C emphasizes that web accessibility also benefits individuals without disabilities, such as elderly people with changing abilities due to their age; people experiencing temporary disabilities, such as having a broken leg; or people having a slow Internet connection. The WAI has developed detailed guidelines on how to ensure web accessibility such as WCAG 2 or WCAG 3 standards, which are universally accepted and frequently used. Various tools exist that can be used for accessibility testing of websites like WAVE accessibility evaluation tool (Massengale & Vasquez, 2016) or DYNO Mapper.

**LMS accessibility:** Similar to web accessibility, LMS are also needed to provide accessible online courses. Most of the LMS companies or providers strive to consider accessibility issues. For example, Blackboard, Desire2Learn, Canvas, and Moodle are committed to providing accessible course platforms and utilize standards that ensure accessibility. Furthermore, there are accessibility tools that help identify accessibility issues in an online course; for example, the University of Central Florida’s Universal Design Online Content Inspection Tool (UDOIT) checks and

reports accessibility, while Blackboard Ally helps make digital course content more accessible through technical design solutions.

**Accessible course/learning design:** The concepts of web and LMS accessibility consider the problem of accessibility from a more technical perspective. However, accessibility is not merely a technical issue but also a matter of learning design (Cooper, 2014). A course website or an LMS might be accessible; however, if the course is designed without addressing accessibility issues, learners will nevertheless experience difficulties when using the course materials. Therefore, designing course materials in a manner that is accessible to all learners, including those in disabling conditions, is important in the online learning environments (Cooper, 2014; Kinash et al., 2004; Massengale & Vasquez, 2016). For example, when delivering the information, multimedia can be used; the information can be presented through a text and a video at the same time. Principles of UDL can help designing accessible courses and learning environments.

## Universal Design for Learning

Having its roots in architectural design, UDL is a framework for increasing the accessibility of learning environments for all learners (Lever-Duffy & McDonald, 2011). UDL focuses on removing barriers from the early stages of instructional design processes, eliminating the need to undertake adaptations for diverse learners (Reiser & Dempsey, 2012). The Center for Applied Special Technology (CAST) has developed the UDL Guidelines suggesting the instruction to be designed to support multiple means of engagement, multiple means of representation, and multiple means of action and expression (UDL, 2021). Presenting learning materials in multiple formats, strategies for optimizing individual choices, and autonomy or the use of multiple media for communication potentially improve learning not only for learners with special needs but also for all learners. This is because individuals learn and engage with learning materials in different ways and use different strategies as part of the learning process, for example, ESL learners, who are able to utilize captions in a video and who have better comprehension regarding the relevant content, and those learners who are hard of hearing or who have learning disabilities. Similarly, learners who lack time due to their professional and familial commitments will be able to benefit from audio materials while commuting or travelling, thereby learning in a similar manner to those with visual impairments. The metaphor “electronic curb-cut” is used to refer to accessible online content; just as the slopes facilitating physical access from sidewalks to streets are designed for wheelchair users, they can also be used by pedestrians of all kinds, people carrying luggage, and cyclists (Kinash et al., 2019; Tandy & Meacham, 2009).

## Assistive Technologies

Assistive technologies refer to devices and software used by people to overcome barriers presented by their disability (Reiser & Dempsey, 2012). Learners with

cognitive disabilities can benefit from optical character recognition software, word processing, and word prediction software, while learners who are deaf or hard of hearing will benefit from close captioning video phones, pocket talkers, and amplified phones (Lever-Duffy & McDonald, 2011; Reiser & Dempsey, 2012). Screen-reader software, text-to-speech software, screen-magnification software, dictation software, and refreshable Braille display can be used to support visually impaired learners (Reiser & Dempsey, 2012). Additionally, learners with mobility involvements will benefit from word prediction software, eye gaze software, voice recognition software, and mouth sticks (Kinash et al., 2019; Reiser & Dempsey, 2012). According to the study conducted by Fichten et al. (2009), the most commonly used software indicated by learners was software that improves writing quality, screen-reading software, scanning and optical character recognition software, and voice dictation software. Assistive technology facilitates access to websites, LMS, and content. In other words, these assistive technologies support learner–content and learner–interface interaction. However, the aforementioned software cannot be used effectively unless the website or LMS interface and the design of the course materials have been developed in accordance with the requirements of the software itself (Kinash et al., 2019). For example, it may not be possible to read certain older versions of PDF documents using a screen reader; therefore, it is important to provide a version of PDF that is compatible with screen readers in the course.

### **Accommodations or Adaptations Offered by ODDE Institutions**

ODDE institutions by nature have a commitment to providing equal opportunities in education through the creation of open, flexible, and accessible learning environments for all learners. Accordingly, a growing number of learners with special needs are registering at ODDE institutions as they offer learning opportunities that are responsive to the various requirements of these learners (Hirose, 2014). Consequently, ODDE institutions place special emphasis on learners with special needs and reflect the underlying philosophies of ODDE in their regulations and guidelines. Furthermore, in most countries there exist national legislations that ensure that support systems are in place for learners with special needs (Hirose, 2014). ODDE institutions announce their regulations, standards, and guidelines on their respective websites (Anadolu University, 2021; Athabasca University, 2021; IGNOU, 2021; OUUK, 2021; UNED, 2021), and these institutions usually have specific support units for students with disabilities. Many ODDE institutions have an office that specifically serves learners with special needs, as is the case for Athabasca University, the OUUK, Anadolu University, Universitat Oberta de Catalunya (UOC), Universidad Nacional de Educación a Distancia (UNED), and Indira Gandhi National Open University (IGNOU), among others (Genç & Koçdar, 2020a). Learners usually inform their institutions about their special needs by presenting documentary evidence of their disabilities. ODDE institutions analyze learners' requests and determine the necessary adaptations to be offered. Consequently, they provide a wide variety of accommodations and adaptations for learners with special

needs, which can be examined according to Berge's (1995) four categories as pedagogical, managerial, social, and technical support. Various examples among the practices of some ODDE institutions are presented below in accordance with these categories.

*Pedagogical support:* Course and exam accommodations can be listed in this category. Course accommodations refer to those changes to the course that do not affect course content (Moisey, 2004). In this regard, alternative formats for course materials are presented. For example, learners with special needs can use course materials in various formats according to their particular needs, such as e-books in DAISY or ePub formats; course materials in MP3 format, PDF, or Word formats; and interactive videos (Cooper, 2014; Genç & Koçdar, 2020b; UOC, 2021). In addition, transcriptions of audio/video materials, subtitle and sign language support for audio/video contents, and descriptions for visual contents are often provided. Extended contract time is provided in some universities (Moisey, 2004). Academic advising, which includes services like giving tips for study techniques and strategies, is often offered (Genç & Koçdar, 2020b). Providing electronic exam papers; exam papers in Braille; a large-font size, colored or audio exam papers; extra time in exams; deferrals; break times; scribe and/or reader support during examinations; and question exemptions can be listed among exam accommodations (Cooper, 2014; Genç & Koçdar, 2020a; Hirose, 2014; Moisey, 2004). Depending on their specific needs, learners can take the exams in a separate room; are allowed to bring equipment, food and drink, and/or medicine; etc.; in the case of bedbound learners, they are allowed to take exams at home. Learners also have the opportunity to have support services in on-site library services, such as assistive technologies, accessible library websites for screen-reader users, Braille books and printouts, computers with screen-reader software, or audiobooks.

*Managerial support:* Financial aid for academic-related expenses or transportation, assistive technology scholarships, lending assistive technologies, discount in tuition fees, service priority for registration or other issues relating to study centers and learners' enrollment in courses, buildings with elevator and ramps, large classrooms for face-to-face activities, wheelchair-compatible desks, ergonomic chairs or footrests, and special parking spaces are among those managerial support services offered by educational institutions (Genç & Koçdar, 2020a; Kim-Rupnow, Dowrick, & Burke, 2001).

*Social support:* Social support is the least observed type of support in ODDE institutions. Organizing concerts or activities that learners with special needs perform, assigning advisers, giving tips concerning learners' well-being, providing free online resources, preparing brochures on staying mentally healthy and coping with anxiety, and encouraging learner-learner interaction through social media groups, forums, e-mails, phone, and face-to-face communication are some of the social support activities provided by ODDE institutions (Genç & Koçdar, 2020a; OUUK, 2021).

*Technical support:* Lending computers, technical equipment, and assistive technologies, providing access to websites and LMS conforming to the WCAG 2.0 or

other accessibility standards, providing information on the required level of computer use or recommendations about special hardware and software that might be needed, providing technical support for LMS use, and homework preparation and submission can be listed among technical support services.

The abovementioned pedagogical, managerial, social, and technical support services are just some examples from some of ODDE institutions; in this sense, it is important to note that those support systems of ODDE institutions that are mentioned herein, as well as those that could not be mentioned, may involve more services than those listed above. This is because ODDE institutions usually offer comprehensive and dynamic learner support systems for learners with special needs in connection with their commitment to providing open, flexible, accessible, and equal learning opportunities for all learners.

---

### **Further Remarks: Equity, Equality, and Justice**

While the focus of this chapter was to discuss those challenges encountered by learners with special needs in ODDE, and to discuss support mechanisms in various dimensions – such as accessibility, UDL, assistive technologies, and pedagogical, managerial, social, and technical support – certain other issues remain, and these can also be taken into account in terms of learners with special needs. The authors of this chapter observed that the literature on learners with special needs mostly focuses on accessibility and support issues. However, considering that there is a gap in the literature, we would like to draw attention to some other issues which can be imported in terms of learners with special needs. According to Xiao (2021), “education is primarily about human beings, for human beings and by human beings” (p. 3), and such a notion requires that education is considered as extending beyond the educational process itself but as a practice for all and for everyone. Sharing the same vision, the United Nations (2015, 2021) introduced Sustainable Development Goals (SDGs); comprising 17 Goals, SDG4 (quality education) suggests ensuring inclusive and equitable quality education and promoting lifelong learning opportunities for all. These are different from practices for learners’ special needs as SDG4 defines inclusive education in a broader perspective and targets a wide range of learners by emphasizing equity, equality, and justice in any educational process. Likewise, UNESCO’s (2021) Futures of Education initiative argues that we need to expand our understanding of the right to education and take actions to prevent inequality in education. Ossiannilsson (2021) notes that “there is room for improvement in the technical area, but most importantly, it is critical to recognize the social dimensions of learning and education” by enacting “resilient open education for all in the context of social justice, human rights, and democracy” (p. 16). That being said, social and affective dimensions should not be neglected, and our practices can be informed by empathy and care-oriented pedagogies. These thoughts and global initiatives imply that inclusive education is not limited to learners with special needs, but rather addresses a broader audience to ensure equity, equality, and justice.

## Conclusion

As introduced at the beginning of this chapter, ODDE offers a back door to education to those with and without special needs. By default, ODDE assumes that all learners are special but that learners with special needs require more attention. For learners with special needs, in addition to keeping the back door open for access to educational spaces, there is a further need to design the nature and contents of these spaces. These efforts range on a wide spectrum. For instance, at a nationwide macro-level, there is a need for guidelines, frameworks, and regulations that ensure that these learners are not left behind and that their participation is warranted assuming the learners are willing to enter educational spaces from either the front or the back door. At an institutional meso-level, and in addition to improving learning spaces and contents accessible, it must be ensured that learning support systems are available, that instructional design processes are guided by necessary requirements, and that adaptive technologies are used for learners with special needs. More importantly, at an individual micro-level, we need to show empathy and care for learners with special needs.

Another significant point is that support mechanisms should not only be provided during the educational processes but should be warranted before and after the educational process in order to ensure a completely inclusive education system. In this book chapter, most of the affordances reported covered practices that were implemented during the educational process. However, these practices can target before and after the educational processes. For instance, higher education institutions can provide guidance and counselling services before learners enroll in a program. Informing and guiding learners in advance about the scope of programs can be very helpful in aiding them to make the right decisions. Practices that are subsequent to the educational process can focus on career opportunities.

In sum, the core values and principles of ODDE support inclusiveness for learners with special needs and, indeed, for everyone. We have to center our arguments and practices around empathy and care-oriented pedagogies and think beyond accessibility and support issues. Such a stance will push all stakeholders in educational processes to design learning processes in a manner to welcome everyone by keeping front and back doors and ensure and enable equity, equality, and justice for every learner, including learners with special needs.

### Abstract

This chapter provides an overview of the 13 chapters in Section 6 of *The Handbook of Open Distance and Digital Education (ODDE)*, which focus on learners, teachers, media, and technology. Through these chapters, which explore the characteristics, competencies, skills, and roles that people need in ODDE contexts and the ways that media and technology support them, it becomes clear that all four areas work together systemically in the pursuit of learning. Three themes can be cultivated from the chapters: learners and instructors share common needs in online learning settings; the field has an ethical obligation to consider how technology-mediated and technology-based learning interventions affect learners and instructors; and the ongoing presence of a tension between human tasks and technology tasks in increasingly automated learning environments.

### Keywords

Characteristics · Ethics · Learners · Media · Online learning · Teachers · Technology

## Introduction

The world of open, distance, and digital education (ODDE) may be driven by institutions and their desire to serve broader markets and transcend international borders, but the work of ODDE occurs at the local level, in individual classes and through individual people's interactions in the pursuit of learning. These interactions may involve course content, classmates, instructors (Moore, 1989), and interfaces (Hillman, Willis, & Gunawardena, 1994), or even interactions with networks (e.g., people, resources, and networks beyond the regular class boundaries; Dennen, 2013). Most of these types of interaction can be found in contemporary formal distance learning contexts, while more informal and smaller-scoped learning contexts may involve a smaller combination of interactions. Regardless of scope and context, the interplay of people, content, and technology is at the core of ODDE.

As the SECTION V title implies, the four main topics covered in this section are learners, teachers, media, and technology. Although each chapter focuses on one of these four topical categories, their contents and argument carry implications for the other topics in this section, too. In other words, successful online learning links learners, teachers, media, and technology a systemic and, in many ways, symbiotic relationship.

---

## A People-First Approach to ODDE

A people-first approach to ODDE (Dennen, 2020) is one that continuously considers the needs of the humans for whom the online learning systems exist. When the COVID-19 pandemic began, educators and learners worldwide found themselves engaged in emergency remote teaching (Hodges, Moore, Lockee, Trust, & Bond, 2020), often manifest as some form of online learning. As tempting (and at times necessary) as it was to focus on the technologies that could deliver subject matter content to students, it was most important to put people first in this endeavor, ensuring that students' needs, pedagogical and otherwise, were met (Dennen, 2020). After all, one could develop the most sophisticated learning tools but the effort would be all for naught if people lacked the access, knowledge, disposition, and environment necessary to make productive use of the tools. As a scholar working directly in this area, I was asked to offer support and advice to many educators struggling to shift their classes online in response to the pandemic. I issued the reminder, "people first, content second, technology third," to help educators keep people at the forefront of their considerations, all while doing the necessary work of locating and/or developing digital course content and learning how to use distance learning technologies. I shared this message via multiple blog posts and reiterated it across various professional development webinars and workshops because of the tendency for individuals to focus first on technology when making a shift in teaching modality. The message resonated deeply with people, who were rapidly discovering what experienced online instructors know very well: that

technology can unite instructors and learners across differences of time and space, but when technology takes center stage in these interactions, some learners may be left behind.

“People first, content second, technology third,” is not only a mantra for education during difficult times, but represents a philosophy for approaching online learning at any time. *People* are the reason why the educational need or opportunity exists. Class success is often measured by whether people persist, learn, and feel that their needs have been met in the educational experience. Conversely, when people feel uncomfortable or have unmet needs, whether related to the course context or not, learning becomes more challenging. Learning institutions have recognized the importance of viewing learners – including online learners who may never visit a physical campus – through a holistic lens and, in response, offering not only learning supports but also fostering technological skills, wellness, and community (Babacan & Thurgood, 2021).

Whereas learners drive the need for ODDE and teachers support the endeavor, *content* is the *raison d’être* of a course. Learning content can be delivered to learners through a variety of media. Whether designed specifically for a class or adopted from a preexisting source, the content represents a pathway to attaining the course learning objectives. Although content may be largely unknown by learners at the beginning of a course, by the end of a class, successful learners “own” that course’s content. In other words, when learners master the course learning objectives, the course content is theirs to apply in future settings of their choosing.

For any given course, content may remain stable across class sections, even as teachers, learners, and course technologies change. Content often brings consistency to educational settings. When it comes in the form of predesigned media, whether static (e.g., books, videos) or interactive (e.g., games and simulations), all stakeholders in the learning context can point to the media as a concrete example of what is to be learned. Still, sometimes content is not just interactive, but also dynamic, delivered by instructors or co-constructed among the members of a class. Regardless of the media and approach, content is inert until the people in a class do something with it.

*Technology* may come third in this people-first approach, but that does not mean that it is unimportant. Instead, technology should be considered foundational to the interactions among people and content. Much as we do not expect people to spend time marveling at the foundations of our buildings, but rather seamlessly enjoying the structures that sit atop them, educators should not strive to make technology the focal point of their classes. Rather, technology is the enabler for a class’s online learning interactions and should be strong, simple, stable, and usable.

All three of these dimensions – people, content, and technology – are critically important to ODDE. Although each dimension can be explored independently, and individual studies in distance education often focus on just a single dimension, the three are fully interdependent in practice. Moreover, they are dynamic and context-dependent. No single system or approach has been shown to be best for all learning scenarios. Although guidance from theories, research, and policies at all levels should be consulted when designing specific distance and digital learning solutions, local knowledge of learners and context also should be reflected in design, facilitation, and assessment decisions.

## An Overview of Chapters

The chapters in this section explore the experiences, needs, and competencies of people (learner and teachers) as they engage in ODDE; the media that hosts content; and the technology that supports both the people and media. These chapters contain references to theories and frameworks that are commonly associated with and researched in ODDE and in some cases addressed in earlier sections of the book, including transactional distance theory (Moore, 1993), cognitive load theory (Sweller, 1994), the Community of Inquiry framework (Garrison, Anderson, & Archer, 2000), self-determination theory (Deci & Ryan, 1980), and experiential learning theory (Kolb, 2014).

Learners are at the core of ODDE; they are the people being served by flexible digital learning opportunities. The flexibility of online courses has made them particularly attractive to certain population sectors. *Von Prümmer* shows how online learning has created new opportunities for women to earn postsecondary degrees and for women to work in higher education settings. She highlights many of the social, cultural, and personal forces that have led women to become distance learners and that make participation in any form of education a juggling act in already busy lives. Von Prümmer leaves no stone unturned in her exploration of women's roles and experiences in distance learning, considering gendered differences in fields of study, accessibility of technology, and forms of communication.

*Lee* looks at a different sector of the online learning population: doctoral students. Online doctoral students are typically different from campus doctoral students in terms of their demographic and goals. Many of the online doctoral programs that have been developed in recent years serve learners who seek to apply research knowledge in professional rather than academic settings. Again, flexibility and access are key attributes that make online doctoral education attractive to learners. Lee notes that these online doctoral learners may struggle due to feelings of isolation or anxiety related to technology and explores many of the advantages and disadvantages of online doctoral programs for varied populations.

ODDE clearly provides learners with increased options and opportunities for earning degrees and, at the postsecondary and professional development level, advancing in their careers. However, the existence of these options alone does not guarantee success. Various learner attributes and skills contribute to the success or failure of online learners, and several of the chapters in this section consider some of these skills and related behaviors.

*Yalcin* reviews learner attributes, such as technology access and socioeconomic status, that can have a profound influence on whether learners are able to effectively participate in ODDE. Further, he shows how macro-, meso-, and microlevel entities can all work to support learners and increase their success. Additionally, Yalcin gives an overview of the basic technology skills and related competences that allow people to be successful online learners. Through this chapter, Yalcin reminds us that although online learning improves access to education for many learners, it is not a global panacea, and some individuals are still at a disadvantage.

In a complementary chapter, *Martin and Castañeda* explore digital literacy skills, which are equally important for learners and teachers. Through a timeline, they show

the development of thought surrounding the concept of digital literacy. Although digital literacy is considered important – online learners and teachers obviously need to be fluent in the tools and practices associated with the medium they have chosen – definitions of “digital literacy” are multifarious and poorly synthesized. Martin and Castañeda discuss several frameworks across different learning contexts and identify areas in which they overlap and diverge. Rather than problematize the existence of so many frameworks, they demonstrate the utility of these frameworks and provide insights into how each provides important considerations for online learning.

*Ehlers* focuses on Future Skills, a set of competencies that people need to be successful in the world. His chapter considers the needs of today’s learners when they enter the workforce, including projections for children who are years from entering the workforce, and considers the role that educational institutions should play in ensuring students are well prepared. The digital literacies discussed by Martin and Castañeda are one component of the larger Future Skills framework, which also includes skill sets in areas such as decision-making and design thinking. From Ehlers’ perspective, these are not merely skills to be checked off as each one is mastered. Instead, their mastery represents a holistic approach to becoming a full and valued participant in the workforce of tomorrow.

Although learners may need basic competencies, as outlined by Yalcin, and perhaps even more extensive digital literacy skills, as presented by Martin and Castañeda, in order to function in online learning spaces, motivation also plays a role in learner success. Motivation is important for keeping learners engaged for the duration of their learning experience. Motivation must be cultivated despite transactional distance, which can act as an opposing force. *Fryer, Shum, and Nakao* consider motivation in ODDE at the primary, secondary, and tertiary levels, showing how learners can be intrinsically motivated and propel themselves forward in an online class and also how they may be motivated by external factors such as teachers, media, and technology. *Fryer, Shum, and Nakao* explore the role of various learning strategies, such as gamification, and learning technologies, such as augmented and virtual reality, in motivating learners. They highlight the connection between online learning motivation and several motivational theories and look closely at how online learning technologies can incorporate principles of motivation.

*Dennen and Jones* discuss the role of the online instructor, focusing on instructors’ responsibilities for shaping multiple dimensions of a course. For all of the competencies and digital literacy skills that online learners need, there are multiple correlating online instructor skills that are necessary. Pedagogy still rests at the forefront of the online instructor’s responsibilities and required skill set, but pedagogy alone is not enough to ensure that learning takes place. Intersecting with topics from chapters written from the learner perspective, Dennen and Jones demonstrate how successful online instructors offer not only pedagogical activities, but also provide the necessary structure, motivation, technical support, and social environment to help learners succeed. They also encourage continuous consideration of various ethical issues that arise in online learning spaces and the role external networks may play in online learning.

*Bong and Liu* consider media usage behaviors, sharing various typologies for classifying online learners. Media usage behaviors provide insights into how

learners access and use digital course content as well as how they interact with instructors and peers through learning communication technologies. These behaviors may or may not reflect learner competencies, and through this overview, Bong and Liu demonstrate how online learners can vary widely in terms of media usage. Learners' use of media can be examined in terms of its intensity, frequency, and purpose although, as Bong and Liu point out, this is an area of research that is currently under-theorized and not well synthesized across typologies. They provide directions for future researchers to consider, both in terms of newer or emerging technologies, in which learner use is not yet well understood, and familiar technologies that can be used to capture and analyze aspects of media usage behaviors.

Online learning tools can be used to help learners interact with instructors and peers in a distributed manner (asynchronously) or in real time (synchronously). In their respective chapters, *Davidson-Shivers and Rand* provide an overview of asynchronous tools used to support ODDE, and *Lowenthal* provides an overview of synchronous tools. In both chapters, the authors are clear that tools alone are limited and that what matters is how instructors use those tools.

*Davidson-Shivers and Rand* list a variety of specific tool categories that can be used to support asynchronous learning interactions, discussing the pros and cons of each. They also share specific strategies for promoting learner interaction via asynchronous tools, rooted in relevant educational theories. In addition to the many ideas that they offer to instructors seeking to foster asynchronous learner interactions, at the end they ask a provocative question about the necessity of learner interaction in ODDE.

*Lowenthal* is provocative in another way, exploring whether a distinction between synchronous and asynchronous tools is meaningful in this current moment, when tools are increasingly multifunctional and can be used for either or both synchronous and asynchronous learning depending on how a course is designed. The modality distinction is blurred because synchronous activities can be recorded and reviewed asynchronously and asynchronous tools can emulate synchronicity when learners access and communicate through them simultaneously. Whether differentiating between synchronous and asynchronous tools remains useful moving into the future remains to be seen, although the distinction between synchronous and asynchronous learning requirements surely will continue to be germane to both teachers and learners who seek to plan their learning experiences and may have varying levels of schedule flexibility.

Other chapters address tools that serve specific functions related to learning. For example, *Ifenthaler*, in his ► [Chap. 61, "Automated Essay Scoring Systems,"](#) provides insights into technologies that can help reduce the labor associated with assessing online learners. Assessment historically has been one of the challenges that limits the scalability of online learning endeavors. Although objective style assessments have been automatically scored for years, written assignments have remained in the domain of student work that must be evaluated by a human. While machines can easily be trained to identify whether learners selected the correct answer or to match simple learner input (e.g., numbers and words) to model responses, training computers to assess writing is much more complicated. It requires comparing learner essays to complex rules governing both the content and

form of a written document. The complex and nuanced nature of essay assignments poses a challenge, but as Ifenthaler shares in his chapter, the technology is rapidly developing and has the potential to allow more diverse forms of assessment to be used in large online classes, including MOOCs, without increasing labor needs.

*Di Mitri, Schneider, and Drachler* consider a different form of automation as they review research on multimodal tutors. These tutors are an example of two technologies, Artificial intelligence (AI) and Learning analytics, working together to provide personalized learner experiences for learners. Whereas human instructors may have limited availability, AI-based tutors can be accessed and used as needed, expanding access to learning and learning possibilities.

Finally, *Prinsloo* explore the role that Learning analytics play in ODDE more generally. In this chapter, he wrestles with the role that theory has played in the development of learning analytics as a discipline, demonstrating that although the field is not united around a singular theory, it is also not atheoretical. Prinsloo makes important connections between analytics and the learner-teacher dynamic, showing how analytics can be used to support pedagogy but also should be implemented with careful consideration for ethics and privacy. In other words, Prinsloo connects technology back to the people who it is designed to help.

---

## Synthesis Across Chapters

The chapters in this section are deeply rooted in the theories, research, and practices of ODDE as they explore the individual components that are united in the classroom. Although each chapter has a unique topic, three main themes can be identified across chapters. These themes connect to larger, ongoing issues being explored in ODDE research and practice.

Learners and instructors have many of the same needs in ODDE, which is evident in the chapters about learners (► [Chaps. 55, “ODDE and Gender,”](#) by Von Prümmer and ► [65, “Online Doctoral Education,”](#) by Lee), instructors (► [Chap. 62, “The Role of the Online Instructor,”](#) by Dennen and Jones), and the literacies and competencies that unite them (► [Chap. 63, “Developing Digital Literacy for Teaching and Learning,”](#) by Martin and Castañeda; ► [Chap. 53, “Learner Characteristics and Competencies,”](#) by Yalcin; ► [Chap. 64, “Future Skills as New Currency for the World of Tomorrow,”](#) by Ehlers). Organizations such as the International Society for Technology in Education (ISTE; <http://iste.org>) and the International Board of Standards for Training, Performance and Instruction (ibstpi; <http://ibstpi.org>) have developed and continuously refine competency lists for both instructors and students at all levels of education. The work done by ISTE, ibstpi, and other organizations globally indicates both the critical importance of identifying and developing learner and instructor skill sets for digital learning success and of creating pathways for practitioners to foster skill development. However, learners and instructors both may be affected by needs unrelated to digital literacies and competencies that nonetheless inhibit their performance in class. For this reason, it is important to always widen the lens and look holistically at the people involved in ODDE.

At all levels, we have an ethical obligation to take a holistic look at learners and instructors, considering their backgrounds and needs. Across multiple chapters, the authors raise ethical issues related to the topics they explore (► [Chap. 63, “Developing Digital Literacy for Teaching and Learning,”](#) by Martin and Castañeda; Chap. 52, “Introduction to Learners, Teachers, Media, and Technology in ODDE,” by Dennen and Jones; ► [Chap. 59, “Learning Analytics in Open, Distance, and Digital Education \(ODDE\),”](#) by Prinsloo), and other authors demonstrate how open distance learning provides opportunities for populations whose needs may not be met via other modalities (► [Chaps. 55, “ODDE and Gender,”](#) by Von Prümmer and ► [65, “Online Doctoral Education,”](#) by Lee). The thread that runs through these discussions of ethics and different learner groups may be summed up as follows: no component of online learning is value-neutral and people-first considerations are always relevant and important.

Finally, the chapters that explore media and technology highlight the tensions between technology and its users. The chapters that directly engage how technology is used in the hands of learners and teachers alternately consider what learners do (Bong and Liu) and how technology is used to connect instructors and learners (Davidson-Shivers and Rand and Lowenthal). There is overlap between learners’ natural media usage and the synchronous and asynchronous technologies implemented for learning, although the tools that people use heavily in their everyday lives, such as social media, may not be as engaging as other, course-specific tools when used to support learning (Bond, Buntins, Bedenlier, Zawacki-Richter, & Kerres, 2020). As Fryer, Shum, and Nakao point out, tools are often developed without strong connections to motivational theory. However, the tools are here to stay and motivation and audience are important concerns when determining who should use the tools and how the tools should be used. Additionally, ongoing technological developments leave the field contemplating how automated technologies can be used to streamline instructional processes and offer new opportunities and insights in ODDE contexts (Ifenthaler; DiMitri, Schneider and Drachsler; Prinsloo).

The tension between humans and technologies as relates to interaction and automation is an important one to explore and extends the conversation begun in many of these chapters. Interaction has become a focal point of much distance learning research (Martin, Sun, & Westine, 2020), with deep roots reflected in Moore’s early work focused on interaction and transactional distance (Moore, 1989, 1993); Anderson and Garrison’s (1998) suggestion that communication in online classes should be reciprocal, consensual, and interactive. National regulations for online learning and accreditation bodies have reified these ideas. For example, the United States Department of Education has defined regular and substantive interaction in the Code of Federal Regulations for Education (34 CFR § 600.2), which has direct implications for federal online learning requirements. In other words, the government is regulating how and how frequently learners should be required to interact their online courses. Although many of the interaction options provided in this regulation involve learner-instructor or learner-learner interactions, provisions are made for interactions with automated systems, such as the multimodal tutor discussed by DiMitri, Schneider, and Drachsler.

Overall, advances in online learning automation could have implications for redefining the instructor role. Over the last two decades, the adoption of increasingly sophisticated learning management systems has relieved instructors of some of their earlier managerial and technological tasks, making recordkeeping simpler and providing a single, consistent learning platform that is typically supported institutionally. Automated grading systems are already in use for some types of assessments and, as Ifenthaler demonstrates, essay grading systems are increasingly becoming a reality. Analytics, as discussed by Prinsloo, can help promote student success, but we still need to figure out how to best implement learning analytic systems in ways that not only provide institutions with data, but also help instructors better support students. With increased use of technologies to teach, assess, and track students, some parts of the instructor's role will naturally shrink. However, change in the instructor role and learner use of technology will likely be uneven across learning contexts and population sectors, reflecting differences in technology access, values, learner characteristics, and learning needs.

---

## Conclusion

The chapters in this section of the handbook explore characteristics, needs, competencies, and responsibilities of online learners and teachers along with the media and technologies that can support them in their learning and teaching endeavors. As noted previously, advances in these technologies are shifting learner needs and competencies and teacher roles and responsibilities. Since the beginning of my career in higher education, a repeated question has led to excited rumblings and nervous fears expressed across different educational stakeholders: Will human instructors be replaced by computers? Selwyn (2019) engages this question head on, noting that the question is not a matter of whether computers can replace human instructors, or whether they will (and he says that they certainly can if we let them), but rather if they *should*. In Selwyn's response, we can see the power and influence that people, both learners and teachers, have in this future. Looking across these chapters, and again considering the interrelationship between learners, teachers, media, and technology, my thoughts are that a "people-first" approach will continue to be valued even with ongoing technological advancements. It is incumbent on this generation and the next generation of researchers to not examine any one of these topics in isolation, but always attend to the larger systems. While changes in one area will necessitate corresponding adjustments in another, technological advancements can be used in ways that maximize learning gains. In practice, this means some tasks will be led or guided by the computer, with computerized feedback and monitoring, but humans will still be needed at various points and for specialized kinds of interaction, feedback, and monitoring. Learners and teachers, as well as other educational stakeholders (e.g., instructional designers, institutional and government leaders), will hopefully continue to recognize and exert their agency over the future of ODDE, celebrating people as the driving forces behind education, with media and technology leveraged as tools that help people reach their goals.

## Abstract

The advances in technology and the demand for open, distance, and digital education redefined the characteristics and competencies of learners in these learning environments. Although technology ownership and access to an Internet connection are growing worldwide, there is still a significant number of learners in need of a computer and Internet access to benefit from the advantages offered by new learning environments. As a result, the obstacles in technology ownership and access put a group of learners from a low socioeconomic status and minorities in a disadvantaged position and prevent them from engaging in learning

experiences. Indirectly, these learners also struggle to develop digital competencies due to their limited access to technology-rich environments. This chapter elaborates on the characteristics of learners in open, distance, and digital education environments with respect to their technology ownership and access, presents a number of competency frameworks, and discusses how the competencies included in the frameworks apply to open, distance, and digital education. The chapter opens with the role of technology in new learning environments and how technology ownership and access vary among certain demographics as well as developed, developing, and underdeveloped countries. The introduction is followed by learner characteristics with respect to varying technology access and ownership among demographics and the implications of technology ownership and access for open, distance, and digital education. Finally, a number of competency frameworks were presented and discussed in regard to their contributions to the development of a competency set for learners in open, distance, and digital education environments.

**Introduction**

The history of distance education informs us that the initial practices comprised mail correspondence that involved sharing printed learning materials with learners and enabling them to study at their own pace. However, advances in information and communication technologies shaped the interaction among learners, instructors, and institutions and allowed new methods to be implemented to deliver instruction to learners who needed to study at a distance for various reasons. These advances enabled education practitioners to take advantage of a variety of synchronous and asynchronous technologies such as radio, educational television, videoconferencing, and audio and video recordings to employ in the distance education process. While all these technologies affected the practice of distance education, it was the Internet that transformed the methods we adopted to deliver instruction to learners who were away from the brick and mortar institutions. The Internet also brought new terms into our lives such as online learning, e-learning, and digital education. Today, the majority of distance education practices rely on computer and Internet technologies as institutions use learning management systems (LMS), synchronous and asynchronous communication software, and various Web 2.0 tools for delivering courses. All these advances in technology and the resulting transformation of distance education practices redefined the characteristics and competencies of the learners in open, distance, and digital education environments.

Being a successful distance learner requires having access to certain technologies and possessing various competencies. Computer and Internet access are among the

major technology requirements as learners need to complete coursework using a computer and use the Internet to retrieve learning material, submit assignments, and communicate and collaborate with the instructor and peers. Computer ownership and broadband Internet access rates are fairly high in developed nations. For example, Anderson (2015) reported that 73% of the adults in the United States owned a desktop or laptop computer in 2015. In another study, Perrin (2021) reported that 77% of the adults in the United States had access to a broadband Internet connection at home. While computer and Internet adoption and access rates are promising in the developed world, a different picture is present among adults in underdeveloped and developing countries as well as adults from a low socioeconomic status in developed nations. Anderson (2015) emphasized that desktop or laptop computer ownership greatly decreases among Black and Hispanic adults, adults with less than \$30 K yearly income, and adults with an educational degree at or below high school level. Perrin's (2021) findings are in line with those of Anderson's (2015) as the researcher reported that home broadband Internet access rates decrease among non-White adults with a high school degree or less and a yearly income of less than \$30 K. Penetration rates of computers and broadband Internet are not at a satisfying level in underdeveloped and developing countries either. Recent statistics show that, in 2016, the percentage of households with a personal computer was 13% in India, 47% in China, 53% in Iran, 56% in Turkey, 28% in South Africa, 52% in Brazil, and 38% in Mexico, while developed countries had higher rates of computer ownership such as 86% in Australia, 91% in Germany, 98% in the Netherlands, 91% in the United Kingdom, 88% in Canada, and 82% in the United States (Baller, Dutta, & Lanvin, 2016). Moreover, as of January 2022, while Western and Northern countries have high Internet penetration rates that are above 90%, the rates drop below 75% in certain regions of Asia and Central America and 30% in Eastern and Central Africa (We Are Social et al., 2022). Considering that computer ownership and Internet access are a must to pursue open, distance, and digital education, learning opportunities afforded by the availability of these technologies vary greatly across the globe.

Competencies to be successful in new learning environments are equally important as having access to a computer and a broadband Internet connection. Recent research informs us that students' technology ownership and technology experiences lead to greater perceived technology competencies (Yerdelen-Damar, Boz, & Aydın-Günbahar, 2017). Moreover, we have been informed that students' frequency of using technology is positively related to the change in their technology competence over a period of time (Hosein, Ramanau, & Jones, 2010). Technology competencies allow learners to successfully engage in learning experiences and carry out responsibilities in open, distance, and digital education environments. Research indicates that digital skills are related to students' engagement in learning with technologies, and students with higher digital skills engage in learning with technologies to a greater extent when compared to students with low digital skills (Bergdahl, Nouri, & Fors, 2020). Furthermore, students' digital competence affects their digital informal learning behaviors as well (He & Zhu, 2017; Heidari, Mehrvarz, Marzooghi, & Stoyanov, 2021). In other words, learners' technology ownership and experiences lead to improved technology competencies and technology competencies allow

students to engage in learning experiences in formal and informal digital learning environments. Ownership of and access to technology emerge as an important prerequisite for developing technology competencies and engaging in learning in new learning environments. Furthermore, digital competencies are gateways to successful learning experiences in digital learning environments. In this chapter, issues related to learners' socioeconomic background and demographics and competencies to be possessed in open, distance, and digital education environments are explored.

---

## **Adoption of Open, Distance, and Digital Education**

### **Learning in the New Century**

Today, open, distance, and digital education practices predominantly rely on information and communication technologies. Most institutions deliver courses via an LMS (e.g., Horvat, Dobrota, Krsmanovic, & Cudanov, 2015), instructors use synchronous and asynchronous tools for learning activities (e.g., DeSantis, 2022; Ironsi, 2021), and students make use of a variety of communication and collaboration tools to engage in the learning process and carry out their responsibilities (e.g., Sullivan, 2021). In order to engage in a successful learning experience, at minimum, a learner must have access to a personal or shared computer, a stable Internet connection, and office and productivity software that will enable her to complete and submit coursework. Admittedly, the quality of the learning experience is in direct proportion to the learner's continuous access to the computer, the computer's computing power, and the speed and quality of the Internet connection. It is not unlikely for the learning experience to be disrupted due to the failure of any of these technologies. Especially, the presence of online synchronous meetings in the learning process increases the significance of the computing power and broadband Internet connection due to the need to process and transmit a significant amount of data per second. Aside from the costs associated with access to education, all these resources require significant expenses on learners' end, and as a result, the adoption of open, distance, and digital education is directly related to the adoption and use of information and communication technologies.

### **Technology Access, Socioeconomic Status, and Demographics**

Ownership of and access to technology have been frequently discussed in relation to individuals' socioeconomic status. This proposition is supported by a number of research studies conducted to explore individuals' access to technology in relation to their demographics. A recent Pew Research Center study revealed that only 59% of adults with less than \$30 K yearly household income in the United States owned a desktop or laptop computer while this number was 92% for adults with \$100 K or more yearly household income (Vogels, 2021). Vogels (2021) further revealed that

29% of the adults with less than \$30 K yearly household income relied on smartphones to connect to the Internet while only 6% of adults with \$100 K or more yearly household income reported that they only had a smartphone but no broadband Internet connection. These findings are similar to those reported for the households of younger learners as well. According to a recent study, 35% of the school-age children who live in households with a yearly income of less than \$30 K do not have a high-speed Internet connection at home while only 6% of children who live in households with a yearly income of \$75 K or more reported that they do not have access to a high-speed Internet connection at home (Anderson & Perrin, 2018). Moreover, students also differed by income level in terms of the device they used to complete homework with a greater percentage of students from low-income households being smartphone-dependent to finish their homework compared to average- and high-income households, a phenomenon referred to as the “homework gap.” While statistics clearly show that there is a difference in the percentage of learners from varying income levels in access to computers and the Internet, there is research suggesting that the quality of the ownership and access differs among low- and high-income individuals who have access to the Internet. Gonzales (2016) argued that low-income individuals frequently experience “dependable instability” which is the “normalization of frequent disruptions in Internet access” (p. 243). While certain portions of low-income individuals have access to technology, the quality of their experiences may not be equal to those of high-income individuals. Furthermore, Gonzales (2016) argued that today the problem is not the initial access to technology, but maintaining that access as “technology maintenance” requires a significant expense that low-income individuals may not be able to afford, and as a result, they may experience disruptions in access to technology due to their low economic power (e.g., having to use second-hand devices that require frequent maintenance). While technology access disruptions emerge as a significant issue, another negative effect of the financial burdens of technology maintenance may be low-income adopters’ un-adoption of technology (Powell, Bryne, & Dailey, 2010).

While income level is one of the important factors determining individuals’ ownership of and access to technology, education level has been found to be related to technology ownership and access as well. It has been reported that the percentage of computer ownership increases with education, and it is around 29% among adults with the education of less than high school compared to 90% with a college degree or more, a trend that is also present in mobile technology ownership such as tablet and e-reader (Anderson, 2015). Access to home broadband Internet varies substantially by education as well. According to Perrin (2021), while only 59% of the United States adults with a high school degree or less had home broadband Internet, 94% of adults with a college degree or more reported that they had broadband Internet at home. These statistics are in line with what has been reported in past research as Mossberger, Tolbert, and Gilbert (2006) found that individuals who lived in residential areas with lower educational attainment were statistically less likely to own a computer at home than the residents in zip codes with higher educational attainment. Moreover, a Tsetsi and Rains (2017) study found that the education level of multimodal users, users with a smartphone and an additional device that can connect

to the Internet, was significantly higher than the education levels of users without access to the Internet and users who were smartphone-dependent. While open, distance, and digital education environments can provide an educational opportunity to individuals who are less educated, taking this opportunity still seems challenging for these learners due to the constraints relating to technology access.

Technology ownership, access, and use have been reported to vary among adults from different races and ethnicities. Recent statistics show that White adults have higher computer ownership compared to non-White adults while Hispanic adults have higher computer ownership than Black adults in the United States (Anderson, 2015). A similar trend is present in terms of home broadband Internet access as well. While White adults have the highest rate of broadband access at 80%, Black adults have higher home broadband Internet access than Hispanic adults (Perrin, 2021). Moreover, smartphone dependency among non-White adults is also an issue. According to Zickuhr and Smith (2012), Black and Hispanic adults access the Internet using their cell phones significantly more than White adults, and Perrin (2021) reported that one in six Black adults and one in four Hispanic adults are smartphone-dependent to access the Internet. These statistics have been supported by past research as Tsetsi and Rains (2017) reported that White users were significantly less likely to be smartphone-dependent in accessing the Internet than minority users. However, it is worth noting that it is not possible for learners to easily complete most coursework on a smartphone (Rowse, Morrell, & Alvermann, 2017). Technology access in households was investigated among school-age children as well. Warschauer and Matuchniak (2010) reported that the mean ratio of home user to computer was highest for Hispanic families with nearly four family members per computer which was followed by African-American, Asian, and White families that had a home user to computer mean ratio of nearly one. Moreover, while computer and Internet access among minority learners is lower than that of non-minority learners, minority learners' technology-using behaviors might be different as well. Kuo (2018) stated that African-American university students used basic software more frequently than advanced software, a phenomenon that should be investigated further.

Disparities in technology access among learners from different demographics constrain disadvantaged learners to search for opportunities to use technology in public locations. However, ease of technology access may be different between learners who can access them at home and those who seek access in public locations (Beaunoyer, Dupéré, & Guitton, 2020). Among these locations, libraries, coffee shops, and community centers are the most commonly visited locations to obtain computer or Internet access. Socioeconomic status and race are among the common variables that differ between learners who access technology at home and those who access technology in public locations. Mossberger, Kaplan, and Gilbert (2008) stated that regular access to and use of technology is less frequent in low-income communities and individuals in low-income communities try to compensate for the lack of home or work technology access by visiting alternate locations. Anderson and Perrin (2018) reported that while 12% of teens in the United States at least sometimes have to use public Internet connection to complete homework, this problem is more

common among Black teens and teens living in households with less than \$30 K yearly income. Additionally, Banerjee (2020) reported that first-generation, low-income, and non-White college students checked out computers from school and used computers and the Internet in public locations significantly more than other students. While access to computers and the Internet is an issue to be resolved, Rubinstein-Avila and Sartori (2016) emphasized the importance of access to software as well. Computer software and tools allow learners to engage in learning activities and are usually required for completing coursework. While some basic software and tools can be accessed freely or via an institutional license, some institutions may not allocate a budget for learners to access other advanced software and tools. Moreover, while public locations such as libraries and community centers can provide learners computer and Internet access, learners may not be able to have access to a broad collection of software and tools due to the budget limitations of these locations. Therefore, the availability of software and tools remains one of the technology access issues in open, distance, and digital education, especially for learners who make use of resources in public locations.

---

## **Implications for Open, Distance, and Digital Education Environments**

Learners' access to resources in the learning process must be an important consideration for education practitioners. Learners must be equipped with a number of technologies that can function properly and continuously in order to benefit from the opportunities and convenience provided by new learning environments. However, research to date shows that there are disparities among learners from different demographics in terms of their ownership of and access to technology such as computers and the Internet. Moreover, while learners may have initial access to technology, they may struggle to maintain their access throughout the learning process due to financial constraints. These conditions imply that education practitioners should be prepared and develop strategies to accommodate learners with limited resources in open, distance, and digital education environments. Major considerations and strategies to be adopted are presented in this section. Additionally, these considerations and strategies are summarized in Table 1.

### **Initial Access to Technology**

The number of learners who indicate that they do not own or have access to some basic technology is significant. A significant portion of learners across the globe experience issues owning a personal computer and having access to an Internet connection that may prevent them from exploring new learning opportunities. In order to make the use of open, distance, and digital education more widespread, learners from low socioeconomic status and minority groups should be provided with opportunities to improve their technology repertoire. While these types of

**Table 1** Major technology considerations and mitigation strategies

Consideration	Mitigation strategies	Who works in the process?			
		State/ government	Institution/ organization	Instructional designer/ developer	Instructor
Initial access to technology	Fund projects to increase learners' technology repertoire	✓			
Technology maintenance	Keep a record of the equipment owned by learners and identify learners with poor technology ownership		✓		
	Gather a collection of technology that can be checked out to learners		✓		
	Be aware of learners' technology shortcomings and have them involved in learning tasks accordingly				✓
Access location	Be aware of learners' conditions (e.g., participating synchronous meetings in shared spaces) and make appropriate adjustments to accommodate learners				✓
	Make sure that learning activities and assignments required of learners can be completed using basic hardware and software			✓	✓

**Table 1** (continued)

Consideration	Mitigation strategies	Who works in the process?			
		State/ government	Institution/ organization	Instructional designer/ developer	Instructor
Mobile device dependency	Provide computers to learners with mobile device dependency		✓		
	Make sure that learning content is optimized to be mobile-friendly		✓	✓	✓
	Record online synchronous meetings and allow learners to download the video file				✓
Lack of supporting tools	Provide learners with free/ discounted software licenses used in courses		✓		
	Make sure learning tasks can be completed using free or open-source software			✓	✓
	Provide a list of free or open-source software to learners				✓
	Encourage learners to use free trials of paid-for software given that the trial period is sufficient for the task				✓

interventions may require support at the state or government level, there are examples of such large-scale projects undertaken (Trucano, 2013). The purpose of these large-scale projects is usually to equip learners with the required technology and improve technology skills in order for learners to have access to and make use of new learning opportunities. While providing laptop or tablet computers to learners is a relatively feasible project, furnishing every part of the residential areas with

broadband Internet infrastructure may not be possible for every country. Satellite Internet, such as SpaceX's Starlink, may be a solution for the Internet access issues in especially rural areas. However, its adoption rate is still very much behind broadband Internet as recent statistics show a 6% adoption rate in overall Internet use in the United States (Statista, 2021).

## **Technology Maintenance**

Similar to the initial access to technology, technology maintenance is also an issue for learners from low socioeconomic status and minority groups. While learners may report having access to technology prior to the beginning of a learning experience, maintaining this access throughout the learning experience may not be possible for every learner. Education practitioners should be aware of learners' possible intermittent access to technology due to failing hardware or Internet outages as these issues may limit learners' ability to be a part of the learning experience and keep up with tasks and responsibilities. There are several strategies that institutions and education practitioners can adopt in order to alleviate the impact of such issues on learners in open, distance, and digital education environments. First, it is a good practice for institutions to keep a record of the equipment owned by learners and identify learners who own technology that may cause issues during the learning process. Keeping such records will have the institution prepared for issues that may arise during the course of a learning experience and inform education practitioners accordingly. Second, institutions should have a collection of technology that can be checked out to learners in cases where learners experience issues due to a failed technology. These technologies such as computers can be provided to a learner for a limited time until the learner's technology issue is resolved. Finally, education practitioners such as instructors should be aware of learners' technology shortcomings and have them involved in learning tasks accordingly. For example, learners may have a limited data Internet subscription that may prevent them from downloading large files and watching videos in a high resolution. If a learner can use only a limited amount of data, it would not be possible for her to assume learning tasks that would entail downloading large files or watching high-resolution videos that will consume a significant amount of data.

## **Access Location**

In line with technology maintenance and affected by similar factors, some learners may be forced to use the technology available in public locations such as libraries, coffee shops, and community centers. While these locations may provide learners with opportunities to engage in open, distance, and digital education experiences, learners may be severely limited in their ability to benefit from the learning experience. There are several points to consider for learners who participate in learning experiences from public locations. First, learners may be constrained to assume a more passive and quieter role during the learning experience, especially online synchronous meetings, in

public locations due to the fact that these locations are shared by a group of individuals. In such cases, it is difficult for learners to express their opinions orally or engage in group activities that would require them to speak. While libraries have private study rooms, the number of these rooms is usually not sufficient to accommodate every learner. For the reasons mentioned above, education practitioners should be aware of learners' conditions and make appropriate adjustments to the learning activities to accommodate learners accessing technology in public locations. Second, access to technology in public locations also brings the struggle of being limited to basic software and hardware. For example, while libraries provide computer access, computers may lack advanced software that would be required for audiovisual design and development, and learners usually do not have the option of installing software on these devices without an administrator's permission. Requiring learners to engage in the design and development work with advanced software will put learners who access technology in these locations at a disadvantage. Education practitioners should make sure that learning activities and assignments required of learners can be completed using basic hardware and software that are available to all learners.

## Mobile Device Dependency

The mobile device or smartphone dependency in open, distance, and digital education environments is a real phenomenon as a considerably large portion of learners try to complete learning tasks via tablet computers or smartphones. Recruiting a nationally representative sample of online learners, Magda and Aslanian (2018) found that 20% of learners complete all of their course-related activities on a mobile device while 47% of them complete at least some of their course-related activities using a mobile device. While mobile devices are extremely useful in having access to information on the go or as learning or performance takes place, they provide a limited experience due to their small screen size and relatively low computing power. Therefore, a mobile device's performance may be significantly inadequate compared to a personal computer's performance in a number of learning activities such as attending online synchronous meetings, retrieving learning content, and completing assignments. There are certain strategies that can be adopted by institutions and education practitioners to mitigate the effect of mobile device dependency on learners' performance. First, similar to the provision of technology to learners who struggle with technology maintenance, institutions may provide computers to learners with mobile device dependency that they can use for the duration of the learning experience. Second, mobile devices are inherently limited in their capabilities to display certain types of content due to their small screens and the types of applications they can run. In order for learners to view learning content on mobile devices conveniently, institutions and education practitioners should make sure that learning content is optimized to be mobile-friendly. Finally, mobile device dependency usually brings the issue of limited data Internet subscriptions together. Learners who are dependent on a mobile device to engage in learning activities may refrain from participating in learning experiences that may consume a

significant amount of data such as attending online synchronous meetings. In the case of online synchronous meetings, it is a good practice for education practitioners to record these meetings in case learners miss a meeting due to insufficient data available. Furthermore, certain synchronous meeting tools only allow learners to view the recorded videos and prevent them from downloading the video files on learners' devices unless the owner of the session gives permission to learners for the video file to be downloaded. Allowing learners to download the video files is especially important as learners with mobile device dependency who also lack an unlimited data subscription prefer to download the recorded sessions on their devices using public networks and watch later to save data. The use of the downloaded content must comply with the institution's copyright policies, but it will not be discussed here as it is beyond the scope of this chapter.

### **Lack of Supporting Tools**

Access to supporting tools such as computer software is critical for learners to carry out learning responsibilities and complete coursework in open, distance, and digital education. However, due to the economic burden of owning a license of some advanced software, learners with a low income may be at a disadvantage. The burden especially exacerbates in low GDP countries due to the weak currencies against USD and Euro, currencies with which most software are sold. There are several strategies that can be used to prevent learners from falling behind in their coursework due to the unavailability of advanced software. First, where possible, institutions should provide learners with free or at least discounted licenses for software that are most commonly used in courses. Having access to software through the institution will allow an equal learning opportunity for learners from different demographic backgrounds. Second, if it is not possible for the institution to provide a license, education practitioners should make sure that learning tasks that are assigned to learners can be completed using free or open-source software and to provide a list of the software to learners. There are a number of free and open-source software that can be used as alternatives to advanced paid-for software. However, as education practitioners encourage learners to use free or open-source software, they should also confirm that they are available for different platforms such as Windows, Macintosh, and Linux. Finally, in cases where an institutional license or open-source software is not available, learners may be encouraged to use free trials of paid-for software. However, trial periods usually range between 7 days and 2 months, and it is the education practitioner's responsibility to make sure that the trial period of a given software is sufficient to complete the learning task.

---

### **Competencies of the New Century**

Competency is defined as knowledge, skills, or attitudes that enable individuals to accomplish certain activities to the expected standards (Richey, Fields, & Foxon, 2001). Competencies needed to be a successful citizen in various spheres of life have

been debated by scholars for a very long time. The transformation of our lives and the reliance on information and communication technologies in the twenty-first century have impacted the competencies that we need to possess as well. Similar to every aspect of society, educational settings also have always required a set of knowledge, skills, and attitudes to succeed. However, it is more difficult now to define the knowledge, skills, and attitudes that should be possessed by learners due to the blurring lines between educational settings and other spheres of society and significant advances in technology. Technology stands out as the most influential phenomenon in shaping what learners of the new century should be able to do when it comes to learning. New learning environments require learners to possess technology competencies and engage in technology-enhanced learning to a significant extent in order to successfully complete learning offerings. The knowledge, skills, and attitudes expected of learners in open, distance, and digital education environments depend on the learning activities that learners take part throughout their learning experience. While the variety and quantity of the activities a learner is expected to involve for a successful learning experience depend on the specific learning context, they can be classified under four main categories:

1. Information activities: Activities that enable learners to search, retrieve, and evaluate information in digital environments.
2. Communication and collaboration activities: Activities that require learners to communicate and collaborate with instructors and peers regarding their coursework.
3. Design and development activities: Activities that require learners to create original works as part of their enrollment in learning offerings.
4. Administrative activities: Activities that enable learners to manage their learning experience such as developing procedures to follow the course schedule and submit assignments.

The aforementioned activities that learners take part in the learning process require learners to develop certain competencies to obtain the intended learning outcomes. There are a number of frameworks created to date that outline competencies to be possessed by individuals in the twenty-first century. While these frameworks were not specifically developed to address the competencies of learners in open, distance, and digital education environments, they include knowledge, skills, and attitudes that are applicable to these learning environments as well. One of the most prominent competency frameworks is developed by the Joint Research Center (JRC) of the European Commission. The Digital Competence Framework for Citizens, also known as DigComp, is currently in its third version, and it offers a tool to assess and improve individuals' digital competence (Carretero, Vuorikari, & Punie, 2017). The framework includes 21 competences in five competence areas along with eight proficiency levels for each competence described as learning outcomes based on Bloom's Taxonomy. The framework is developed to facilitate individuals' development of digital competence in their education and occupation which is illustrated by the inclusion of learning and employment scenarios. The competence areas and competences are presented in Table 2.

**Table 2** Digital Competence Framework for Citizens: competence areas and competences (Carretero et al., 2017; p. 11)

Competence area	Competences
1. Information and data literacy	1.1. Browsing, searching, and filtering data, information, and digital content 1.2. Evaluating data, information, and digital content 1.3. Managing data, information, and digital content
2. Communication and collaboration	2.1. Interacting through digital technologies 2.2. Sharing through digital technologies 2.3. Engaging in citizenship through digital technologies 2.4. Collaborating through digital technologies 2.5. Netiquette 2.6. Managing digital identity
3. Digital content creation	3.1. Developing digital content 3.2. Integrating and re-elaborating digital content 3.3. Copyright and licenses 3.4. Programming
4. Safety	4.1. Protecting devices 4.2. Protecting personal data and privacy 4.3. Protecting health and well-being 4.4. Protecting the environment
5. Problem solving	5.1. Solving technical problems 5.2. Identifying needs and technological responses 5.3. Creatively using digital technologies 5.4. Identifying digital competence gaps

DigComp delineates the competences in five domains with an emphasis on information search, retrieval, and evaluation, interaction and collaboration through digital technologies, content creation, practice of safe technology use, and problem solving using digital technologies. In addition to DigComp developed by JRC, the European Commission developed another set of competences for lifelong learners. Key Competences for Lifelong Learning are general recommendations for citizens and key stakeholders to develop and update competences that enable individuals to succeed in various aspects of life including education, employment, and social relations (European Commission, 2019). While the framework has a broad application to a learner's life and is more comprehensive than DigComp, it includes critical competences such as digital and personal, social and learning to learn competences. Each key competence includes a description statement as well as details as to what it entails in terms of knowledge, skills, and attitudes. The key competences and a brief description of each competence are presented in Table 3.

Key Competences for Lifelong Learning address a broad range of competences citizens need in educational, professional, and social settings throughout their lives. The framework emphasizes the competences in communication in the native and other languages, science, technology, engineering, and mathematics fields, digital technologies, interpersonal relations and learning strategies, civic and social life,

**Table 3** Key Competences for Lifelong Learning (European Commission, 2019)

Competence	Brief description
1. Literacy competence	Communicating effectively with others in oral and written forms using audiovisual and digital materials
2. Multilingual competence	Communicating and interacting with others in oral and written forms in languages other than the mother tongue
3. Mathematical competence and competence in science, technology, and engineering	Mathematical competence is the ability to solve real-world problems using mathematical thinking and insight while competences in science, technology, and engineering refer to explaining the natural world by observation and experimentation and applying knowledge to human needs
4. Digital competence	Use of and engagement with digital technologies for various reasons including learning, employment, and participation in society
5. Personal, social, and learning to learn competence	Knowledge, skills, and attitudes relating to time management, working with others, and self-regulated learning
6. Citizenship competence	Acting a responsible citizen and participating in civic and social life
7. Entrepreneurship competence	Using opportunities and ideas to create cultural, social, and financial value for others
8. Cultural awareness and expression competence	Understanding and respecting the expression and communication of ideas and meaning in different cultures

entrepreneurship, and cultural awareness. While both the Digital Competence Framework for Citizens and Key Competences for Lifelong Learning were developed predominantly with adult citizens in mind, another set of competencies was developed to address the knowledge, skills, and attitudes students should possess in learning environments in the digital age. The student standards developed by the International Society for Technology in Education (ISTE) address knowledge, skills, and attitudes for students to achieve excellence in learning (ISTE, 2019). The standards have a broad application area that ranges from K-12 to higher education settings and include critical skills that enable students to become successful learners in the new century in various learning environments including open, distance, and digital education. The standards emphasize skills such as using technology to manage learning goals, taking advantage of the opportunities the digital world provides, constructing knowledge via digital tools, using technology in the design process, using technological methods to understand and address problems, communicating clearly and creatively, and collaborating effectively with local and global partners. An analysis of the skills included in the framework reveals that the appropriate application of the standards covers the learning process and potential

**Table 4** ISTE Student Standards (ISTE, 2019)

Standard	Brief description
1. Empowered learner	Taking advantage of technology to assume an active role in managing learning goals
2. Digital citizen	Recognizing and acting upon the opportunities and responsibilities in terms of living, learning, and working that the interconnected digital world provides
3. Knowledge constructor	Collecting resources using digital tools to construct knowledge, create artifacts, and engage in learning experiences
4. Innovative designer	Using technologies in a design process to address problems by innovative solutions
5. Computational thinker	Developing and using strategies to understand and address problems by making use of the technological methods
6. Creative communicator	Communicating clearly and creatively via the methods applicable to the identified goals
7. Global collaborator	Collaborating with local and global partners effectively to expand perspective and enhance learning

stakeholders entirely and offers a smooth learning experience for the learner. The domains of ISTE student standards and a brief description for each domain are provided in Table 4.

---

## Competencies in Open, Distance, and Digital Education Environments

Competency frameworks developed by organizations to date inform us about the knowledge, skills, and attitudes today's citizens should possess in order to achieve success in educational, professional, and social aspects of their lives. These frameworks also include critical competencies that institutions and education practitioners can make use of to ensure learner success in open, distance, and digital education. The novelty of the experiences that new learning environments offer and the learning activities that learners are expected to engage necessitate learners to possess certain competencies to fulfill the requirements of these learning environments. In this section, deriving from the frameworks developed and the learning activities a learner is expected to engage in open, distance, and digital education environments, a collection of competencies applicable to these settings is presented.

### Information Literacy

Learners in open, distance, and digital education settings are expected to engage in a significant amount of information searching and retrieving tasks especially due to the autonomy that these learning environments inherently impose. Searching and

retrieving information includes a number of skills to employ in the process. Learners should be able to conduct a search on the Internet using relevant keywords to identify information sources, obtain a copy of the learning content by downloading it on their device, and locate and access the learning content when needed. Information literacy is usually considered to consist of skills to access and obtain learning content; however, as mentioned in DigComp 2.1, it also entails the evaluation and management of information and learning content. Therefore, learners should be able to evaluate the accuracy and reliability of information retrieved from various sources via critical thinking and manage retrieved learning content by practicing content management skills such as controlling permissions, keeping different versions, and content organization.

## **Communication and Collaboration**

Communication and collaboration are a must for all learning environments as learning experiences entail the exchange of ideas among instructors and learners and work to be completed by the joint efforts of multiple partners. Due to the importance of both communication and collaboration, relevant competencies are included especially in DigComp 2.1 and the ISTE student standards. Communication and collaboration are especially important in open, distance, and digital education due to the physical and psychological distance between learners and the instructor and among learners themselves. In addition to being effective communicators and collaborators in one-on-one and team settings, learners should be able to identify and use a variety of digital tools to interact with the instructor and their peers at a distant location, share content via email and cloud technologies, schedule and conduct online synchronous meetings, collaborate on projects using digital tools that allow simultaneous work among collaborators, use digital project management tools to manage tasks and follow deadlines, and resolve issues that may arise in the process. Similar competencies in the communication and collaboration domains are included in DigComp 2.1, Key Competences for Lifelong Learning, and ISTE Student Standards as well.

## **Design and Development**

A learning experience requires learners to create original work for assessment purposes as well as to practice the performance in learning objectives. A growing number of students are using digital tools to design and develop content as a part of their enrollment in learning offerings. Open, distance, and digital education settings also entail a significant amount of design and development work using various digital tools and technology. While the complexity of the design and development activities varies among disciplines, learners in open, distance, and digital education settings should possess fundamental design and development

competencies. At a minimum, a learner should be able to identify and use a variety of digital tools to design and develop original content and revise and remix existing content based on learning needs. Additionally, learners should be able to identify the copyright of existing digital content, evaluate its use for a specific purpose, and choose and apply a copyright license to their creations based on the sharing needs they identified. These competencies to use digital design and development tools and identify and apply appropriate copyright licenses allow learners to engage in effective and ethical design and development activities. The importance of design and development competencies is also evident in the inclusion of related knowledge, skills, and attitudes in DigComp 2.1 and the ISTE student standards.

## **Administration**

A learning experience requires a certain amount of administrative work to be assumed by instructors and learners. While instructors can assume a significant number of administrative tasks and facilitate learners' performance in face-to-face learning settings, learners are expected to take over more responsibilities and manage their learning processes in open, distance, and digital education environments. Administrative tasks allow learners to follow their projected learning experience and reach their learning goals. Learners should be able to set clear and attainable goals, identify personal learning needs, and use digital tools to create, update, and follow a learning schedule. Learners who successfully manage their learning process will show a better use of cognitive, motivational, and behavioral resources.

---

## **Concluding Remarks**

Similar to many aspects of society, educational environments are also going through an everlasting transformation to meet the needs of citizens of the current age. While these transformations bring opportunities to society, unintended disparities also result among individuals from different backgrounds. Today, we are fortunate to have access to learning opportunities provided by renowned scholars in the field of our interest while sitting at a desk in our homes, but the reality is that a significant number of learners do not have the required resources to engage in these learning experiences. A closer look into these disparities shows us that socioeconomic status and minority status are the determining factors of individuals' access to education. Individuals of low income, minorities, and underdeveloped or developing countries struggle with access to new learning environments due to the difficulties associated with technology ownership and access. This situation indirectly tells us that high-income and highly educated learners have access to more learning

opportunities while those who need them the most struggle to create learning opportunities for themselves. The lack of access to new learning environments also results in the deficiency of competencies needed to succeed in open, distance, and digital education. This chapter explored the characteristics of learners in open, distance, and digital education with respect to their technology ownership and access and discussed competencies that should be possessed by learners in these settings deriving input from a number of competency frameworks that were developed to date.

and complementary area of research is the accompanying motivation students' exhibit to learn in ODDE environments. This chapter critically examines the existing literature on student motivation in ODDE at each of the primary, secondary, and tertiary levels, and beyond. Much existing research involves one-off comparisons between students' motivation in using popular tools such as MOOCs, gamification of learning, interactive whiteboards, and AR/VR tools with not using them. While mixed effects have been observed, seldom are tools catered to theory and context in a manner that best supports students' learning. To see the field continue to mature, results from studies must be situated within robust theories of motivation in educational psychology. More program-level research built on more stringent standards in design, analysis, and replication is required. Future directions of research are discussed.

---

**Introduction**

This chapter addresses the role of student motivation within ODDE environments and the implications of ODDE environments for student motivation. This reciprocal relationship between environment and individual differences is one that is still poorly understood, even in the long-researched context of face-to-face teaching and learning (for robust theoretical modelling of this relationship consider reciprocal framing by Bandura, 1997; Biggs, 1993; Skinner, 1995). Given that research in ODDE environments is a relatively nascent field, much of what will be presented will not have been replicated across contexts, making the review presented here a preliminary sketch much in need of color and shading. Additionally, many ODDE researchers often do not have a firm foundation in educational psychology, ODDE's intersections with student motivation can yield theoretically weak research outputs. This chapter highlights research which demonstrates the best theoretical and empirical rigor available. It begins by defining motivation, and then reviews ODDE in three main sections, addressing motivation to learn in each of primary, secondary, and tertiary/adult education contexts. These reviews are then summarized in the form of critical insights that inform theory and practice. The chapter concludes with future directions for researching ODDE motivation.

**Motivation and Its Outcomes in ODDE Environments****Motivation Definition and Framework for Interpretation**

This chapter is situated in the succinct and well-established definition presented by Brophy (2004) as a summary of Maehr and Meyer's (1997) seminal review of

motivation research: “Motivation is a theoretical construct used to explain the initiation, direction, intensity, persistence, and quality of behaviour, especially goal-directed behaviour” (p. 3). This definition is broad, covering each of the mediated behaviors through which an individual’s motivation impacts learning outcomes. It provides five specific, if overlapping, lenses for examining motivations in ODDE environments. This hopefully reminds researchers that motivation is not a nebulous source of locomotion for students, but that motivation instead has impact on at least five components of the learning process. This is particularly important for researchers focused just on one motivational theory and its implications for learning. It is very unlikely that one theory could address all five components (i.e., initiation, direction, intensity, persistence, and quality of behavior). It is also unlikely that any one theory addresses the needs of the wide array of ODDE environments effectively. A collage of robust theories is necessary to comprehensively address each component and offer any sensitivity to ODDE environments.

### **Motivation Theories Central to Understanding ODDE Experiences**

As noted at the outset, there are a dizzying multitude of motivational theories for ODDE researchers and practitioners to draw upon. Both practical considerations and convenience play important roles when determining which theories to employ to investigate ODDE environments. For educational technology researchers, selecting a motivational theory is likely to be based on a combination of what is being used in target journals for their research and the relative convenience of available instruments. This means that motivational theories which got an early start in leading educational technology journals such as *Computers & Education* and *Internet and Higher Education*, including self-determination theory (Deci & Ryan, 1985) and self-regulation related models (e.g., Barnard, Lan, To, Paton, & Lai, 2009) have grown in prominence. Educational psychology orientated researchers in contrast often come to educational technology research with a preferred theory, looking to test and establish it in this new environment. Scant educational technology research puts the environment or learning related research questions at its heart. Even less research seeks to address the five aspects of the learning process that motivation in large part explains. It is more common for educational technology research to focus on technology and treat teaching and learning theory secondarily (Hew, Lan, Tang, Jia, & Lo, 2019).

This chapter reviews the wide variety of digital environments encompassed by ODDE and engages with educational contexts ranging from primary to tertiary and beyond. A large net was cast for the selection of the published research to include. However, this review seeks to connect this research to the five areas consistent with Brophy’s (2004) definition and will return to this definition in its summary. Furthermore, an emphasis is given to research that matches context, questions, and theory in a way that provides robust direction for practitioners and a foundation for further replication and extension of research.

## Motivation in Open, Digital and Distance Education

### Primary Education

The focus of a considerable proportion of early ODDE research was on whether digital education was substantively useful to elementary school students. Research reviewing the benefits of ICT for elementary school students supported the inclusion of digital education, citing the potential for supporting student-student and teacher-student relationships in the classroom (Cooper & Brna, 2002; Wegerif & Scrimshaw, 1997). This research also suggested that the well-integrated use of ICT can enhance motivation and thereby support longer-term engagement with subject studies. Research tests of the efficacy of e-mail exchanges in elementary school were a strong example of how individual students and groups of students can be connected, and their communication skills be enhanced (van der Meij & Boersma, 2002).

As ICT became more prominent in elementary school contexts, a considerable proportion of ODDE research shifted to testing a broad range of digital tools' and applications' efficacy for supporting learning outcomes and motivations to learn. Many of these studies employed weak research designs and were under-theorized (i.e., cross-sectional correlative or simple quasi-experimental such as traditional teaching vs new e-learning) leading to Hawthorne effects and inability to even hint at causal implications. Results often failed to provide effect sizes, focusing only on "significant effects," therefore giving an inadequate sense of the impact of interventions.

Building on early research exploring e-mail as a connecting tool for digital education during elementary school, research during the past two decades has worked to integrate video conferencing into elementary school digital education. The benefits traverse the broad range of simply enabling communications in schools (e.g., Anastasiades et al., 2010) and motivating students to broaden their social connections, to supporting the learning of new languages (e.g., Whyte, 2011). During and since the COVID-19 pandemic, there has been an explosion of research in this area but mostly addressing the practical demands of its delivery methods, with only tangential interest in impact on students' motivation (e.g., Moorhouse & Beaumont, 2020).

Gamification is often seen as the best and maybe easiest possible way to motivate primary school students in ODDE environments. Some of the most direct research assesses the impact of adding gaming to specific subject study. Shin, Sutherland, Norris, and Soloway (2012) is an unusually strong example of a robust test, adding games to math studies, indicating that well-structured gamification can add to students' motivation, engagement, and learning outcomes. Results are strengthened by other simpler comparative studies (i.e., traditional classroom vs. online gamification; e.g., Tüzün, Yilmaz-Soylu, Karakuş, Inal, & Kizilkaya, 2009) pointing to the potentially untapped and misunderstood benefits of gamification for digital education in primary schools. The way forward is being forged by studies pairing gamification with other learning tactics (Chen, Liu, & Hwang, 2016), and testing the efficacy of specific online experiences' power to motivate students' through self-

determination theory's intrinsic and extrinsic motivation framework (e.g., online escape rooms; Vidergor, 2021).

In primary school environments, motivational ODDE can also support opening new doorways through experiential learning affordances (e.g., AR, VR, or livestreaming; Radu et al., 2014). Ongoing research suggests the growing consensus that digital education has much to offer student motivation and that it will be a progressively critical gear in the educational engine for the coming decades.

## Secondary School

In contrast to research on elementary school digital education, considerably less literature has focused on whether ICT is appropriate for classrooms. This has as much to do with the nature of secondary education (focused on specific knowledge development) as it does with students' increased knowledge of and access to ICT. While there are differences, there are also substantial overlaps between elementary and secondary research, with many studies covering both contexts (e.g., Taylor, Casto, & Walls, 2007) and major reviews generally lumping them together. Many of the same motivational questions are being asked, such as whether gamification is a solution to students' motivational malaise or whiteboards are worth the expense. At the same time, secondary schools are on the forefront of issues such as the full adoption of tablets and the use of mobile tools to enhance learning and collaboration at school (Courtois et al., 2014).

Gamification and Augmented and Virtual Reality (A/VR) (sometimes paired) have historically been the focus of a substantial body of digital education research in secondary schools (Perrotta, Featherstone, Aston, & Houghton, 2013). Much of the research centers on how these digital education approaches support motivation, as well as engagement and knowledge related learning outcomes. Early reviews of gamification within education have heralded its central role in stimulating and sustaining motivation (Shaffer, Squir, Halverson, & Gee, 2005). Shaffer et al., go so far as to proclaim that questions of *whether* to use gamification should be put aside, and that the only meaningful question going forward is *how* to use it. In contrast to this positive tone from gamification researchers, many stakeholders do not see games as valid parts of classroom learning and note that teachers are often not a good judge of a "good" game design (Williamson, 2007). Gamification research regularly yields no significant benefit for students' motivation, often citing technical issues (e.g., Huizenga, Admiraal, Akkerman, & ten Dam, 2019) or sense of disconnect (leading to lower educational value) from subject materials (Brom, Preuss, & Klement, 2011). Despite these types of issues, reviews such as McClarty et al. (2012) echo Shaffer et al. (2005). McClarty et al., argue that digital games afford unique and valuable combinations of "...motivation, engagement, adaptivity, simulation, collaboration..."(p. 22). In this spirit, researchers have started to begin to re-examine how digital gaming might fit into secondary education by learning more about students' habits and preferences (e.g., Beavis, Muspratt, & Thompson, 2015). Others have begun to situate digital gaming questions within well-defined motivational theories (e.g., Huizenga et al., 2019).

Despite more than a decade of increasingly intensive use, AR/VR are still emerging technologies for secondary education. Their support for secondary student motivation can be moderately positive (Allison, 2008; Gandolfi, 2018). AR/VR appear to be most powerful when used with specific teaching methods (i.e., narrative, Calvert & Abadia, 2020), for skills development (Papanastasiou, Drigas, Skianis, Lytras, & Papanastasiou, 2019) and for complexity visualization (Thompson et al., 2020). It is reasonable to suggest that when AR/VR use is aligned well with supporting pedagogical practices and knowledge to be acquired, that its motivating capacity is also maximized.

## Tertiary and Lifelong Education

The abundance of ODDE motivation research in tertiary and lifelong education has yielded both benefits and weaknesses, which has led to a stream of more robust theory-driven research in this area. Concurrently, much of the ongoing quantity of research is of low quality, limited in validity and insight.

There is a considerable amount of higher education ODDE research comparing face-to-face and blended or entirely online learning experiences and resulting motivations to learn. Specific research comparing the use of online applications for these populations sometimes result in unusual findings (e.g., Pellas & Kazanidis, 2014) pointing to high self-efficacy and satisfaction in some online environments (relative to hybrid arrangements). More general tests of the student experience on and offline generally point to students being more motivated offline, although not necessarily perceiving themselves to be more self-efficacious (e.g., Mullen & Tallent-Runnels, 2006). However, comparisons of graduate and undergraduate students online suggest that graduate students engage more effectively online while procrastinating less, and that undergraduate students experience greater task value for online learning, expressing a stronger intention to enroll in future online courses (Artino & Stephens, 2009). Some of the more insightful research points to the positive (interesting) and negative (distracting) aspects of studying online (Sansone, Smith, Thoman, & MacNamara, 2012).

Drilling down on motivational issues in general digital education, a program of self-determination theory research with blended language students raised three issues worth noting. First, students who are autonomously motivated tend to stay that way, but those that are not have room and can improve and develop their motivation (Fryer, Nicholas Bovee, & Nakao, 2014). Second, classroom teachers can have a powerful impact on students' motivation for online learning (Fryer & Bovee, 2016), but have more difficulty beyond a certain threshold of actual student competence (Fryer & Bovee, 2018). Parallel research has highlighted the cost-value differences when studying online (e.g., workload for face-to-face vs. working in groups for online), and the role these trade-offs play in persistence (Vanslambrouck, Zhu, Lombaerts, Philipsen, & Tondeur, 2018).

The theme of collaboration is central to digital education research and motivation to learn online. Researchers range from creating and testing online tools (Antonaci et al., 2015), noting motivation derived from collaborative Wikis (Zou, Wang, &

Xing, 2016), to suggesting that more motivation might not necessarily be any more linked to collaborating online (Zhang, Pi, Li, & Hu, 2021).

Perhaps the most important kind of research seeking to navigate online students' motivation is the work that straddles tertiary and adult/lifelong learning. Research that seeks to explain how the modality of the online experience and its affordance/constraints motivates, engages, and results in learners' performance. McPartlan, Rutherford, Rodriguez, Shaffer, and Holton (2021) explain how strictly online tertiary students often differ from tertiary students in blended or face-to-face contexts; how online students are generally studying for very different reasons, have less time to reach their goals and on average fare worse.

Another popular area of motivational research that bridges tertiary and adult/lifelong ODDE are MOOCs. MOOCs are so reliant on student motivation (and resulting retention), that it is often the focus of research in this area (Zhu, Sari, & Lee, 2018). There is evidence to suggest that the autonomous nature of MOOCs can mean that students' motivation and goals shape how they understand MOOCs and their experience online (Littlejohn, Hood, Milligan, & Mustain, 2016). This finding should be cross-referenced with results suggesting that the impact of participation in and initial intrinsic motivation for a MOOC is at least partially mediated by the situational interest students experience across the MOOC course (de Barba, Kennedy, & Ainley, 2016).

Students have reported engaging in MOOCs for a handful of specific reasons (e.g., Hew & Cheung, 2014). However, different kinds of students completing MOOCs have very different orientations across the learning experience (Watted & Barak, 2018): university-affiliated students tend to seek knowledge and certificates, while general participants often work toward research and their own professional development. These pair of findings make understanding students' motivations for learning in MOOC environments (initial and across the experience) critical to solving retention issues.

Gamification is an active area of motivational research in digital tertiary environments. Unlike in some areas of tertiary ODDE research, higher quality research is not as prevalent. Results are still often simple comparisons of gamified vs traditional engagement and rely on self-reported data for independent and dependent variables (e.g., Putz, Hofbauer, & Treiblmaier, 2020). Some studies in this vein are, however, applying more rigorous motivational frameworks (e.g., Buil, Catalán, & Martínez, 2020). However, it is still common for studies, much like those in secondary and primary contexts, to find gamification failing to support student motivation and/or achievement, even weakening one or both (see Donnermann et al., 2021; Murillo-Zamorano, López Sánchez, Godoy-Caballero, & Bueno Muñoz, 2021).

Pedagogical agents for online learning materials can improve motivation, engagement, and knowledge development (e.g., Dinçer & Doğanay, 2017). Research seeking to refine pedagogical agents as a source of support for students has proliferated during the past decade (e.g., Lin, Atkinson, Christopherson, Joseph, & Harrison, 2013). Similarly, gesturing (embodied) pedagogical agents are a substantial improvement over static versions (Wang, Li, Mayer, & Liu, 2018). Early research findings with chatbots as language learning partners (Fryer & Carpenter, 2006) noted that some,

especially weaker, students were more motivated to engage with a chatbot than a partner. Despite the growth of research in this area (Fryer et al., 2020; Wollny et al., 2021) and the broad recognition that, like pedagogical agents, chatbots can be motivating (Fryer, Nakao, & Thompson, 2019), there has not been enough refinement-orientated research (e.g., for an important exception Li, Wang, Mayer, & Liu, 2019).

---

## **Critical Insights from Researching Motivation in ODDE**

### **General Insights**

#### **ODDE Has Matured**

The field has matured, as questions shift from whether ICT is of any use to education, to how specific aspects should be employed within ODDE contexts. Gamification is a good example of this development. While gamification's value as a support for ODDE is still often debated, many researchers have shifted to acknowledging that gamification is here to stay. Therefore, ongoing questions should focus on the kinds of contexts in which gamification should be used, and how individual differences can be accounted for.

#### **Context and Individual Differences**

Consistent with the example of gamification, motivational research in ODDE environments must move past the idea that any specific piece of hardware or software will be a silver bullet for student motivation. Furthermore, it is rare that a new tool is focused only on enhancing motivation; the hope is generally that it will also yield strong knowledge outcomes as well. Research thus far suggests that findings are likely to be localized; where motivational supports cross contextual boundaries, support for learning outcomes might not. As will be discussed in the conclusion to this chapter, one way the external validity of findings might be buttressed is by consistently employing robust motivational theory and clearly building on past research both in ODDE and parallel classroom contexts.

### **Specific to Primary Education**

Questions regarding the value of gamification for supporting motivation in digital education abound are particularly acute in primary education. The variance around findings suggests gamification might not be easy to modulate for young learners. The clarification of modulation approaches would support researchers in investigating and supporting the development of student motivation.

In contrast, online tools that effectively increase and enhance social interaction are a relatively clear path to supporting primary school student motivation on and offline. Especially, in the aftermath of COVID-19, it is critical that positive findings showing how students can be brought together effectively be shared and

collaboratively be built upon. Continued research in this vein should support classroom motivation as well as in blended environments.

The research on tools that bring digital education to classrooms such as whiteboards are broadly supported by research, teachers, and students alike. Given the substantial investment made by many schools, and the motivational implications hinted at by exploratory studies, researchers should begin to apply stricter theory and design, to begin testing specific practices, and ensure teachers and students maximize their use.

Particularly in primary school settings, several important factors moderate the motivating potential of digital education tools. The first is one that has been discussed extensively, teacher ICT proficiency (often packaged as TPAK; Koehler & Mishra, 2009). Researchers can further the field by clarifying the correspondences between specific teacher ICT proficiencies to their relevant digital education environments. Students' subject competence and their ICT proficiency are also critical moderators for enhancing digital education motivation. Both of these deserve greater attention, by programs of research, rather than once-off explorations.

### **Specific to Secondary Education**

Some of the best AR and VR research has sought to support motivation and learning outcomes across specific, often challenging secondary school learning experiences. Due in part to carefully situated use of AR/VR, many modest but positive outcomes have been reported. Across this research a few findings have the potential for external validity, providing direction for future research. The first is the power of AR/VR to support learners across complex topics, such as visualizing intricate objects or processes. The second for VR in particular, is the opportunity for socialization. This socialization can amplify classroom experiences or expand on them. There is, as always, a need to match AR/VR use carefully with curricular aims and ensure teaching methods applied through this medium are appropriate, rather than relying on it or treating it as something completely different from classroom practice. Similar to AR/VR, secondary school is a hotbed for gamification. As noted earlier, gamification has progressed beyond *whether it should* be applied in secondary education. Its unreliable contribution to motivation and learning outcomes can be attributed partly to poor design and situation. Future programs of research in specific learning contexts found to be amenable to gamification are necessary for this approach to supporting motivation in ODDE to find its place.

### **Specific to Tertiary and Adult Education**

While flipped learning has its roots in secondary education, tertiary education has quickly made it its own. The field is now substantial enough to yield several comprehensive reviews which point to this online support for classroom engagement as a consistent support for student motivation and positive attitudes, but not necessarily for learning outcomes. Research has long ago, and now more recently, noted

that not all areas of learning are conducive to being effectively transferred to video. That said, separate from flipped learning specifically, recent reviews of recording of classes and class materials have demonstrated broad small to moderate benefits to students (Noetel et al., 2021). Flipped learning is one area of ostensibly online research where more classroom research, rather than online research, is needed. The benefit of moving more material online (and out of the class) is that more time in class can be devoted to engage students in meaningful learning. Figuring out how to use that time effectively is likely the gap between small to large benefits to students' motivation and knowledge outcomes.

Some of the best research bridging tertiary and adult lifelong learning has highlighted very different goals these populations have and the resulting motivations that support them in succeeding. More research is necessary to better understand and adapt tertiary offerings for adults to meet their specific lifestyle and motivational needs. MOOCs which serve both populations of students could benefit from this kind of research and adapt their offerings in a manner to support these diverse groups of learners more effectively.

---

## **Open Questions and Directions for Future Research**

### **When Will Motivational Theory Be Stretched to Fit ODDE Experiences?**

In the vast majority of cases, new motivational theory, specific to ODDE is not needed. Existing motivation theory needs to either be applied within its limits (see Fryer and colleagues applying self-determination theory) or, even better, carefully adapted and built upon to address ODDE specific questions (see Mayer and Colleagues work applying cognitive load theory to multimedia). Both approaches demand programmatic research and cutting-edge research design/analyses to be effective.

It is worth highlighting the contributions of educational psychology theory-driven research. In place of researching "motivation," which is more common in primary and secondary contexts, specific theories are increasingly drawn upon for research questions in tertiary contexts. From clear to more diffused, Skinner et al.'s (1995) self-theory has been drawn up to examine simulations (Buil et al., 2020); Self-Determination Theory (Deci & Ryan, 1985) is increasingly employed to explore student motivation online (e.g., Fryer & Bovee, 2018); various models of self-regulation are used to explore procrastination (Cheng & Xie, 2021); or, in some cases, a constellation of psychological constructs (and theories) is grouped to test ODDE questions. What these efforts often lack, however, is a connected program of sustained research or even any concerted effort at building on previous work in the same or parallel areas.

### **When Will Digital Education's Affordances Really Drive Life-Long Learning?**

When will digital education really start to impact life-long learning? How is motivation for ODDE different for adult and life-long learning and how can it be

supported best? These questions are not meaningfully addressed by MOOCs and tertiary education broadly. This is partly due to lack of robust theory being applied to programmatic research, and financial viability. The corporate sector, which has been investing in digital education for its employees' continuing professional development might be an area to learn from going forward.

### **When Will Gamification's Potential Contributions Be Clarified?**

As has been noted across this chapter, gamification is here to stay. Programs of research are needed now at each level of education and in some cases in specific subject areas. These programs need to apply robust motivational theory, research design, and analysis to progressively test the affordances and constraints of gamification for the support of short and long-term motivation in ODDE environments. Furthermore, the propensity of gamification for supporting different facets of motivation as laid out by Maehr and Meyer (initiation, direction, intensity, persistence, and quality of behavior, especially goal-directed behavior; 1997) should be tested to clarify the strengths and weaknesses of gamification.

### **Doing More of What We Know Works**

It is time for ODDE motivation-orientated researchers to realize that educational technology is a *sub*-applied science that relies on educational psychology, in the way that educational psychology relies on psychology. Both research and practice should direct its efforts toward applying educational technology toward education in a manner we know works, because it is already supported by theory and a sound empirical base. Educational technology researchers need go no further than recent meta-analyses and reviews (e.g., Dunlosky, Rawson, Marsh, Nathan, & Willingham, 2013; Hattie & Anderman, 2019; Richardson, Abraham, & Bond, 2012) for high impact theoretical constructs, and the learning and instructional practices they build upon. Examples of strong areas highlighted consistently are academic self-efficacy, feedback, meta-cognitive strategies, formative testing, summarization, practice tests, spaced learning, interleaved learning, and reciprocal teaching.

---

## **Implications for ODDE Practice that Arise from this Research**

### **Robust Motivational Theories for the Road Ahead**

Researchers might consider giving special attention to three motivational theories which have been conceptually and empirically validated both online and in classrooms. These theories are consistent with the five motivational behaviors reviewed and are relevant to the aims toward which educational technology is employed. First is self-determination theory (Deci & Ryan, 1985) and specifically its continuum of value from lacking regulation (amotivation), to external regulation (extrinsic

motivation), and finally internal regulation (intrinsic motivation). This organization of value can explain variance in learning behaviors such as initiation, direction, and quality. It also spans learners avoiding (amotivation), being forced to (extrinsic), and seeking to (intrinsic) learn online. The second, is social cognitive theory (Bandura, 1993), specifically self-efficacy and its model of reciprocal determination. Self-efficacy is central to understanding learner persistence (Bandura, 1993) and the model of reciprocal determination is useful for understanding how the environment and learner behaviors affect future motivation. Finally, interest, specifically the Four Phase Model of interest (Hidi & Renninger, 2006), is one of just a few developmental models which can contribute explanatory power to the full gamut of learning behaviors (i.e., all five within Maher and Mayer's definition). This is dependent on the phase of interest (Stimulated, Maintained, Emerging, and Well developed Individual) the individual experiences for the material's (object) understudy.

### **ODDE Motivation Research Design and Analysis Must Improve to Be Substantive**

The use of robust motivational theories is a necessary but not sufficient step toward substantively improving ODDE research and learning outcomes. Based on the present review of the recent ODDE motivation research literature three recommendations stand out. First, interventions must stop comparing a new digital addition to traditional classroom teaching with traditional classroom teaching (i.e., doing nothing new). This sets up the very likely chance of a Hawthorne effect, making all findings from the prospective study suspect. At the very least, two separate additions to traditional teaching should be compared and if possible, the traditional classroom should be added as a second control (e.g.,  $2 \times 2$  experimental design; Donnermann et al., 2021). The second recommendation is the greater use of intensive longitudinal designs (Fryer, Ainley, Thompson, Gibson, & Sherlock, 2017; Fryer et al., 2019). One great benefit of researching ODDE is the relative ease with which data can be collected. The third and final recommendation is that observed outcomes be included in research designs and that effect sizes for all findings are presented in publications.

### **Stop Asking Whether and Start Asking for Whom and How**

Echoing many prominent contributors to the field of ODDE, it is time for researchers and educators alike to stop asking whether digital education has a place in schools and begin recognizing that these tools are here to stay. Some tools like interactive whiteboards, demand considerable time on the part of both educators (teachers and curriculum developers) to integrate effectively into classes. Others like gamification, augmented and virtual reality need context specific development, testing, and refinement to estimate their compatibility. There is a third type of ODDE development that gets far less attention and that is development aimed at addressing educational issues raised by the research literature more broadly. For example, meta-analyses (e.g.,

Hattie & Anderman, 2019) and strategic reviews (e.g., Dunlosky et al., 2013) have consistently raised spaced learning and formative testing as powerful sources of support for teaching and learning, yet few ODDE developers, let alone researchers work in these areas. Another interesting area is interleaved learning, which although interesting and promising, presents challenges to research with traditional textbook approaches.

There is still much to do, with many avenues unexplored. ODDE has the potential to make substantial contributions to students' motivation to learn at every stage of their lives. Developers, educators, and researchers will need to work together to bring this future to our present.

## Abstract

Gender and the concern with gender issues is important for open and distance education (ODE) which is associated with the provision of educational opportunities for minority groups. In countries and cultures the world over, including Western industrialized societies, girls and women are educationally disadvantaged compared to their male counterparts. This educational discrimination is especially prevalent in social minorities. Since 1982, with the start of the Women's International Network WIN within the International Council for Open and Distance Education ICDE, women working in ODE have brought a feminist and gender perspective to their own situation and to that of women distance students. A manifestation of this was the proliferation of women's/gender studies

into ODE curricula. With the goal of equal access and conditions for women to succeed, women working in ODE researched and analyzed the cultural and social factors underlying the inequalities and identified ways for redressing gender imbalances. The chapter discusses four areas of inequality and points out ways for the empowerment of women: (1) gender roles and the social division of labor, (2) learning environments, (3) access equity, and (4) course content and choice of subject. A focus on gendered access and use of technology highlights factors affecting women's participation in e-learning and the way in which they use electronic communication for overcoming isolation, for networking, and for empowerment.

**Introduction**

This chapter addresses the issue of gender in open, distance, and digital education (ODDE), which came to the fore in the 1980s and has been an ongoing concern since then. The increasing digitalization of the field led to a focus on online learning and virtual learning environments (von Prümmer, 2004b).

The concept of open and distance education (DE) has always been associated with the ideal of providing educational opportunities for minority groups and those who cannot access the educational system in the regular way. The establishment of single-mode distance teaching universities (DTUs) such as the Open University in Britain (OUUK) and the FernUniversität (FeU) in West Germany was an outcome of the political will in the 1970s to provide working-class people and other educationally disadvantaged groups with a "second chance" to access tertiary education and to obtain an academic degree (Boothroyd, 1994; McIntosh, 1977). In fact, research at the German FeU has shown that DE does serve as a second chance for women from a working-class background to achieve an academic degree previously denied them (von Prümmer, 1997, 2000).

Why is gender an issue in ODDE? Without a gender perspective differences between men and women were traditionally explained in terms of a deficit model, which saw women as lacking the qualities needed to be successful distance students. A case in point is gendered learning styles. The German FeU with its predominantly male student population propagated the ideal typical distance student as the "autonomous, independent" learner who neither needed nor wanted extensive support. If women wanted "support and connectedness" (Kirkup & von Prümmer, 1990), they clearly lacked the necessary autonomy and independence. Similarly, if women chose to study a limited range of subjects, it was basically their problem. And if women

didn't manage to organize their lives and give priority to their studies, maybe they were not suited for this type of education and didn't deserve the opportunities offered.

Introducing the concept of gender into the picture brings a different perspective. It means looking at all aspects of the provision of DE and the situation of the students. It identifies gender factors and ways to turn gender differences into assets rather than disadvantages. For instance, in terms of this paradigm the need of women for personal contact with tutorial staff or support networks is not seen as psychological dependence but as bringing to DE valuable communication and affiliation skills (Kirkup, 1995: 11). In the same way, the observed gender differences in course choice lead to a reevaluation of the androcentric way in which the subject matter is presented.

As DE has moved from its traditional forms toward ODDE and virtual learning environments, there is even more need for concern regarding the effects of gender and the equitable participation of women in online education. Gender is an issue simply because – no matter how “virtual” they are – these environments are part of the “real” world and therefore gendered. Learner support, in particular, has to acknowledge gender as a category, which shapes the provision of online education and which affects students and their ability to participate fully in it. With regard to ODDE students who must work with information and communication technologies (ICTs), evaluation studies show persistent gender differences in three areas: (1) access to, and control over ICTs, available resources, and the gendered division of labor; (2) know-how and computer literacy, confidence, language and writing skills; and (3) learning styles, communication preferences, and usage of ICTs.

---

## **Gender Issues in Distance Education: Historical Context**

### **The Situation of Women in Open and Distance Learning (ODL)**

The 1970s saw the rise of tertiary distance education (DE) and its transformation into open and distance learning (ODL). Single-mode Open Universities (OUs) and Distance Teaching Universities (DTUs) were established around the globe to provide opportunities for “second chance” academic qualification for mature students already settled into jobs and family life.

If women were expressly mentioned as target groups for this type of education, they were often typecast as “housewives” for whom DE was ideally suited (McIntosh, 1977: 78). While house-bound and unable to attend face-to-face classes, housewives, especially mothers of small children, were supposed to be flexible in their time-management and therefore able to pursue their educational aspirations through home study. The fact that in many ODL courses female students were the majority was seen as proof of the success of opening these educational opportunities to women. Yet this unreflected view of the life circumstances of women contributed to a disregard of the needs of women distance students. Increasingly, teachers and

institutional researchers were concerned with gender differences in DE, not only in access and participation but also in course choice, drop-out rates, and study success.

By 1982 the situation of women in DE had become a focus of feminist educators and researchers who started to connect globally in the *Women's International Network WIN* within the *International Council for Open and Distance Education ICDE*. The insights gained by cross-cultural discourse and research were not simply additive but created added value for the understanding of the role of gender in DE. This was first manifested in Karlene Faith's (1988) pioneering collection *Toward New Horizons for Women in Distance Education: International Perspectives*. This book is commonly referred to as the *WIN-Book* since it originated in the *WIN* movement and not only the editor and her team but all contributors were active *WIN* members, distance educators, and researchers. Its continued relevance is evidenced by the fact that the book was republished in 2017, both as hard copy and eBook (Faith, 2017).

### **Women Working in ODL**

The concern with gender in DE first emerged as a global issue four decades ago at the *12th ICDE World Conference in Vancouver* because the organization glaringly ignored the presence of women working and studying in the field. Even though 25% of the conference delegates were women they felt marginalized because of the gender-exclusive language and the male-dominated production and transmission of knowledge (Burge, 1988: x). This reflected the androcentrism in universities and schools, including DE institutions. Women were underrepresented in the higher ranks of academic and administrative positions and overrepresented in lower-level office and technical jobs and insecure positions.

Yet undeniably the learning experience of women distance students is shaped by the visibility – or invisibility – of women working in their DE institution (von Prümmer, 2000: 15). A preponderance of men in the higher levels of the academic hierarchy not only affects teaching but also research opportunities and activities and the publication of findings. A literature review of five prominent DE journals between 2000 and 2008 shows gender differences in research areas and research methods. Exploring the associations between gender, collaboration, and research the study found that women, whether as single authors or co-authors, were more likely to report on qualitative methods and on topics related to learners, their characteristics, support or interaction, and to communication in learning communities. Men, on the other hand, are stereotypically more concerned with technology and management (Zawacki-Richter & von Prümmer, 2010: 95).

The gender-differentiated academic hierarchies are widely reflected in research that typically requires funding, which also is more accessible to men than to women researchers. Looking into the productivity and impact of papers authored by men and women, a 2015 study showed a distinct underrepresentation of women in the most productive group of researchers. This is associated with gender differences in age, authorship position, and academic rank (van den Besselaar & Sandström, 2017 p. 1).

### **Women Distance Students**

Gill Kirkup, an institutional researcher at the OUUK, points out that one of the important points to arise from the *WIN-Book* is the refutation of the view that ODL is a type of education particularly suited to women. This assumption was based on the well-known facts that compared to men adult women have many more restrictions on their time and mobility, and at the same time have less access to disposable income. Yet implicitly it presumed that there is no difference between men and women with regard to their study motivations, their intellectual styles, and their domestic circumstances (Kirkup, 1996:154).

In this context Gill Kirkup refers to the first internationally comparative research project in 1986–1988, conducted from a feminist perspective and explicitly directed toward the gendered circumstances of DE students. It was a large-scale parallel survey of women and men studying at the German FeU and the British OUUK. Addressing a wide range of themes, the research provided information on the composition of the student body and student characteristics, class background and social mobility, family and work commitments, study motivation and learning styles, communication and student support, subject preferences and prior educational attainment, the economic situation and access to resources, domestic division of labor; and control over one's study time and space (von Prümmer, 2000). The data yielded gender differences in all of these areas and acted as starting point for further analysis and investigation.

The data analysis of the FeU study concentrated in the first instance on students' choice of major subject and degree program, testing the assumption that the underrepresentation of women was due to a predominance of "male" subject areas (von Prümmer & Rossié, 1988). The starting point of the comparative analysis of FeU and OUUK data was focused on students' private situation and their use of support services (Kirkup & von Prümmer, 1990). It showed that women leaned toward a connected style of learning, which tended to conflict with the distance teaching mode as practiced by FeU at the time (von Prümmer, 2004b:180).

The research confirmed the existence of gendered life circumstances. At the same time it refuted another presumption often used to explain gender inequality in DE, namely, a deficit model of women students who were seen to be less suited for independent study in ODL than their male colleagues (Kirkup, 1996: 155). Feminist theories and debates confirm that women are different, not deficient, and that DTUs must take these differences into account if they want to serve their women students (Kirkup, 1995: 11, von Prümmer, 2004b: 180–181).

### **Feminist Perspectives and ODL**

The emergence of women, bringing with it feminist perspectives and the concern not only with the representation of women in the field but more broadly with gender issues, challenged the androcentrism of the DE world. Although, as Karlene Faith

notes in the *WIN-Book*, not every contributor to this book would identify as a feminist, they all describe radical alternatives to the educational status quo (Faith, 1988:13).

To accept that gender is an overriding concept in ODL is to open a Pandora's box, which will affect all facets of teaching and learning at a distance such as content and language, curriculum design, course delivery and technologies, student support and communication, cost and resources, as well as institutional and other research, policy decisions, staff development, and administration.

### **Women's/Gender Studies (WGS) and Distance Education**

An obvious deviation from androcentric content and curriculum are courses and degree programs in Women's/Gender Studies (WGS), which often are explicitly founded in feminism and the women's movement (AU Athabasca University, 2021). Due to their very nature as both a learning exercise and a consciousness-raising experience, WGS represent special challenges to teaching and learning at a distance as described by Edith Smith and Valerie S. Norlen in their account of "*Tele-Distance Education in Women's Studies*" (1994). This confirms the findings Elizabeth Burge and Helen Lenskyj collected during their first graduate course in women's studies at the *Ontario Institute for Studies in Education (OISE)*. They conclude that promoting distance mode women's studies courses is a challenge in itself. It also presents implications for women-centered teaching in all other DE programs regardless of their possible explicitly feminist orientation. Gender analysis of all content and acknowledgment of the specific life circumstances and experiences of women students need to be integrated into teaching and learning processes across the board (Burge & Lenskyj, 1990).

Today Women's/Gender Studies (WGS) programs look back on a long tradition and are nearly universally offered at a distance, as undergraduate and graduate degree programs as well as for personal development. Nearly four decades ago the OUUK offered its first Women's Studies (WS) course (Kirkup, 1983), and 30 years later looked back on it as a success story. Gill Kirkup and Liz Whitelegg (2013) described the program as influential nationally and internationally for many feminists and WGS teachers and scholars who either enrolled at the OUUK or at other institutions, which had bought the materials. It is not as clear whether the WS course was successful in spreading gender analysis to the Open University's other subjects and degree programs.

On the opposite side of the world the Indian Indira Gandhi National Open University (IGNOU) started its *M.A in Women's and Gender Studies* program in 2013 aiming to enable students to apply gender perspectives to the complex power hierarchies and relationships of society (IGNOU, 2021). The WGS program thus stands in the feminist tradition of encouraging and equipping women to challenge the given power relationships even if they study at a distance and may not be supported by a local women's group. Looking at DE from a perspective of women's studies Natasha Patterson (2012) identifies three main issues for feminist pedagogy: it must (1) include the virtual classroom with its gender, race, and class inequalities; (2) provide strategies and frameworks for addressing the special needs of women in diverse circumstances; and (3) focus on the female adult learners who use the

technologies in their online studies and contribute valid insights concerning their implementation and use. She concludes that teaching women's studies at a distance offers broader insights and challenges about the teaching and learning of feminism.

Worldwide there are many *WGS* courses and degree programs on all levels of DE, as the most cursory internet search will testify. Googling "*Women's Studies Programs Worldwide*," for instance, leads to a University of Maryland, Baltimore County (UMBC) website on "*Women's/Gender Studies Programs & Research Centers*" claiming to provide links to more than 900 women's/gender/feminist studies programs, departments, and research centers around the world that have web sites (UMBC, 2021). These programs are by no means uniform in their focus and pedagogy. But WGS on the whole have provided an important platform for the exploration and development of feminist, or at least women-friendly, content and distance learning environments. Gender is an all-pervasive issue, which must be addressed across the board to overcome long-established patterns of androcentrism, even sexism, and male dominance.

### **Feminist Pedagogy and New Horizons for Women**

Feminist pedagogy plays an important role in DE beyond the confines of Women's/Gender Studies (WGS). The perspectives it brings to ODL have become even more relevant since the emergence of Information and Communication Technologies (ICTs), which have first supplemented the traditional forms of delivery and later replaced them to a large extent. In the 1980s and 1990s ODL evolved from mainly written and printed materials delivered through postal services and augmented by video and audio and by face-to-face meetings. The beginning of the twenty-first century saw a rapid expansion of the use of ICTs in all areas of teaching, studying, communication, delivery, and administration. As DE continued to evolve in further stages and different directions it was variously called e-learning, online education, studying at the virtual university, and eventually Open, Distance and Digital Education (ODDE).

Addressing ODDE and gender, this chapter deals with general issues affecting women in DE and their opportunities for equitable participation in this path to gaining vocational and professional qualifications or personal development. More specifically, it also deals with the various interrelations of gender and technology, which can act as a hindrance to equal participation or as an instrument of empowerment.

---

### **Issues of Equity and Empowerment**

From the beginning, the world of DE has been closely associated with issues of equal access to education. Originally meant to provide education for people in remote areas, DE also became a means of extending educational opportunities to anybody who could not attend classes in person. Apart from geographical distance, reasons that prevent children or adults from attending traditional educational institutions may lie in social, cultural, or personal factors. Social class, for instance, may be a

distancing factor, as people from a lower, minority, or working-class background cannot afford better schooling for their children or traditionally do not value advanced education. Cultural factors may prevent people of certain religious or ethnic backgrounds from providing their children, especially their daughters, with higher education. Or the mainstream culture may deny minority groups access to educational opportunities. Personal factors may be at work when a potential student is disabled, has to take care of children or other family members, works full time at a job, or is imprisoned or institutionalized.

This shift in focus was accompanied by a corresponding shift away from the original concept of “teaching at a distance” to “open learning,” which corresponded to a twofold commitment: an emphasis on open access and on the learning process and the needs of learners. These developments are often thought to open educational opportunities automatically to women, especially to those with multiple factors working against them. Research and experience has shown that it takes deliberate action and policies to mitigate the adverse effects of androcentric pedagogy and content and to ensure equity of access and study success for women.

A recent literature survey by Suzan Koseoglu and colleagues, covering 30 years of literature, focused on gender inequality in post-secondary and higher DE contexts and confirmed that gender inequality remains a pressing issue on a global scale (Koseoglu, Öztürk, Ucar, Karahan, & Bozkurt, 2020). Yet according to their analysis the majority of publications does not address gender issues but ignores both the causes of gender inequality (patriarchy and androcentrism) and their effects (women having less access to educational resources and formal learning opportunities). The authors conclude that better access to educational opportunities alone does not ensure gender equity. Rather, curriculum design should be informed by gender perspectives and centered on empowerment and agency in order to challenge existing cultural and traditional assumptions and political systems. In joining critical pedagogy in general and feminist pedagogy in particular to achieve these ends, Koseoglu and colleagues close the circle to the earlier demand of Elizabeth Burge and Helen Lenksyj (1990) to integrate gender analysis into all content, whether it be explicitly feminist or not.

The following sections deal with four areas of inequality and point out ways for the empowerment of women: (1) Gender roles and the social division of labor, (2) Learning environments, (3) Access equity, and (4) course content and choice of subject.

## **Gender Roles and the Social Division of Labor**

### **A Woman’s Work Is Never Done**

The gendered division of labor, which exists in most societies means that women are responsible for taking care of children and the household. Since many women DE students also work full-time or part-time outside the home, they have multiple commitments even before enrolling as distance students. Their courses are then an additional workload – a “third shift” (Kramarae, 2001) – which has to be fitted around their other roles. Recently, Covid-19 and pandemic-induced “work-from-home” (WFH)” has brought forth an impressive amount of research testifying to its

gender-differentiated impact, both in the private sphere and in work-related areas, which reinforces the traditional division of labor and gender roles.

There exists a myth of flexibility and self-determination with regard to the domestic and family responsibilities of women. It is often assumed that DE is especially suited for “housebound mothers of small children” believed to enjoy flexible schedules and the freedom to organize their own days. In fact, the demands of home-making and childcare provide a fragmented workday over which the women have little control, making it difficult to free up time for studying, especially for the uninterrupted or lengthy periods necessary for in-depth reading or exam preparation.

### **Making Time for Her Studies**

Despite these adverse circumstances women DE students do manage their course loads and exams by reorganizing their lives and negotiating the domestic division of labor with their partners and children. One of the most difficult tasks is the changing of priorities so housework and mothering no longer take precedence and outside help is accepted with childcare, cleaning, etc. (grandparents, daycare, cleaning service, take-away food).

To succeed in this, women must realize, at the beginning of their studies, how great the workload will be, how much time and concentrated effort has to be invested, that it is their right to study, even if they don’t aim for a degree, and that they need not feel guilty for “neglecting” their families. DE universities can and must assist this process by providing new students with information about likely difficulties so they can make allowances and prevent counterproductive behavior patterns to set in. Institutional support can help women to develop coping strategies, encourage students to share their experiences, and assist with setting up support networks and communication channels for the exchange between students.

## **Learning Environments**

### **Home Study**

Easily the most obvious difference between distance and campus-based education is the physical learning environment in which students and staff are situated. DE and e-learning in effect means the privatization of the learning environment (Evans & Grace, 1995), which has become the concern of the individual student. This means (1) The learning environment is no longer provided on a campus and in buildings supplied by the university; (2) Factors outside the university determine the learning setup to at least the same extent as do the university’s study rules and regulations; (3) The student rather than the university takes responsibility for the conditions in which studying takes place; and (4) The student’s personal life, resources, and access to technologies become increasingly important for her/his study success (based on data from FeU research; see von Prümmer, 2004a).

### **Privatized Learning Environments**

The privatization of the learning environment brings with it both advantages and disadvantages, which affect women and men in different ways. The advantages in

the case of “home study” are mostly savings in cost and time. Students do not have to fit in with schedules and locations set by the university and their learning activities are more compatible with other commitments. Many students, especially women, cannot pursue their education face-to-face at a traditional university. Through DE they can communicate with other students, tutors, and lecturers either live or through asynchronous channels. Thus working in groups and co-operating with others can be done via electronic channels, the telephone or even “snail mail” and does not cost as much time and money as traveling to meetings and classes would.

The disadvantages of such a privatized learning environment result from the fact that the students themselves are responsible for setting up their own learning environment and supplying the necessary equipment. *“Electronic communication and online studying require expensive hardware, software and online-access but not all (potential) students have the necessary resources and financial means”* (von Prümmer, 2004a:24). Women, who often have less or no income of their own, are more likely to find it hard to afford studying via the internet.

In this context it is worth noting that the domestic study situation of women and men depends to a large extent on their family status. While women and men are equally able to set up an undisturbed learning environment as long as they have no children, data shows that it is fundamentally different for parents: *Fathers* show similar patterns to men who live with a partner but without children. *Mothers*, by contrast, are much less likely to have their own undisturbed study space or private computer work place (von Prümmer, 2004a).

### **Taking Control of the Learning Environment**

Research conducted with DE students who were (mostly single) mothers of small children taking vocational courses has shown that women can and do overcome these difficulties and take control of their learning environment if they (a) are aware of the problems caused by an inadequate learning environment, (b) set or change their priorities to make time and space for their studying, and (c) are sufficiently self-confident to claim their own space. This is very difficult to achieve in isolation but is possible if this isolation can be overcome. The women taking part in this project overcame the disadvantages of low income, inadequate housing, and lack of support by pooling their resources, co-operating in domestic chores, such as cooking, trading childcare and homework supervision, and by mutual support through discussion and self-help groups. In this way they were able to claim their own space, even in the face of opposition, and to make the most of limited resources to improve their domestic learning environment (von Prümmer, 2000: 75–78).

## **Access Equity**

### **Factors Affecting Access to Education**

Gendered access to education may be attributed to material factors and to cultural or religious factors regarding the role of women and men in society, and often these reasons overlap. On the material level it may be argued that a family lacks the money to send all children to school or that the family income needs to be supplemented

through putting children to work. Where limited financial resources make it necessary to prioritize which child should get an education or attend secondary school and university, boys tend to be systematically preferred over girls regardless of intellectual ability and individual wishes. On the level of cultural and religious factors, it may be argued that a woman's place is in the home and that she does not need higher education or vocational training to fulfill *her* "natural duties" as housewife and mother. Conversely, as future "head of household" and "breadwinner," a boy is expected to get an education, possibly complete a degree, to obtain employment and start a career and take *his* "proper place" in the public sphere.

Looking at DE as a second chance for people previously excluded from (higher) education, it is easy to see that girls and women on the whole are more in need of such additional educational opportunities. This is especially true where gender discrimination meets discrimination based on class, race, or other factors affecting equal access. Women are also more likely to live in situations that make it difficult to impossible to attend face-to-face classes and/or to afford the direct (tuition fees, books) and indirect (child care, transport) costs associated with attending classroom-based educational programs.

### **Opening Educational Opportunities**

The example of women from a working-class background (von Prümmer, 2000: 138–165) shows how they utilize DE for overcoming educational and career disadvantages such as the lack of opportunities for secondary and tertiary schooling combined with the fact that job – instead of career – choices are often based on practical considerations rather than aptitude and inclination. As a result they entered the workforce and started earning "their own money" at a young age, even if earnings were low and it was a dead-end, traditionally female job. The role of DE for these women was to provide a second chance through access to higher degrees and formal qualifications while continuing their paid work and earning a living. It also allowed them to enter nontraditional fields and test new or advanced subject areas without existential risk.

In addition to work-related and career interests, women from a working-class background also used DE to overcome other disadvantages such as a cultural environment not geared to intellectual pursuits, a pronounced gendering of social and family roles, and fewer opportunities to explore their own interests coupled with more pressures to be "practical." In this context the role of DE was to widen their horizons and gain a "liberal arts" education, study nontraditional subject areas and pursue intellectual interests without pressure, build up self-assurance and a more positive self-image – in short, women from a working-class background use DE for personal as well as professional development.

### **Gendered Course Content and Choice of Subject**

One source of educational discrimination is the traditionally gendered nature of subject areas where girls and women are encouraged to make different choices from boys and men. A 1983 comparison of students at the Canadian Athabasca University

(AU) and the German FeU showed a marked divergence: while nearly two thirds of AU students were women, nearly four fifth of FeU students were men. At the time this could be attributed to a large extent to the different subject areas and degree requirements of the two universities (von Prümmer, 1983). Subsequent research showed persistent gender differences in students' choice of degree programs (von Prümmer & Rossié, 1988). At FeU for example, even in 2021, while the overall proportion of women students has risen to 46%, the distribution across the five academic departments shows familiar gender patterns: Seventy-one percent of students in the Psychology Department and 59% in the Cultural and Social Sciences Department are women while, at the other end of the spectrum, 78% of FeU students in the Mathematics and Computer Science Department are men (FeU, 2021).

Students' choice of subject is directly related to the courses and degree programs offered by their preferred school or university. Traditionally, women are more likely to enroll in subject areas such as social sciences and cultural studies, education, psychology, or nursing while men tend to choose STEM (Science, Technology, Engineering, and Mathematics) subjects and business. The increasing use of ICTs favors the enrollment of men who show more affinity to computers and technology. Unfortunately, in spite of numerous initiatives in countries around the world to attract more women into STEM fields, such gender differences in subject choice are the rule rather than the exception. Simply googling "women into stem subjects" yields dozens of items. It provides a Wikipedia (2021) entry and a number of websites with information, data, and publications from different countries. The links are too numerous to list or review here but should be easy to find.

Gendered course content manifests itself not only in the subject area itself but also in the androcentric presentation and language within the subject matter. In all kinds of subject areas, course material that is not gender-inclusive not only fails to engage women students, it may be off-putting or even offensive. Course authors and teachers without a gender perspective do not even realize the extent to which the language and images they employ marginalizes and alienates women and makes them all but invisible. In order to achieve equal study conditions and equal chances for successful studying, affirmative action and gender mainstreaming measures are needed to provide all teaching with gender awareness and training. The similarities and differences in the experiences, interests, expectations, attitudes, and behavior of women and men must be taken into account, and the causes and consequences of gender inequality identified in order to achieve equity (AQU Catalunya, 2018, p 13).

---

## Feminist Perspectives on Women and Technology

Coinciding with the rise of Second-Wave feminism in the 1970s there was increasing concern with women and technology, both with the potential impact IT has on women's jobs and with the advent of home computers and PCs, which initially functioned as the proverbial "toys for the boys" and men (Kirkup, 1992: 270–273). An early collection by Joan Rothschild (1983), entitled *Machina ex Dea: Feminist Perspectives on Technology*, sparked off research and theorizing in this new field,

bringing together a variety of scholarly articles without imposing specific approaches either to feminism or to technology. The only shared premise was that a male bias exists in most technology research and analysis, and that that bias must be confronted and changed (Rothschild, 1983: 213).

In 1992 the OUUK started its revised women's studies course, which featured four volumes of readings on the topics covered in the course. The volume entitled *Inventing Women: Science, Technology and Gender* was an introduction to acquaint students of women's studies with some of the most important areas of debate of women's studies scholars in the fields of science and technology (Kirkup & Keller, 1992: 1–2).

Fifteen years later Judy Wajcman's (2007) article *From Women and Technology to Gendered Technoscience* situated current discussions of women's positions in ICTs in the wider context of feminist debates on gender and technology and provided an overview of the various approaches to conceptualizing the link between gender and technology, both past and present (Wajcman, 2007: 287–288). Paralleling the increasing use of media and technology in DE, issues of equitable access to, and usage of, ICTs became more important, especially to potential students from disadvantaged backgrounds.

## Availability of ICTs in ODE

DE and e-learning settings rely almost exclusively on media, including printed materials as well as audio- and video materials, and ICTs with few elements of face-to-face and classroom interactions. Distance students are usually responsible for providing their own learning environment and equipment. The divergent life circumstances of men and women impact differently on their ability to study. The gendered division of labor affects the financial resources available to students and on their (in)ability to participate fully in the electronic campus.

With regard to technology, "access" denotes more than the physical availability of technical devices and connection to the internet. In order to make full use of ICTs for studying, students must have a degree of control over their equipment so they can set it up to fit the requirements of their studies (Kirkup, 1999). In this respect women are still faced with persistent gender differences, which are detrimental to the successful pursuit of a course of studies at a distance or via e-learning.

Superficially it may seem that the gender gap has narrowed, yet underneath the surface there remain crucial differences between male and female distance students. For one thing, more men own their equipment while women often rely on sharing someone else's. This affects the extent to which men and women can freely access the equipment and the control they have over their technology-related learning environments. Even when women are the main users, the equipment is often set up to suit the needs and interests of other family members (von Prümmer, 2004b: 185). Also, women are less likely to have computer and internet access at work, partly because of a lower participation rate in paid work, partly because the jobs women hold often don't allow them to utilize company equipment for private

purposes, or the equipment isn't suitable for study needs. Women therefore must rely slightly more on the provision of the technology in study centers and other external sources (von Prümmer, 2011: 122).

## Acceptance of Technology

Students may be prevented from utilizing ICTs not only because they literally have no access to the necessary technologies and electronic devices but also because of feelings of alienation and lack of confidence.

## Factors Affecting Women's Participation in E-Learning

Research into gender issues in ODL environments has yielded divergent results concerning the participation of women in e-learning. On the one hand, gender differences in the use of ICTs seem to have all but disappeared with women and men having equal access to the new media and internet (Remmele & Holthaus, 2013). On the other hand, women are seen to have less access and less inclination to utilize ICTs, or they use them for different purposes than their more technology-oriented male peers. The latter findings are often summed up in the catch-phrase "toys for the boys, tools for the girls" (Dolch, 2020), which signals a different attitude with consequences for the equitable design and delivery of e-learning elements (Kelan, 2007; Kirkup, 1992: 270). In addition, women are still underrepresented in STEM subject areas (Hill, Corbett, & St Rose, 2010), which in turn are associated with computers and technology.

Traditionally, technology and science are male domains all but inaccessible to women, especially as developers (Kramarae, 2001: 5). Technology is often associated with masculinity and the underrepresentation or invisibility of women explained in terms of a biological determinism (Mawson, 2015: 40) or a masculine culture (Laigo, 2020). Girls and young women engaging in STEM subjects and ICTs used to be the exception rather than the rule. Though they may no longer be disbarred from entering scientific and technological fields, women are still discouraged from pursuing masculine subject areas and predominantly male fields. If they do, they are not only the minority of students and workers but are also faced with an inhospitable environment and women-unfriendly working conditions as, for instance, a study by Ruth Carter and Gill Kirkup (1990) showed for the field of engineering.

This results in the underrepresentation of women in these subject areas and occupational fields which were, and to a large extent still are, considered male domains. At the same time, it is these fields which are most likely to develop and utilize technologies, thus reinforcing their androcentric image. One example of transforming the character of a "male dominated field" is the work of Cecile Crutzen of the Dutch Open Universiteit (OUNL) (1994). As a feminist and female scientist she designed the OUNL's introductory informatics courses. In her paper *The Influence of Feminist Theory on Informatics Course Design* Cecile Crutzen describes the process and how both the relation between feminist theories on objectivity in the sciences and Informatics and the dynamic concept of emancipation in education

were her guidelines for choosing the contents, the examples, the subjects, and their sequence (1994: Abstract). Referring to Nelly Oudshoorn's contribution to the *Win-Book* she addresses (1) The relation between objectivity and masculinity, (2) The focus of scientific thinking on mastery and control, (3) The impact of female experiences on scientific thinking, and (4) The existing dichotomies (1994: Sect. 4).

### **Women Using Technology for Communication**

Continual research in the field of ODDE has confirmed the importance of communication for the successful studying of women distance students as reported by Kirkup and von Prümmer in 1990. Communication technologies can help women to assess their own situation through comparison with others in similar circumstances. It shows where difficulties and "failure" might be due to structural factors rather than to individual inadequacies. It shows potential ways to improve their situation through learning about solutions used by other students and is a means of breaking out of the isolation associated with distance and virtual learning (von Prümmer, 2000: 131–137).

In this context and thinking about conferencing technologies for learning Elizabeth Burge (1995) suggests that the metaphor of the internet as a weaving loom may be more appropriate for women than the often used metaphor of the electronic highway. Allowing asynchronous as well as synchronous contacts, exchanges and collaboration ODDE offers opportunities for co-operation and connectedness without forcing women to travel and be present at a specified time in a specified place outside the home. During the Covid-19 lock-downs and enforced working-from-home, with round-the-clock childcare and home-schooling, for many women the internet was the only means of communication with co-workers and friends, and a veritable life-line.

### **Internet Communication and Empowerment**

Although it is sometimes assumed that the internet provides an ungendered environment, there is evidence that discussions and intercourse in "anonymous" mixed virtual meetings often silence and alienate women participants. Conversely, provision for women-only communication, off limits to men, offers networking opportunities in nonthreatening environments. Excluding men from conversations and social media groups may seem threatening to a gender used to dominating interactions in academic discourse and to defining the content. A "Women's Room" and women-only chat-groups can provide an opportunity for open and unguarded exchange not possible in mixed groups. By exchanging personal experiences women can recognize similarities in their circumstances and patterns of discrimination and oppression. They can then identify the need for action and develop strategies.

Just how can internet communication contribute to the empowerment of women? From a feminist perspective, the internet embodies the two elements "power" and "communication," which are extremely relevant for the success and empowerment of women – incidentally, staff as well as students. The following section draws on

the keynote presentation “*Perspectives from Global Research for Women in E-learning*” to the first *IFWE* conference in Phoenix, Arizona (von Prümmer, 2004a).

Looking at the role of internet communication for women, Dale Spender’s, 1995 book *Nattering on the Net* comes to mind. The title of the book does not conjure up the usual images of the information superhighway. Rather, *Nattering on the Net* refers to chats with friends, “Kaffee-klatsch”-type gossiping sessions or an exchange of everyday information. Dictionaries define “*nattering*” as a “friendly conversation without any particular purpose” which is aimless, if not pointless, and dismiss it as “talking much about little.” What, if anything, does this have to do with power and the empowerment of women?

Dale Spender, the author of *Nattering on the Net*, is a pioneer of feminist linguistics and research into the power relationships of male-female discourse. It is not surprising that she dispels the notion of the internet as a place for informal gatherings and chats: The subtitle of her book makes the connection between “*Women, Power and Cyberspace.*” Together, the title and subtitle of Dale Spender’s book spell out the connection between communication – even informal communication – and power. In order to achieve empowerment, women must discover common ground with other women and forge bonds, which are strong enough for joint action. Communication is a precondition of creating a strong and powerful community and organizing political action. One of the fundamental slogans of the women’s movement in the 1970s, “*Sisterhood is powerful,*” applies also to DE and e-learning.

Over 30 years of institutional ODDE research have shown that women are under more pressure from family and work-related commitments, that they have to fit their studies around these commitments, and that they tend not to be relieved of their burdens when they take up studying. According to a widespread cliché DE is especially suited for family women who are stuck at home but assumed to be flexible in their schedules. Consequently, each individual student who fits this cliché tends to feel guilty if she has problems combining her course of studies with her family duties and employment. In reality, any such “failure” is not due to individual shortcomings but to patterns related to the gendered organization of society and the socialization of girls and boys. Through communication with other students, the women can recognize this and develop solutions and strategies for dealing with their situation. The isolation experienced by many students in ODDE tends to be more of a problem for women than men. Offering channels for asynchronous as well as synchronous contacts and exchanges the internet and social media provide a real chance for communication and networking, the basis for empowerment.

The second fundamental slogan of the women’s movement, “*The personal is political,*” also applies to virtual and e-learning environments. The internet offers possibilities for networking on all levels from local to global, from small groups to large organizations. In order to make the internet work for women, though, its development must not be left to others – be it men, international corporations, or interest groups. Where women take possession of the virtual space they can discover or create structures, which offer them the best possibilities for their own development and the widest scope for action on their own behalf. In the spirit of the two

feminist slogans, “*The personal is political*” and “*Sisterhood is powerful*,” internet communication is political and has the potential for empowering women. It challenges both the obvious male dominance and the latent androcentrism of ODDE and e-Learning environments.

---

## Closing Remarks

Contributing a short chapter on “*ODDE and Gender*” for a comprehensive *Handbook of Open, Distance, and Digital Education* is an exercise equally exciting and frustrating. There is no way this chapter can address the full spectrum of “*ODDE and Gender*” but it points out some of the relevant gender issues that must concern everyone in the field. Most importantly it must be noted that “*Gender*” is not an isolated topic but is all-pervasive and a lens for looking at all aspects of Open, Distance, and Digital Education.

Looking at ODDE from a gender perspective brings with it challenges, chances, and changes not only for women in distance education but for everyone engaged in online and distance teaching and e-learning. This is as true today as it was 20 years ago when the first monograph on “Women and distance education” was published, focusing on the present and future “challenges and opportunities” of this non-traditional form of education (von Prümmer, 2000).

In ODDE there is a tendency to assume that more and better equipment, more sophisticated computer programs, more powerful data transmission, and increased communication technologies equate higher quality education. Yet “better servers” in the university do not automatically mean “better service” for the students, especially with regard to gender-specific patterns in access and study conditions. ODDE must no longer ignore the social and political implications of its educational provision as this adversely affects gender equity. For instance, a focus on the technologies at the expense of the human element leads to undesirable results: Seemingly endless amounts of money are spent on hardware, and little or no money on hiring and training the staff who will have to work with this technology, or on making sure all students and staff are computer-literate. (This section draws on von Prümmer, 2004b).

There is also a tendency of funding bodies and decision-makers to focus on subject areas, which have an obvious affinity to technology such as the male-dominated fields of Computer Science and Electrical Engineering, and to be less open to developments in “non-technical” subject areas such as philosophy and literature, which are more popular with women students. To the extent that ICTs replace the traditional media and access to advanced technologies becomes an essential prerequisite for studying in the virtual university, there is an increasing danger that women will be disproportionately disbarred from entering and enjoying the virtual learning environment – unless gender issues are taken into account and the definition and construction of the virtual university is no longer left to the existing male-dominated, androcentric academic and political decision-making processes or to “market forces.”

In addition to these issues, which have emerged with the advent of ODDE, we still have to contend with the unresolved gender issues of traditional open and distance education. If anything, the gendered effects of students' home also being their place of study are more pronounced in the "virtual "or" electronic" university. Not only must women students find the space and time for undisturbed studying, they now need unrestricted access to sophisticated computer equipment and fast Internet connections. They also need the know-how to operate the equipment and the inclination to work online. A gender perspective will mitigate the gender differences, which still exist and threaten the equitable participation of women in ODDE. It is necessary to recognize the danger of women being inadvertently excluded from equal access to the new online learning environments and to employ measures for ensuring equality for all.

## Abstract

In the digital era and with the prevalence of media usage in open, distance, and digital education, learners increasingly use media to facilitate their learning in various ways. Media usage in today's learning environment ranges from watching a video or listening to a podcast to annotating a digital book collaboratively or sharing thoughts on Twitter. Learners demonstrate diverse media usage behaviors under different settings for different purposes. The goal of this chapter is to provide a comprehensive overview of learners' media usage in open, distance, and digital education settings. In this chapter, the authors first review the development of media usage in open, distance, and digital education, as well as learner media usage behavior as a research-agenda shift from a contemporary research

and practice perspective. Next, the diverse learner typologies regarding media usage behaviors, as well as research on learner media usage and its implications, are discussed. The chapter concludes with an outlook on media usage in open, distance, and digital education and research directions in the near future. Understanding learners' media usage will guide research on how to promote learning with the facilitation of media and provide insights into the design and development of future open, distance, and digital education.

**Introduction**

Open, distance, and digital education platforms are often purported to promote equity by extending education to a larger population and to empower learners by focusing on learners' agency (Bozkurt, 2019). In the digital era, this mission is closely related to the adoption of various forms of media. Media are used "to present course content and to facilitate interaction and collaboration (Dolch et al., 2021: p. 32)." As media become an increasingly important mediator between learners and open, distance, and digital education, the attendant research focus has shifted from designing or implementing instructional media to promote learning to a student-centered research agenda of investigating how learners can use media to support their own learning.

Although media and technologies are not new to learning, which relies on communication (Bateson, 1972: p. 279), the development of media has led to a wide range of media-related learning activities. In the past, distance learning relied heavily on one-way communication such as radio or instructional television (Saettler, 1990). Today, learners can actively use multimedia and social media to immerse themselves in a much more interactive, collaborative, and networked open and distance learning experience. The goal of this chapter is to review the development of media and learners' media usage, discuss the research on learners' media usage behaviors in open, distance, and digital education, and finally, provide insights to inform future research on how to understand and support learning in open, distance, and digital education settings.

---

**Media Evolution in Open, Distance, and Digital Education:  
A Historical View**

Open education and distance education have very long histories and cover a wide range of activities facilitated by various forms of media. The idea of open education dates back to as early as the middle ages when universities grew out of cathedral

schools under the name of *stadium generale* (Peter & Deimann, 2013), which aimed at spreading knowledge within the entire Christendom regardless of nationality or boundaries (Riddle, 1993). Although media usage was minimal at that time, in the mid-eighteenth century, media started to facilitate learning via correspondence education (an early form of distance education) due to the advancement of print media. For example, in 1840 Issac Pitman offered shorthand instruction to the public via letters delivered by England's penny post (Simonson et al., 2019). Later, the development of media at the beginning of the twentieth century (e.g., motion pictures and public radio) made open and distance learning much more accessible (Saettler, 1990). As various media continued to develop, early open and distance education evolved from using print-based learning materials to multimedia and mass communication technologies (Sumner, 2000). For example, instructional television and satellite technologies helped open and distance education reach a broad population (e.g., Open University in UK and TI-IN Network in USA).

Open and distance education started to spread even more widely when it becomes digital with the onset of personal computers and Internet technologies. Although interest in computer-assisted learning garnered minimal attention before the 1980s, experimentation with this format began much earlier (Reiser, 2007). For example, IBM researchers developed the first computer-assisted instruction author language and brought it to public schools as early as the 1960s (Atkinson & Hansen, 1966). As computers and the Internet become increasingly accessible, learning options took on new forms, such as self-paced modalized learning content, interactive learning environment, real-time two-way video conferencing, and so on (Sumner, 2000).

---

## From Learning from Media to Learning with Media

In the early stages of media development, educators and researchers focused mostly on how to design media to deliver instructional content. Proponents of different media technologies were enthusiastic about the “revolutionary change” each medium would bring to education. For example, in the 1930s, the National Education Association predicted radio in education would be as common as books, but the passion was short-lived (Reiser, 2007). Similar stories are associated with other media, such as instructional television, satellite technologies, personal computers, and more recently, MOOC. This view was described by Jonassen (1996) as learning *from* technology, because the medium is considered as nothing more than a delivery tool. Under this view, education is centered around the designers and developers of instructions and learning. For example, teachers are responsible for deciding what media technologies (e.g., print-based media, multimedia, or video conferencing) are best for delivering the instruction. However, when the content and the learning facilitated by media are ignored, these discussions are often limited (Clark, 1983).

In contrast to learning *from* media, Jonassen (1996) proposed learning *with* media. Under this view, a medium is a tool that facilitates learning. Open, distance, and digital learning today are no longer one-way communications from teachers to learners. These learning formats are now considered socially constructed activities

and as networked, distributed, and collaborative activities. In this type of learning, learners take the initiative for their learning and construct their own personal learning networks. Instead of serving merely as a delivery tool, media mediate between learners and their learning. As a result, research has emerged emphasizing learners' agency and media usage behaviors. It is increasingly important to understand learners' media usage preferences and patterns so that researchers can best support their learning.

This view shift surrounding media-based learning did not happen out of thin air. Rather, it has been in concert with the development of media throughout the twenty-first century. Due to the popularity of personal devices and social media, agency surrounding educational media began to shift to the learners' side. Researchers began to notice the power of self-initiated learning from networks and communities (i.e., networked learning). For example, the American Society for Training and Development (2009) reported that 67% of the employees in business and industry were using online communities of practice to support their performance in 2008.

In a twenty-first-century context, media usage encompasses a wide range of different technologies and applications, and learners use media for different purposes. Learners now are equipped with more and more choices. Zawacki-Richter et al. (2015) surveyed 2339 students from full-time, part-time, face-to-face, and distance programs in German universities on their media preferences for learning. Across all students, the highest-rated media tools included search engines, email, printed texts, and word processing tools, while social media tools including podcasts, blogs, microblogging, and social bookmarking were not well-liked by all students. Nontraditional students (e.g., students enrolled in distance programs or part-time) reported significantly higher acceptance of many of the aforementioned e-learning tools. Thompson (2013) identified nine uses for media among college students, who often get labeled as "digital natives": (a) rapid communication technology, (b) multimedia creation, (c) active web reading and writing, (d) gaming, (e) web resource use, (f) collaborative web tool use, (g) productivity tool use, (h) microblogging, and (i) nondigital book reading. These different purposes for using media can lead to a diverse range of learning behaviors and opportunities (see Table 1). Among the nine uses, students' positive view of using rapid communication (e.g., texting) and microblogging (e.g., tweeting) for learning is mostly correlated with students seeing themselves as more "digital" in terms of claims being made about the digital generation. With the transition from traditional learning to digital, open, and distance learning, learning today is becoming very different from learning in the past.

Learning today is becoming increasingly democratized and often happens in diverse learning environments. Internet technologies and personal devices make information communication accessible at almost all times. Many families now own multiple devices. For example, more than half of US households own more than five digital devices, such as smartphones, desktops, laptops, tablets, or streaming devices (Pew Research Center, 2017). Learning today occurs in many different and informal settings (e.g., viewing a YouTube tutorial). Such types of learning opportunities are typically voluntary and embedded in real-world contexts.

**Table 1** Media usage factors and potential learning opportunities and behaviors in the twenty-first century

Media factors (Thompson, 2013)	Learning opportunity/behavior examples
Rapid communication technology	Learners can use rapid communication technologies to facilitate community building and collaboration in their learning (e.g., Sotillo, 2006)
Multimedia creation	Learners can create multimedia content to reflect their learning outcomes, which engages a wide range of skills and encourages sharing within communities (e.g., Hernández-Ramos & De La Paz, 2009)
Active web reading and writing	Learners can consume and produce resources beyond print media, which can be more flexible, ubiquitous, and interactive (e.g., Behjat et al., 2012)
Gaming	Learners can construct their knowledge and acquire skills through simulated and highly interactive environments (e.g., Shute et al., 2020)
Web resource use	Learners are equipped with more accessible resources from various sources and in diverse formats (e.g., Afreen, 2014)
Collaborative web tool use	Learners can use collaborative web tools to facilitate collaboration (Chen & Chen, 2014)
Productivity tool use	Learners are equipped with productivity tools (e.g., word processing tools, spreadsheets, databases, presentation tools) to produce content in various forms.
Microblogging	Learners can share, collect, broker, negotiate, and construct knowledge through a social network linked by microblogging tools (e.g., Dennen, 2019)
Nondigital book reading	Learners can consume resources in print media

As the context of learning is becoming more diverse, learning interactions are now often mediated by social tools and rely on user-generated content. Learners can form and join communities of practice and construct knowledge collaboratively with the help of social media. Although research on the effect of incorporating social media into learning is ongoing, research has shown promising results on how social media can facilitate learning in various settings. For example, Schroeder and Greenbowe (2009) introduced Facebook as a course communication tool in an introductory chemistry course. Students enrolled in the Facebook group generated nearly four times the number of posts compared to the posts generated by students who used the learning management system.

---

## Learners' Media Usage Behaviors

Media provide learners a range of opportunities for supporting learning practices, as discussed in the previous section. This section focuses on learners' behaviors regarding media usage. With abundant learning options, learners behave

differently in diverse media-integrated learning spaces. Additionally, diverse learners do not behave in the same manner even in the same media-enhanced learning space. It is important to map the typologies of learners and understand learners' media usage behaviors in order to support their learning accordingly. Researchers have identified different typologies (i.e., types of usage patterns) due to varying areas of focus, such as different users, media, and contexts. As an effort to provide a comprehensive set of typologies, the authors intentionally chose nine media usage typologies to describe in this section. In this section, the authors describe each typology or media usage pattern and explain how the researcher(s) built it by examining its context (e.g., users, media, and learning contexts) and the set of dimensions chosen and used by the researcher(s) to distinguish usage behaviors. At the end of this section, the authors provide a list of dimensions that can be considered to identify new media usage behaviors for future studies and discuss the implications of media usage typology research.

## Media Usage Typologies: Media in General

Media user typology categorizes users into distinct user types that describe the various ways individuals use different media, considering a set of dimensions such as frequency of use and variety of use (Brandtzaeg, 2010). Brandtzaeg (2010) reviewed 22 studies on media usage typologies from 2000 to 2009 and suggested the Media-User Typology (MUT), consisting of eight types of media users: (a) nonusers, (b) sporadics, (c) debaters, (d) entertainment users, (e) socializers, (f) lurkers, (g) instrumental users, and (h) advanced users (see Table 2 for definitions of each type of media user). Each type of media user demonstrates distinctive media behaviors that are explained by a set of dimensions such as frequency of use, variety of use, typical activity, and typical media platform used. This well-known typology has provided a comprehensive classification of general media usage. However, Brandtzaeg's typology did not emphasize learners and educationally relevant usage patterns, as he reviewed studies targeting different populations and involving general activities including those unrelated to learning, such as online shopping and gaming (Dolch et al., 2021).

More recently, researchers have targeted learners and identified their media usage typologies. Zawacki-Richter et al. (2015) investigated media usage patterns of traditional and nontraditional students at German universities. The researchers considered dimensions such as frequency of use, digital learning formats/tools (e.g., virtual seminars, lecture recordings, etc.), and activities (e.g., recreational use and use for learning) and identified four types or profiles of media usage patterns pertaining to students: (a) entertainment users, (b) peripheral users, (c) advanced users, and (d) instrumental users. The researchers also found that, unlike with traditional students, the proportion of instrumental users was high among non-traditional students.

**Table 2** Media usage typologies: Media in general

Study subjects and authors	User types or usage behaviors
Diverse groups of users (Brandtzaeg, 2010)	Media-user typology (MUT) <ul style="list-style-type: none"> <li>(a) Nonusers: Do not use any media</li> <li>(b) Sporadics: Use any kind of media to do nonparticular activities with low frequency and low variety of use</li> <li>(c) Debaters: Use media such as blogs and social networking sites (SNS) at a medium level of frequency for discussion and information acquisition and exchange</li> <li>(d) Entertainment users: Use new media in general at a medium level of frequency for entertainment purposes such as gaming, passively watching videos, and shopping</li> <li>(e) Socializers: Use SNS at a medium level of frequency to socialize, connect with friends and family, and make new acquaintances</li> <li>(f) Lurkers: Spend passive time using SNSs, user-generated sites, shopping, and other media in general at a medium level of use and with low variety of use</li> <li>(g) Instrumental users: Choose media content for information with specific intentions, such as comparing brands and promotional offers when shopping. They use media in general at a medium level and medium variety of use</li> <li>(h) Advanced users: Engage in diverse activities, including the activities mentioned earlier, at a high level of frequency</li> </ul>
German higher-education students (traditional and nontraditional) (Zawacki-Richter et al., 2015)	<ul style="list-style-type: none"> <li>(a) Entertainment users: Frequently use internet/online media (e.g., chats, music download/streaming, search engines, social networks, etc.) for entertainment purposes or subjective benefits</li> <li>(b) Peripheral users: Show low application and acceptance of all media, tools, and services</li> <li>(c) Advanced users: Use e-learning tools, social networks for learning, and online media for entertaining purposes</li> <li>(d) Instrumental users: Frequently use office software (e.g., text processing, spreadsheets, etc.)</li> </ul>
German higher-education students (Dolch et al., 2021)	<ul style="list-style-type: none"> <li>(a) Entertainment users: Use the internet, especially social media, often for leisure purposes</li> <li>(b) Intensive users: Use the internet, social networks, and e-learning tools for learning and use the internet for leisure.</li> <li>(c) Peripheral users: Comparatively show the lowest use and acceptance of media.</li> <li>(d) Utilitarian users: Use office software and e-learning tools often – The use of social media for learning and use of the internet for leisure were less important to the utilitarian users</li> </ul>

Dolch et al. (2021) conducted a longitudinal study exploring changing media usage patterns of German higher education students over time (in 2012, 2015, and 2018). The identified media usage types were (a) entertainment users, (b) intensive users, (c) peripheral users, and (d) utilitarian users. The researchers considered dimensions such as frequency of use, variety of use, digital learning formats/tools, and activities to identify these four types. Approximately half of the students were entertainment users all three years, and these students used the Internet – especially social media – frequently for leisure purposes. The type of users that increased considerably over time were intensive users, who used the internet, social networks, and e-learning tools for their learning, as well as the internet for leisure. The other two types of users, peripheral users and utilitarian users, decreased slightly in 2018. The researchers assumed that their findings reflected a media trend in the use of e-learning tools. They also suggested that educators and instructional designers should improve the use of e-learning tools, SNS, and recreational tools for teaching and learning in higher education.

### **Media Usage Typologies: Learning-Related Usage Behaviors and Media Trends**

Researchers have also explored learners' media usage patterns in more granular ways by focusing on specific usage behaviors or considering media trends such as social media and open learning platforms. First, there have been typologies or frameworks focusing on the acts of knowledge building or sharing. Dennen (2019) suggested the Networked Knowledge Activities (NKA) framework, articulating six discrete knowledge-related media user behaviors in networked learning contexts such as social media, online classrooms, or virtual communities of practice. These six behaviors are (a) collect, (b) curate, (c) share, (d) broker, (e) negotiate, and (f) construct (see Table 3 for definitions of each behavior/knowledge activity). The NKAs tend to co-occur and to flow from one to another during the learning process. Dennen et al. (2020) examined learning-related social media usage behaviors while applying the NKA framework to the archival data from six major SNS: Facebook, Twitter, Instagram, LinkedIn, Pinterest, and YouTube. The observed NKAs were discussed considering the technological affordances of the SNS. While Dennen et al.' (2020) study shows one way to capture learners' learning-related activities in informal learning contexts, it also illustrates the potential for context collapse, since SNS can be used as both learning and nonlearning spaces.

Given the prevalence of social media, researchers have examined its usage in general. Özlü and Kalyoncuoglu (2017) identified six types of higher-education student users of social media platforms in Turkey. The dimension their typology considered was cognitive use (passive and active). The types identified were (a) movers and shakers, (b) game lovers, (c) abstainers, (d) followers, (e) sharers, and (f) socializers. Breines et al. (2020) specifically targeted international distance education students and explored their nonuse of social media and developed a typology of social media nonuse. Their typology has four themes: (a) exclusion owing to access issues or the social environment on social media; (b) distrust due to

**Table 3** Media usage typologies: Specific media and usage behaviors

Study subjects and authors	User types or usage behaviors
Archival data from six major SNS: Facebook, Twitter, Instagram, LinkedIn, Pinterest, and YouTube (Dennen et al., 2020)	Networked knowledge activities (NKA) framework <ul style="list-style-type: none"> <li>(a) Collect: Collect items or information they find</li> <li>(b) Curate: Purposefully create organized or annotated collections of online items or artifacts</li> <li>(c) Share: Share their collected or curated items online</li> <li>(d) Broker: Connect online and offline groups or networks via knowledge transmission</li> <li>(e) Negotiate; engage in a collaborative and discursive process in which learners work together to agree upon meaning</li> <li>(f) Construct: Construct knowledge and create a product that can be shared with others by making something new or combining existing things in a new manner.</li> </ul>
Higher-education student users of social media platforms in Turkey (Özlu & Kalyoncuoglu, 2017)	<ul style="list-style-type: none"> <li>(a) Movers and shakers: Actively create original content and multimedia content</li> <li>(b) Game lovers</li> <li>(c) Abstainers: Use and consume content at the low level</li> <li>(d) Followers: Actively consume and share content as a twitter user</li> <li>(e) Sharers: Consume content and intensively criticize or share the content</li> <li>(f) Socializers: Intensively interact with content, play games, and use twitter actively, but do not create original content</li> </ul>
International distance education students (Breines et al., 2020)	Typology of nonuse of social media (themes) <ul style="list-style-type: none"> <li>(a) Exclusion owing to access issues or the social environment on social media</li> <li>(b) Distrust due to issues of authenticity, security, privacy, and noncollaboration</li> <li>(c) Distraction due to overwhelming or irrelevant information, interactions, or communication</li> <li>(d) Online discrimination</li> </ul>
MOOC learners (Kizilcec et al., 2013)	<ul style="list-style-type: none"> <li>(a) Completing: Completed the majority of the assessments</li> <li>(b) Auditing: Watched video lectures but completed assessments infrequently if at all. Also, followed the course for the majority of its duration</li> <li>(c) Disengaging: Completed assessments at the beginning of the course but then either disappeared from the course entirely or participated sparsely</li> <li>(d) Sampling: Watched video lectures for only one or two assessment periods</li> </ul>

(continued)

**Table 3** (continued)

Study subjects and authors	User types or usage behaviors
MOOC learners (Ferguson & Clow, 2015)	(a) Samplers: Watched some course videos (b) Strong starters: Completed the first assessment of the course, but then dropped out (c) Returners: Completed the assessment in the first week, returned in the next week, and then dropped out (d) Mid-way dropouts: Completed three or four assessments, but then dropped out about halfway through the course (e) Nearly there: Consistently completed assessments but then dropped out before the end of the course (f) Late completers: Completed most of the assessments, but were either late or missed out (g) Keen completers: Engaged actively and completed the course
MOOC learners (Poellhuber & Bouchoucha, 2019)	(a) Ghost: Engaged in no or almost no activity during the second and third weeks of the course (b) Browser: Viewed some videos or other resources. Their activity level was very low (c) Self-assessor: Completed most of the quizzes and tests (d) Serious reader: Actively viewed and read course materials (e) Active-independent: Actively engaged with all of the learning components/activities at least once (f) Active social: Engaged with everything that was expected in the MOOC

issues of authenticity, security, privacy, and noncollaboration; (c) distraction due to overwhelming or irrelevant information, interactions, or communication; and (d) online discrimination.

Open learning platforms, including MOOCs, have also become increasingly available to the public. Due to some of their main features such as openness and scalability, more diverse user profiles or media usage behaviors have been identified compared with those in formal learning management systems (LMS). Kizilcec et al. (2013) identified four types of behaviors: (a) completing, (b) auditing, (c) disengaging, and (d) sampling. Ferguson and Clow (2015) provided a typology that included seven profiles: (a) samplers, (b) strong starters, (c) returners, (d) mid-way dropouts, (e) nearly there, (f) late completers, and (g) keen completers. Poellhuber and Bouchoucha (2019) examined open learners' engagement quantitatively and qualitatively and identified six different MOOC user profiles. They are (a) ghost (no-shows), (b) browser, (c) self-assessor, (d) serious reader, (e) active-independent, and (f) active social. To identify MOOC learner typologies, scholars have commonly considered variables such as engagement level, type and quantity of

activities/items students completed, and students' individually chosen timelines for their learning.

## Dimensions in Media Usage Typologies

The studies discussed above reported different types of usage patterns because they had varying focuses, such as different users (e.g., general users, higher-education learners, workers, or open learners), different media (e.g., media in general, social media), and/or different contexts (e.g., daily life, formal, or informal learning contexts). The researchers also considered different sets of dimensions to build these typologies and media usage patterns. Many extant typologies share some common dimensions, but also contain unique dimensions or criteria. The dimensions used in previous research are summarized in Table 4. This list of dimensions is useful for researchers who want to identify new media usage typologies in their specific study contexts. The vast amount of potential media usage patterns or typologies can be captured by identifying new sets of dimensions based on those given in the summary (Table 4), as well as having different levels or categories for each dimension.

Educators and practitioners can also consider the work summarized in this chapter to assist themselves in understanding the vast diversity of learners' media usage. Additionally, these media usage behaviors or typologies can help educators and instructional designers capture both major and minor media-adoption groups of learners and their needs when designing, developing, and facilitating media-enhanced learning. Learners can also consult the summarized typologies to reflect on their media usage behaviors for learning and find different and better ways to use media to maximize their learning experiences. Typologies assist scholars engaging in research on learners' media usage behaviors. For example, researchers have made predictions regarding how diverse user types respond to different media usage patterns (Brandtzaeg, 2010). Policymakers and administrators can also consider the typologies and develop digitalization strategies (Dolch et al., 2021). Due to the increasingly complex media landscape and its diverse uses, it is challenging to characterize the nature of media usage behaviors and distinctive user profiles/types. It is also widely acknowledged that the "design" aspect of media-enhanced learning spaces plays a key role in the way learners use media. Well-designed media-enhanced learning supports learners' behaviors concerning knowledge management, creation, communication, and collaboration.

---

## Research in Learners' Media Usage Behaviors

Researchers have studied media, technologies available for learning, and learners' media usage behaviors in diverse learning contexts. Three themes of research have expanded the media usage typology research: (a) the potential learning consequences associated with media usage, (b) factors impacting media usage behaviors

**Table 4** Summary of dimensions used to identify learners’ media usage behaviors or typologies

Dimensions	Levels or categories of each dimension	References
<b>General usage</b>		
Use or nonuse	Yes or no	Zawacki-Richter et al. (2015)
Frequency of use	<ul style="list-style-type: none"> <li>• [level] very often, . . . , never</li> <li>• [level] several times daily, . . . . , never</li> <li>• [level] almost every day, a few times a week, between once a week and once a month, less than once a month, never</li> </ul>	Dolch et al. (2021) and Zawacki-Richter et al. (2015)
Variety of use	<ul style="list-style-type: none"> <li>• Utility oriented (often work-related).</li> <li>• Entertainment/hedonic usage (e.g., gaming).</li> <li>• Socializing.</li> <li>• Multiple activities.</li> </ul>	Özlü and Kalyoncuoglu (2017) and Zawacki-Richter et al. (2015)
<b>Media</b>		
Media, tools, programs	<ul style="list-style-type: none"> <li>• All/different media including internet in general, e-learning tools, and office software.</li> <li>• Social media.</li> <li>• Open learning platforms (e.g., MOOCs).</li> </ul>	All studies reviewed
Digital formats/functions	<ul style="list-style-type: none"> <li>• Online-media: Chats, music download/streaming, social networks, wikis, search engines, etc.</li> <li>• Digital learning formats: Virtual seminars, web-based trainings, e-portfolios, virtual labs, lecture recordings, online-tests, podcast, etc.</li> </ul>	Dolch et al. (2021) and Zawacki-Richter et al. (2015)
Perceived acceptance	<ul style="list-style-type: none"> <li>• [level] very useful, . . . , not useful at all</li> <li>• [level] very important, . . . , not important at all</li> </ul>	Dolch et al. (2021) and Zawacki-Richter et al. (2015)
<b>Learning activity preferences</b>		
Cognitive use	<ul style="list-style-type: none"> <li>• [passive use] accessing content/information acquisition/consuming content (e.g., news)</li> <li>• [active use] creating and sharing content.</li> </ul>	Özlü and Kalyoncuoglu (2017)
Knowledge management	<ul style="list-style-type: none"> <li>• Collecting content/items.</li> <li>• Curating content/items.</li> </ul>	Dennen (2019) and Dennen et al. (2020)
Communication	<ul style="list-style-type: none"> <li>• Forming study groups, etc.</li> <li>• Sharing collected or curated items online.</li> <li>• Connecting groups of people or networks via knowledge transmission (broker).</li> <li>• Engaging in collaborative and discursive processes in which learners work together to agree upon meaning (negotiate).</li> </ul>	Dennen (2019); Dennen et al. (2020) and Dolch et al. (2021)

(continued)

**Table 4** (continued)

Dimensions	Levels or categories of each dimension	References
	<ul style="list-style-type: none"> <li>• Constructing knowledge and creating a product that can be shared with other learners.</li> </ul>	
Learning activity preferences in specific online learning platforms (e.g., MOOCs)		
Quantity of activities	<ul style="list-style-type: none"> <li>• (level) none, low (one or two), medium, high (the majority of resources/activities)</li> </ul>	Ferguson & Clow (2015); Kizilcec et al. (2013) and Poellhuber & Bouchoucha (2019)
Variety of use (activities)	<ul style="list-style-type: none"> <li>• Reading/watching/browsing/auditing content.</li> <li>• Social activities.</li> <li>• Discussions.</li> <li>• Assessment items (e.g., quizzes, tests).</li> </ul>	
Individually chosen timeline for learning	<ul style="list-style-type: none"> <li>• Engaged at the beginning of the course (e.g., the first and second weeks).</li> <li>• Engaged halfway through the course.</li> <li>• Engaged in the majority of the course’s duration.</li> <li>• Engaged but late.</li> </ul>	

in learning, and (c) challenges of media usage. First, the research has examined the associations between the use of different or multiple media (e.g., e-learning tools, web 2.0 applications, and/or social media) for specific learning purposes (versus in general) and its positive consequences such as attention, engagement (behavioral, cognitive, and emotional), motivation, creativity, critical thinking, collaboration, interaction, positive learning attitudes, academic performance (knowledge, skills, and GPA), and access to professional communities (Barton et al., 2021; Carpenter & Harvey, 2020; Greenhow et al., 2020). These researchers have argued that learners’ knowledge activities (e.g., exchanging knowledge, discussion, interaction, and networking) are the main mediators in the relationship between media use and positive learning effects (Gulzar et al., 2021). A handful of researchers also specified the relationship between media usage and positive consequences by adding new factors (e.g., facility conditions, performance expectancy, effort expectancy) or rearranging the constructs to find predictors or moderators (Barton et al., 2021; Rahman et al., 2021). By classifying learners’ behaviors, purposes, and consequences, researchers have been capturing the nuances and inferring what could be beneficial to learning from learners’ media usage.

Researchers have further discussed the critical factors influencing media-enhanced learning and learners’ different behavior patterns. Personal factors include digital literacy, social media competencies, perceived usefulness of digital media, and digital media self-efficacy (Pumptow & Brahm, 2020; Zawacki-Richter, 2009). Situational or cultural factors include countries or regional areas that have poor technical infrastructures or a lack of adequate Internet provision. To overcome this

challenge, some countries use mobile or smart devices rather than computers and make online materials or open educational resources (OER) available (Conole, 2014). Relatedly, Breines et al. (2020) have pointed out that research on social media use typologies has predominately been led by scholars who conduct empirical studies in western countries from western imperatives. Breines et al. (2020) highlighted that researchers should focus more attention on developing countries and to the social media nonuse phenomenon. There are also studies targeting specific groups of learners, such as educators and first-generation college students. For example, Deng et al. (2021) identified the constructs shaping first-generation college students' social media use (social, cognitive, and hedonic) and their academic experiences (academic support, emotional support, and distractions impeding work). Their findings revealed that first-generation students differed from their peers in social media use and perceptions.

Although media technologies hold many promises, learners may not always engage in the best practices. Researchers have also examined the challenges of media use for learning purposes, as well as learners' inappropriate uses of media and the negative outcomes. For example, challenges in using social media for learning purposes include content quality issues and learning resources at the low level of cognitive demands (Carpenter & Harvey, 2020). The open nature of social or other media can also cause "context collapse" risks (Marwick & Boyd, 2011), such as reaching almost infinite and unintended audiences and the possibility of being misinterpreted by audiences (Carpenter & Harvey, 2020).

---

## **Future of Learners' Media Usage**

### **Future Directions of Research in Learners' Media Usage**

Though the literature on learners' media usage is growing, learner media usage continues to evolve as technologies progress. More empirical research identifying learners' usage behaviors in new media and exploring the association among existing and new factors, as reported by a number of researchers, is necessary (Pumptow & Brahm, 2020). Additionally, many extant studies were conducted in higher education or informal learning contexts. There has been a lack of research on educational or knowledge activities occurring within and around social media and their connections to K-12 teaching and learning practices (Greenhow et al., 2020). Research on creating and testing educational programs or other interventions in promoting new media use for learning would be another helpful addition to the current discussion in this area. More research focusing on nondesired media usage behaviors, such as nonuse or the low-level of cognitive activities in media-enhanced learning contexts, and more research targeting developing countries and minority groups of learners should also be conducted.

More importantly, future studies should focus on well-designed media-enhanced learning experiences, grounded in robust media or learning theories. This area represents a current weakness of the field. Only a few studies in the field have used theories

or theoretical frameworks, such as Uses and Gratification (U&G) theory (Katz et al., 1973), the 4C framework (Milligan et al., 2014), the Technology Acceptance Model, or Expectancy-Value theory (Palmgreen & Rayburn, 1985). These theories have been used to explain learners' media usage. With the understanding of why and how learners use media to facilitate learning, researchers should focus on building empirical evidence for how to design better learning experiences with media.

Another direction for future research is better measurement of media usage through analytic technologies. So far, many researchers have relied solely on self-report to measure quantities and forms of media use. Parry et al. (2021) assessed the alignment between self-reported and log-based measures to test the validity of self-reports using pre-registered meta-analysis. They reported that self-reports on media use did not accurately reflect the logged media use. Their findings are consistent with ongoing criticisms of self-reported measures in human behavior (Kuncel et al., 2005). This raises concerns about the validity of studies on self-reported media use, and researchers should carefully design their measures to address this issue. With modern analytic technologies, researchers can track, analyze, and predict learners' media usage behaviors at a much finer grain and with much higher precision. For example, recently, Wu (2021) has analyzed Facebook group messages through natural language processing to represent learners' cognitive engagement and predict academic performance.

## Future of Media Development

As new forms of media emerge, the field should change to reflect the new learning possibilities that these new media bring. In the past few decades, multimedia technologies have expanded the channels of learning and Internet technologies have widened the borders of learning. Opportunities, contexts, and methods for learning have never been so diverse. Similar to the ways learning has evolved through these developments in media technologies, new technologies will bring impacts, changes, and challenges to learning in the future. Three themes for the near future of the evolution of distance, open, and digital learning are predicted:

First, future digital learning experiences will become increasingly immersive and interactive with the help of extended reality (XR) technologies. XR refers to a collection of media technologies that aim at combining virtual and real environments (e.g., virtual reality, augmented reality, mixed reality). Previous media (e.g., multimedia and Internet technologies) are primarily accessed through a digital device with a screen interface. This setup separates learners from real-world settings and draws them into a virtual world, which has caused many problems, including a lack of social presence. The goal of XR technologies is to bring an immersed learning experience to learners by either simulating real-world settings or merging the virtual world and real world (Kang et al., 2021). With XR, learners may demonstrate more complex media usage behaviors. Additionally, media behavior will no longer only refer to the usage of one or more specific tools. Instead, it will be immersed with real-world interactions and embedded in authentic settings.

Second, due to the advancement of artificial intelligence technologies, digital learning experiences will be more personalized and adaptive in the future. Although artificial intelligence technologies per se are not necessarily a medium, they constitute an important component of future media by mediating learners and their learning. The research endeavors in this field help to (a) better capture learners' complex media usage behaviors and their relationships to learning and (b) design and deliver a more personalized learning experience. Matching the most appropriate learning module or support to learners relies on an accurate estimation of students' cognitive and affective states (Liu et al., 2020). With machine learning and deep learning technologies, learning systems can model and understand the complexities in learner behaviors and then make personalized learning experiences possible.

Third, learning in the future will become even more accessible, connected, and equitable with networked technologies. Networked technologies have been developing at a very high speed over the past two decades. The ubiquity of the media (e.g., Internet of Things) will make learning no longer reliant on one or limited devices or places – it can happen virtually anywhere and anytime. Further, learners worldwide will no longer be isolated in their own local communities. Online communities interconnect with offline communities, and the distance between learners is going to be increasingly closer. This should lead to a more equitable and open future of learning. Technologies like blockchain will further help to break the boundaries between local institutes. For example, learning certificates will be stored distributedly around the world and be able to be recognized by everyone (Gräther et al., 2018). New media and technologies will provide both opportunities and challenges for learners. Researchers should identify the new media usage patterns and guide educators and practitioners to understand learners' behaviors and needs when designing and facilitating learning with new media in diverse contexts.

---

## Conclusion

As a wide range of different media, technologies, and applications have become available to twenty-first-century learners, views on the roles of media and instruction have also shifted. A perspective that once upheld teacher-centered practices and considered media almost solely as a tool for content delivery is now being supplanted by the concept of learning with media as people begin to support learner-initiated practices.

Learners use media for different purposes in diverse learning contexts. Therefore, it is increasingly important to understand learners' media usage preferences, behaviors, and patterns so that educators, researchers, and other stakeholders can provide appropriate, relevant support. This chapter described the media evolution in open,

distance, and digital education and discussed diverse typologies and media usage behaviors, as well as the current research on learner media usage and future directions for research.

The diversity of typologies and media usage behaviors were identified, due to the different focuses of extant studies, such as the specific media, groups of users, contexts, and/or knowledge-related activities under study. Typologies and media usage patterns have also been developed based on combinations of the selected dimensions or criteria by researchers applying these combinations to their study contexts. The summary of the dimensions provided in this chapter can be useful to gaining insight into the vast amount of different media usage patterns that could be captured in different settings.

Today, media technologies are more prevalent than ever, and as a result, learning should be more accessible than ever. Nevertheless, challenges in learning with media persist. Therefore, understanding learners' media usage will be instrumental to research seeking to promote learning with the facilitation of media and will provide insights into the design and development of future and better open, distance, and digital education.

## Abstract

The history of distance education in many ways is a history about the evolution of synchronous and asynchronous communication technologies. Distance education, and online learning in particular, has primarily relied on asynchronous communication technologies over the years. However, COVID-19 has sparked a new interest in using synchronous tools for interaction and collaboration in open, distance, and digital education. Given this it is incumbent upon educators and researchers alike to be familiar not only with the current iteration of synchronous communication technologies but also with how they have developed and evolved over time, the affordances and constraints of synchronous communication, interaction, and collaboration, some of the different types, and the overall implications for future research and practice.

**Introduction**

Open, distance, and digital education have evolved almost overnight with the demands of the COVID-19 pandemic. To be clear, open, distance, and digital education are not new. Distance education in the form of correspondence education dates back to the 1800s (Wedemeyer, 1981); open education, in the form of open universities, has been around since the 1960s (Tait, 2008); and digital education in its various forms (e.g., radio, television, online) has evolved throughout the last 100 years (Casey, 2008; Saba, 2011; Saettler, 2004). However, even with college enrollments in online learning consistently growing, and recently outpacing traditional in-person enrollments, before COVID-19, only about a third of students took online courses, and fewer instructors taught online (see Jaschik & Lederman, 2016; Seaman, Allen, & Seaman, 2018). This all changed with COVID-19. Within a couple of months, nearly every teacher and student on the planet gained some experience with distance and digital education (Stewart, 2021). However, as others have pointed out, the actual implementation of distance and digital education during COVID-19 has been more often than not an ad hoc version of distance and digital education (Hodges, Moore, Lockee, Trust, & Bond, 2020). Most colleges and universities found themselves with little time and resources and often little if any prior experience with distance education. Confronted with the need to continue teaching traditional in-person face-to-face courses at a distance, many faculty chose to simply hold classes online in live synchronous web meetings using web conferencing tools like Zoom, Google Meet, Microsoft Teams, or Webex (Dias, Lopes, & Teles, 2020; Lederman, 2020a, b). Web conferencing tools like these have enabled instructors and students to meet at the same time as their normally scheduled class but from a distance during COVID-19. These tools have also enabled administrators, faculty, and staff to work successfully from a distance during the pandemic (Lowenthal, West, Archambault, Borup, & Belt, 2021). Despite some of the challenges that arose with using these tools, many people suspect that communication technologies like these will continue and increasingly be used in both inside and outside of the classroom in various capacities in higher education when this pandemic is over (Dias et al., 2020; Lowenthal et al., 2021). Therefore, it is incumbent upon educators and researchers alike to be familiar not only with the current iteration of synchronous communication technologies but also with how they have developed and evolved over time, the affordances and constraints of synchronous communication, interaction, and collaboration, some of the different types, and the overall implications for future research and practice.

## Evolution of Synchronous Communication in Distance Education

Synchronous communication is communication that happens at the same time or what some describe as in real-time (e.g., communicating in-person face-to-face, talking over the phone, meeting in a web conference). Synchronous communication is usually compared and differentiated from asynchronous communication in which communication does not happen at the same time or in real-time (e.g., when sending a letter or an email). The history of distance education in many ways is a history about the evolution of synchronous and asynchronous communication technologies. As new technologies, and specifically communication technologies, were developed, educators have experimented with how they could be used for teaching and learning (Garrison & Anderson, 2003). Over the years, as new forms of communication technology have become more mainstream, forms of distance education using that new technology have increased in popularity as educators gained more familiarity and expertise with using it (Garrison & Anderson, 2003; Harasim, 2000).

Most people trace the history of distance education back to early forms of correspondence study in the 1800s (McIsaac & Gunawardena, 1996). This early form of distance education relied on asynchronous communication via the postal service; students would receive lessons in the mail and then mail the completed lessons back to a tutor to correct them (Bower & Hardy, 2004). This early form of distance education enabled learners to be able to learn essentially from any place and at any time—an ideal and defining characteristic of distance education (see Garrison, 2009). However, due to the reliance on the postal service, there was little interaction between a student and a tutor.

During the 1920s, educators began experimenting with using radio and then later television to broadcast lessons for people to learn at a distance (Casey, 2008; Saba, 2011). This new form of broadcasting distance education enabled educators to communicate with a larger audience while still being able to learn from anywhere that had access to the broadcast. Despite these advantages, it strayed away from the ideal that one could learn at any time. It also did not provide a way for learners to interact with their instructor or peers and therefore did not enable back and forth synchronous communication and interaction (McIsaac & Gunawardena, 1996). This type of distance education continues to persist, even today, but it still has never arguably become mainstream, likely because of issues like this as well as issues of the cost, infrastructure, and planning required to deliver this type of distance education. Thus, broadcasting forms of distance education were never able to fully replace earlier forms of correspondence study (Garrison & Anderson, 2003; McIsaac & Gunawardena, 1996). Instead, advances in recording technology enabled educators the ability to supplement correspondence study print materials with audio and video cassettes, thus preserving the benefits of being able to learn from anywhere, at any time (Gunawardena & McIsaac, 2004; McIsaac & Gunawardena, 1996).

This all began to change during the 1980s. Educators were interested in finding better ways to not only share instructional materials but also to communicate and interact with students from a distance. As the rise of the Internet and personal

computers grew during the 1980s, educators began to experiment with using computer-mediated communication to communicate and interact with groups of learners from a distance (Harasim, 1986, 2000; Moore, 1989). For instance, Linda Harasim (1986) is often attributed with offering the first for-credit online course in 1986 in which she had a group of learners posting in text-based asynchronous discussion forums over the course of a semester. While it took some time to catch on and grow, online learning became the most prevalent form of distance education during the 1990s and 2000s (Rovai, 2009). These early iterations of online learning largely relied on asynchronous text-based communication (i.e., email and discussion boards) to interact, communicate, and collaborate with one another.

Online learning has continued to grow over the years. However, even long before COVID-19, many argued that there was not one type of online learning (Lowenthal, Wilson, & Parrish, 2009; Moore, Dickson-Deane, & Galyen, 2011). Rather, online learning has manifested itself in different ways based not only on its use of technology but also other situational factors (e.g., for credit vs. not for credit; synchronous vs. asynchronous; self-paced vs. group paced). Academics have tried to develop taxonomies to help differentiate and make sense of these differences (Garrison & Anderson, 2003). With that said, early on and in many ways still to this day, one of the most common ways to differentiate online learning is by how instructors and students meet, interact, and communicate with each other. Thus, educators have often simply differentiated between in-person face-to-face, blended/hybrid, and online courses—and more specifically, between synchronous or asynchronous online courses. As helpful as it can be to describe and differentiate online courses in this manner, it fails to recognize that few courses have ever truly been 100% synchronous or asynchronous. For instance, even courses that primarily used and relied on synchronous communication (e.g., instant messaging, web conferencing) also used other forms of asynchronous communication (e.g., email, a discussion forum, or a grade book in a learning management system); just as courses that relied heavily on asynchronous communication might use synchronous forms of communication to some degree (e.g., initial kickoff meetings on campus, phone calls, proctored exams or office hours on campus). As web conferencing technology has advanced and become more reliable during the last decade, educators have increasingly experimented with intentionally using both synchronous and asynchronous communication in online courses; some have described this practice as “blended online learning” (Fadde & Vu, 2014; Power, 2008) while others have more recently described it as bichronous learning (Martin, Polly, & Ritzhaupt, 2020). Around the same time, others began experimenting with providing even more flexibility by blending all possible course formats into what has been referred to as multi-access (Irvine, 2009; Irvine, Code, & Richards, 2013) and hybrid-flexible course design or HyFlex (Beatty, 2007, 2019). These types of courses have attempted to be what Smith, Reed, and Jones (2008) referred to as mode neutral, enabling students to choose to attend courses in person or online—whether synchronously or asynchronously—each week.

A few things are clear. Distance education has continued to evolve over the years. This evolution has been influenced in part by advances in technology as well as a

desire to balance the ideals of anytime anywhere learning with regular interaction and collaboration. Early adopters have been eager over the years to experiment with new technologies; however, ultimately it is the pedagogy and perceived affordances and not simply the technology that influences which new iterations persist and grow (Garrison & Anderson, 2003; Irvine, 2020; Lowenthal & Mulder, 2017). Putting issues of labeling and semantics aside, boundaries between in-person face-to-face and online learning are disappearing with the help of COVID-19; most courses in higher education in the coming years will likely entail a blend of synchronous and asynchronous communication. But questions remain on which types of tools one should use and why.

---

### **Affordances and Constraints of Synchronous Communication**

Online learning, from the first online course during the 1980s until today, has relied mostly on asynchronous text-based communication (Peterson et al., 2018). As mentioned earlier, this has enabled instructors and students to interact, collaborate, and ultimately learn from any time and from any place. However, despite affordances like these, people have been skeptical and even overtly critical of online learning, largely because of the perceived drawbacks of text-based asynchronous communication (Lowenthal & Dunlap, 2020; Oztok et al., 2013). Education is a social process that relies on social interaction and communication. Text-based asynchronous communication, though, has been criticized over the years for being inherently task-based and inadequate with relational and social communication (Lowenthal, 2010). More specifically, people have pointed out how text-based asynchronous communication lacks visual cues, takes time for conversations to develop, and can lead to misunderstanding or in educational settings it can feel like busywork (Gao et al., 2013; Fadde & Vu, 2014; Murphy & Coleman, 2004).

Research suggests, though, that synchronous communication might be able to address many of the challenges of text-based asynchronous communication (Johnson, 2006; Watts, 2016). For instance, synchronous communication, whether text-based (e.g., chat), audio-based (e.g., conference call), or video-based (e.g., web conferencing), happens in real-time. Communicating in real-time makes communication more efficient; it can help solve problems and clarify meaning by enabling one to pick up on one's tone and to ask follow-up questions, which in turn can help improve not only overall communication but ultimately the ability to collaborate (Lowenthal et al., 2017; McDaniels et al., 2016). In addition to the affordances of real-time communication, video-based synchronous communication enables people the ability to look others in the eyes, see their body language, and improve affective communication by establishing immediacy and social presence (Belt & Lowenthal, under review; Hrastinski, 2008; Park & Bonk, 2007; Parker & Martin, 2010). Web conferencing applications, in particular, enable participants the ability to share and view, discuss, and create materials in real-time—and even record meetings for later (asynchronous) viewing (Snyder & Garner, 2020).

However, despite the affordances of synchronous communication, it is not a panacea; there are a number of notable constraints with synchronous communication. Perhaps most notable is that synchronous communication requires participants to meet in real-time, at the same time. It can be challenging, and sometimes even impossible, to find a time that works for everyone to meet—especially, when students might live across the world or simply have busy lives or nontraditional work schedules (Liu & Alexander, 2017; Lowenthal et al., 2020; Themelis, 2014). People also regularly face technical difficulties when using web conferencing applications, such as poor audio or video quality, often due to poor broadband connectivity (Lowenthal et al., 2021). Broadband issues, coupled with practices to require students to turn on their webcam, can also highlight inequities and aspects of students' lives that they could keep private in text-based asynchronous discussions (Bali & Meier, 2014). At the same time, affordances are lost when all or most students keep their webcam off or when the enrollment is so high that it makes it difficult to make eye contact, view one's body language, or even see all students webcam (see Day & Verbiest, 2021; Dennen, Word, & Arslan, 2021; Lowenthal et al., 2021). This is not to mention how class sessions held in web conferencing applications can turn into long lectures, which can encourage disengagement, distraction, and multitasking and result in students feeling frustrated and even exhausted (Lowenthal et al., 2020; Schulman, 2020).

---

## Overview of Synchronous Tools

Educators have used a variety of synchronous tools over the years to improve interaction, communication, and collaboration in open, distance, and digital education. In the following section, some of the main types of synchronous tools used by educators, how they have been used and are currently used, and some relatively newer and emerging synchronous tools will be discussed.

### Audio-based Tools: Telephone and Audio Teleconferencing

The telephone was the first widespread tool used in distance education for real time two way communication (Barron, 2004). Educators began experimenting with using the telephone for real time communication in the 1930s and 1940s but it did not become more commonplace until the 1970s and 1980s with audio teleconferencing (Garrison, 1985). There were four main ways that educators used the telephone as an instructional aid during the 1970s (i.e., teleteaching, telelecturing, dial-access, tele-tutoring; Flinck, 1975). Then, during the 1980s, universities even began offering “audio courses” for college credit (Olgren, 1997). This all became possible because as Garrison (1985) explains,

audio teleconferencing built upon the foundation of correspondence study by enhancing the quality of the interactive process among students and teacher. The ability of the student to receive immediate feedback from the teacher as well as fellow students without a corresponding loss of independence is a significant development in distance education. (p. 237)

Advances in telecommunications soon enabled educators to supplement audio teleconferencing with images or data transmissions (i.e., audiographic conferencing) and then video (Wolcott, 1994). But when people talk about audio-based synchronous tools in distance education, they are usually focusing on what Garrison (1985) referred to as the second generation of distance education and differentiating it from video or web conferencing (which will be discussed later). The telephone—whether that be with traditional landlines, cell phones, or VOIP (e.g., Skype)—is still used today to supplement distance education, however, it is often used more for one-to-one communication between an instructor and a student (Dunlap & Lowenthal, 2010). And while this is not scalable in many ways, Garrison (1985) pointed out that “the use of the telephone by a teacher for instructional purposes is perhaps the most personalized use of telecommunications in distance education” (p. 237).

While a telephone or audio teleconferencing can add two-way real-time communication to distance education and online learning, it still (for the most part) lacks a visual channel and therefore as Wolcot early on pointed out “the abilities to both convey messages and to relate interpersonally is strained when the participants cannot see one another” (p. 141).

## **Text-based Tools: Chat and Messaging**

Another common type of synchronous tools used in open, distance, and digital education are text-based chat and messaging tools. Text-based chat dates back to the early days of the Internet (Chatterjee, Abhichandani, Li, TuIu, & Byun, 2005). While the technology and features have changed over the years (e.g., Many chat applications today also enable video and/or asynchronous features), even in the early day’s text-based chat was defined by short, rapid, text-based conversations happening in real time (Preece, Maloney-Krichmar, & Abras, 2003). These chat and messaging tools essentially could be used one-on-one in a private text-based chat or in a many-to-many group chat format (e.g., in chat rooms).

Internet relay chat, in particular, was created in the late 1980s (Chatterjee et al., 2005); though chat and messaging arguably did not become mainstream until the late 1990s with the development of applications like AOL Instant Messenger. But by the mid-1990s, educators were already experimenting with using chat and instant messaging in distance education courses (Duin & Archee, 1996; Kimbrough, Hochgurtel, & Smith, 1998). The use of text-based synchronous chat increased even more once learning management systems (LMS) began including their own chat tools. For instance, Kirby (1999) used chat rooms in WebCT to have online debates; students were apprehensive at first but after the second debate Kirby stated “were overwhelmingly positive about the synchronous learner-learner interaction and the activity as a learning experience” (p. 204). Early on researchers found that while text-based asynchronous discussions might be better for deep reflection, synchronous chats were sometimes more effective with simulating a real conversation, building a sense of immediacy and community, and establishing social and teaching presence which in turn can decrease feelings of loneliness (Motteram, 2001;

Stein et al., 2007; Wang & Chen, 2007). However, researchers quickly identified some drawbacks to chat and messaging tools. They found that they could favor fast typers, fast thinkers, and native speakers of a language, and lead to out-of-sync contributions and confusion, while also presenting accessibility issues (Bober & Dennen, 2001; Calvo, Arbiol, & Iglesias, 2014; Stein et al., 2007). Given this, researchers like Cox et al. (2004) concluded that chats should be supplemented with other forms of communication (e.g., text-based discussions). Thus, while chat and instant messaging tools continue to be used in open, distance, and online learning, they are often used in conjunction with other communication technologies. Further, increasingly chat and messaging apps today tend to have synchronous and asynchronous capabilities leading some to describe things like chat as almost being semi-synchronous because while you can see when someone is online and chat in real time, you can also send a message to be read and replied to sometime in the future when the other person is not online or not available to chat at that time.

## **Video-based Tools: Video and Web Conferencing**

Video-based tools – sometimes called videotelephony, video conferencing, or web conferencing – are the most used synchronous communication tools today. Video conferencing dates back to the 1960s (Correia, Liu, & Xu, 2020); however, for the first few decades, special equipment was needed to essentially connect two or more locations – such as two different classrooms. Video conferencing, though, arguably did not really begin to catch on until the early 2000s with the development of applications such as Webex and Macromedia Breeze and the increase of high speed broadband Internet.

These new web conferencing applications eliminated the need for special equipment and for the first time allowed teachers and students to log on and join a web conference from anywhere with a stable high-speed internet connection. By the mid-2000s, educators were increasingly experimenting with using web conferencing for distance education, whether that be by offering weekly synchronous class sessions, supplemental synchronous sessions (e.g., review sessions, class presentations, guest presenters), or even weekly office hours. However, just as Cox et al. (2004) recommended in terms of using text-based chat, rarely have educators solely used web conferencing to teach a distance or online course; at minimum, email but often a learning management system are used in conjunction with these video-based tools.

From these early days until today, most web conferencing applications include a number of different synchronous applications—thus, making it difficult to truly label any of them simply as “video-based tools.” For instance, they include not only the ability to share video through a webcam but also the ability to share audio and text-based communication in real time as well as the ability to screen share, share files, and complete polls to name a few others. To complicate matters further,

instructors and/or students can use a web conferencing application like Webex or Zoom and choose not to enable or use certain features. For example, an instructor can enable students to turn their webcams on or to use audio to communicate with others but students can choose to simply chat with others using text only.

Around 2010, companies started developing video chat tools (e.g., Skype and FaceTime) that enabled people to use video-based synchronous communication in one-on-one or in small groups. Instructors and students continue to use tools like this in distance and online learning but for the most part they are either in ad-hoc situations or for small groups but its use has never been as popular as web conferencing.

### **Other Synchronous and Semi-Synchronous Tools**

There are still a number of other tools like online whiteboards that can be used without a web conferencing application or a number of tools that might better be classified as semi-synchronous because they can be used asynchronously or synchronously depending on when and how they are used. For instance, tools like Jamboard or Padlet that enable instructors to use them in real time like a whiteboard but students can also collaborate asynchronously over a period of time. Then there are other social networking tools like Twitter that have been used a lot in massive open online courses to enable students an authentic way to collaborate with other learners in a course as well as a larger community of practice. Tools like twitter enable users to post and for other users to view and if they choose to respond after the fact or if they are online at the same time (e.g., for twitter chats or as a back channel during live events) they can respond and chat in real time. Different tools like this, though not unlike web conferencing applications, continue to blur the boundaries between classifying something as purely synchronous or asynchronous.

---

### **Implications for Research and Practice**

Research on open, distance, and digital education suggests that while there are some inherent affordances and constraints with different communication technologies, ultimately the success of using these communication technologies—whether they are synchronous, asynchronous, or even semisynchronous—depends not only on situational factors (e.g., how they are used in a given learning environment, the context they are used, etc.) but also on the experience, comfort level, and actual use of participants. For instance, web conferencing applications have the potential to address many of the constraints of text-based asynchronous communication; however, this assumes things such as that all of the users have their webcams on, that the group is not too large, and that the instructor is using the tool in an

interactive, if not collaborative, way. Therefore, as the use of synchronous tools, and specifically synchronous video-based tools increases, more research needs to be conducted to find out under what contexts and which ways do adding synchronous tools to courses make up for the inconvenience of taking away the benefit of learning from any time that they want.

## Abstract

The shift from conventional classrooms to the use of various types of distributed education is well documented in the literature. This shift occurred over the past 30 years, if not longer. Open, distance, and digital education (or ODDE) has become ubiquitous in education and training in a variety of settings such as the military, business, higher education, and K12 schools. More recently, ODDE has seen a rise in use in other settings, such as health care organizations. Although both synchronous and asynchronous technologies are available for teaching and learning, it appears that asynchronous tools are predominant in these settings. The use of asynchronous tools is the primary focus of this chapter, with consideration of both the technologies employed and the strategies applied. The purposes are to summarize their appropriate uses in terms of collaborative learning and share any insights to guide future research and practice. The chapter begins with a brief definition of terms used in this chapter along with descriptions of the types and

purposes of asynchronous tools. The chapter culminates in directions for future research as well as any improvements in ODDE practice.

**Introduction**

Open education can be viewed narrowly as being focused on OER and MOOCs (Zawacki-Richter & The COER Group, 2020). A broader view considers open education as being the dissemination and access to education and training to widen participation for all (Wikipedia, 2021). Zawacki-Richter and The COER Group (2020) views open education as an umbrella term to encompass distance and digital education. However, one distinction among the terms is with distance education in that it is often found in formal educational settings, whereas open education may be found in both formal and informal settings. However, as technologies and ways of learning evolved, distinctions tend to blur. The inclusive term: open, distance, and digital education and its acronym (ODDE) will be used in this chapter. ODDE can be found at all levels of education and in a variety of settings, such as the military, business, higher education, and K12 schools (Moore, 2019; Zawacki-Richter & Naidu, 2016; Zawacki-Richter & The COER Group, 2020). ODDE has given rise in other settings, such as the health sciences (Glover & Bodzin, 2021).

The various environments of open education, or ODDE, can be considered synchronous, asynchronous, or both. Generally speaking, *synchronous* is participants being together at the same time, but at either the different location (Davidson-Shivers, Rasmussen, & Lowenthal, 2018), whereas *asynchronous* is when participants may be in different places and at different times. Again, these two terms have seen a merging and blending over the years due to new technologies being used in terms of face-to-face, blended or hybrid, or fully online or at a distance type of environments (Petronzi & Petronzi, 2020). With newer technologies, participants may meet or work together simultaneously even when they are in different time zones and locations. The focus in this chapter is asynchronous tools for interaction and collaboration.

---

**A Brief Review of Early and Current Research**

Early research indicated an interest in media comparison; that is, whether online learning is better or worse than on campus learning or comparison of different types of mobile learning. Zawacki-Richter and Naidu (2016) among others pointed out such comparisons were not promising or helpful. Later, Bozhurt et al. (2015) using bibliometrics found that the highest ranking conceptual or theoretical background

concepts were community of inquiry, collaborative learning, constructivism and connectivism, blended learning, and transactional analysis. Although some of these concepts or topics are still present in the literature, others are found as well. They include online social communities, socialized e-learning, mobile assisted language learning, and game-based learning among others (Chen & Kinshuk, 2020). One other area, instructional design theories, was mentioned in Bozhurt et al.'s (2015) article. Chen et al. (2020) also found that case studies were mentioned often.

## Defining Interaction and Collaboration

A basic definition of *Interaction* is when two or more people communicate or act together for mutual or reciprocal influence. Moore (1989) identified three types of interaction needing to occur for learning to place: student to instruction (or content), student to student, and student to instructor. Student to instruction is when the student is connecting to information and activities contained within the [ODDE]. Student-to-student interactions occur when participants interact with each other on an individual, small group, or large group basis and should facilitate some affiliation with each other (Davidson-Shivers et al., 2018). With student to instructor, the instructor and participants communicate with each other directly through many various formats: emails, feedback on assignments, and general communiques; these formats may be either on an individual or group basis (Davidson-Shivers, 2009). Northrup (2002) identified a fourth type of interaction, the student-to-learning management system (LMS), in which learners are able to see their grades, post assignments, and so on.

*Collaboration* is defined as when participants communicate and work together to complete a task or achieve a common goal. Through the use of participants' interactions and collaborations, a learning community may form. Collaborative learning is considered as a strategy to help students engage in activities to encourage a collaborative process to share and create information and meaning (Inchaouh & Tchaïcha, 2020). At a basic level, the elements of a learning community include the instructors, learners, and the instructional information (Davidson-Shivers et al., 2018) and given Northrup's (2002) fourth interaction type, the environment itself. To form a learning community, they provide not only cognitive presence from shared ideas and experiences, but also may form a shared or social presence by sharing skills and developing mutual relationships (Gast as cited in Mahoney & Hall, 2020).

Furthermore, collaborative learning is a situation in which participants communicate with each other to improve their learning and is best when they share information, ask questions, provide their own reflections, and learn or attempt to learn something together (Goodman, Geier, Haverty, Linton, & McCready, 2001). Such participation often assists learners to form some type of learning community (Palloff & Pratt, 2007) in which they can be cognitively and socially engaged in activities and construct new understandings (Inchaouh & Tchaïcha, 2020). Inchaouh and Tchaïcha (2020) also suggest that collaborative learning is thought to be

effective because students gain new habits and approaches to gain new information while interacting with each other or the instructor. However, they also mentioned a few challenges might occur when a team organizes and the following results occur: a) the free ride effect, when a member does not complete their tasks, b) the sucker effect, when a member does all the work, or c) the silo effect in which members split the task and work alone and later combine their information or product at the end; these effects often lead to poor quality results and inefficiencies (Nebel et al., 2017).

To reduce such an intended outcome, various instructional tools and strategies can promote participant collaboration and interaction. Such tools and strategies among others might be used to not only meet student needs, but support collaborative efforts as well.

---

## Asynchronous Tools for Teaching and Learning

Additionally, another way to consider asynchronous tools as the hardware and software, or technologies with a second way being to view tools as instructional or learning strategies (Lai, 2020). The advancement in these current technologies has the potential for students to enhance their negotiation skills, obtain instant feedback, and become more efficient in their learning according to Lai (2020). However, even when the advancement in the technologies is promising, it is only when appropriate technologies are used along appropriate instructional strategies that the potential of student engagement can be effective (Bozhurt et al., 2015; Clark & Mayer, 2016a, 2016b). Thus, asynchronous tools can also be considered as the instructional/learning strategies used to support student learning in such environments (Mahoney & Hall, 2020).

## Background on Asynchronous Tools and Use of Technologies

Although the Internet was developed and in use in the 1960s, it was not until the mid-1980s that wider applications for teaching occurred (Zawacki-Richter & Naidu, 2016). Access to the Internet was through Local area networks and Wide area networks (Davidson-Shivers et al., 2018) and communications were a text-based form of communication (Al Tawil, 2019). Harasim (2012) stated online applications had become a part of traditional courses in a substantial manner during this time. The early asynchronous technologies mainly consisted of discussion boards or forums and chats. However, with the advent of the World Wide Web or Web, graphics could be combined with text-based applications and access became easier. With the inclusion of graphics, new forms of technology were developed for use in ODDE. Currently the ODDE environments, comprised of interrelated and integrated components which interact with each other, facilitate online learning situations through LMSs. These open environments have had exponential growth in education and training (Seaman, Allen, & Seaman, 2018).

The advancements in technologies such as interactive whiteboards, webcams, web simulations, and video conferencing made such things possible. New media continue to be developed and used (Mahoney & Hall, 2020). The main technologies currently in use are as follows:

*Discussion boards/threaded discussion.* Discussion boards and threaded discussions refer to e-learning applications using a text-based forum in which the instructor posts discussion topics (Chen & Kinshuk, 2020). In this student-centered environment, learners are tasked with responding to the initial prompt and are required to also read and respond to classmates (Jo, Park, & Lee, 2017). This interaction is to facilitate the learners' exposure to alternate ideas, experiences, and perspectives of their peers as well as sharing their own. With discussions, there are pros and cons for their use.

*Pros:* Ability to participate in discussions about the content with others and the instructor can occur irrespective of time and place. Opportunity to reflect on and ponder the topic and readings before responding is valued. Non-native language participants have additional time to compose their responses.

*Cons:* Opportunities for misunderstandings, going off topic, bullying, and/or domination of the conversation can occur if immediate feedback from the instructor is missing. Some students delay posting to the forum that can be frustrating for early responders and lead to a less dynamic interchange.

*Instant messaging or IMs.* Messages sent via mobile, wireless, and desktop devices allow real time text chat in a pop-up notification window to a select list of recipients (Rambe & Bere, 2013). Message metadata may include timestamps and messages can contain links to images, websites, podcasts, and maps (Robles, Guerrero, LLinas, & Montero, 2019).

*Pros:* IMs promote social interaction. They can support immediate communication notices and facilitate group cohesion (Sun, Lin, Wu, Zhou, & Luo, 2018).

*Cons:* Learners may engage in off-topic conversations. They might be less effective at generating knowledge construction (Rambe & Bere, 2013; Sun et al., 2018).

*Social media.* Social media apps are designed with features to promote social interaction (Akcaoglu & Lee, 2018). They have an advantage over learning management systems (LMS) which are designed to hold course content, assignments, and assessments in a format more conducive to task management.

*Pros:* facilitates connections between formal and informal learning (Gurjar, 2020).

Familiarity with social networking sites can increase the likelihood of students using the tools and interacting with each other and with the course content (Beach & O'Brien, 2014; Pallas, Eidenfalk, & Engel, 2019).

*Cons:* Learners may attend to social connections to the detriment of engaging with the course content and may not make connections between social content and the learning objectives. Heavier workload for the instructor due to efforts to post,

administer the social site, and patrolling for student misconceptions and even cyberbullying. The social media platform privacy settings and business model may be contradictory to the academic institution's requirements.

*Online websites and learning management systems (LMSs).* Online websites, LMSs, and mobile device applications designed with features that promote social interaction (Akcaoglu & Lee, 2018). They have an advantage over LMSs which are designed to hold course content, assignments, and assessments in a format more conducive to task management.

*Pros:* Online websites facilitate connections between formal and informal learning (Gurjar, 2020). Familiarity with social networking sites can increase the likelihood of students using the tools and interacting with each other and with the course content (Beach & O'Brien, 2014; Pallas et al., 2019).

*Cons:* Learners may attend to social connections to the detriment of engaging with the course content and may not make connections between social content and the learning objectives. Could be a heavier workload for the instructor due to efforts to post, administer the social site, and patrolling for student misconceptions and even cyberbullying. The social media platform privacy settings and business model may be contradictory to the academic institution's requirements.

*Screencasts (authoring tools)* capture recordings of a computer screen accompanied by explanatory video (Wakefield, Tyler, Dyson, & Frawley, 2019). Captured recordings can include text, audio, video, slides, and webcam images.

*Pros:* Screencasts promote active learning and can increase skills identified in Bloom's Digital Taxonomy, such as communication, creativity, and multimedia skills (Wakefield et al., 2019).

*Cons:* The technological infrastructure needs can be vast and vary greatly with different tools. File storage needs vary with some requiring cloud storage and others' needing local storage. Users may not have threshold technology skills needed to use the tool. LMS integration varies across platforms.

*Video conferencing* is a digital learning environment using the Internet to broadcast one-to-many, or one-to-one, instruction sessions either synchronously, pre-recorded, or recorded during broadcast for sharing at a later time. Video conferencing supports the transmission of information for instructional and non-instructional purposes. Instructors and students can use video conferencing to send and receive information and communications to complete learning objectives (Gegenfurther & Ebner, 2019).

*Pros:* Video conferencing is effective at facilitating academic achievement and positive outcomes are possible for foundational or procedural knowledge whether presented as a single event or over time. Longer broadcasts can be more effective than shorter ones, but no optimal duration has been identified.

*Cons:* Many platforms lack social opportunities such as comments, likes, and emojis that might promote interactions.

*Gamification/role play/simulations* refers to the addition of game structures and elements for educational purposes. Gamification can be achieved through the use of quests, simulations, role-play, and quizzes and often incorporates multimedia elements, hand-held mobile devices, and a variety of Web-based tools (Faiella & Ricciardi, 2015; Karaaslan et al., 2018).

*Pros:* Gamification of instruction elicits motivation to learn and facilitates a host of cognitive, behavioral, and affective skills development. It is useful for problem-based learning, developing critical thinking, and creative exploration. Gamification is appropriate for business and humanities disciplines and in employee training and development.

*Cons:* Some students may exhibit resistance to group competition. Gamification relies on sufficient student self-efficacy and technological skills. The novel effects of game use may affect learning outcomes when the novelty wears off. This tool or strategy is not appropriate for final assessment. They can be time consuming to design.

*Interactive whiteboard/slide show/collaborative canvas* are online interactive shared digital screens for writing and sketching, to which multimedia, audio, and images can be added during collaborative assignments (Ng, Ting, Lam, & Liu, 2020; Sweeney, Beger, & Reid, 2021).

*Pros:* Most tools in this category feature the ability to record and share activities for later viewing; zoom features for close-up views. They provide a means to facilitate student interaction and collaboration and they promote social interaction. These tools can support a self-directed learning experience and students can access many of them via mobile devices and desktop browsers. Group assignments are supported with features that allow multiple participants to work on one board at the same time. Lesson and project templates are freely available. The nonpermanent surface supports student exploration of topics.

*Cons:* Some learners may experience high cognitive load and resist using these tools. Preinstruction lessons for teaching the tool can be time consuming. There are some limits to the size of the board and some tools do not allow audio and video media.

*Podcasts* are serially broadcast information in audio format presented as lectures, conversations, commentaries, and interviews. Broadcasts can be streamed live on the Internet and are downloadable to be listened to on digital and mobile devices for just-in-time listening (Shiang, Cerniglia, Lin, & Lo, 2021; Elekaei et al., 2020).

*Pros:* Podcasts contribute to improved listening skills and the variety of topics covered is vast. They are easy to access and share via desktop or mobile devices.

Podcasts are motivating to students as an alternative to text-based content and they can be listened to while performing other activities. Podcasts support independent study and learning.

*Cons:* Podcast transcripts are often not available. Students may become overwhelmed and not listen when they perceive podcasts to be extra work and they are not suitable for long, elaborated lectures. Podcasts are subject to fading or sporadic broadcasts. There is a lack of empirical research on knowledge retention when using podcasts for instructional purposes.

*Blockchain/badging.* Blockchain is a network of encrypted databases housing a digital ledger of educational credentials (Weller, 2020). It is a binder, or e-portfolio, for diverse academic accomplishments and credentials such as formal course work, degrees, certifications, badges, and Personal Learning Environment (PLE). In a blockchain learning environment, learners choose their own learning adventure by accessing a network of open access resources (Alexander & Wang, 2019).

*Pros:* Users can update educational records in one place and changes are populated across the network of databases linked by blockchain. Employers and academic institutions have access to applicants' credentials without having to log into various accounts. Addresses issues of Universal Design for Learning (UDL), motivation, and self-efficacy when learners can seek out preferred learning experiences.

*Cons:* Its application to educational use is in its infancy. Expanded use of digital ledgers places a power consumption and the proposed transparency it offers may not be forthcoming (Weller, 2020). Blockchains in their current form appear to be expensive in terms of climate energy.

---

## Background on Asynchronous Tools and Use of Strategies

Strategies are the design elements for individual and group activities to align with objectives; they also may be ways the instructor communicates about the content assignments and assessment methods (Rios, Elliott, & Mandernach, as cited in Mahoney & Hall, 2020). In other words, strategies are used as tools to meet student needs, build on their capabilities, and strengthen their skills to interact and collaborate with others (Davidson-Shivers et al., 2018).

To support the development of a shared community and student learning in such environments, the design elements and strategies for individual and group activities should be aligned with course objectives and the ways instructors communicate about the course goals, procedures, contents, assignments, and assessment methods (Rios, Elliott, & Mandernach, as cited in Mahoney & Hall, 2020). Such strategies among others might be used to not only meet student needs, but support collaborative efforts as well.

Theoretical underpinnings of strategy use. Online instructional strategies have come a long way from early learning communities using online discussion boards.

Expanded access to the Internet and digital technologies and devices spurred development of innovative strategies to support learning. The following are the main theoretical ideas, which relate to asynchronous tool use.

*Clark and Mayer's Guidelines.* Clark & Mayer (2016a, 2016b) suggest that asynchronous and synchronous instruction share a common goal in support of collaboration and interaction. They suggested that in order for interaction to promote meaningful learning, it requires strategies and activities to have high cognitive engagement (Clark & Mayer, 2016a, 2016b). Effective asynchronous tools can stimulate varying levels of psychological processing leading to knowledge construction. They also suggest that interaction activities should be designed to promote cognitive processing along a continuum of engagement leading to learning. The learners and learning context drive the need for varying interactions which support low to high psychological engagement (Clark & Mayer, 2016a, 2016b). At the lowest level of engagement, the instruction is designed to strengthen associations between what is already known and the new content being presented. At the high end of the continuum, instruction prompts and guides the learner toward the acquisition of new mental models. Clark and Mayer (Clark & Mayer, 2016a, 2016b) also explained that behavioral engagement such as clicking, dragging elements on screens does not lead to learning unless appropriate instructional strategies which are activities that deliberately lead to cognitive engagement. Furthermore, designing instruction that includes cognitive engagement can be effective even in the absence of physical activity. The benefit of designing instruction that includes having learners construct artifacts is in the evaluation and feedback process.

Additionally, Bozhurt et al. (2015) found that collaboration does not occur without active interactions with each other in accordance with other theoretical perspectives of constructivism and connectivism. Their findings suggested that “these theories explain how learning occurs on networks through collaboration in a community by interactions” (Bozhurt et al., 2015, p. 344) among other theories such as community of inquiry, cognitive load theory, and transactional distance theory. Bozhurt et al. (2015) also found that learner motivation and being self-regulated as well as instructional design theories were important for efficient and effective learning.

*The community of inquiry.* Garrison, Anderson, and Archer (1999) developed the Community of Inquiry (COI) as a framework to study text-based computer-mediated communication used to exchange ideas and experiences in online learning environments. Within the framework, cognitive presence, social presence, and teaching presence encompass a range of interactions within a dynamic relationship that can be used to influence instructional design to elicit optimal learning outcomes (Akyol & Garrison, 2008; Garrison et al., 2010).

*Cognitive load theory.* Sweller's (2011) Cognitive load theory (CLT) is also important to consider. It relates the amount of memory needed when learning or problem solving, especially in online environments. CLT demonstrates the limitations of the human brain when processing information from multiple sources. CLT posits the human brain has limited working memory capacity, and that activating auditory and visual channels as points of entry into memory facilitates remembering

and learning. This means allowing learners time on tasks to process new information with the goal of moving the information into long term memory.

When using technology tools, it is important to avoid introducing extraneous cognitive load. Providing detailed instruction on how to use a tool prior to using it in a lesson will help reduce cognitive load. During instruction, using techniques such as priming, chunking, rehearsal, and worked examples allows learners time to make connections between the new information and what they already know. The implications of CLT become apparent when faced with creating instruction using digital tools. The sheer vastness of options and features available for some tools, coupled with the complexity of becoming familiar with how to use the tool, and new content being introduced can easily lead to cognitive overload and negatively impact learning.

*Transactional Distance theory.* According to Moore (2019), transactional theory is based on the idea of “transactional distance as the gap between the understanding of a teacher (or teaching team) and that of a learner, and distance education is the methodology of structuring the courses and managing dialogues between teacher and learner to bridge that gap through communications technology” (p. 34). That is, as structure increases, the transactional distance increases and as dialog decreases, transactional distance decreases. For instance, in low transactional distance, in which structure is low and dialog is high, learners receive information and guidance in an ongoing, frequent manner with the instructor and the instructional materials. Lower distance might be more suitable for a less self-directed learner, whereas a learner who is highly self-directed might prefer a higher structured lesson and with less dialog.

*Self-regulated theory.* Bozhurt et al. (2015) suggested that learners needed to have some sense of self-regulated learning when in an open environment. Self-regulation is attributed to Bandura’s early work. Self-regulation emphasizes that the learner has the capability to set goals and monitor and reflect on their learning and the outcome in a cyclical manner (Kirk, 2021; Ormrod, 2016). Rand and Davidson-Shivers (2013) suggested that online learners should have a minimal working knowledge of the computer, Web, and software applications. However, more importantly, they need to be self-directed and motivated. It also requires that learners display self-motivation and good study skills. Kirk suggests that it is different for each learner and the various learning tasks.

*Motivational theories.* Ormrod (2016) defined motivation as “an internal state that arouses us to action, pushes us in particular directions, and keeps us engaged in certain activities” (p. 424). Motivational theories direct designers and teachers to consider appropriate conditions to incorporate into instruction (Driscoll & Burner, 2005), and there are multiple theories which relate to student learning successfully and to participate effectively in the learning environment (Davidson-Shivers et al., 2018).

One motivational theory, Wlodkowski and Ginsberg’s (2009) Motivational Framework for Culturally Responsive Teaching, works well in all types of learning. It contains four elements: establish inclusion, develop learner attitudes, enhance meaningful learning, and promote learner competence (Ginsberg & Wlodkowski, 2009) and provide strategies to assist learners to become a member of the learning community and engage in their learning processes (Wlodkowski & Ginsberg, 2010). For establishing inclusion, the strategies of using icebreakers might help learners get to know each other. Having open chats or discussions to talk about the course could

also be useful for assisting students. Angleo and Cross (1993) suggest using what they call the “muddiest points” discussion or chat to clear up any misconceptions in the instruction or preconceptions in a learner’s prior knowledge. A strategy for the second element, develop learner attitudes, might allow learners to choose types of assignments or project topics to help facilitate relevance and volition for learners. The next element, make learning meaningful, could be obtained by creating instruction which is engaging and challenging (to a degree) by using case studies that are challenging to allow for critical thinking and problem-solving techniques or strategies that ask learners to reflect or apply their knowledge. The last element, promote learner competence, might use the strategy of providing ways for learners to practice at various levels of Bloom’s Taxonomy or Gagne’s Categories of Learning (Davidson-Shivers et al., 2018).

---

## Instructional Design Strategies for Asynchronous Teaching and Learning

Based on the various theories described above, strategies for teaching and learning become a part of the asynchronous tools. Davidson-Shivers et al. (2018) developed a strategy worksheet to assist in the design of online learning. It is based on various learning, communication, and design theories. The main four sections frame the instruction/learning process from start to finish:

1. *Orientation to learning* purpose is to draw student awareness to the instructional purposes and goal, establish learner expectations, determine learners’ prior knowledge, and assist in their navigating the lesson site.
2. *Presenting the instruction* purpose is to provide the content and learning activities along with guiding the learners, allow for practice with feedback, and at the end of the lesson summarize the major concepts and help learners plan for any assessments to occur.
3. *Measuring and assessment of learning* is to provide an appropriate measurement tool that is aligned with the learning goal, advise the learners of their progress and scores, and offer remediation as necessary.
4. *Summary and closing the lesson (or unit or course)* is to provide additional opportunities for retention, remediate for unmet learning, and enhance and enrich students’ learning.

Other authors such as Ko & Rossen (2017) developed guidelines for online teaching. Angleo and Cross (1993) provided information about types of assessment that can be used throughout the instruction and as ways of measuring learner knowledge, attitudes, capabilities, and needs. According to Davidson-Shivers et al. (2018), the following list is a compilation of various strategies that could be incorporated in ODDE environments. The list of strategies is based on the work of Davidson-Shivers et al. (2018) as well as other sources cited throughout this chapter and is as follows.

***Strategies used for orientation and helping the learner attend***

- Use questionnaires, pretests, or advance organizers to probe learners' prior knowledge, skills, interests, and understandings.
- Use stories, scenarios, etc., to draw attention to the learning goal or purpose and expected learning performance.
- Use a concept map or other navigational tools to orient the learner to the environment.
- Use icebreakers to help build the learners' community.
- Use reflection questions to relate to personal or professional interests.
- Use advance organizers.

***Strategies used for presenting instruction to facilitate learner knowledge gain***

- Provide content information through a variety of media: audio, video lectures, or discovery learning.
- Elaborate on the content by interaction with experts.
- Use case studies or problems solving techniques.
- Use pertinent games or simulations for students to connect prior knowledge to new learning.
- Provide learning cues such as Socratic dialogues, pose questions.
- Highlight key information through visuals or audio
- Allow students to practice their knowledge gains through roleplaying, games, reciprocal teaching, etc.
- Provide rubrics on scoring prior to any practice or assessment.
- Provide feedback on learners' performance by text or media comments, peer reviews, automated feedback from the course site.
- Close the lesson with a review or summation of the content by instructor or students.
- Preview the next topic or task (if any) with a question or directions.

***Strategies for measuring and assessing the learners***

- Use low stakes quizzes or tests for units within a course.
- Use projects or roleplaying situation.
- Pose interesting questions or issues for learners to address through discussions, debates either text-based or video-conferencing tools.
- Provide rubrics or checklists to score or measure learning.
- Ask students to recall, summarize, or make meaningful connections about the content and learning.

***Strategies for summarizing and closing the instruction***

- For retention, ask learners to summarize or highlight main points of learning.
- For remediation, allow learners to review assessment to understand their errors and have them review the content again.

- For enhancement and enrichment, discuss how the lesson relates to future lessons.
- Ask learners to provide their next steps toward advancing their learning.
- Provide wrap-up remarks or ask students to provide them to close the lesson.

---

## Two Issues Within ODDE Environments to Ponder

Is collaboration really necessary? Although this chapter's primary focus is on interaction and collaboration, there may be situations when interaction or collaboration with others is not necessary for learning to occur. Davidson-Shivers et al. (2018, p. 14) developed a continuum of interaction with “. . . one end, individual learners participate in independent, self-paced learning and interact with the content, but have minimal to no direct interaction with learners or the instructor” and “at the other end, participants are highly interactive with each other and the instructor and are motivated to build a sense of community.” In between is a combination of both independent activities with other actions involving interaction and collaboration with other learners, the instructor and the content. Some individuals might prefer an independent, self-study mode. Transactional distance and self-regulated theories appear to suggest that some learners who are autonomous in nature might only need to interact with the instruction with the proviso that it has higher structure. If that is true, then further research is needed to determine how much structure is needed and for whom (i.e., the learner). One investigation could center around the questions of who are autonomous learners and how can they be supported in an environment that requires collaboration with others?

What happens when collaboration is needed, but does not occur? The second issue centers around learners not fully engaged or interacting with each other even though collaborative learning is viewed by the instructor as a necessary and beneficial part to their learning. Instead, student interactions may only be perfunctory with each other by doing the typical “respond once and reply twice” in a discussion. They might not always function as a team when trying to complete a team-based task or achieve specific goal, instead they tend to divide and conquer the task so-to-speak separately and then assemble the pieces together for the final product. As such, this could not be considered as collaborative, engaged learning. Although some studies have addressed this issue, further research study is necessary to address increasing effective collaboration among the students.

---

## Summary and Conclusion

In this chapter, we have provided a brief overview of some important learning theories and best practices for designing instruction in asynchronous online learning. We offer a glimpse of technology tools that, when used appropriately, can enhance student engagement and result in positive learning outcomes.

Inventions and innovations in digital technologies have improved accessibility to programs and products that facilitate human communication processes and that can be enlisted into teaching and learning scenarios. Today instructors, learners, and content interactions are mediated through computer technologies such as personal computers, cellular phones, and mobile computing devices. Innovations in technology have borne new ways of communicating that can be visual, vocal, or textual. These types of communication have increasing implications for how teaching and learning are conducted. Clark & Mayer (2016a) provide scientific evidence supporting the efficacy of using multiple forms of computer-mediated communication when designing instruction. These multiple forms of communication enable elaborate and effective ways of communicating and they have potential to leverage student motivation, self-directed learning, engagement, and interaction in online learning environments.

A recent synthesis of student engagement with digital technologies conducted by Nkomo and Daniel (2021) reports on some issues of concern that have serious implications for the future of online learning. They caution that student engagement is a complex concept and educational researchers do not always agree on what constitutes engagement. However, this concept is extremely important in a digitally mediated learning environment because it influences academic success, soft skills development, and personal growth. Student engagement is multi-dimensional and includes behavioral, emotional, and cognitive components. Behavioral engagement is demonstrated when students complete assignments and plan for success. Emotional engagement can reveal itself in interest in course topics or through negative stress responses. Self-reflection and regulating learning are indicators of cognitive engagement. Nkomo and Daniel (2021) emphasize the importance of engaging all three dimensions of student engagement when designing instruction.

Eliciting appropriate engagement can be challenging for asynchronous learning and instructors should avoid using digital technologies in a way that might disengage students. By attending to the three elements of: (a) having students interact with peers, (b) making sure they can log into and navigate digital tools, and (c) by offering content in a format that can be replayed or viewed multiple times sets the stage for engagement. Careful design of instruction remains crucial to student engagement. Conducting a learner analysis and using good design principles will assist students in having a more successful learning experience.

## **Suggestions for Future Research**

Based on this review of the literature, there are suggestions for future research. One area of research is to study emerging technology tools for use in ODDE environments. For example, Lund (2021) calls blockchain the fourth phase of the industrial revolution characterized by a level of interconnectedness and automation that will change the world. Tapcott and Kaplan (2019) predict blockchain will be a next

generation network with nodes of teachers and learners connecting and collaborating across a secure and easily accessible network of knowledge resources.

Although artificial intelligence has been found in recent literature (e.g., a recent special issue of *British Journal of Educational Technology*), AI might be another focus area of future research. One area to explore is how AI can be incorporated or used as a tool for interaction and collaboration among participants in ODDE environments.

Past research appears to have focused on exploratory studies, case studies, and bibliometrics. Perhaps it is time to use what has been found in such studies and shift focus to the use of standard methodologies and large sample sizes in the research. Additionally, it would be good to pursue research to investigate how asynchronous tools (i.e., technologies and strategies) could be used to address current topics, which might include social justice issues, underserved populations, or diversity concerns and potential issues when algorithms are used in the analyses or configuration of a software application.

## Implications for Practice

This chapter has three main implications for practice. First, when developing instruction in any ODDE environment, it would be wise to consider what technologies would be appropriate. The list of common technologies in this chapter, which briefly highlight pros and cons for each technology, may be one way to make that determination. Second, if either interaction or collaboration is considered important, consider the types of strategies and technologies that might be employed in the ODDE environment and choose wisely. Learners need to see they are relevant and meaningful. Third, consider whether collaboration is really necessary for the type of instruction being planned; it might not be necessary after all.

## Abstract

Data, and specifically student data, has always been an integral part of good teaching as well as providing evidence for strategic and operational planning, resource allocation, pedagogy, and student support. As Open, Distance, and Digital Education (ODDE) become increasingly datafied, institutions have access to greater volumes, variety, and granularity of student data, from more diverse sources than ever before. This provides huge opportunity for institutions, and specifically educators and course support teams, to better understand learning, and provide more appropriate and effective student support.

With the emergence of learning analytics (LA) in 2011, the measurement, collection, analysis, and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs, gained momentum, both as research focus and practice. Since

then, LA have become institutionalized in many higher education institutions, mostly in residential institutions located in the Global North, and established a prolific presence in research on student learning in digitized environments. While LA has become institutionalized in the Open University (UK), it remains an emerging research focus and practice in many ODDE institutions across the world.

This chapter considers the implications of LA for ODDE research and practice by first providing a brief overview of the evolution of LA, and specifically the theoretical influences in this evolution. A selection of major research findings and discourses in LA are then discussed, before the chapter is concluded with some open questions for a research agenda for LA in ODDE.

## Introduction

As higher education becomes increasingly digitalized and datafied, not only did pedagogy, curriculum and assessment practices change in response to the availability of synchronous and asynchronous technologies, but also institutions had access to more granular and often real-time student and learning data, from a variety of sources (Prinsloo, Slade, & Khalil 2021). Collecting, measuring, and analyzing student data for the purposes of improving the effectiveness of teaching and learning, for use by educators, students, and course development and support teams, came to be known as *learning analytics* (LA) (Siemens & Long, 2011).

Since the emergence of LA in 2011 as a distinct research focus and practice, the field has matured and become institutionalized predominantly in the Global North and in residential institutions, with research into LA being dominated by the Global North (Guzmán-Valenzuela, Gómez-González, Tagle, and Lorca-Vyhmeister, 2021). While there is evidence emerging that LA is making inroads also in the Global South, its adoption by traditional distance and open distance education institutions remains mostly limited to the Open University in the UK (Prinsloo, Slade, & Khalil, 2022).

This chapter first provides a brief overview of LA and its relevance, especially for Open, Distance, and Digital Education (ODDE). Following this, theoretical influences guiding LA are discussed before providing a review of selected discourses and research in LA. This is followed by some open questions and directions for future research before this chapter concludes with implications for ODDE practice that arise from this research.

Central to the value contribution of this chapter is not *if* LA can contribute to more effective and successful learning in ODDE contexts, but rather, *under what conditions* will LA become an essential part of teaching and learning in ODDE institutions.

## Overview of LA and Its Relevance

It is crucial to understand LA against the *historical* use of student data in service of improving teaching strategies, student support, and student learning. Collecting and using student data – whether referring to demographic, registration, prior learning experiences, or current learning behavior data – has always been essential to teaching, regardless of the modality. Data on students’ performance and progression in their courses and chosen program of study inform not only institutional strategic and operational planning such as enrolment plans and resource allocation, but also teachers’ choice of pedagogical strategies and assessment approaches, as well as student and course support teams’ strategies. Feedback on progress in attaining the envisioned outcomes of courses, whether in the form of assignments, tasks, and examinations, is furthermore key to informing students on their progress, probabilities of passing or failing courses, and serves as an essential resource for students to make informed decisions. It is, however, clear that as institutions become digitalized and datafied, they have access to increasing volumes, variety, and granularity of student data from a variety of courses so that student data, and particularly LA, will increase in strategic and operational importance.

### What Is the Relevance of LA for ODDE?

- Teachers in ODDE contexts often feel as if they are “teaching in the dark” due to physical separation between students and teachers inherent in distributed learning contexts. Teachers and institutions therefore rely on student learning data (e.g., assignments and online behavioral and engagement patterns) to get a sense of students’ progress, students’ risk of dropping out, and/or need for additional guidance and support.
- Since its emergence in 2011, LA has matured not only as institutional practice but also as research focus and provides a wide range of empirical evidence of its potential to predict students’ performance, provide decision support for teachers and student, predictive analysis of retention/dropout, descriptive and predictive analysis of cognitive states, and learning interactions (Du, Yang, Shelton, Hung, & Zhang, 2021) (Also see Bart, Olney, Nichols, & Herodotou, 2020).
- Student retention and success in distributed learning contexts have always been and remain a cause for concern (Kember, 1995; Subotzky & Prinsloo, 2011). The measurement, collection, analysis, and use of student data therefore offers huge potential to increase student retention and success, inform learning design, assessment strategies, and student support interventions.

In the next section, the major theoretical insights that guide and emerge from LA are discussed.

---

## Guiding Theories

Theoretical influences and the importance of theory in LA is well-established and appreciated (Wise & Shaffer, 2015). For example, Rogers, Gašević, and Dawson (2016) state that theory “is an explicit articulation of the causal forces and mechanisms in a domain of interest that purports to connect empirical findings to each other and to the whole, making sense of what is figure and what is ground” (p. 237). As such theory lays out the core assumptions and fundamental principles, in general hypothetical terms, that inform research into a particular phenomenon or practice. How theory and which theories shaped the evolution of LA and continue to shape research into and the adoption of LA are, however, more difficult to establish. Though many of the published research in LA do not explicitly mention any theory, but the mere “absence of explicit theory in [e.g.] predictive analytics research does not mean ‘no theory’” (Rogers et al., 2016, p. 238).

To understand the role of theory in LA, it is important to first understand the emergence of LA in broader context and history of data-informed decision-making in higher education, and second, understand the interdisciplinary nature of LA.

Student and organizational operational data have always formed part of and as basis for data-informed decision-making in higher education institutions’ planning and reporting through what has come to be known as Educational Data Mining (EDM) (Baek & Doleck, 2021; Liñán & Pérez, 2015). The specific focus on *student* learning data, to inform decisions teachers and students make, emerged from the intersection of several disciplines such as, but not limited to, psychology, education, computer science, and the broader social sciences (Ferguson, 2012). Though LA and EDM are often used interchangeably, LA is distinct from EDM with regard to theoretical influences, its purpose, and the data it collects as well as the users of the analytics (Baker & Inventado, 2014; Ferguson, 2012). The interdisciplinary nature of LA also results in discipline-specific theories and practices shaping how student learning is understood, what data are collected, as well as understandings of the data.

Though it is impossible to provide a comprehensive overview of all the theoretical insights in the field of LA as an interdisciplinary field, the next section maps some key, selected theoretical “moments” that shaped the development of theorizing the field of LA as well as LA as praxis.

---

## Theoretical Influences

The article by Siemens and Long (2011) was the first specific overview not only of the expectations and aims of learning analytics, but also clarifying the difference between *academic* and *learning* analytics. *Academic* analytics refer to institutional (learning profiles, performance), regional, national, and international analytics used by administrators, funders, and marketing as well as a range of educational authorities and governments. In contrast, *learning* analytics refers to course-level (student behavioral and learning data) and departmental data used by students and faculty.

They warn that confining learning analytics to behavioral data risks “a return to behaviourism as a learning theory,” and they ask, “how can we account for more than behavioural data?” (p. 38). This early warning has continued to haunt LA up to the present day (Rogers et al., 2016; Selwyn, 2019).

The first published article that made specific reference to theories informing LA is the article by Clow (2012) in which he refers to the five-step model proposed by Campbell and Oblinger (2007) and the need to put LA on “an established theoretical base” (p. 134). Theories referred by Clow (2012) include Kolb’s (1984) Experiential Learning Cycle which refers to the work of Dewey and Piaget, Schön (1983), and Argyris and Schön’s (1974) work on reflective practice. He also refers to Laurillard’s (2002) Conversational Framework. Other educational literature mentioned are approaches to learning – deep, surface, or strategic – referring to the work of Richardson (2000) and Trigwell and Prosser (2004), as well as a reference to closed and open-loop control systems in “engineering theory” (Clow, 2012, p. 136).

Very early in the evolution of LA was considering the role of theory in making sense of having access to more data. Higher education institutions and certain forms of delivery (e.g., MOOCs) increasingly have access to more data not only on the institutional Learning Management System (LMS) but also from a range of other sources, such as geolocation, multimodal, and other forms of data “across sites and multiple identities” (Siemens & Long, 2011, p. 38). With this access to more data, a particular imaginary emerged that theory is no longer needed because “the data deluge makes the scientific method obsolete” (Anderson, 2008), and that “with enough data, the numbers speak for themselves” (in Siemens & Long, 2011, p. 34) (Also see Wise & Shaffer, 2015).

Pointing to the apparent tension between access to more data and theory, Clow (2013) states “As a field, learning analytics is data-driven and is often *atheoretical*, or more precisely, is not explicit about its theoretical basis,” and although there are attempts to ground LA in theory, “this is not universal, running the risk of treating the data that have been gathered as the data that matter” (p. 692; emphasis added). Later in 2015, Gašević, Dawson, and Siemens (2015) remark that “learning analytics tools are generally not developed from *theoretically established* instructional strategies, especially those related to provision of student feedback” (p. 65; italics added). Reflecting on the relative success of the *Signals* project at Purdue University, “the tool design did not have sufficient theoretically informed functionality to encourage adoption of effective instructional and intervention practices” (p. 66). In following Winne (2006, in Gašević et al., 2015, p. 66), the authors reflect on three axioms from the field of educational psychology – “learners construct knowledge, learners are agents, and data includes randomness” (p. 66). Building on the principles of Self-Regulated Learning (SRL), the authors focus on students *as agents*, and their freedom to make choices, however constrained by internal and/or external conditions.

Recent research by Wang, Mousavi, and Lu (2022) mapped key theoretical constructs found in LA research and based on their analysis and found that most of the research in LA “were guided by the theories of self-regulated learning and social constructivism; most integrated theories into LA for better interpreting the

data analysis results; and most linked theoretical constructs and log variables directly.” The authors also found that researchers employed survey-instruments to measure theoretical constructs. (Also see Prinsloo et al., for an overview of the complexities in identifying the dominant theories in LA research.)

Though the above is anything but a systematic and comprehensive overview of theoretical underpinnings and emergent theoretical issues in LA since 2011, it does provide a very useful, and insightful, basis for which to consider, in the rest of this chapter, key theoretical moments in LA. In the next section, this chapter outlines selected major research and discourses in LA.

---

## **Selected Major Research and Discourses in LA**

In selecting major research and discourses in LA of particular importance for ODDE, it is important to note that the field of LA and scope of published research are rich and wide. For example, research and discourses include, *inter alia*, stakeholder perspectives, new developments such as multimodal analytics and Artificial Intelligence (AI), the use of dashboards, measuring the impact of LA, and issues pertaining to student consent, privacy, and ethics. The selected research in the following section maps research into the adoption and institutionalization of LA, the role of LA in informing learning design and pedagogy, privacy and ethics in LA, and evidence of the impact of LA.

### **The Adoption and Institutionalization of LA**

Since the emergence of learning analytics in 2011, one of the main foci in LA discourses and research was to do research on factors that may influence the adoption and institutionalization of LA. For example, the first research to provide a framework, not only for understanding LA from an institutional perspective but also to inform its adoption, was provided by Greller and Drachler (2012). They proposed six interdependent and mandatory critical dimensions encompassing “stakeholders, objectives, data, instruments, external constraints, and internal limitations” (p. 45). Of particular interest is the authors’ foregrounding of “theories of learning, teaching, cognition and knowledge” (p. 55) as it points to a recognition of theoretical influences that shape the institutionalization of LA. They state that “more empirical evidence is needed to identify which pedagogic theory LA serves best” (p. 53). They further opine that while there is evidence of LA being informed by “behaviourist-instructionist style approaches... [...] there is as yet little evidence for the support of constructivist approaches to learning” (p. 53). They conclude that “technologies are not pedagogically neutral” and, as such, moot the need for constant evaluation of approaches taken.

The Learning Analytics Readiness Instrument (LARI) developed by Arnold, Lonn, and Pistilli (2014) refers to “literature [that] offers would-be practitioners a solid base of theory, process, and research” (p. 163) but does not provide any detail

pertaining to what this “solid base of theory” entails. In another article, Arnold et al. (2014) refer briefly to the work of Kotter (2008), on “leading change,” and emphasize “using the existing research and theory as the foundation to begin building out new theory and research in system level thinking to support learning analytics” (p. 260). The authors refer to the five stages of Puglise’s student success analytics (2010, in Arnold et al. (2014), p. 258) namely (1) technology infrastructure, analytics tools, and applications; (2) policies, processes, practices, and workflows; (3) values and skills; (4) culture and behavior; and (5) leadership.

The Supporting Higher Education to Integrate Learning Analytics (SHEILA) project (<https://sheilaproject.eu/sheila-framework/>) cofunded by the European Commission via the Erasmus+ program (Tsai et al., 2018) is one of the more recent, comprehensive, and widely used frameworks for institutionalizing LA. The framework was developed “based on interviews with 78 senior managers from 51 European higher education institutions across 16 countries,” and Tsai et al. (2018) report on findings of the implementation of the framework in four different institutional settings.

The purpose of the SHEILA project was “to guide individual institutions to develop a comprehensive policy that speaks to the needs of their particular contexts and stakeholders therein” (p. 4), and the project focused on the following research questions: (1) What is the state of the art in terms of LA adoption among European HEIs? (2) What are the key drivers for LA from the perspectives of institutional leaders, teaching staff, and students? (3) What are the key challenges for LA from the perspectives of institutional leaders, teaching staff, and students? (4) How can we move toward systematic adoption of LA in higher education? The SHEILA framework highlights four important areas of work in the implementation of LA namely (1) tool development; (2) policy development; (3) user-centered implementation; and (4) communication with primary stakeholders. As such, the SHEILA framework provides a structured approach to drafting a policy for learning analytics by allowing institutions wanting to implement LA to map the political context, identify key stakeholders, identify desired behavior changes, develop an engagement strategy, and analyze the internal capacity to effect change and establishing monitoring and learning frameworks (<https://sheilaproject.eu/sheila-framework/>).

## LA As Informing Learning Design and Pedagogy

Ameliorating the effects of the geographic separation between students and teachers has been central to the evolution of ODDE praxis and theorization, for example, Moore’s (2019) work on transactional distance, the promise of guided didactic conversation (Holmberg, 1999), getting the right mix of different elements and technologies in the design of learning experiences (Anderson, 2003), and the Community of Inquiry Framework (Garrison & Arbaugh, 2007), to mention but a few. Considering that LA and research into LA is about improving the effectiveness of teaching and learning (Gašević et al., 2015), the success of LA in informing

learning design and pedagogy is one of the most important themes in LA analytics research.

Reflecting on the alignment of LA with learning design in the context of the Open University (OU) in the United Kingdom, (UK), Rienties, Nguyen, Holmes, and Reedy (2017) report that “learning design decisions made by OU teachers seem to have a direct and indirect impact on how students are working online and offline, which in part also influenced their satisfaction and learning outcomes” (p. 147). Learning design at the OU focuses on what students do and is in contrast to many approaches that emphasize what teachers do. As such student digital engagement data in the different activities allow teachers to design formative learning activities to not only address student needs, but also ensure that students are retained and supported toward success. LA analytics allows teachers to provide feedback to students on what students do and the progress they make. Rienties et al. (2017) state that while there has been claims that learning design impacts on the effectiveness of learning and teaching, LA provides the opportunity to provide evidence of such impact. LA at the OU is based on an institutionally approved learning design taxonomy consisting of a number of learning design activities namely (1) assimilative; (2) finding and handling information; (3) communication; (4) productive; (5) experiential; (6) interactive/adaptive; and (7) assessment.

Another study providing evidence of the positive correlation between LA, pedagogy, and student engagement is the research by Macfadyen, Lockyer, and Rienties (2020) foregrounding the impact of the decisions made by educators, and “how students are reacting to these decisions” (p. 10). Considering the diversity of students, especially in ODDE environments, LA provides key insights into how to personalize learning experiences depending on student profiles, behavior, and support needs.

## **Where Is the Evidence? Mapping the Impact of LA**

Considering evidence that suggests that LA helps to improve learning design and pedagogy (as discussed above), it is less clear to what extent LA impacts on student retention and success.

One of the first published reports on the impact of LA, by Arnold et al. (2012), shares findings of the use of a “predictive student success algorithm (SSA) is run on-demand by instructors,” and the reported positive outcomes of the *Signals* project. An algorithm was developed consisting of four components namely “performance, effort, as defined by interaction . . .; prior academic history. . .; and, student characteristics, such as residency, age, or credits attempted.” Each of these components was weighted and then operationalized by the algorithm to determine students’ chances of success resulting in red, yellow, or green signals that were then displayed on students’ course homepages. “A red light indicates a high likelihood of being unsuccessful; yellow indicates a potential problem of succeeding; and a green signal demonstrates a high likelihood of succeeding in the course.” The authors conclude that “The use of learner analytics through the application of Course Signals

to difficult courses has shown great promise with regard to the success of first- and second-year students, as well as their overall retention to the University” (Arnold et al. 2012). In the light of the fact that the study by Arnold et al. (2012) is the “most frequently cited institutional deployment of learning analytics,” it is important to note that some of the claims of the improved retention of students have been disputed (Jisc, 2016) by Caulfield (2013), Straumsheim (2013), and Clow (2013).

Forward to 2017, Ferguson and Clow (2017) point to a number of problems with evidence pertaining to the impact of LA such as a lack of geographical spread, gaps in the knowledge base of LA such as no evidence of LA in, for example, informal learning contexts, “little evaluation of commercially available tools” and a “lack of attention to the learning analytics cycle (by Clow, 2012), limited attention to ethics, issues pertaining to sample selection, access to research findings, and an “over-representation of LAK conference papers.” The authors conclude that “there is considerable scope for improving the evidence base for learning analytics.” The quest to find evidence of the impact of LA on student learning is also addressed in Kitto, Shum, and Gibson (2018) who opine that the lack of evidence could be attributed to the “mistake of concentrating development in LA upon a concept that is easy to define and track, but not particularly useful to learning” combined with an overemphasis on “upon valuing what we can measure, instead of measuring what we value — a longstanding concern in educational assessment” (p. 454).

A more recent attempt to map evidence of the efficacy of LA is found in the systematic review by Larrabee Sønderlund, Hughes, and Smith (2019). Their research found only 11 studies that evaluated the effectiveness of interventions based on LA. The authors conclude “While there is plenty of research on the forecasting of student performance and retention, there is very little on the effectiveness of LA interventions” (p. 2613). They further note that “The LA interventions that we have identified centre on the idea that alerting students to their risk status, and engaging them on this basis, will change their performance for the better,” and according to the authors, there are several caveats in this assumption. These research findings are also confirmed by Ifenthaler, Mah, and Yau (2019). Viberg and Gronlund (2021) confirm that there is still “very little existing evidence” that LA improves teaching, learning, and student support *at scale*, and Guzmán-Valenzuela et al. (2021) propose that there is a “preponderance of analytics but very little learning” in their bibliometric and a content analysis. These authors venture the existence of two communities within the LA landscape namely “a *practice-based community* led by management units within higher education institutions and an *academic community* whose object of research study is LA as such” (p. 16). Of specific importance to this chapter is their finding that “there is a shortage of papers devoted to developing or expanding educational theories about students’ learning” (p. 16).

Early research on understanding student retention and success in distance education environments from a socio-critical perspective (Subotzky & Prinsloo, 2011), points to the role the lack of and inefficiencies in administrative support attribute to student frustration and dropout. In a recent article by Herodotou, Naydenova, Boroowa, Gilmour, and Rienties (2020), they explore how predictive learning analytics and motivational interventions increase student retention and enhance administrative

support in distance education. The research used a Student Probabilities Model (SPM) that “produced predictions of whether an individual student would reach specific milestones (different points in a course presentation or between courses), such as completing and passing a course, or returning in the next academic year” (p. 75). Based on the outcomes of the SPM, proactive interventions were executed including text, mail, and phone calls and “likely helped students remain engaged and progress through their studies” (p. 78) and confirmed that “interpersonal contact and communication with support and academic teams is more likely to contribute to a sense of belonging and social integration with the university, connecting students with the institution from a distance” (p. 80). Also see Herodotou et al. (2020).

## Ethics and Privacy in LA

Concerns about privacy and ethics in the measurement, analysis, and use of student data have been part and parcel of the evolution of LA from before its official launch in 2011 (Knox, 2010; Slade & Galpin, 2012). Since then, various issues and concerns regarding ethics and privacy in LA formed part of the mainstream discussions in LA. The first comprehensive attempt to map the ethical and privacy concerns and propose a pointer for consideration is found in the work of Slade and Prinsloo (2013) mooted several principles for consideration namely (1) LA as moral practice; (2) students as agents; (3) student identity and performance are temporal dynamic constructs; (4) student success is a complex and multidimensional phenomenon; (5) transparency; and (6) higher education cannot afford to not use data. Of particular interest in the context of this chapter, this work by Slade and Prinsloo (2013) formed the basis for the first institutional policy for ethics in LA, developed at the Open University (UK) (OUUK, 2014). Other examples of how ethics and privacy claimed a space in LA research, discourses, and practice include an article by Pardo and Siemens (2014) on ethical and privacy principles in LA and a proposal by Willis (2014) to go beyond utilitarianism in thinking about ethics in LA.

Since these early research into the ethical and privacy concerns in LA, numerous initiatives, both institutional and as research, followed such as a Code of Practice for Learning Analytics (Jisc, 2018), a Discussion Paper, “The ethics of learning analytics in Australian higher education” (Corrin et al., 2019), “Global guidelines: Ethics in learning analytics” developed by the Association for the Advancement of Computing in Education (Alayan, 2019), and codes of practice/ethics for learning analytics in several higher education institutions such as the University of Leeds (UK) (2019). See Pargman and McGrath (2021) for a systematic review on ethics in LA.

---

## Open Questions and Directions for Future Research

From the preceding and selective overview of some of the major research foci and discourses in LA research, several questions arise that may serve as directions for further research. Most probably, the most pertinent question that arises pertains to the

scattered and incomplete evidence that LA impacts positively on student retention and success. While it falls outside of the scope of this chapter to speculate regarding the lack of unequivocal evidence, there are glimpses in the above overview that may hold clues such as the following:

- How does LA research build on existing theory? Many authors pointed to the lack of theoretical grounding in LA research (e.g., Misiejuk & Wasson, 2017). Despite or amid the reality that LA is found in the nexus of various disciplines, and methodological approaches and theoretical frameworks, the evident lack of explicit theory is cause for further research, if not concern. Even when reference is made to the work of Tinto (e.g., Arnold et al. 2012), the reference is as background. Considering the rich theoretical and empirical history of research into student success and retention (e.g., Spady, 1970; Tinto, 1975, 1982; Kember, 1995; Subotzky & Prinsloo, 2011), it is not clear to what extent LA as field and as practice takes its cues from theory.
- What does LA research contribute to theory? We also have to ponder the inverse, namely, to what extent does LA contribute to theory development on student success and retention? Tinto (1982) proposes we have to recognize that “current theory cannot do or explain everything” (p. 688). Acknowledging current theoretical limitations should not “constrain us from seeking to improve our existing models or replace them with better ones” (Tinto, 1982, p. 689). We therefore have to contemplate to what extent LA can expand existing theories or provide novel understandings of student persistence and success.
- What are the practical effects of LA? We also need to heed the words of Tinto (1982) that we should “also recognize that there are deep- rooted limits to what we can do to reduce dropout both at the national and institutional levels of practice” (p. 699). The chapter provided evidence that much of LA focuses on providing students with information to make better choices, institutions with information on how to support identified at-risk students better, and data to teachers and learning designers to design better pedagogical strategies. Considering that student success is multidimensional and emerges from various, interdependent, and often mutually constitutive factors in the nexus of *students* (habitus, loci of control, self-efficacy, and prior learning experiences), *institutions* (character, disciplinary domains, efficiencies, and responsiveness), and *macro-societal* factors, is LA measuring the wrong things? It is therefore significant that Tinto (1982) proposes that we “need ask not whether we should eliminate dropout (since that is not possible) but for which types of students in which types of settings we should act to reduce it” (p. 699). This may also require that we question some of the defaults and normalized assumptions in LA (Archer & Prinsloo, 2020).
- What is the student role in LA? Lastly, growing a student-centered approach to LA means that we need to reconsider the role students play not only in providing data, but also in making sense of the data. We need to engage them on classification systems and categories used (e.g., household), the proxies for their (dis)engagement, as well as preventing LA from becoming a datafied voice-

over of the student experience (Broughan & Prinsloo, 2020), ignoring the complexities not only of student learning, but also in facilitating learning and providing administrative, affective, and cognitive support.

The above questions and pointers for future research are, of course, neither comprehensive, nor neutral. For a more comprehensive analysis of current research in LA, see the systematic review by Du et al. (2021). There are, also, a number of authors who have mapped alternative research agendas for LA such as Gunn (2014), Selwyn (2019, 2020), Wise, Sarmiento, and Boothe (2021), and Prinsloo et al. (2021).

---

## Implications for ODDE Practice

The introduction to this chapter made it clear that collecting and using student data has been part and parcel of education, irrespective of the mode of delivery or its openness. With the emergence of LA in 2011 as a distinct research focus and practice, the potential of using the increasing volumes, diversity, and granularity of data from a variety of sources opened opportunities but also raised several ethical and privacy issues. In the light of concerns about student retention and success in ODDE contexts, LA offers scope for critical interrogation and ethical operationalization. Despite that most, if not all open, distributed, and online provision is, in one form or the other, digitalized and therefore datafied, it is somewhat strange that, outside of the adoption and institutionalization of LA at the Open University (UK), there is no evidence of the adoption of LA, at scale, in other ODDE institutions (Prinsloo et al., 2022).

Following from this, the most important question that emerges is to understand what is preventing ODDE institutions to embrace and operationalize LA? Considering that LMSs may form, to a large extent, the backbone of administrative and teaching systems in ODDE institutions, more research is needed to investigate the reasons why not more ODDE institutions are adopting LA. The issue is not if LA can contribute to more effective and successful learning in ODDE contexts, but rather, under what conditions will LA become an essential part of teaching and learning in ODDE institutions?

## Abstract

This chapter describes the insights derived by the design and development of the Multimodal Tutor, a system that uses artificial intelligence for providing digital feedback and to support psychomotor skills acquisition. In this chapter, we discuss the insights which we gained from eight studies: (1) an exploratory study combining physiological data and learning performance (Learning Pulse); (2) a literature survey on multimodal data for learning and a conceptual model (the Multimodal Learning Analytics Model); (3) an analysis of the technical challenges of Multimodal Learning Analytics (the Big Five Challenges); (4) a technological framework for using multimodal data for learning (the Multimodal Pipeline); (5) a data collection and storing system for multimodal data (the

## Introduction

Learning is a fundamental part of human nature. The knowledge acquired from learning new skills helps individuals change their cognition and affection, the center of human growth and development, and is hoped to be the mean for happiness, safety, emancipation, productivity, and societal success. *Education*, as the set of all planned learning processes and activities, is a “means by which men and women deal critically and creatively with reality and discover how to participate in the transformation of their world” (Freire, 1970).

Despite being so important in the development of an individual, learning is not always easy. In 1978, Vygotsky explained the difficulty of learning by introducing the *Zone of Proximal Development* (Vygotsky, 1978) indicating the psychological processes that the learner can reach with the support of knowledgeable guidance. According to Vygotsky, there are certain skills and competencies that the learner can only acquire if given the right support. With the right guidance, each learner can stretch outside of the *zone of comfort* and can experience and learn new skills and concepts. Besides external guidance, also internal factors play a determining role in learning success. Those are, for example, motivation to learn (Pintrich, 1999), the self-determination of an individual (Ryan & Deci, 2000) or metacognitive skills like self-regulation (Winne & Hadwin, 1998; Zimmerman, 2002), and the right set of dispositions (Shum & Crick, 2012), skills, values, and attitudes. Among all these individual factors, the learning science field also provides best practices to instruct an individual or a group of learners by providing evidence-driven instructional models like 4CID (Van Merriënboer, Clark, & De Croock, 2002).

For several decades, educational researchers were busy understanding the “black box” of learning, unveiling the underlying dynamics and factors that lead to successful learning. More recently, the education technology research community was busy trying to understand the following question: *Is there place for technology to facilitate learning and teaching?*

## An Historical Perspective on Education Technologies

The first massive implementation of digital technologies in education dates back to the mid-1980s, with the diffusion of the modern personal computer. American

universities started sharing course content in the university libraries implementing the so-called *Computer-Based Learning*. Higher education institutions took advantage of the computer by developing distance courses and primitive forms of e-learning systems. The 1980s constituted a “new spring” for *Artificial Intelligence* research. The invention of the *back-propagation rule*, which allowed *Artificial Neural Networks* to learn complex, nonlinear problems, generated a new wave of enthusiasm. The 1980s were characterized by the surge of *Expert Systems*, computer programs typically written in LISP that modeled specific portions of knowledge. In the domain of education and training, these systems took the name *Intelligent Tutoring Systems (ITS)*, adaptive computer programs which aimed at providing rich interaction with the student (Anderson, Boyle, & Reiser, 1985; Yazdani, 1986). The ITSs introduced the idea of the *Tutor*, an intelligent algorithm able to adapt to the individual learner characteristics, and that works as “instructor in the box” (Polson, Richardson, & Soloway, 1988) capable of replacing the human teacher. The AI-ITS vision was both controversial as well as technically complex to achieve for the 1980s. It did not fully take off as much as other educational technologies such as e-learning.

In the 1990s, the e-learning systems took further steps of developments. The computer in education shifted from being a knowledge diffusion system to a platform that encouraged sharing and developing knowledge between groups of learners. E-learning, however, became more popular as it was less ambitious and more applicable also to more ill-structured subjects, other than mathematics, programming, or other natural science. E-learning became a tool that could support *computer-supported collaborative learning* (Dillenbourg, 1999).

In the 2000s, digital technologies met a fast development also thanks to the fast-spreading of the Internet and the *World Wide Web*. In education research, the *Technology-Enhanced Learning* (TEL) community emerged. The initial focus of TEL was the e-learning systems and multimedia educational resources. While these educational contents were previously only accessible via a personal computer, in the late 2000s, they became available for portable computing devices such as smartphones, tablets, or laptops. These new technological affordances established the research focus on *ubiquitous and mobile learning* (Sharples, Arnedillo-Sánchez, Milrad, & Vavoula, 2009), i.e., learning *anywhere at any time* without physical nor geographical location constraints.

In the 2010s, we observed a *data-shift* in education technologies with the rise of the *Learning Analytics* (LA) research community (Ferguson, 2012). The core idea at the basis of the LA research was that learners interacting with computer devices leave behind a considerable number of *digital footprints* which can be collected and analyzed for describing the learning progress and help to optimize it (Greller & Drachslar, 2012). Ten years later, after LA research was introduced, the field moved significant steps forward by identifying additional fundamental challenges. Despite the vast amount of data collected, there is still confusion about how these data can be harnessed to support learners. One part of the LA research aims to foster *self-regulated learning* by stimulating learners to improve their metacognitive skills through self-reflection and social comparison with peer learners (Winne, 2017). Nevertheless, the common idea of providing learners with LA dashboards for raising

their awareness does not naturally lead to change their behavior and meet their goals (Jivet, Scheffel, Drachler, & Specht, 2017). LA deals also with challenges like how to ensure ethics and privacy (Drachler & Greller, 2016), and how to change and improve learning design with the support of learning analytics and data-driven methods (Schmitz, van Limbeek, Greller, Sloep, & Drachler, 2017).

Another limitation of LA relates to the data source used. So far, LA data are mostly related to learners interacting with a digital platform (e.g., Learning Management System) utilizing mouse and keyboard. LA research – as well as its predecessors – were born nested into the *glass slab era*: The primary learning and productivity tools are mediated by a computer screen, a mouse, or a keyboard. With such tools, there is little space for interactions with physical objects in the physical world. The lack of physical interactions during learning led to a *reality drift* for learning science. According to the theory of *embodied cognition*, humans have developed their cognitive abilities together with the use of their bodies and that is encoded in the human DNA (Shapiro, 2019). For example, the hands are made for grasping physical objects, or the human senses developed for witnessing sound, smell, or light. The limited data sources raise valid questions concerning the *understandability* and *interpretability* of the digital footprints analyzed by LA researchers. Trying to derive meaning from limited educational data brings the risk of falling into the *street-light effect* (Freedman, 2010), the standard practice in the science of searching for answers only into places that are easy to explore.

To include novel data sources and new forms of interaction, a new research focus has emerged within the LA research, coined as *Multimodal Learning Analytics* (MMLA) (Blikstein, 2013). The objective of MMLA is to track learning experiences by collecting data from multiple modalities and bridging complex learning behaviors with learning theories and learning strategies (Worsley, 2014). The *multimodal shift* is motivated from a theoretical point of view by the need to achieve more comprehensive evidence and analysis of learning activities taking place in the physical realm such as colocated collaborative learning (e.g., Pijera-Díaz, Drachler, Kirschner, & Järvelä, 2018), psychomotor skills training (e.g., Di Mitri, Schneider, Specht, & Drachler, 2019a; Schneider & Blikstein, 2015), and dialogic classroom discussions (e.g., D’mello et al., 2015) which were underrepresented in LA research and other data-driven learning research. In parallel, the *multimodal shift* is also stimulated from a technological push given by the latest technology developments (Dillenbourg, 2016). Learning researchers are making use of new technological affordances for gathering evidence about learning behavior. In recent years, the low costs of sensor devices made them more affordable. Sensors can be found embedded in smartphones, fitness trackers, wrist-based monitors, or Internet of Things devices and provide the possibility to continually measuring human behavior. These devices can collect streams and measure life aspects such as hours and quality of sleep, working and productivity time, food intake, and physiological responses such as heart rate or electrodermal activity. The multimodal sensors can collect “social signals” – thin slices of interaction that predict and classify physical and nonverbal behavior in group dynamics. Multimodality is relatively a novelty in

the field of learning. For this reason, we introduce the metaphor of the *new land* which encloses the promise – or probably the hope – to understand learning and human behavior better.

In the 2020s, a new kind of educational technology is taking off. We introduce this new technology under the name of *Multimodal Tutor*, a new approach for generating adaptive feedback from capturing multimodal experiences. The Multimodal Tutor capitalizes on the support of multimodal data for understanding learning and human behavior pushing it to the next level. It proposes a theoretical and methodological approach to deal with the complexity of multimodal data, combining artificial intelligence with human assessment. With this hybrid approach, the Multimodal Tutor carries an advanced promise for learners, making learning more authentic, adaptive, and immersive. We argue the Multimodal Tutor may enable us to move toward a *learner-centered* and *constructionist* idea of learning as an active and contextualized process of construction of knowledge (Piaget, 1952). The multimodal approach is learner-centered as it focuses on the entire span of human senses and embodied cognitive abilities. It moves away from nonnatural interactions introduced by computers or smartphones, and it stimulates interactions with the physical world. In the meantime, it tracks information about the learner's physiology, behavior, and learning context.

The Multimodal Tutor advocates for reuniting two branches of developments in education technology which have been developing in parallel. The first one is Learning Analytics and TEL research focusing primarily on deriving insights from learning data to support human decision-making. The second one is AI-ITS research, which for almost three decades has designed, developed, and tested artificially intelligent systems that model the knowledge of the learners and guide them through the learning activities domain.

## Outline of This Book Chapter

This book chapter reports the insights of eight subsequent studies, which lead to the final design, ideation, and technical implementation of one example of Multimodal Tutor in the field of Cardiopulmonary Resuscitation.

The first study is *Learning Pulse* (section “Research study: Learning Pulse”) where we investigate the complexity of using multimodal data for learning which paved the way to the Multimodal Tutor. Learning Pulse discovered empirically a series of complex dynamics, of both conceptual and methodological nature, derived by using multimodal data for predicting learning performance.

In the literature study *From Signals to Knowledge* (section “Literature Study on Multimodal Data for Learning”), we explore the concept of multimodality by analyzing existing constructs and by conducting a literature survey. This qualitative research approach leads to the formulation of the *Multimodal Learning Analytics Model* (MLeAM), a conceptual model which serves as the “Map of Multimodality.” The MLeAM sheds light on the multimodal feedback loop that the Multimodal Tutor is set to accomplish.

If the MLeAM indicates the “way to go,” it does not say “how to get there.” There is, in fact, the need for a better understanding of the problem from a technological standpoint and the formulation of a possible solution. We describe this in 2.3 with the “Big Five challenges” for the Multimodal Tutor.

The Multimodal Pipeline (section “Position Paper: The Multimodal Pipeline”) proposes a technological framework for the cyclic nature of the MLeAM and addresses the “Big Five” challenges with technical infrastructure. The *Multimodal Pipeline* reveals to be the most critical part of the Multimodal Tutor research. The multimodal data streams are complex to align, synchronize, and store.

The *Multimodal Learning Hub* (section “Technical implementation: The Multimodal Learning Hub”) is the first prototype of the Multimodal Pipeline, which is designed to track learning experiences using customizable multisensor setups flexibly.

In section “Technical implementation: the Visual Inspection Tool,” we decide to focus on one specific, unsolved aspect of the Multimodal Pipeline, the Data Annotation. From this challenge emerges the idea of creating a *Visual Inspection Tool*, an application for annotating and inspecting multimodal data streams, which allows to “read between the lines.”

In this phase, we decide to narrow the focus to the specific domain of Cardiopulmonary Resuscitation Training (CPR). In section “Feasibility Study: Detecting CPR Mistakes,” we focus on modeling the CPR domain, mainly how to detect multimodal mistakes using machine learning techniques. Finally, the CPR Tutor is employed in a field study for feedback generation in (section “Research Study: Keep Me in The Loop”) where we report the design, development, and experimental testing of the CPR Tutor.

---

## Main Findings

### Research Study: Learning Pulse

The exploratory study *Learning Pulse* (Di Mitri et al., 2017). Learning Pulse aimed at predicting levels of stress, productivity, and level of flow during self-regulated learning. In the study, we gathered multimodal data from nine participants. The data consisted of (1) physiological data (heart rate and step count) from Fitbit HR wristbands; (2) software applications used on their laptops from RescueTime; and (3) environmental information (temperature, humidity, pressure, and geolocation coordinates) using web APIs. In two weeks, the participants had to self-report every working hour via a mobile application, the *Activity Rating Tool*. The participants’ data were collected in a *Learning Record Store* using custom *Experience API* (xAPI) triplets. The experimental setup chosen allowed too much diversity of tasks, resulting in an uncontrolled study and negatively influencing the results’ quality. Although the nine participants were PhD students of the same department, throughout the 2 weeks of the data collection, they used different laptops and software applications, which were grouped into categories. The collected data were

heterogeneous: Some attributes as “step-count” exhibited random behavior, and some other attributes such as “heart-rate” had continuous values instead. To accommodate both types of continuous and random effects, we opted for *Linear Mixed Effect Model* (LMEM), a multilevel prediction algorithm typically used for time-series forecasting.

The collection of the labels needed for the data annotation was among the biggest challenges of Learning Pulse. The self-perceived levels of stress, productivity, and flow were reported by the participants retrospectively every hour using the Activity Rating Tool. We thus realized that the number of labels was not sufficient for supervised machine learning. For this reason, from each labeled hour, we derived 12 labeled intervals of 5 minutes. Finally, the data-processing approach was elementary, especially the *Data Processing Application*. The processing pipeline was tailor-made and not flexible nor reusable for other purposes outside of the study. The xAPI format revealed being a bottleneck when used for high-frequency sensor data such as heart rate or step-count. Storing each heart-rate update with an xAPI triplet store generated a load of redundant information that slowed down the data import and the overall computation. Finally, the poor results in the model accuracy did not allow to explore further the feedback mechanisms.

## Findings

- Data collections during long periods need to deal with the task diversity of each user and uncontrolled setups.
- Tracking software applications used by the user leads to diverse sets of attributes for each user, which makes it more difficult to compare them.
- Some modalities are continuous variables (e.g., heart-rate), and some others are random variables (e.g., step-count), which makes it hard to combine them and analyze them.
- Fixed-time (e.g., hourly) self-reports are not always reliable and are subject to bias.
- There is a trade-off between the number of labels needed for supervised machine learning and the time that humans need to annotate the data.
- Harnessing the potentials of multimodal data require run-time systems such as data-processing pipelines instead of data analysis scripts which run only once.
- xAPI is not suitable for storing and exchanging high-frequency sensor data due to the high overhead of the XML format.

## Literature Study on Multimodal Data for Learning

This literature study (Di Mitri, Schneider, Specht, & Drachsler, 2018a) aimed at mapping the state of the art of Multimodal Data for learning. This field was emerging as *Multimodal Learning Analytics* (MMLA). The exploratory study Learning Pulse in (Di Mitri et al., 2017) and the related work done in the field were the main motivations driving this scientific investigation. Surveying the related literature showed that MMLA covered a scientific field scattered and not yet coherent. This

work contributed to framing the mission of MMLA: using multimodal data and data-driven techniques for filling the gap between observable learning behavior and learning theories. We coined this mission “from signals to knowledge.” We conducted a literature survey of MMLA studies using the proposed *classification framework* in which we separate two main components: the input space and the hypothesis space that are separated by the *observability line*. The literature survey led to the *Taxonomy of multimodal data for learning* and the *Classification table for the hypothesis space*. Surveying the related studies allowed discovering exciting commonalities. For example, most of the studies using multimodal data looked primarily at metacognitive dimensions as a hypothesis as the presence of specific emotions in learning.

The literature survey led to propose a new theoretical construct, the *Multimodal Learning Analytics Model* (MLeAM), a conceptual model for supporting the emerging field of MMLA. MLeAM has three main objectives: (1) mapping the use of multimodal data to enhance the feedback in a learning context; (2) showing how to combine machine learning with multimodal data; (3) aligning the terminology used in the field of machine learning and learning science.

## Findings

- Sensors can capture observable learning dimensions that include behavioral, activity, and contextual data – we refer to this as the *input space*.
- The unobservable learning dimensions such as cognitive, metacognitive, or emotional aspects stand below the *observability line* –we refer to this as the *hypothesis space*.
- Using human-driven data annotation and machine learning, it is possible to infer the unobservable from the observable dimensions. This process is described by the *Multimodal Learning Analytics Model* (MLeAM).
- MLeAM shows how best to exploit machine learning and multimodal data to support human learning.
- The work in MMLA is jeopardized as it cannot yet rely on standardized approaches and techniques.
- Further research efforts must be put in technical prototypes, standardized technical infrastructure, run-time systems, and common practices for multimodal data for learning.

## Position Paper: The “Big Five” Challenges

In the Big Five, we address one structural shortcoming in the MMLA field, as evidenced by the literature survey conducted in (Di Mitri et al., 2018a): the lack of standardized technical approaches for multimodal data support of learning activities. We claimed that this technical gap is holding back the development of the MMLA field by imposing the MMLA researchers to duplicate efforts in setting up data collection infrastructures and preventing them from focusing on data analysis research questions answering. In (Di Mitri, Schneider, Specht, &

Drachsler, 2018b), the identified technical challenges are grouped into five categories, named the “*Big Five*” *challenges of Multimodal Learning Analytics* which are the (1) *data collection*, (2) *data storing*, (3) *data annotation*, (4) *data processing*, and (5) *data exploitation*. The chapter attempts to provide possible solutions to the flexible enough challenges for being employed in different contexts.

### Findings

- The technical challenges of MMLA can be grouped into five categories (1) data collection, (2) data storing, (3) data annotation, (4) data processing, and (5) data exploitation.
- The five challenges represent the steps that need to be addressed for implementing a data-driven feedback loop.
- Each of the challenges categories presents a set of subchallenges that need to be addressed by MMLA researchers.
- Tackling all these challenges together is a complicated research effort.

### Technical Implementation: The Multimodal Learning Hub

As tackling all the five challenges requires a complex effort, we decided to build upon an existing research prototype, a solution for the data collection and synchronization and the data storing: the Multimodal Learning Hub (Schneider, Di Mitri, Limbu, & Drachsler, 2018) (LearningHub). The LearningHub is a platform that can collect data from multiple sensor applications and synchronize them into session files. The most significant research outputs of the LearningHub are (1) a software prototype that can connect to multiple sensor applications running on Windows, and (2) the introduction of a new data-storing logic and custom data-format which we coined as *Meaningful Learning Task* (MLT-JSON).

### Findings

- Sensor devices have different software systems making the integration of data.
- From multiple sources not trivial.
- Sensors generate data at different frequencies.
- One sensor stream can be composed of several attributes.
- A typical problem of sensor fusion is the time synchronization of different devices. This problem can be addressed using having the LearningHub working as “master” that decides when the sensor applications should begin collecting the data.
- As data continuous data collection is complex and expensive to realize. It is easier to adopt a “batch approach,” in which the user can decide when to “start” and “stop” the data collection.
- The MLT-JSON format allows creating a document for each sensor device with multiple attributes and stores the data into human-readable format.
- Although MLT-JSON adopts a verbose format (due to repetitive JSON tags) when compressed, its file size is reduced by 90–95%.

## Technical Implementation: The Visual Inspection Tool

In (Di Mitri, Schneider, Klemke, Specht, & Drachsler, 2019), we focused on one of the five big challenges, the *data annotation*. This challenge deals with how humans can make sense of complex multidimensional data. In this chapter, we proposed a new technical prototype, *Visual Inspection Tool* (VIT). The VIT allows the researchers to visually inspect and annotate various psychomotor learning tasks captured with a customizable set of sensors. The file format supported by VIT is MLT-JSON, meaning that any recording session recorded with LearningHub can be loaded, visualized, and annotated using the VIT. The VIT enables the researcher (1) to triangulate multimodal data with video recordings; (2) to segment the multimodal data into time intervals and to add annotations to the time intervals; and (3) to download the annotated dataset and use the annotations as labels for machine learning predictions. Besides generically addressing the data annotation, the VIT also facilitates data processing and exploitation. The VIT is released as Open Source software (Code available on GitHub (<https://github.com/dimstudio/visual-inspection-tool>)).

### Findings

- Sensor data are poorly informative when visualized; for this reason, they need to be complemented by evidence interpretable for humans, such as video data. Without video, data is not easy to make sense of what happened in the recorded session.
- The numerical sensor attributes (as opposed to categorical variables) can be visualized as time series. The visualization of more than a couple of time series is tricky for the human eye; manually selecting the attributes to visualize, therefore, is crucial.
- Audio and video data can be transformed into numerical time series (e.g., by extracting colors of pixels or audio features) and added in the multimodal dataset.
- The annotation is a human interpretation of the data which apply to a specific time interval with a begin and end.
- Each time interval (annotation) can consist of multiple attributes; this approach allows the optimal definition of binary and nonbinary classes.
- Manually selecting the time intervals is an expensive task, which should be automated if possible – in the best-case scenario, the human role should be only of supervising, i.e., correcting and integrating the (semi)-automatic annotations.

### Position Paper: The Multimodal Pipeline

The VIT, as well as the LearnigHub and its custom data format MLT-JSON, constitutes a chain of technical reusable which we coined as Multimodal Pipeline and that we described in (Di Mitri, Schneider, Specht, & Drachsler, 2019c). The Multimodal Pipeline is an integrated technical workflow that works as a toolkit for supporting MMLA researchers to set up new studies in various psychomotor

learning scenarios. Using components from this toolkit can reduce developing time to set up studies, and it can facilitate and speed up the transfer of research knowledge in the MMLA community. The Multimodal Pipeline connects a set of technical solutions to the “Big Five” challenges described presented in (Di Mitri, Schneider, Specht, & Drachsler, 2019c). The Multimodal Pipeline has two main stages; the first one is the “offline training,” in which the collected sessions are annotated, and the ML models are trained with the collected data. The second stage is the “online exploitation,” which corresponds to the “run-time” behavior of the Multimodal Pipeline.

## Findings

- The Multimodal Pipeline describes in technical terms the data-driven feedback cycle proposed by MLeAM in (Di Mitri et al., 2018a).
- There are two flows of data in the Multimodal Pipeline, the “offline-training” and the “online-exploitation.”
- The Data Annotation happens typically before the data processing, as annotations are required for training the models.
- The Data Annotation is not always required. The Multimodal Pipeline can serve different strategies of exploitation for the Multimodal Pipeline, besides predictive feedback using supervised ML; these include rule-based corrective feedback, pattern identification, historical reports, diagnostic analysis, or expert learner comparison.
- The Multimodal Pipeline can harness multimodal data both for Learning Analytics Dashboards, for example, for raising awareness and stimulating orchestration in the learning activities; similarly, it can be embedded in Intelligent Tutors to achieve better adaptation personalization of the tutoring experience.

## Feasibility Study: Detecting CPR Mistakes

In (Di Mitri, Schneider, Specht, & Drachsler, 2019a), we selected Cardiopulmonary Resuscitation (CPR) as an application case for the Multimodal Tutor. We selected CPR training as a representative learning task for carrying a study on mistake detection. CPR was chosen primarily because it is an individual learning task. It is repetitive and highly structured. It has clear performance indicators and training with high social relevance. Among the different specialization options that the Multimodal Tutor could take, we decided to focus on the design of a CPR Tutor. We introduced a new approach for detecting CPR training mistakes with multimodal data using neural networks. The proposed system was composed of a multisensor setup for CPR, consisting of a Kinect camera and a Myo armband. We used the system in combination with the ResusciAnne manikin for collecting data from 11 experts performing CPR training. We first validated the collected multimodal data upon three performance indicators provided by the ResusciAnne manikin, observing that we can classify the training mistakes accurately on these three standardized indicators. We further concluded that it is possible to extend the

standardized mistake detection to additional training mistakes on performance indicators such as correct locking of the arms and correct body position. So far, those mistakes could only be detected by human instructors.

## Findings

- The quality of the data-training corpus is crucial for ensuring solid model training. Collecting data and training classifiers for a small number of participants leads to particular models that do not generalize well. Diversity and amount of the training data is the key.
- There is no gold number in the number of annotated samples (chest compressions – CC) which needs to be collected; there is, however, a dependency with the number of attributes that will be considered.
- Given that the samples (CCs) have different duration, it is important to resample to a fixed number of bins applying some trimming or.
- Applying normalization, and min-max scaling of all attributes is important for achieving the best result; this has to follow the activation function used in the neural networks.
- Increasing the number of input attributes (e.g., adding new modalities) increases the classification accuracy of the model; these attributes work as regularization factor, adding more “background noise” to the model and making it more robust.
- Neural Network seems robust in accepting heterogeneous input while converging to good results; we decided that we could use the participants’ data as part of the same training set with the individual body differences.
- It is difficult to capture the span of all possible mistake with a restricted number of participants; each participant tends to make only a small subset of mistakes; the solution found was asking participants to mimic some types of mistakes.
- The task structure two sessions of 2 minutes performing CC is a tiring task for the participants.
- Body size is different among participants, and it has an effect on sensor wearing, for instance, people with thinner forearms had some trouble wearing the Myo, which was too loose.

## Research Study: Keep Me in The Loop

In (Di Mitri et al., 2021), we presented the design and the development of real-time feedback architecture for the CPR Tutor. To complete the chain of flexible technical solutions proposed by the Multimodal Pipeline, we developed *SharpFlow* (Code available on GitHub (<https://github.com/dimstudio/SharpFlow>)), an open-source data-processing tool. SharpFlow supports the MLT-JSON format used as well by the VIT and the LearningHub. The data serialized in this format are transformed by SharpFlow into a tensor representation and fed into a Recurrent Neural Network architecture trained to classify the different target classes contained in the annotation files. SharpFlow also implements the two data-flows of *offline training* and *online exploitation*. SharpFlow achieves the latter using a

TCP server for classifying in real-time every new chest compression. In (Di Mitri et al., 2021), the architecture was employed first in an Expert Study involving ten participants, aimed at training the mistake classification models, second in a User Study involving ten additional participants in which the CPR Tutor was prompting real-time feedback interventions.

## Findings

- Learning from experts is complicated as experts do not make enough mistakes; instances of mistakes are needed to train the machine learning algorithm; in (Di Mitri et al., 2021), we asked the experts to mimic some common mistakes.
- The amount of training data got from 10 experts was limited; while the findings could not be generalized, they provided some indication that the feedback of the CPR tutor had a positive influence on the CPR performance on the target classes.
- The proposed architecture used for the CPR Tutor allowed for successful provision of real-time multimodal feedback.
- The generated feedback seemed to have a short-term positive influence on the CPR performance on the target classes considered.
- There is a hierarchy among the performance indicators: Some mistakes are less frequent but more critical than others, and they need to be corrected first; some other mistakes are more frequent but not so critical.
- Imbalanced class distribution is a real problem; there seems to be an amplifying effect: The majority class in the training set tends to prevail even more in the test set and in the classification of new instances.
- Down-sampling is not trivial; as we had five target classes, down-sampling one class would also affect the other ones; finding a fair balance among the classes was hard.
- Oversampling seemed not trivial either with time series; generating fake data could undermine the prior class distribution.
- Highest feedback frequency was set to 10s interval; more frequent feedback would distract or confuse the participant.
- The feedback messages must be explained to the participants beforehand so that they know what to expect and what each message means, preventing confusion.
- The SharpFlow online exploitation was swift (70 ms for classifying each instance); in this way, the overall system was not heavily disrupted every time it had to assess each single CC.
- For the longer-term influence of the feedback on the target performance indicators, we would need to (1) collect data from more participants; (2) increase the number of sessions per participant; and (3) select participants with less experience so their performance is not optimal and feedback is fired more frequently.

The Multimodal Tutor presents a set of advantages for the MMLA community. It builds on top of a new proposed technological framework, the *Multimodal Pipeline*, which, in turn, is composed by a chain of technological prototypes such as the (1) *Multimodal Learning Hub*, (2) the *Visual Inspection Tool*, and (3) *SharpFlow*. All these tools are released, adopt the same data-exchange format (MLT-JSON), and are

released under the Creative Commons – ShareAlike 4.0 International license (<https://creativecommons.org/licenses/by-sa/4.0/>).

The main advantage for the MMLA researcher of using such tools is that there is no longer a need to reinvent solutions for data collection, synchronization, storing, annotation, and processing. The MMLA researcher can focus on more specific aspects of their experiments, such as deciding which sensor configuration to use, depending on which modalities they need to be monitored. Similarly, decide what hypothesis to formulate, what unobservable dimensions of learning have to be assessed, and how can these dimensions be translated into an annotation scheme. MMLA researchers can ultimately focus on modeling the learning task, what sets of atomic actions, and what pedagogical and feedback intervention is suitable for correcting or optimizing the performance in each of these actions. The use of the Multimodal Tutor and its underpinning technological frameworks (Multimodal Pipeline) and conceptual model (Multimodal Learning Analytics Model) provide *flexibility* and *multi-purposeness*, pushing forward the entire MMLA field. By explaining how to support learning using multimodal data, the Multimodal Tutor generates scientific added value for different data-driven learning research communities, like the Learning Analytics & Knowledge and the Intelligent Tutoring System / Artificial Intelligence in Education. Ultimately, the Multimodal Tutor set the way for more “emerging” fields of research such as *Hybrid Intelligence* (Kamar, 2016), *Social Artificial Intelligence*, or Social Robotics (Kanda & Ishiguro, 2017) that are concerned how to best interface human communication with artificial (robotic) intelligence.

---

## Limitations

Among many advancements in MMLA research, the Multimodal Tutor still carries some limitations. First and foremost, the Multimodal Tutor consists still in a set of research prototypes not ready to be launched in the market as fully working products. There has to be extensive testing, quality-checking, or control of the existing functionalities to achieve production-ready software. Within the research applications of the Multimodal Tutor, there exist also additional limitations which can be divided into different levels: (1) learning domain level, (2) hardware level, (3) software level, (4) data level, and (5) model level.

At the *learning domain level*, we have been focusing primarily on CPR training, which is a common type of medical simulation. Related research using the components of the Pipeline have been created for Presentation Trainer (Schneider, Börner, van Rosmalen, & Specht, 2015), Calligraphy Tutor (Limbu, Schneider, Klemke, & Specht, 2018), and Tennis Table Tutor (Sanusi, Di Mitri, Limbu, & Klemke, 2021). We group all these learning tasks as *individual psychomotor learning tasks in the physical space*, i.e., practical training tasks where the learner has to individually master skills that require a high level of psychomotor coordination that takes place in the physical realm. For this reason, in this subset, we intentionally left out learning scenarios such as *cognitive learning*, i.e., tasks that require more reasoning and

cognitive abilities, or *social learning*, tasks that require interaction by multiple actors and or by groups, or *distance and online learning*, including activities mediated by mouse and keyboards. We decided to narrow the focus to make the research contribution of the Multimodal Tutor more evident to the community. At the same time, we believe the boundaries of these scenarios are blurry; therefore, the proposed categorization may run into inconsistency. As specified in the next section, we firmly believe that in the future, the Multimodal Tutor can evolve to support also different types of learning scenario outside of its current focus. Modeling the learning task is a fundamental part of assessing how the Multimodal Tutor can be most supportive. Psychomotor learning tasks can differ primarily by two factors: (1) by their *repetitiveness* and (2) by their *structuredness*. Learning how to perform chest compressions during CPR is a highly repetitive learning task, as the learner needs to perform repetitive movements; at the same time, CPR is highly structured, as there are apparent performance indicators that define the characteristics of a good CPR performance. These two characteristics make CPR an ideal application scenario for the Multimodal Tutor. On the contrary, the calligraphy or foreign alphabet learning in the Calligraphy Tutor consists of repetitive tasks without clear performance indicators. The domain of public speaking of the Presentation Trainer consists of diverse and not repetitive movements which lack clear performance indicators for assessment.

At the *sensor hardware-level*, the quality of the collected data, the quality of the model training significantly, and thus of the feedback can be influenced. In the CPR Tutor and related reference application scenarios, we opted for commercial sensor devices in place of custom-made boards. Compared to custom-made boards, sensor devices such as Microsoft Kinect, Myo Armband, or Fitbit HR have the advantage of being widely tested, providing high-level drivers and having an API to connect and offer broad community support easily. Still, however, commercial devices have known limitations in terms of precision. In this research, we realized that the choice of the sensor setup should be based on compromises between precision, easiness of use, and relevance for the learning task investigated.

The third level concerns the limitations at the *software level*. The CPR Tutor and the LearningHub have been programmed using C# programming language that runs on Microsoft Windows 10 machines. The reason for such a choice was to make the best use of Microsoft devices like Kinect. The VIT has been developed in Javascript and HTML 5 but tested primarily with the Google Chrome browser. SharpFlow has been developed using Python 3.7. These choices could compromise the portability of the software components on different operating systems, browsers, or platforms.

The fourth level of limitation is at the *data level*. As mentioned earlier, the precision and quality of the sensor devices can influence the quality of the data gathered. However, the data limitations lay also in the choice of the participant size and the diversity of these participants. Participants can have different body sizes, way to approach the task, and physiological responses. We call this the *inter-subject variability* among the participants. This variability can be mitigated by training a model with a diverse population, which can generalize their behavioral characteristics. There is, however, always the risk that the general model flushes out individual

peculiarities. As an alternative, it is possible to train one classifier for each participant. The drawback of this approach is that the models will be suitable only for one person and not generalizable to new participants.

Finally, some limitations can stand at the *model level*. There are several limitations to using the supervised machine learning approach. In CPR, the more collected CCs, the more robust and general neural networks can be trained for mistake classification. Such an approach is optimal when having a high number of annotated training samples available. Similarly, to set a clear division line between correct and incorrect learning performance, the learning task must have clear performance indicators. For example, in CPR, the compression rate needs to have between 100 and 120 beats per minute for being optimal. The machine learning research community well knows the drawback of supervised learning. There are alternative ways that can be explored to reduce the amount of annotated samples needed; those are unsupervised learning, one-shot learning, or transfer-learning techniques. Concerning the use of Recurrent Neural Networks, aside from the amount of training data, the other standard limitation is the tendency of *overfitting* the training set. Besides dividing the collected data set between training, test, validation, and performing cross-validation at the level of the training samples, it is essential to do it at the level of subject level. For example, it would be helpful to *hold-one-participant-out* to make sure that the data of one or more participants are entirely new and unseen by the model.

---

## Conclusion

In this chapter, the limitations can be seen as a research plan for the future implementations of the Multimodal Tutor. Future research endeavors should go both in the theoretical and in the technical directions. From the theoretical standpoint, as evidence in the literature survey in (Di Mitri et al., 2018a), future works of the Multimodal Tutor should also look into empirical studies and meta-analysis to focus on the most suitable data representation for each modality and propose guidelines for efficient modality combination. It could be helpful to know the best between modality and available sensors in commerce, providing guidelines for the data analysis of multimodal data sets.

The Multimodal Tutor “of the future,” the Multimodal Pipeline, will improve and evolve as a concept to accommodate more reference application scenarios. For instance, one aspect deliberately left out both from the theoretical and from the application side is the *social dimension of learning*: the extent to which the teacher and the learning peers influence each other in a social context. For example, during collaborative learning or physical classroom activities, social learning is of paramount importance. We think of the implementation of the Multimodal Tutor in the *Classroom of the Future*. Along the line of experimentation proposed by the *EduSense* prototype (Ahuja et al., 2019), the Classroom of The Future will embed a run-time framework which controls different sensors, for example, installed in

laptops, chairs, or desk and connect to various actuators such as the projector, the smart board, some lights. The purpose is to automatically orchestrate learning activities in the classroom. For this purpose, a renewed conceptualization of the Multimodal Pipeline as a framework that runs continually on run-time is needed (Schneider, Di Mitri, Drachsler, & Specht, 2019). From such a system, learners and teachers could profit, for example, the system could identify students at-risk. Along this line, the system *Lumilo* provides an inspiring example of real-time teaching support using augmented reality by identifying and signaling students at-risk to teachers with the help of “virtual hands” (Holstein, McLaren, & Aleven, 2018).

From the technical point of view, future implementation of the Multimodal Tutor can move away from collecting short and high-frequency data sessions toward more extended data collection periods, which can last days or weeks. In our vision, the Multimodal Tutor can become a *learning companion* that supports the learner throughout the entire duration of a course until the target skill is mastered correctly. For this reason, we imagine future personalized learning technologies like the Multimodal Tutor can be *on-demand*, *wherever* and *whenever* the learner needs them. The functionalities of the Multimodal Tutor should be embedded in personal devices such as smartphones or smartwatches, which can be at the learner’s fingertips. To become entirely ubiquitous, the Multimodal Tutor needs to better leverage cloud-based technologies. In that case, the learner would need only a device and an Internet connection for using the functionalities of the Multimodal Tutor for learning support. Given the significant amount and the data gathered from the sensors, sending the complete streams to the cloud might be an overhead for the network infrastructure. An option alternative to cloud computing that should be explored is *fog computing*, in which only relevant data or decisions are sent to the online server.

Future research of the Multimodal Tutor should look at improving the user experience from the learner perspective. As argued in this book chapter, self-reports, questionnaire, and user ratings are essential for collecting the learning labels necessary to annotate the multimodal experiences and allow the system to learn from historical data. Repeatedly asking the learner to answer a questionnaire or to submit a report can become, nevertheless, a pretty tiring task. Stratagems have to be thought to maximize usability and user retention, to mature the Multimodal Tutor from a research to a productivity tool.

Another paramount issue connected to the user experience is ensuring user privacy when collecting high-frequency and highly personal multimodal data. Future Multimodal Tutor applications need to be designed with better *privacy* features. For instance, they need to implement multiple privacy layers, consisting of features such as end-to-end encryption, authentication, or distributed data saving. The Multimodal Tutor should connect and use the concept of *Trusted Learning Analytics* (Drachsler & Greller, 2016). The learner has to become the ultimate authority over the data and the algorithms. The technology embedded in the Multimodal Tutor rather than judge and punish the learner should ultimately support and improve learning which is a fundamental part of human nature.

## Abstract

Essays are scholarly compositions with a specific focus on a phenomenon in question. They provide learners the opportunity to demonstrate in-depth understanding of a subject matter; however, evaluating, grading, and providing feedback on written essays are time consuming and labor intensive. Advances in automated assessment systems may facilitate the feasibility, objectivity, reliability, and validity of the evaluation of written prose as well as providing instant feedback during learning processes. Measurements of written text include observable components such as content, style, organization, and mechanics. As a result, automated essay scoring systems generate a single score or detailed evaluation of predefined assessment features. This chapter describes the evolution and features of automated scoring systems, discusses their limitations, and concludes with future directions for research and practice.

**Introduction**

Educational assessment is a systematic method of gathering information or artifacts about a learner and learning processes to draw inferences of the persons' dispositions (E. Baker, Chung, & Cai, 2016). Various forms of assessments exist, including single- and multiple-choice, selection/association, hot spot, knowledge mapping, or visual identification. However, using natural language (e.g., written prose or essays) is regarded as the most useful and valid technique for assessing higher-order learning processes and learning outcomes (Flower & Hayes, 1981). Essays are scholarly analytical or interpretative compositions with a specific focus on a phenomenon in question. Valenti, Neri, and Cucchiarelli (2003) as well as Zupanc and Bosnic (2015) note that written essays provide learners the opportunity to demonstrate higher order thinking skills and in-depth understanding of a subject matter. However, evaluating, grading, and providing feedback on written essays are time consuming, labor intensive, and possibly biased by an unfair human rater.

For more than 50 years, the concept of developing and implementing computer-based systems, which may support automated assessment and feedback of written prose, has been discussed (Page, 1966). Technology-enhanced assessment systems enriched standard or paper-based assessment approaches, some of which hold much promise for supporting learning processes and learning outcomes (Webb, Gibson, & Forkosh-Baruch, 2013; Webb & Ifenthaler, 2018). While much effort in institutional and national systems is focused on harnessing the power of technology-enhanced assessment approaches in order to reduce costs and increase efficiency (Bennett, 2015), a range of different technology-enhanced assessment scenarios have been the focus of educational research and development, however, often at small scale (Stödberg, 2012). For example, technology-enhanced assessments may involve a pedagogical agent for providing feedback during a learning process (Johnson & Lester, 2016). Other scenarios of technology-enhanced assessments include analyses of a learners' decisions and interactions during game-based learning (Bellotti, Kapralos, Lee, Moreno-Ger, & Berta, 2013; Kim & Ifenthaler, 2019), scaffolding for dynamic task selection including related feedback (Corbalan, Kester, & van Merriënboer, 2009), remote asynchronous expert feedback on collaborative problem-solving tasks (Rissanen et al., 2008), or semantic rich and personalized feedback as well as adaptive prompts for reflection through data-driven assessments (Ifenthaler & Greiff, 2021; Schumacher & Ifenthaler, 2021).

It is expected that such technology-enhanced assessment systems meet a number of specific requirements, such as (a) adaptability to different subject domains, (b) flexibility for experimental as well as learning and teaching settings,

(c) management of huge amounts of data, (d) rapid analysis of complex and unstructured data, (e) immediate feedback for learners and educators, as well as (f) generation of automated reports of results for educational decision-making.

Given the on-going developments in computer technology, data analytics, and artificial intelligence, there are advances in automated assessment systems, which may facilitate the feasibility, objectivity, reliability, and validity of the assessment of written prose as well as providing instant feedback during learning processes (Whitelock & Bektik, 2018). Accordingly, automated essay grading (AEG) systems, or automated essay scoring (AES systems, are defined as a computer-based process of applying standardized measurements on open-ended or constructed-response text-based test items. Measurements of written text include observable components such as content, style, organization, mechanics, and so forth (Shermis, Burstein, Higgins, & Zechner, 2010). As a result, the AES system generates a single score or detailed evaluation of predefined assessment features (Ifenthaler, 2016).

This chapter describes the evolution and features of automated scoring systems, discusses their limitations, and concludes with future directions for research and practice.

---

## Synopsis of Automated Scoring Systems

The first widely known automated scoring system, Project Essay Grader (PEG), was conceptualized by Ellis Battan Page in late 1960s (Page, 1966, 1968). PEG relies on proxy measures, such as average word length, essay length, number of certain punctuation marks, and so forth, to determine the quality of an open-ended response item. Despite the promising findings from research on PEG, acceptance and use of the system remained limited (Ajay, Tillett, & Page, 1973; Page, 1968). The advent of the Internet in the 1990s and related advances in hard- and software introduced a further interest in designing and implementing AES systems. The developers primarily aimed to address concerns with time, cost, reliability, and generalizability regarding the assessment of writing. AES systems have been used as a co-rater in large-scale standardized writing assessments since the late 1990s (e.g., e-rater by Educational Testing Service). While initial systems focused on English language, a wide variety of languages have been included in further developments, such as Arabic (Azmi, Al-Jouie, & Hussain, 2019), Bahasa Malay (Vantage Learning, 2002), Hebrew (Vantage Learning, 2001), German (Pirnay-Dummer & Ifenthaler, 2011), or Japanese (Kawate-Mierzejewska, 2003). More recent developments of AES systems utilize advanced machine learning approaches and elaborated natural language processing algorithms (Glavas, Ganesh, & Somasundaran, 2021).

For almost 60 years, different terms related to automated assessment of written prose have been used mostly interchangeably. Most frequently used terms are automated essay scoring (AES) and automated essay grading (AEG); however, more recent research used the term automated writing evaluation (AWE) and automated essay evaluation (AEE) (Zupanc & Bosnic, 2015). While the above-

mentioned system focuses on written prose including several hundred words, another field developed focusing on short answers referred to as automatic short answer grading (ASAG) (Burrows, Gurevych, & Stein, 2015).

---

## Functions of Automated Scoring Systems

AES systems mimic human evaluation of written prose by using various methods of scoring, that is, statistics, machine learning, and natural language processing (NLP) techniques. Implemented features of AES systems vary widely, yet they are mostly trained with large sets of expert-rated sample open-ended assessment items to internalize features that are relevant to human scoring. AES systems compare the features in training sets to those in new test items to find similarities between high/low scoring training and high/low scoring new ones and then apply scoring information gained from training sets to new item responses (Ifenthaler, 2016).

The underlying methodology of AES systems varies; however, recent research mainly focuses on natural language processing approaches (Glavas et al., 2021). AES systems focusing on content use Latent Semantic Analysis (LSA) which assumes that terms or words with similar meaning occur in similar parts of written text (Wild, 2016). Other content-related approaches include Pattern Matching Techniques (PMT). The idea of depicting semantic structures, which include concepts and relations between the concepts, has its source in two fields: semantics (especially propositional logic) and linguistics. Semantic oriented approaches include Ontologies and Semantic Networks (Pirnay-Dummer, Ifenthaler, & Seel, 2012). A semantic network represents information in terms of a collection of objects (nodes) and binary associations (directed labeled edges), the former standing for individuals (or concepts of some sort), and the latter standing for binary relations over these. Accordingly, a representation of knowledge in a written text by means of a semantic network corresponds with a graphical representation where each node denotes an object or concept, and each labeled being one of the relations used in the knowledge representation. Despite the differences between semantic networks, three types of edges are usually contained in all network representation schemas (Pirnay-Dummer et al., 2012): (a) Generalization: connects a concept with a more general one. The generalization relation between concepts is a partial order and organizes concepts into a hierarchy. (b) Individualization: connects an individual (token) with its generic type. (c) Aggregation: connects an object with its attributes (parts, functions) (e.g., wings – part of – bird). Another method of organizing semantic networks is partitioning which involves grouping objects and elements or relations into partitions that are organized hierarchically, so that if partition A is below partition B, everything visible or present in B is also visible in A unless otherwise specified (Hartley & Barnden, 1997).

From an information systems perspective, understood as a set of interrelated components that accumulate, process, store, and distribute information to support decision making, several preconditions and processes are required for a functioning AES system (Burrows et al., 2015; Pirnay-Dummer & Ifenthaler, 2010):

1. **Assessment scenario:** The assessment task with a specific focus on written prose needs to be designed and implemented. Written text is being collected from learners and from experts (being used as a reference for later evaluation).
2. **Preparation:** The written text may contain characters which could disturb the evaluation process. Thus, a specific character set is expected. All other characters may be deleted. Tags may be also deleted, as are other expected metadata within each text.
3. **Tokenizing:** The prepared text gets split into sentences and tokens. Tokens are words, punctuation marks, quotation marks, and so on. Tokenizing is somewhat language dependent, which means that different tokenizing methods are required for different languages.
4. **Tagging:** There are different approaches and heuristics for tagging sentences and tokens. A combination of rule-based and corpus-based tagging seems most feasible when the subject domain of the content is unknown to the AES system. Tagging and the rules for it is a quite complex field of linguistic methods (Brill, 1995).
5. **Stemming:** Specific assessment attributes may require that flexions of a word will be treated as one (e.g., the singular and plural forms “door” and “doors”). Stemming reduces all words to their word stems.
6. **Analytics:** Using further natural language processing (NLP) approaches, the prepared text is analyzed regarding predefined assessment attributes (see below), resulting in models and statistics.
7. **Prediction:** Further algorithms produce scores or other output variables based on the analytics results.
8. **Veracity:** Based on available historical data or reference data, the analytics scores are compared in order to build trust and validity in the AES result.

Common assessment attributes of AES have been identified by Zupanc and Bosnic (2017) including linguistic (lexical, grammar, mechanics), style, and content attributes. Among 28 lexical attributes, frequencies of characters, words, sentences are commonly used. More advanced lexical attributes include average sentence length, use of stopwords, variation in sentence length, or the variation of specific words. Other lexical attributes focus on readability or lexical diversity utilizing specific measures such as Gunning Fox index, Nominal ratio, Type-token-ratio (DuBay, 2007). Another 37 grammar attributes are frequently implemented, such as number of grammar errors, complexity of sentence tree structure, use of prepositions and forms of adjectives, adverbs, nouns, verbs. A few attributes focus on mechanics, for example, the number of spellchecking errors, the number of capitalization errors, or punctuation errors. Attributes that focus on content include similarities with source or reference texts or content-related patterns (Attali, 2011). Specific semantic attributes have been described as concept matching and proposition matching (Ifenthaler, 2014). Both attributes are based on similarity measures (Tversky, 1977). Concept matching compares the sets of concepts (single words) within a written text to determine the use of terms. This measure is especially important for different assessments which operate in the same domain. Propositional matching compares only fully identical propositions between two knowledge

representations. It is a good measure for quantifying complex semantic relations in a specific subject domain. Balanced semantic matching measure uses both concepts and propositions to match the semantic potential between the knowledge representations. Such content or semantic oriented attributes focus on the correctness of content and its meaning (Ifenthaler, 2014).

---

## Overview of Automated Scoring Systems

Instructional applications of automated scoring systems are developed to facilitate the process of scoring and feedback in writing classrooms. These AES systems mimic human scoring by using various attributes; however, implemented attributes vary widely.

The market of commercial and open-source AES systems has seen a steady growth since the introduction of PEG. The majority of available AES systems extract a set of attributes from written prose and analyze it using some algorithm to generate a final output. Several overviews document the distinct features of AES systems (Dikli, 2011; Ifenthaler, 2016; Ifenthaler & Dikli, 2015; Zupanc & Bosnic, 2017). Burrows et al. (2015) identified five eras throughout the almost 60 years of research in AES: (1) concept mapping, (2) information extraction, (3) corpus-based methods, (4) machine learning, and (5) evaluation.

Zupanc and Bosnic (2017) note that four commercial AES systems have been predominant in application: PEG, e-rater, IEA, and IntelliMetric. Open access or open code systems have been available for research purposes (e.g., AKOVIA); however, they are yet to be made available to the general public. Table 1 provides an overview of current AES systems, including a short description of the applied assessment methodology, output features, information about test quality, and specific requirements. The overview is far from being complete; however, it includes major systems which have been reported in previous summaries and systematic literature reviews on AES systems (Burrows et al., 2015; Dikli, 2011; Ifenthaler, 2016; Ifenthaler & Dikli, 2015; Ramesh & Sanampudi, 2021; Zupanc & Bosnic, 2017). Several AES systems also have instructional versions for classroom use. In addition to their instant scoring capacity on a holistic scale, the instructional AES systems are capable of generating diagnostic feedback and scoring on an analytic scale as well. The majority of AES systems use focus on style or content-quality and use NLP algorithms in combination with variations of regression models. Depending on the methodology, AES system requires training samples for building a reference for future comparisons. However, the test quality, precision, or accuracy of several AES systems is publicly not available or has not been reported in rigorous empirical research (Wilson & Rodrigues, 2020).

---

## Open Questions and Directions for Research

There are several concerns regarding the precision of AES systems and the lack of semantic interpretation capabilities of underlying algorithms. Reliability and validity of AES systems have been extensively investigated (Landauer, Laham, & Foltz,

**Table 1** Overview of AES systems

AES system	Methodology	Output	Quality	Requirements
<b>CRASE</b>	Statistics and NLP; machine learning; style and content-quality	Score on an essay, short constructed response item, and graphic item	N/A	75 responses for training samples and 500 responses for cross-validation
<b>IEA</b>	LSA, NLP, machine learning, content quality	Score, customizable dashboard	Reliability and validity studies	100–300 training samples
<b>e-rater</b>	NLP, linear regression, style and content quality	Holistic and analytic score; immediate feedback on traits through its instructional application (Criterion)	Reliability and validity studies	465 training samples
<b>Benchmark-SkillWriter</b>	NLP, neural networks, style and content quality	Analytic scores, rubric scales, and immediate feedback	Reliability and validity studies	N/A
<b>IntelliMetric</b>	NLP, statistical model, style and content quality	Holistic and analytic score, immediate feedback on traits through its instructional application (MY Access)	Reliability and validity studies	300 training samples
<b>AKOVIA</b>	NLP, statistical model, similarity matching, structure and content quality	Customizable feedback including immediate score, written and graphical feedback	Reliability and validity studies	None, requires reference text/model
<b>PEG</b>	Statistical model, style	Holistic and analytic scoring; immediate feedback on traits through its instructional application (PEG Writing)	Reliability and validity studies	100–400 training samples
<b>Markit</b>	NLP, pattern matching, linear regression, content quality	Score on an essay	N/A	1 reference essay
<b>LightSIDE</b>	Machine learning, multilevel modeling techniques; content-quality	Score on an essay	N/A	300 training samples

(continued)

**Table 1** (continued)

AES system	Methodology	Output	Quality	Requirements
<b>Lexile</b>	NLP, Lexile measure, style and content quality	Score on text characteristics	N/A	0
<b>SAGrader</b>	Fuzzy logic, rule-based analysis, semantics	Score on semantics, immediate feedback through its instructional application	N/A	0
<b>BETSY</b>	Bayesian text classification, style and content quality	Trait scoring and feedback	Reliability and validity studies	1000 training samples

*Note.* NLP = Natural Language Processing; LSA = Latent Semantic Analysis

2003; Shermis et al., 2010). The correlations and agreement rates between AES systems and expert human raters have been found to be fairly high; however, the agreement rate is not at the desired level yet (Gierl, Latifi, Lai, Boulais, & Champlain, 2014). It should be noted that many of these studies highlight the results of adjacent agreement between humans and AES systems rather than those of exact agreement (Ifenthaler & Dikli, 2015). Exact agreement is harder to achieve as it requires two or more raters to assign the same exact score on an essay while adjacent agreement requires two or more raters to assign a score within one scale point of each other. It should also be noted that correlation studies are mostly conducted at high-stakes assessment settings rather than classroom settings; therefore, AES versus human inter-rater reliability rates may not be the same in specific assessment settings. The rate is expected to be lower in the latter since the content of an essay is likely to be more important in low-stakes assessment contexts.

The validity of AES systems has been critically reflected since the introduction of the initial applications (Page, 1966). A common approach for testing validity is the comparison of scores from AES systems with those of human experts (Attali & Burstein, 2006). Accordingly, questions arise about the role of AES systems promoting purposeful writing or authentic open-ended assessment responses, because the underlying algorithms view writing as a formulaic act and allows writers to concentrate more on the formal aspects of language such as origin, vocabulary, grammar, and text length with little or no attention to the meaning of the text (Ifenthaler, 2016). Validation of AES systems may include the correct use of specific assessment attributes, the openness of algorithms, and underlying aggregation and analytics techniques, as well as a combination of human and automated approaches before communicating results to learners (Attali, 2013). Closely related to the issue of validity is the concern regarding reliability of AES systems. In this context, reliability assumes that AES systems produce repeatedly consistent scores within and across different assessment conditions (Zupanc & Bosnic, 2015). Another concern is the bias of underlying algorithms, that is, algorithms have their source

in a human programmer which may introduce additional error structures or even features of discrimination (e.g., cultural bias based on selective text corpora). Criticism has been put toward commercial marketing of AES systems for speakers of English as a second or foreign language (ESL/EFL) when the underlying methodology has been developed based on English language with native-English speakers in mind. In an effort to assist ESL/EFL speakers in writing classrooms, many developers have incorporated a multilingual feedback function in the instructional versions of AES systems. Receiving feedback in the first language has proven benefits, yet it may not be sufficient for ESL/EFL speakers to improve their writing in English. It would be more beneficial for non-native speakers of English if developers take common ESL/EFL errors into consideration when they build algorithms in AES systems. Another area of concern is that writers can trick AES systems. For instance, if the written text produced is long and includes certain type of vocabulary that the AES system is familiar with, an essay can receive a higher score from AES regardless of the quality of its content. Therefore, developers have been trying to prevent cheating by users through incorporating additional validity algorithms (e.g., flagging written text with unusual elements for human scoring) (Ifenthaler & Dikli, 2015). The validity and reliability concerns result in speculations regarding the credibility of AES systems considering that the majority of the research on AES is conducted or sponsored by the developing companies. Hence, there is a need for more research that addresses the validity and reliability issues raised above and preferably those conducted by independent researchers (Kumar & Boulanger, 2020).

Despite the above-mentioned concerns and limitation, educational organizations choose to incorporate instructional applications of AES systems in classrooms, mainly to increase student motivation toward writing and reducing workload of involved teachers. They assume that if AES systems assist students with the grammatical errors in their writings, teachers will have more time to focus on content related issues. Still, research on students' perception on AES systems and the effect on motivation as well as on learning processes and learning outcomes is scarce (Stephen, Gierl, & King, 2021). In contrast, educational organizations are hesitant in implementing AES systems mainly because of validity issues related to domain knowledge-based evaluation. As Ramesh and Sanampudi (2021) exemplify, the domain-specific meaning of "cell" may be different in biology or physics. Other concerns that may lower the willingness to adopt of AES systems in educational organizations include fairness, consistency, transparency, privacy, security, and ethical issues (Ramineni & Williamson, 2013; Shermis, 2010).

AES systems can make the result of an assessment available instantly and may produce immediate feedback whenever the learner needs it. Such instant feedback provides autonomy to the learner during the learning process, that is, learners are not depended on possibly delayed feedback from teachers. Several attributes implemented in AES systems can produce an automated score, for instance, correctness of syntactic aspects. Still, the automated and informative feedback regarding content and semantics is limited. Alternative feedback mechanisms have been suggested, for example, Automated Knowledge Visualization and

Assessment (AKOVIA) provides automated graphical feedback models, generated on the fly, which have been successfully tested for prelection and reflection in problem-based writing tasks (Lehmann, Haehnlein, & Ifenthaler, 2014). Other studies using AKOVIA feedback models highlight the benefits of availability of informative feedback whenever the learner needs it and its identical impact on problem solving when compared with feedback models created by domain experts (Ifenthaler, 2014).

Questions for future research focusing on AES systems may focus on (a) construct validity (i.e., comparing AES systems with other systems or human rater results), (b) interindividual and intraindividual consistency and robustness of AES scores obtained (e.g., in comparison with different assessment tasks), (c) correlative nature of AES scores with other pedagogical or psychological measures (e.g., interest, intelligence, prior knowledge), (d) fairness and transparency of AES systems and related scores, as well as (e) ethical concerns related to AES systems, (f) (Elliot & Williamson, 2013). From a technological perspective, (f) the feasibility of the automated scoring system (including training of AES using pre-scored, expert/reference, comparison) is still a key issue with regard to the quality of assessment results. Other requirements include the (g) instant availability, accuracy, and confidence of the automated assessment. From a pedagogical perspective, (h) the form of the open-ended or constructed-response test needs to be considered. The (i) assessment capabilities of the AES system, such as the assessment of different languages, content-oriented assessment, coherence assessment (e.g., writing style, syntax, spelling), domain-specific features assessment, and plagiarism detection, are critical for a large-scale implementation. Further, (j) the form of feedback generated by the automated scoring system might include simple scoring but also rich semantic and graphical feedback. Finally, (k) the integration of an AES system into existing applications, such as learning management systems, needs to be further investigated by developers, researchers, and practitioners.

---

## Implications for Open, Distance, and Digital Education

The evolution of Massive Open Online Courses (MOOCs) nurtured important questions about online education and its automated assessment (Blackmon & Major, 2017; White, 2014). Education providers such as Coursera, edX, and Udacity dominantly apply so-called auto-graded assessments (e.g., single- or multiple-choice assessments). Implementing automated scoring for open-ended assessments is still on the agenda of such providers, however, not fully developed yet (Corbeil, Khan, & Corbeil, 2018).

With the increased availability of vast and highly varied amounts of data from learners, teachers, learning environments, and administrative systems within educational settings, further opportunities arise for advancing AES systems in open, distance, and digital education. Analytics-enhanced assessment enlarges standard

methods of AES systems through harnessing formative as well as summative data from learners and their contexts in order to facilitate learning processes in near real-time and help decision-makers to improve learning environments. Hence, analytics-enhanced assessment may provide multiple benefits for students, schools, and involved stakeholders. However, as noted by Ellis (2013), analytics currently fail to make full use of educational data for assessment.

Interest in collecting and mining large sets of educational data on student background and performance has grown over the past years and is generally referred to as learning analytics (R. S. Baker & Siemens, 2015). In recent years, the incorporation of learning analytics into educational practices and research has further developed. However, while new applications and approaches have brought forth new insights, there is still a shortage of research addressing the effectiveness and consequences with regard to AES systems. Learning analytics, which refers to the use of static and dynamic data from learners and their contexts for (1) the understanding of learning and the discovery of traces of learning and (2) the support of learning processes and educational decision-making (Ifenthaler, 2015), offers a range of opportunities for formative and summative assessment of written text. Hence, the primary goal of learning analytics is to better meet students' needs by offering individual learning paths, adaptive assessments and recommendations, or adaptive and just-in-time feedback (Gašević, Dawson, & Siemens, 2015; McLoughlin & Lee, 2010), ideally, tailored to learners' motivational states, individual characteristics, and learning goals (Schumacher & Ifenthaler, 2018). From an assessment perspective focusing on AES systems, learning analytics for formative assessment focuses on the generation and interpretation of evidence about learner performance by teachers, learners, and/or technology to make assisted decisions about the next steps in learning and instruction (Ifenthaler, Greiff, & Gibson, 2018; Spector et al., 2016). In this context, real- or near-time data are extremely valuable because of their benefits in ongoing learning interactions. Learning analytics for written text from a summative assessment perspective is utilized to make judgments that are typically based on standards or benchmarks (Black & Wiliam, 1998).

In conclusion, analytics-enhanced assessments of written essays may reveal personal information and insights into an individual learning history; however, they are not accredited and far from being unbiased, comprehensive, and fully valid at this point in time. Much remains to be done to mitigate these shortcomings in a way that learners will truly benefit from AES systems.

### Abstract

Online instructors draw upon a complex set of skills, activities, and values to meet the needs of students who are separated from them by time and/or space, but united with them through digital technologies. Berge (1995) introduced the idea that the instructor's job could be represented through four interrelated roles: pedagogical, managerial, social, and technological. Instructors who develop expertise in all four of these dimensions are well-situated for supporting online students, who similarly must navigate these dimensions. This chapter explores each of these roles and their relationship to online learning. Two additional areas of concern for online instructors, the ethical dimension and the networked dimension, are also discussed.

## Introduction

*Instructors teach.* That sentence is, of course, an oversimplification focused on the intended outcome of their work. If students are to learn, instructors are expected to teach. Teaching is the instructor's primary activity, but the full constellation of tasks that an online instructor must undertake in support of teaching are more varied and nuanced.

Berge (1995) initiated the conversation on what roles online instructors should expect to fulfill for their students. The four roles that he listed – pedagogical, social, managerial, and technological – provided guidance for early online instructors who sought to understand their students' needs. These roles were born out of Berge's experiences and observations and went on to serve as the framework for various studies that followed (e.g., Bonk, Kirkley, Hara, & Dennen, 2001; Dennen, Bagdy, Arslan, Choi, & Liu, 2021; Gómez-Rey, Barbera, & Fernández-Navarro, 2018; Liu, Bonk, Magjuka, Lee, & Su, 2005).

Renewed interest in online instructor roles arose during the first year of the COVID-19 pandemic, when educational institutions swiftly moved to remote (and often online) learning formats. At that time, instructors were not only challenged to provide learning content and assessments online, but also to support online students along both social and technical dimensions (König, Jäger-Biela, & Glutsch, 2020). The modality shift also posed new pedagogical challenges, reflecting the systemic nature of instructor competencies. Knowledge of content, pedagogy, and technology as isolated fields is insufficient for instructor success; rather it is at their intersection that robust learning is best supported (Mishra & Koehler, 2006). Various studies reporting instructional shifts during the pandemic highlighted the challenges instructors faced when navigating new roles (e.g., Dennen et al., 2021; Rapanta, Botturi, Goodyear, Guàrdia, & Koole, 2021).

This chapter discusses research on the roles of the online instructor using the four dimensions of Berge's (1995, 2008) framework as a primary organizing element. In addition, two dimensions that are not often discussed in conjunction with the existing roles – the ethical and the networked dimensions – are introduced for consideration. These two dimensions do not align directly with any single existing role but rather overlap with several of them, which is consistent with Berge's (2008) view of the roles. These additional dimensions and their underlying functions encourage individuals to reflect on the increased complexity of online learning contexts that have co-developed with advances in online learning pedagogy and technology. Collectively, all six areas – pedagogical, managerial, social, technological, ethical, and network – represent competencies that are needed by online instructors.

---

## Background and Context

One of the first things people think about when considering online learning is the transactional distance. Transactional distance, a concept first introduced by Moore (1993), is the perception that instructors and students are separated from each by

time and space, creating an interaction gulf that is exacerbated by reliance on computer-mediated interactions and a reduction in communication channels or cues when compared to physical classroom settings. This perceived distance can lead to individuals feeling isolated in online learning spaces. However, instructors can work to reduce the perception of distance by fostering a highly interactive environment, which might include instructor-learner and learner-learner interactions in addition to learner-content interactions (Moore, 1989). After all, without these human interactions, an online course effectively becomes a correspondence course.

Planning for interactions is not enough to foster positive online learning experiences for students. Students needs vary widely, and instructors are challenged to engage students across the cognitive, affective, and behavioral dimensions (Martin & Borup, 2022). In a systematic review of research on blended learning, the following issues that affect student performance in online contexts were identified: self-regulation, technology (literacy, self-sufficiency, and complexity), and isolation (Rasheed, Kamsin, & Abdullah, 2020). Each of these areas can be broken down into smaller, more specific challenges students face. Online instructors need to be attuned to these challenges and develop skills to help mitigate the challenges.

The concept of instructor roles, notwithstanding Berge's (1995, 2008) framework, can be challenging to neatly define. Various researchers have sought to describe the concept of instructor role, as can be seen in the following examples:

- In an effort to measure student perceptions of instructor roles, M.-L. Hung and Chou (2015) developed and validated the Online Instructor Role and Behavior Scale (OIRBS). OIRBS contains five subscales: course designer and organizer, discussion facilitator, social supporter, technology facilitator, and assessment designer. These constructs overlap with Berge's framework along two dimensions (social and technology) but consider pedagogical and managerial tasks in different ways.
- Alvarez, Guasch, and Espasa (2009), through an analysis of the literature, suggested five roles. Three were the identical to Berge's framework, but course design and cognitive roles were listed in lieu of the pedagogical role.
- Bawane and Spector (2009) studied eight roles, finding that three of the top four roles (pedagogical, social, technological, and evaluator) aligned with Berge's framework.
- A systematic literature review by Baran, Correia, and Thompson (2011) added two roles to Berge's framework, instructional design, and facilitator. However, as their review notes, these are not always distinct roles. For example, one might consider the instructional designer role to be subsumed by the pedagogical role, and Berge (1995, 2008) directly states that facilitation is part of the pedagogical role.
- Martin, Budhrani, Kumar, and Ritzhaupt (2019) found that instructor roles and tasks vary across institutional contexts. Larger, better-staffed institutions may provide greater support structures, and as a result instructors may be able to rely on other staff to perform certain tasks.

Regardless of the terminology, framework, and task definitions and groupings that are used, online instructors undeniably have multifaceted job duties that draw upon diverse areas of expertise. Most of the scholarly work about instructor roles, including the aforementioned studies, either situates itself in or references and builds upon Berge's (1995, 2008) framework. Thus, Berge's framework will be used to structure the discussion of instructor roles.

---

## Pedagogical Role

The pedagogical role is the role that is most commonly associated with online instruction and has been deemed the primary or most important of the roles (Bawane & Spector, 2009; Gómez-Rey, Barbera, & Fernández-Navarro, 2017). Most scholars include tasks related to course design and facilitation as part of the pedagogical role, although some may parse roles more finely and discuss facilitation or instructional design separately from pedagogy, implying that the method of teaching is somehow separate from, although undeniably interdependent on, these other two areas.

Berge (2008) states that facilitation is an essential component of the pedagogical role. Facilitation entails not only helping students navigate course materials and activities but interacting with them and fostering peer interactions as described by Moore (1989). Scholars have been exploring online facilitation competencies since the early days of online learning, with the recognition that there is no singular approach, but rather a multitude of facilitation styles and skills (e.g., advisor, assessor, researcher) that an instructor may draw on (Goodyear, Salmon, Spector, Steeples, & Tickner, 2001).

Facilitation is often a responsive task, occurring when an instructor reacts to students over the course of a semester, but good facilitation is based on a plan and builds on a solid foundation of course design. Thus, while instructional approaches vary and course design may or may not be undertaken by instructors and considered part of the pedagogical role (e.g., Gómez-Rey et al., 2017 view design as separate from pedagogy, but Liu et al., 2005 include design as part of pedagogy), course design is nonetheless critical to the work of an online instructor (Martin, Sun, & Westine, 2020), and in particular their pedagogical tasks.

It may be futile to try to determine whether course design or facilitation is more important. In practice, the two tasks are interrelated but are recognized by instructors and students in different ways. In a study that compared instructor and student perceptions, instructors were more focused on course design and feedback, whereas students rated facilitation and communication as factors most likely to contribute to their success (Dennen, Darabi, & Smith, 2007). These findings suggest that instructors should not neglect facilitation and focus on course design, but instead they should factor facilitation and formative points of instructor-student communication into their course design. Additionally, students may not consider course design as important as course facilitation, because good facilitation is the element that connects students to course activities and materials. Instructors with strong facilitation skills may be able to compensate for poor course design, whereas good course

design may not be sufficient to overcome the ill effects of poor facilitation. This premise was discovered by many instructors during the early parts of the COVID-19 pandemic. When these instructors made a rapid shift to remote teaching via online technologies, they learned that designing and delivering course content was not the only or even the most important pedagogical task. Instead, instructors needed to consider how students would interact within the course and provide opportunities for engagement (Rapanta et al., 2021).

Together, instructional design and facilitation shape the way that students perceive activities and engage in a class. Whereas the course design includes not only content but also learning activities and assessments and sets up the overall expectations for what students will do, instructors communicate their pedagogical values and expectations to students through facilitation. Ma, Han, Yang, and Cheng (2015) found that course design has an effect on how students access learning materials in an online course, but that interactions and guidance affect how students complete learning tasks. Further, the manner and frequency of instructor interaction with students can be planned and affects how students approach learning activities (Dennen, 2005). When instructors are absent from interaction spaces, students will assume their work in those spaces is not valued or monitored, likening it to busy-work. Alternately, when instructors are overly dominant in the learning space, students will orient closely toward the instructor and may seek continuous instructor affirmation and place less value on peer interactions. Although this may sound like an ideal situation for students, as the dominant instructor in Dennen's (2005) study learned, it is not a sustainable solution.

Looking to the future, more work might be done to support the needs of diverse student populations in online environments. Although little studied at this time, students from different backgrounds and cultures will likely benefit when their instructors embrace anti-oppressive pedagogies and promote critical awareness through reflection and discussion (Migueliz Valcarlos, Wolgemuth, Haraf, & Fisk, 2020). This recommendation is consistent with the notion that course design and pedagogical decisions made by instructors should be flexible and empower students (Rapanta et al., 2021).

---

## Managerial Role

The instructor's managerial role, alternately referred to as the administrative role, refers to course oversight. Berge (1995) suggested that this role is associated with managing objectives, time, and structural components of learning activities. In this sense, one can see a direct connection between the pedagogical role and the managerial role. Whereas the former is concerned directly with how students make meaning out of their course experiences, the latter provides the supporting structures and conditions for successful pedagogy.

Bonk et al. (2001) elaborated on Berge's (1995) description of the managerial role with concrete examples from four cases. Under the managerial role, instructors engaged in tasks such as determining the class schedule and deadlines; planning

and assigning groups; evaluating and revising parts of the course; and providing students with regular announcements and updates (Bonk et al., 2001). In this sense, the managerial role intersects directly with the instructional design process and includes localized tasks related to setting up and running each unique course offering. When these elements are in place at the start of a course, the instructor is better able to focus on student engagement and their pedagogical role (Arbaugh, 2010). Gómez-Rey et al. (2017) found that the importance or uniqueness of the managerial role for the online instructor has subsided in recent years, likely due to improvements in course design and technology.

Course-level administrative tasks also fall under the managerial role. A major task for online instructors is setting up the learning space, whether within an LMS or some other tool (Berge, 2008). Instructors also need to organize, provide access to, and monitor files and file sharing spaces (Alvarez et al., 2009). Course oversight may also require collecting and reporting data to other institutional offices, such as attendance dates and student learning outcomes. These data may be used to support institutional research and for accountability reporting to government and accreditation agencies.

Digital learning spaces make it easy for instructors to monitor student data, such as log-ins, course material accesses, and assignment submission times. Interestingly, despite the heavy focus on learning analytics as a means of supporting learning and retention in recent years, in one study both instructors and students rated instructor monitoring of student course access as the least important activity contributing to student satisfaction (Dennen et al., 2007). Analytics are useful for identifying students who are absent or at risk of failure, but they are limited because they sit at the gateway of pedagogy. Still, this represents a growing area of research with the aim of amplifying an instructor's ability to meet both students' managerial and pedagogical needs. Perhaps with improvements in artificial intelligence, future analytic systems will be able to not only provide alerts for at-risk students but also suggest moment-by-moment facilitation strategies, also supporting the instructor's pedagogical function.

Even without using analytics, Berge (2008) suggested that instructors might monitor student interactions and intervene when students are not participating in the desired manner. In other words, instructors may need to monitor student attendance and progress in a course from an administrative perspective (e.g., maintaining attendance records) and communicate with students when their actions are not consistent with course expectations – not just for the absent or underperforming students, but for all students. For example, Berge (1995) suggests that instructors should manage students who dominate interaction spaces, encouraging them to sit back and listen more. These forms of monitoring and intervention may help uphold the course structure and foster student behaviors and a learning community that supports pedagogical functions, even if they do not directly contribute to learning.

Additionally, during their online learning journeys, students have needs at different institutional levels. The instructor's immediate sphere of influence is the micro-level, or the class, where learning is the main focus. However, an online instructor's tasks are not limited to learning or classroom-focused interventions. Online

instructors often serve as the face of the university for their students, who in some instances may never visit the physical campus. Although staff members and advisors may assist with admissions and guide students toward class enrolment, once students are registered for classes, the learning management system (LMS) becomes the entry point to the university and instructors become a primary point of contact.

However, students may need help with advising or other issues related to their degree program, in which case the instructor may directly help or may connect the student to someone who works at the mesolevel, such as a department administrator or advisor. Additionally, during the pursuit of learning, students may find themselves needing to access institutional or macrolevel resources, such as information technology, instructional technology, and the library. There are myriad other reasons why a student might need to access macrolevel resources, which typically include financial aid, career centers, student groups, and recreational services. Based on best practices in online learning, Quality Matters ([www.qualitymatters.org](http://www.qualitymatters.org)) recommends that online course instructors look beyond the microlevel needs of students and facilitate awareness of and access to macro- and mesoresources by providing links to these resources in the class's learning management system.

---

## Social Role

Initially stemming from an awareness of the need for faculty to facilitate discussions in online environments (Berge & Collins, 2000), the social role of online instructors has continued to evolve. Facilitation is common to both the pedagogical and social roles, although each role invokes a different skill set and focus. Just as virtual learning opportunities have expanded, the social role of online educators has grown to include both the formal and informal supporting of meaningful, cooperative student-faculty, and student-student relationships (Alvarez et al., 2009; Baran et al., 2011; Berge, 2008). Alvarez et al. (2009) suggested this more encompassing understanding of the social role of online instructors could be observed in the language and naming conventions that are frequently used for online educators. They noted that terms such as facilitator, coach, mediator, and moderator, which are commonly used as titles for online instructors, are all indicative of the rising value being placed on social functions.

Some explanations for the increasing focus on the social role of online instructors can be attributed to transactional distance (Moore, 1989) and the resulting awareness of the lack of a shared physical space (Varvel, 2007) and difficulties related to expressing sensory and emotional expressions (Guasch, Alvarez, & Espasa, 2010). However, as Baran et al. (2011) noted, as technologies continue to offer increasingly advanced and accessible opportunities for people to be more social, students who use these technologies have likely grown accustomed to being engaged as active participants in online environments. These developments and changing expectations may push some instructors to reflect on and change their beliefs and practices.

While the instructor's social role is often understood in terms of supporting and maintaining relationships between students and their peers, and between students

and their instructors, the process of creating these relationships involves nearly every aspect of the online learning environment. The practices associated with creating meaningful relationships often revolve around instructors' abilities to serve as guides throughout the learning process, to express empathy and understanding of their students' experiences, and to establish a sense of cohesion between the members of the class community (Bailey & Card, 2009; Guasch et al., 2010; W. C. Hung & Jeng, 2013). The social role of the instructor goes beyond the facilitation of interactions to also include the design and teaching practices that foster connectedness and identity congruence, or a shared sense of values, goals, and beliefs among the students (Hughes, 2007). In many online learning environments, these practices are rooted in social constructivism and are well-aligned with those who value student-centered approaches to learning (Berge, 1997; Berge & Collins, 2000; Varvel, 2007).

Although there is a need to situate some conversations about the social role of instructors contextually, Richardson and Lowenthal's (2017) discussion of strategies for establishing instructor social presence can be applied broadly as a way to support relationship-building in online learning environments. The three strategies they identified include the development of instructor personality or *persona*, a term they credit to Dennen (2007); the design of the course, most notably interactions and clear expectations; and the inclusion of intentional online communications, which they suggested continues to be the main way to establish social presence. Instructors must establish their own identity through various channels (Dennen & Arslan, 2022), serving as a model for their students to do likewise. Their presence in learning spaces, whether direct or indirect, indicates to students the importance and expectation of participating in these learning activities (Dennen, 2005). When students share their identity, they establish presence. Additionally, as instructors work toward best practices in online teaching, these strategies can be most effective when coupled with the understanding that the social aspects of an online class can be supportive of diverse student voices. By encouraging these voices to speak and be heard, instructors can foster more inclusive learning environments and an increased sense of belonging for learners who may feel marginalized.

Online instructors may initially see the social role as one that asks them to design and facilitate opportunities for students to form social and emotional bonds in order to improve satisfaction and motivation (Liu et al., 2005). While these practices are often associated with the affective domain of learning, the significance of the social role extends into the cognitive domain as well. When students feel as though they are part of the learning community and feel a sense of connection with each other and with their instructors, the environment becomes one that engages them with the learning outcomes, provides them with the opportunity to ask questions, and gives them the space to co-construct knowledge (Aragon, 2003; Liu et al., 2005).

---

## Technological Role

The technological role of the online instructor is one that continues to evolve. Berge (2008) suggested that the "ultimate technical goal is to make the technology transparent to the user" (p. 410) and that the online instructor is often the initial point of

contact for students with technical questions. As technologies have continued to expand, the technical skills and expected competencies of online instructors have increased as well. Online instructors often need to have plans in place to mitigate technical disruptions, system requirements, and learning curves (Berge, 2008), in addition to their focus on teaching. While some of the competencies related to the technical role can be measured through their practical applications, effective instruction goes beyond the instructor's abilities to implement and maintain the tools and platforms. Those instructors who are often seen as the most successful in online environments are the ones who are able to apply both their pedagogical and technological skills to improve instruction through the adoption of creative designs and innovative technologies that support the desired learning outcomes (Bailey & Card, 2009; W. C. Hung & Jeng, 2013).

In what Guasch et al. (2010) referred to as the technological domain, the technological role is more complex than the expected general knowledge related to computers, multimedia, and educational technologies. They noted that in their review of studies concerning online instructor competencies, the technological role, along with the managerial role, is unique in that it is associated with all the other roles and functions. As online instructors navigate the various roles, distinctions between technology and teaching become less defined and more intersectional. Rather than understanding the technological role as task-based and separate from the other roles, online instructors should work to bridge potential gaps between technology and teaching. Instructors must not only know how to work with the technologies, but also how to use the technologies in ways that support the chosen teaching and learning models (Alvarez et al., 2009; Guasch et al., 2010). Effective teaching in digital spaces relies on the instructor's awareness of the "mutually reinforcing" relationships between teaching, technology, and content (Koehler, Mishra, & Yahya, 2007).

Much like the competencies of the other roles, the competencies of the technological role tend to be understood by how they are applied (Alvarez et al., 2009), and the practical applications are often contextual (Gay, 2016). When asked to rank online instructor roles in order of importance, instructors placed the technological role toward the middle of the list (Bawane & Spector, 2009). Faculty also tend to report their technological skill level as lower than the importance of the skill, suggesting that they feel they still have room to learn and improve (Martin, Budhrani, & Wang, 2019). However, this prioritization varies across studies, though, depending on how technologist is defined, who is asked to provide the ranking, and which skills and abilities are considered essential (Egan & Akdere, 2005; Williams, 2003).

At the most basic level, online instructors should not only be comfortable using the learning systems provided by their institutions, but they should also be able to share and maintain content resources, troubleshoot both their own and their students' basic technical problems, and communicate with their students in a variety of ways. While considered fundamental, these practices are continuous and take a considerable amount of time throughout the preparation and teaching of the course. Beyond these essential competencies, online instructors also work to evaluate the ways in which technologies can enable and enhance the learning process. In the role of the

course technologist, instructors should be intentional with the technology solutions they choose and transparent with their students about how they should be used and what their expected benefits are. The best educational technologies are accessible and easy to navigate and offer solutions that improve teaching and learning, and online instructors are often the ones who can determine how well technologies meet those criteria.

---

## Ethical Dimension

None of the prior four roles explicitly discusses ethical issues related to online learning, although ethical concerns may arise in pedagogical, managerial, social, and technological contexts. The instructor's ethical role has two sides. First, the instructor has an ethical obligation to meet the needs of their students, which includes considering issues of access and equity. Instructors are models and arbiters of ethical behavior for their online students, setting the expectations and tone for their classes. Second, online instructors should strive to minimize discomfort related to learning in online spaces, which may occur due to concerns with privacy, intellectual property, and context collapse.

Prior online learning research has discussed issues of access and equity mostly at the macrolevel (Martin et al., 2020). While societal and institutional actions, which may focus on ensuring an institution has a diverse student population and fosters cross-cultural exchange, are important, the online instructor's ethical purview must operate within the microlevel of the individual class. Access and equity are not ethical issues unique to online learning, but they can be exacerbated by it. In contrast to views that learning via digital tools can lead to the democratization of education (Semerikov et al., 2020), other scholars have shown they can also widen gulfs. Technology is not a neutral force in online learning (Migueliz Valcarlos et al., 2020). The COVID-19 pandemic laid bare some of the digital inequities that students may face, not all of which are explained by socioeconomic status. Some of the issues that arose included loss of access to campus-based learning resources such as computer labs, libraries, and Internet, and home bandwidth or environmental conditions that were not conducive to completing coursework. While these situations were temporary and occurred during a time when instructors were heavily encouraged to make accommodations for struggling students, they nonetheless represent inequities and highlight the potential fragility or volatility of online learning access.

In nonpandemic times, students in rural areas often suffer from bandwidth problems and students with older devices and software may struggle to complete assignments. Additionally, instructors need to pay attention to tool accessibility issues. Some learning tools may be unavailable to or unable to be used by some students due to disabilities, geography (e.g., some online tools are blocked in China), or technological limitations (e.g., smartphone-only apps). Institutional guidelines and instructional technology support staff may help instructors navigate these challenges, but even learning management systems that are adopted institutionally

require additional instructor knowledge and effort to be used in ways that minimize access problems.

Other scenarios that have historically excluded or diminished the learning opportunities of some online students include rigid temporal expectations. Many online students choose the modality because of its flexibility. However, when instructors hold synchronous sessions for a class that was meant to be asynchronous, require groupwork without providing time and guidance for completing the work, or set rigid participation deadlines (e.g., posting to a discussion on specific days of the week), students who became online students because they needed temporal flexibility may find themselves at a disadvantage. These situations may occur in the classes of well-intentioned instructors who have valid pedagogical or social reasons for their course design and expectations.

Supposing there are no issues related to access, instructors still need to grapple with concerns related to student comfort in the online learning environment. Students may be concerned with privacy, digital footprints (Dennen, 2015), and intellectual property issues (Dennen, 2016) in online learning environments. Instructors need to be able to provide assurance and guidance on these issues, reassuring students about who can see, save, and share their course contributions. When learning activities are limited to the semi-private confines of the LMS, some of these concerns may be mitigated, although instructors still need to provide leadership in this area and set expectations that help respect student privacy (e.g., *no screenshotting and sharing discussion posts*). When learning activities extend beyond the LMS, occurring on social media or when students need to share contact information or use personal accounts to access learning spaces, some students may experience discomfort due to context collapse, which occurs when personal and school life collides in digital spaces. Students have reported this phenomenon to be undesirable in prior research, and most prefer to keep their personal digital activities separate from school-related ones (Dennen & Burner, 2017).

Student comfort may also be diminished when students feel they do not belong in the class setting. This sense of othering can result in student disengagement and can be caused by students feeling they are different from their peers and, as a result, less valued in the class. Othering may occur due to ethnic, academic, or professional backgrounds (Phirangee & Malec, 2017), as well as differences in international location or origin (Choi, Arslan, Adolfson, & Screws, 2021). Instructor choices in all areas of online learning (e.g., epistemology, content, interaction, technology) wield power and have the potential to include or oppress different groups of students (Migueliz Valcarlos et al., 2020). In the ethical dimension, instructors should continuously consider the background and perspective of each student, ensuring that each is provided with activities, content, technologies, and interaction opportunities that empower them to succeed in the online class.

These ethical concerns span across the four established instructor roles. When students struggle to access or fully participate in a course or feel discomfort in the learning environment, they are affected along the pedagogical and social dimensions. Instructors have the potential and an ethical responsibility to modify their courses to be fully inclusive. Adjustments to course design, management (e.g.,

policies and oversight), and technologies may help minimize learning inequities, maximize student comfort, and help all students fully understand their learning options and behavioral expectations.

---

## Network Dimension

One of the exciting dimensions of online learning is the network dimension, which suggests that class boundaries can be more fluid and expansive than they are for classes meeting in physical spaces. The temporal and geographic boundaries of a campus-based learning experience tend to confine learning experiences to people listed on the roster. The same can be true of online classes if instructors replicate the same activities and build virtual boundaries that are the equivalent of physical classroom walls. However, online learning provides instructors with opportunities to lead their students in making connections between their class and the larger online world. When students are encouraged to use the Internet as part of their learning experience, learner-network interactions (Dennen, 2019) are added to the three types of within-class student interactions identified by Moore (1989). In other words, with the instructor's blessing, support, and perhaps co-participation, students can explore and connect their class learning to content from and interactions with relevant online people, spaces, and tools. Through these opportunities, instructors find themselves playing a network role in which they demonstrate how to develop a meaningful professional learning network (PLN; Krutka, Carpenter, & Trust, 2017) and exist as co-learners alongside their students in a connectivist learning experience.

Increasingly, connectivism has become a popular approach for online learning. Connectivism was proposed as an alternate learning theory acknowledges the diverse and distributed learning experiences people have when interacting with other people and resources in online spaces (Siemens, 2005). Downes (2019) reminds that connectivism is not simply a pedagogical strategy to invoke in a class or to be measured via formal assessments. Rather, connectivism represents a contemporary way of navigating the world and making sense of one's interactions in online spaces. Invoking a connectivist approach in a formal learning context is effectively committing to supporting students as they explore relevant online spaces, each of which contributes to a unique experience that reflects both course learning objectives and personal ones.

Instructors who embrace connectivism as an online learning epistemology and who wish to support students in developing PLNs (Krutka et al., 2017) need to develop another set of skills, so they can navigate online worlds themselves and support students in doing the same. The Networked Knowledge Activities (NKA) framework (Dennen, 2019; Dennen et al., 2020) can be used to support this endeavor, highlighting the subskills (e.g., collect, curate, share, broker, negotiate, and create) that occur in a networked environment and support learning. These skills are familiar to most social media users, but are neither mastered by nor ubiquitous to all students. Integrating the skills into online classes merges classroom learning and everyday life information-seeking behaviors. By parsing larger, authentic online

activities into smaller, well-defined actions instructors can be intentional about encouraging students to develop and practice skills that promote lifelong learning and productive development of and interaction in PLNs. Instructors have opportunities to help students locate and evaluate online resources, access online expertise, and develop networks that will serve them in the future.

This networked dimension of the overall instructor role has implications for each of the other roles. Networked learning reflects both pedagogical and technological choices and positions instructors and students in the midst of social spaces that may be inhabited by others. Instructors need to help students navigate these social spaces, invoking facilitation, managerial, and technology skills. Finally, when learning shifts into increasingly public online spaces, a new range of ethical concerns arise.

---

## Conclusion

Online instruction is a complex activity, drawing upon a diverse set of skills. Attempts to separate these skills into different roles, such as Berge's (1995) framework, mark a first step toward articulating important instructor competencies and organizing them in a logical manner. These roles can be used alternately to support professional development or enable focused discussion of a single dimension of the online instructor's job. The heavy crossover and interplay among these roles are emblematic of the systemic nature of online instruction. No single role or dimension alone is sufficient to support learning, not even the pedagogical role.

Notably, these four core roles have remained constant for more than two decades and have gained widespread acceptance among educators and educational institutions. This constancy, however, does not mean that our understanding of each role has not changed. Developments in both pedagogy and online learning technologies have stretched the roles to encompass different approaches to learning. Newer concerns related to ethics and networked learning, leading to the discussion of each as its own dimension in this chapter, similarly represent developments in educational and everyday practices and values. Looking to the future of online instruction, it seems likely that these core roles will continue to guide online instructors, even as specific approaches to each role continue to develop and reflect systemic changes and advances in online education research and practice.

## Abstract

Digital literacy is a critical competence for empowering citizenship in a digital world. It has become a key element in teaching and learning across the different educational stages that has been addressed since the last decade of the twentieth century within the field of open, distance, and digital education. The literature so far has not agreed on a common definition, but multiple international, national, and even local, frameworks exist to foster digital literacy and to evaluate and certificate it, especially with a focus on educators and students in different educational levels, but also with the citizen perspective. These frameworks are

reviewed in this chapter, along with the evolution and conceptualization of digital literacy and some strategies to foster digital literacy in different educational sectors, with a focus on the educator as a key player in this fostering action. The most remarkable challenges for developing digital literacy for teaching and learning include the same conception of digital literacy, which is multiple and situated, the digital divide and the actual consideration of digital literacy as a social practice. Being digital literacy a transversal competency nowadays, clear implications for education can be drawn, such as reshaping organizations to the digital conditions, thinking on digital literacy as a collective effort, and enriching the global discourse through diversity in debates.

## Introduction

Digital literacy (DL) in teaching and learning is one of the areas of research and practice in the field of open, distance, and digital education with a longer trajectory and evolution in its history. The interest around DL started when the mere reading and writing abilities ceased to be sufficient for participating as full citizens in the new technological and communicative era. Nevertheless, being intimately linked to the development of two amazingly changeable concepts – technology and education – the term “digital literacy” itself is not free from complexity and polemic. This fact cannot be omitted in a chapter such as this one.

Since DL has been studied from a huge number of perspectives since its development in the last decade of the twentieth century, it is difficult to capture the complexity and abundance of information available of DL by doing another review. Instead, this chapter draws upon existing systematic literature reviews to provide a reliable way of representing the essence of the broad range of digital literacy scholarship. For this book chapter, 33 reviews that are indexed in Web of Science during the period 2010–2021 were collected to cover classical, critical, and current definitions, frameworks, and strategies to foster DL in teaching and learning.

---

## What Is “Digital Literacy”?

DL is not presented in the literature as a concept itself but as a kind of ensemble and joining of cultural and historical understandings and practices regarding the use of information, mediated by digital technologies, on any aspect of daily human life (Canchola-Gonzalez & Glasserman Morales, 2020; Cetindamar Kozanoglu & Abedin, 2020; da Silva & Behar, 2019; Nichols & Stornaiuolo, 2019; Reyes &

Avello-Martínez, 2021). Still, authors agree on considering it as a critical competence for personal fulfillment, active citizenship, social inclusion, and employment in the twenty-first century (Guardia et al., 2017; Littlejohn et al., 2012), and as the only way to participate and contribute to the contemporary life (MacLure & Stewart, 2016).

Nevertheless, there is not a clear definition of DL (Esteve-Mon et al., 2020). The rise of the conceptualization of DL is intimately connected not just to the technological evolution itself and the requirements of the new technological scenario (de Paulo Moura, 2019), but also to the transformation of the main aspects that define the way information is produced and shared in multimodal approaches (de Paulo Moura, 2019): the change in the code (from verbal to multimedia), the difference in the main support (from paper to screen), and the change in structure (from a linear-reading structure to a hypertextual and hypermedia) one (Avello Martínez et al., 2013).

The conceptual evolution of DL recognizes the rising importance of integrating not just instrumental components of the new communicational aspects but also the intellectual, informational, and other skills related to the role of information and technologies in people's life. This is also clear from the evolution of the DL's European Union definitions, turning from an almost instrumental perception on the first definitions before 2010 (European Communities, 2007), and becoming more focused on being critical and participating in the most recent approaches (European Commission, 2019).

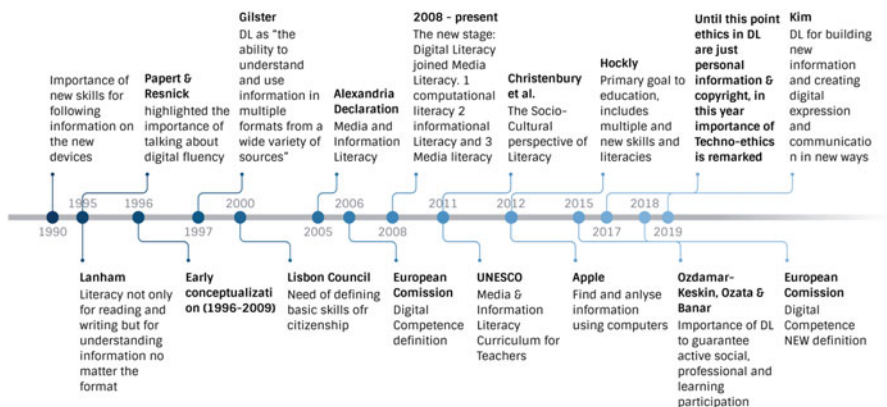

Instead of a monolithic concept of literacy, specialized literature proposals mention "multiliteracies" – as 'Information Literacy', 'Computer Literacy', 'Media Literacy', 'Communication Literacy', 'Visual Literacy', and 'Technological Literacy' – when authors speak about DL to remark the complex and entangled notion they refer to (Avello Martínez et al., 2013; Manca et al., 2021; Reddy et al., 2020). Moreover, the literature remarks the importance of not considering the new communicative scenarios opposite to the traditional ones, but as more complex and networked (de Paulo Moura, 2019).

DL includes technological, attitudinal, and cognitive components, linked to the need of humans (as individuals and as groups) to express, explore, question, communicate, and understand ideas (Avello Martínez et al., 2013). This need is also historically engaged with the use of technologies to do tasks, solve problems, and communicate (Arango Morales et al., 2021).

The impact and influence of DL over time and contexts include its presence in classical frameworks and programs such as the twenty-first century skills framework (<https://www.battelleforkids.org/networks/p21/frameworks-resources>), the International Computer and Information Literacy Study, the OECD's Program for the International Assessment of Adult Competencies, the European Commission Key Competences for Lifelong Learning (European Commission, 2019; European Communities, 2007), as well as specific models for areas (e.g., health, see Oh et al., 2021) or countries (e.g., India, see Nedungadi et al., 2018).

In Fig. 1, some of the most important milestones on the conceptual story of DL have been collected to provide a general perspective of the field.

**Fig. 1** Timeline for the conceptualization of DL

*Note:* The dates for the European Union definitions refer to the publication year of the corresponding recommendations (2006 and 2018), being the final publication of the reports a year later, which corresponds to the references cited in the text (European Commission, 2019; European Communities, 2007). This figure has been created based on the information provided by several of the reviews for the conceptualization of DL (Avello Martínez et al., 2013; Canchola-Gonzalez & Glasserman Morales, 2020; Gibson & Smith, 2018; Manca et al., 2021; Perdomo et al., 2020; Reddy et al., 2020; Reis et al., 2019; Reyes & Avello-Martínez, 2021).

DL is considered a situated concept, closely linked to the specific characteristics of people, territories, and historical moments (Avello Martínez et al., 2013; Cetindamar Kozanoglu & Abedin, 2020). At the same time, the way societies understand DL has essential cultural and social connotations (Gonzalez-Martinez et al., 2019). DL is also defined for specific uses, such as the employees' DL (Cetindamar Kozanoglu & Abedin, 2020) or the life-long learners' DL (European Commission, 2019; European Communities, 2007). Both differences and similarities between child and adults' literacy developments exist and should be considered (Esteve-Mon et al., 2020).

The definition of DL may remain elusive and not completely clear. Still, one concept that emerges around the perception and development of the desired levels of DL is the concept of digital fluency. Digital fluency is very popular in institutional implementations and has been included, for example, in the curriculum of New Zealand or Indonesia (Canchola-Gonzalez & Glasserman Morales, 2020). The most cited definition of digital fluency in the specialized literature is the one created by Christian Briggs and Kevin Makice in their 2012 book. This definition refers to the ability to achieve outcomes using digital technology reliably and remarks that a digital fluent person "not only knows what to do with a technology and how to do it but also when and why to use it" (Canchola-Gonzalez & Glasserman Morales, 2020, p. 10). It is worth saying that the concept of fluency appears as an evolving state of literacy, and both fluency and literacy appear to be very close to the notion of competence, a term that is more typically used in Europe (Canchola-Gonzalez & Glasserman Morales, 2020; Dias-Trindade & Ferreira, 2020). The three concepts of

fluency, competence, and literacy include knowledge, skills, and attitudes interacting together. Even if they are not exactly the same concepts, they are used interchangeably in the global specialized literature (Arango Morales et al., 2021; Esteve-Mon et al., 2020; Fernandez-Batanero et al., 2020).

It is remarkable that almost every publication about DL, as well as digital fluency, comments on the importance of institutions and other stakeholders providing resources and conditions to support the development of the DL and digital fluency of individuals – what would be called the agency (Eteläpelto et al., 2013; Jääskelä et al., 2017). Furthermore, these publications also discuss the relevance of other people's fluency to enacting personal fluency (Arango Morales et al., 2021; Canchola-Gonzalez & Glasserman Morales, 2020). In this way, the notion of DL is intimately related to people's right to social inclusion, equity, and access to knowledge (Martinez-Bravo et al., 2020).

In sum, taking all this incredible complexity for defining DL into account, it can be concluded that **DL emerges as a notion of situated multiple integrated skills and practices (conceptual, attitudinal, procedural, and ethical) that empower people (individuals and groups) to participate and communicate efficiently in society.** Consequently, DL is a permanently evolving concept within the communicative environment.

---

## Digital Literacy Frameworks in Education

Developing DL in educational contexts is shaped internationally, nationally, and, even in some cases, locally or institutionally, within frameworks that provide concrete dimensions to understand the concept, organize resources around, foster and evaluate individuals regarding DL. The number of frameworks developed in the last 20 years has been enormous.

In the last few years, some initiatives tried to create global frameworks that integrate and summarize all the skills and literacy competencies that anybody on any condition would need to efficiently face the new technological and social moment. The main argument for doing this is that too many frameworks are already developed (see Fig. 2) and that a global one would help to have a better overview and synthesis. However, the problem of some of those initiatives is that, even if they state to include global perspectives – as the collection in Fig. 2, the reality is that most of them do not include any framework developed outside the Western-North context.

Other approaches try to integrate different frameworks to consolidate global approaches that include intercultural perspectives and different individual interests (teachers, students, families, organizations) (Trujillo Sáez et al., 2020).

Nevertheless, with the ambition of mapping the current overview regarding DL, the most used, adapted, well known, and recognized frameworks for understanding DL are presented below. The skill-oriented operational perspective of know-how is the predominant approach in the DL frameworks due to the initial definition of the concept. Nonetheless, DL frameworks present two other perspectives: the plural

## Common Framework for Digital Literacy, Skills and Readiness

*A neutral and impartial platform that aggregates leading ideas, knowledge and practices around the world*

form of DLs that emphasizes the situated nature of the concept and the more critical perspective of digital competence as a reflective approach (Spante et al., 2018).

### General Focus (Learners)

With a focus on lifelong learners, the **Digital Competence Framework for Citizens (DigComp)** (<https://data.europa.eu/doi/10.2760/38842>) developed by the Joint Research Centre (JRC) of the European Commission is the foundation for many other DL frameworks worldwide. The last published version at the moment of writing this book chapter (the 2.1) includes the following five competence areas. Dimension 1 is information and data literacy, communication and collaboration,

digital content creation, safety, and problem-solving. The other four dimensions of the framework include competence descriptors and titles (dimension 2), eight proficiency levels for each competence (dimension 3), knowledge, skills, and attitudes applicable to each competence (dimension 4), and examples of the use of the proficiency levels (dimension 5). A new version of the DigComp framework (2.2) is expected to be published in early 2022. In addition, multiple instruments have been developed to measure or evaluate DL using this framework (e.g., SELFIE, for schools: [https://ec.europa.eu/education/schools-go-digital\\_en](https://ec.europa.eu/education/schools-go-digital_en)).

The **Digital Literacy Global Framework (DLGF)** (<http://uis.unesco.org/sites/default/files/documents/ip51-global-framework-reference-digital-literacy-skills-2018-en.pdf>) developed by UNESCO emphasizes that “sustainable development and cohesion of society critically depend on this new set of digital competencies” (Manca et al., 2021, p. 4). Using as the reference DigComp and looking beyond it through a systematic search for DL frameworks in targeted regions and countries, this framework proposes the following competence areas: (0) hardware and software operations, (1) information and data literacy, (2) communication and collaboration, (3) digital content creation, (4) safety, (5) problem-solving, and (6) career-related competencies. Competence areas (0) and (6) and the competence 5.5 computational thinking within (5) are the novelties concerning DigComp.

With a focus on students, the **International Society for Technology in Education (ISTE) Standards for Students** (<https://www.iste.org/standards/for-students>) is the United States (US) framework, which is one of the oldest DL frameworks in the world (since 1998, with different names). The framework includes the following standards: (1) empowered learner, (2) digital citizen, (3) knowledge constructor, (4) innovative designer, (5) computational thinker, (6) creative communicator, and (7) global collaborator.

In the context of the United Kingdom (UK) higher education, a review of DL frameworks found three broad areas of supported capability (Littlejohn et al., 2012, p. 6): (1) academic practice or learning skills, (2) information and media literacies, and (3) ICT skills or techno-literacy. For instance, following the Beetham and Sharpe’s pyramid model of DL development model (inspired by Maslow’s hierarchy of needs), the **Joint Information Systems Committee (JISC) developed a framework for DLs** (<http://web.archive.org/web/20141011143516/http://www.jiscinfonet.ac.uk/infokits/digital-literacies/>) with the following elements: information, media, data literacy (critical use), digital identity and well-being (self-actualizing), digital creation, scholarship and innovation (creative production), digital communication, collaboration and participation (participating), and digital learning and personal/professional development (learning). This is one of the few well-known DL frameworks developed by organizations that refer to the plurality and situated nature of the concept.

Looking at nonconventional or noninstitutional frameworks, Selber’s (2004) **multiliteracies for a digital age** considers three student positions towards technology critical to DL: users, producers, and questioners. Therefore, three filters need to be used to view those positions: functional literacy (effective use, prerequisite for the others), critical literacy (informed critique), and rhetorical literacy (reflective praxis).

## Focus on Educators

The DL focus on teachers appears in the literature under other similar terms as digital teaching competence or digital teaching literacy, and its definition, especially with the aim of training and evaluating teachers worldwide, has been a priority in the educational literature over the last years.

Digital teacher competencies are “the set of skills, attitudes and knowledge required by educators to support student learning in a technologically rich world, design and transform classroom practices and enrich their own professional development” (Esteve-Mon et al., 2020, p. 1). In addition, Tarraga-Minguez et al. (2021, p. 1) sustain that the digital teaching competence “is a complex pedagogical concept that involves a series of dimensions and aspects linked to forms of pedagogical representation of technology in the classroom, learning, and teacher training” and this makes it different from DL.

In the systematic literature review on digital teaching competence of university teachers done by Esteve-Mon et al. (2020, p. 401), the authors identify four common areas in the studies they reviewed ( $n = 43$ ): (1) basic digital skills, (2) the pedagogical application of digital technologies, (3) the use of technology for continuous professional development, and (4) the ability to further digital competencies for university students. Similarly, the review conducted by Starkey (2020) in the context of pre-service teachers, teacher educators, and the initial teacher education programs identified three complementary ways of interpreting digital competence for teachers: (1) generic digital competence, (2) competence to integrate technologies into teaching practice (using technology for teaching), and (3) critical use of technology and teaching children who are using technology, and professional digital competence (teaching, managing the digital learning environment and professional work of being a teacher).

UNESCO developed for the first time their **ICT Competency Framework for Teachers** (<https://unesdoc.unesco.org/ark:/48223/pf0000265721>) in 2008 and is in its third version at the time of writing this publication. It refers to six aspects of teacher professional practice in any of the three phases of teacher professional development (pre-service, in-service, and on-going formal and informal pedagogical and technical support): (1) understanding ICT in education policy, (2) curriculum and assessment, (3) pedagogy, (4) application of digital skills, (5) organization and administration, and (6) teacher professional learning. These aspects are organized over three successive stages of teacher development regarding ICT: knowledge acquisition, knowledge deepening, and knowledge creation.

The US version of the DL framework for educators is the **ISTE Standards for Educators** (<https://www.iste.org/standards/for-educators>), with its first version published in 2000, that includes the following standards, considering the educator as: (1) learner, (2) leader, (3) citizen, (4) collaborator, (5) designer, (6) facilitator, and (7) analyst. In the Latin American context, **ENLACES** is the Chilean Framework for Teachers' Digital Competences (<https://bibliotecadigital.mineduc.cl/handle/20.500.12365/2151>). ENLACES was one of the first in the geographical area, and that included five dimensions and standards for the teaching profession: educational,

technical, management, social and ethical, and professional development and responsibility.

Addressing the needs of lifelong learners, the JRC of the European Commission developed a specific digital competence framework for educators at all levels of education, the **Digital Competence Framework for Educators (DigCompEdu)** (<https://doi.org/10.2760/178382>). The framework details 22 competencies organized in 6 areas: professional engagement (educators' professional competencies), digital resources, teaching and learning, assessment, and empowering learners (educators' pedagogic competencies), and facilitating learners' digital competence (learners' competencies). DigCompEdu has inspired other framework developments worldwide, especially in the European sphere of influence (north of Africa and East Europe) and in Latin America.

Similarly, Pozos Pérez and Tejada Fernández (2018) identify six digital competencies that university teachers need to develop in order to meet the current needs in their educational contexts: (a) teaching planning and design in virtual environments, (b) development and implementation of collaborative learning experiences, (c) research, development, and pedagogical innovation with/for the use of ICT, (d) orientation, guidance, and evaluation, (e) management of the growth and professional development with ICT support, (f) diversity, ethics, and responsible use of ICT, and (g) environment, health, and work safety with the use of ICT. Each of these competencies can differ in mastery level or complexity degree and relation to steps related to time (integration phases: access, adoption, adaptation, appropriation, and innovation) ranging from non-developed competency to expert level, going through basic, medium, and high level.

---

## Strategies to Foster Digital Literacy in Education

After the statement of frameworks, the second most important concern related to DL is how to foster it across the different educational stages (and actors). In this section, some of the most relevant strategies are presented.

### K-12 and Secondary Education

In their review, Gibson and Smith (2018) found that children develop a mobile literacy – DL regarding the use of mobile phones and tablets – through implicit and explicit scaffolding by their parents and other family members from an early age. The same authors highlight the importance of critical DL, to develop skills to critically examine digital texts and make connections at school against the backdrop of the increase of fake news and the wealth of information available online. Strategies that teachers can apply to do it include: aiding in what young students need to know and where they can find the information, giving time to discuss texts and the choices of their authors, and analyzing practice to explore connections and own online relationships (Gibson & Smith, 2018). These practices, empower children

through participation with others. Accordingly, Kirchoff and Cook (2017) propose digital comics as a way to introduce students to (critical) DL skills, accomplished by skills, accomplished by reading digital texts and creating three types of comics with different digital platforms, coupled with Selber's (2004) framework (functional, critical, and rhetorical literacy development within a digital context).

Also emphasizing the teacher's role, Hadjerrouit (2010) presents a theoretical framework to foster DL in school education by training teachers to design and critically evaluate digital learning resources. The two main factors impacting this action are pedagogical usability and cultural usability (students' preferred choices and ways of learning). Regarding pedagogical usability, the curriculum must integrate DL in all subjects in a goal-oriented way, so that it deeply affects teachers' pedagogy, shifting to constructivist or learner-centered methods (Hadjerrouit, 2010). Also, digital learning resources should add value to the learning process when compared to other materials, and teachers must be made aware that ICT is not value-neutral.

## Higher Education

Research of DL in the context of higher education has been extensively done with undergraduate students, especially focusing on their perception and level of DL (Zhao et al., 2021). On the other hand, few studies focus on the pedagogical approaches to foster DL. Those that do generally emphasize teacher education.

The study in the context of UK higher education based on a literature review and an empirical study by Littlejohn et al. (2012) describes three modes of professional services offered to students: modular, freestanding resources to be studied flexibly; outreach, digitally literate individuals acting as ambassadors; and integrated, as a digital and learning skills program. The same authors highlight important considerations for designing strategies that foster DL in higher education. For instance, learners' control and ownership of technologies boosts their confidence to engage in learning; nevertheless, a variety of learners' technological skills and practices needs to be considered. In addition, findings from Littlejohn et al. (2012, p. 8) point towards the need for the process of teaching and learning that includes authentic tasks that suitably integrate digital technologies, time to explore digital academic and professional practices; consideration of the construction of academic communication through media; and recognition of previous student learning practices as resources for learning. In order to support students take ownership of search for information in their academic field, higher education institutions could shorten the duration length of their information make this search shorter and efficient. This could be done through open access journals and open education resources and providing information literacy strategies (Gibson & Smith, 2018).

For the specific, well-researched, context of teacher education programs, there are different approaches to develop DL, especially focusing on the future role of these students in schools (Starkey, 2020): including a course on technology integration, offering pedagogical tools for teaching and learning as subject specific, and by

integrating DL in all subjects. Also, as the author highlights, “developing expertise in generic competencies can occur when technology is embedded in the broader educational and societal context that student teachers and teacher educators have experienced” (Starkey, 2020, p. 13). Multiple studies in this context show that pre-service teachers have developed some technical skills but not the required competence to digitally enrich the teaching-learning processes (Tarraga-Minguez et al., 2021). Howard et al. (2021) suggest an integrated approach to teaching strategies to develop digital competence in teacher education based on the Synthesis of Qualitative Evidence model (SQD), which includes six teaching strategies: (1) teacher educators as role models, (2) opportunities for reflection, (3) learning by design, (4) collaboration, (5) authentic experiences, and (6) providing feedback. Based on data from a validated SQD-scale concerning 931 pre-service teachers from Belgium, Howard et al. (2021) identified four clusters that integrated the six teaching strategies, with a clear greater importance of teacher educators as role models, learning by design and authentic experiences.

To develop critical DLs, academics and teaching staff must explore and share educational approaches (Littlejohn et al., 2012). For example, self-regulated learning strategies and domains such as metacognitive knowledge, resource management, and motivational beliefs are useful to foster DL in higher education and lifelong learning (Anthonysamy et al., 2020). Also, librarians can play an important role supporting DL among faculty and students through novel educational techniques. They may develop tools to support students’ interaction in the institutional learning spaces or support faculty in creating course curriculum (Kenton & Blummer, 2010).

## Vocational Education

According to a European report on the Vocational Educational Training (VET) sector and its connection to digital competencies (Broek & Buiskool, 2020), the latter are usually best embedded in training delivery but less embedded in learning outcomes and assessment since they are not a formal requirement. Nevertheless, these competencies are considered essential and regarded as transversal in the learning process. However, the same report observes that the most significant impact of policies is on the teacher’s digital competence, encouraging teachers to work with digital technologies in education.

An example is the European project EVET2EDU (2012–2014), which aimed to support VET teachers in developing competencies to use eLearning with their students and created a task-based learning online course to do so (Gutiérrez et al., 2017). The authors’ report on the course implementation results, demonstrating the improvement of both pedagogical skills and technical skills (89% and 83% of the participants, respectively).

Some countries, at least in the European and Latin American areas, have implemented some modalities of VET that include training at work. In those approaches, the development of DL appears more and more connected with the integration of digital processes and routines in the workplace (Naji, 2018). These

routines do not just affect the formal training of students, but they also affect day-to-day work.

Other initiatives have opted for more global perspectives, such as IKANOS (<https://ikanos.eus/en/>), an initiative of the Basque Government (Spain) focused on digital competencies that has been especially concerned about DL of workers and students of VET. This initiative developed a methodology to create holistic support on DL, not only for VET students but also for employees. This methodology ranges from raising awareness of the importance of DL for work through DL self-assessment, diagnosis of how to improve DL, and the creation of specific training programs for students, employees, and trainers, not only in generic digital skills but also in digital skills for learning.

## Continuing Education

This section refers specifically to the professional development of educators. Unfortunately, there is little reference to continuing education in other professions within the DL literature base.

Pozos Pérez and Tejada Fernández (2018) suggest that digital competence should be considered as a continuous, recurrent, and gradual process for higher education instructors. Also, “pedagogical training is crucial for adequate digital competence of university teachers” (Esteve-Mon et al., 2020, p. 403). However, it is important to balance technical and pedagogical knowledge, both of which are needed to properly solve problems (Perdomo et al., 2020). The same latter authors observe that educators also need assistance to develop metacognition about their same competencies.

## Lifelong Learning

The link between theory and practice for DL research in the context of working adults as lifelong learners is not broad.

However, adults are one of the groups that is increasingly taken into account in initiatives to improve DL (Flauzino et al., 2020). Adults are a large and diverse group, including workers, nonworking family members, seniors (older people, some of them retired), and any other type of person that is not covered by other initiatives. This group is not a collective because of their diverse characteristics and contexts. Still, their need to adapt to contemporary digital requirements may be higher than for the rest of the population; some of them have experienced the entire communicative revolution of the last 50 years. Therefore, they need to be able not only to enact their participative citizenship in the new technological moment, but also to set an example for their families (Costa et al., 2015).

In the LIDIA “Literacia Digital de Adultos” project (started in 2014, <http://lidia.ie.ulisboa.pt/>), some of the project’s initiatives focus on the development of materials to be used by educators and trainers who work with adults. In other projects, such as the Initiative Faro Digital (<https://farodigital.org/>), an NGO that develops DL in Latin

America), the work involves publishing guides for improving specific skills and capabilities. Current projects and initiatives address an increasingly important literacy within DL for citizenship: data literacy (e.g., DALI: <https://slate.uib.no/projects/data-literacy-for-citizenship>). In addition, many countries have started national programs that integrate DL in the whole infrastructure of citizen services. This is the case in New Zealand, where a strategy for empowering every person in the country to actively participate in the digital world has been developed (<https://2020.org.nz/>). This strategy includes training for trainers and educators, a digital inclusion map (<https://digitalinclusion.nz/>) to improve the awareness about the need for inclusion in some zones of the country, as well as specific resources in libraries and other community development centers (<https://natlib.govt.nz/schools/digital-literacy>), among other initiatives.

For the specific case of workers, Oberlaender et al. (2020, p. 13) define digital competencies at work as “a set of basic knowledge, skills, abilities, and other characteristics that enable people at work to efficiently and successfully accomplish their job tasks regarding digital media at work.” Focusing on white-collar workers with office jobs, the same authors identified basic (i.e., needed for everyday tasks) and workplace-specific digital competencies, which also depend on external factors such as the structure and size of the work tasks, and the company’s background. Suggested strategies to foster DL in education for the workplace include enhancing talent management programs based on specific digital competencies needed in the workplace (Oberlaender et al., 2020).

---

## Challenges and Future Research

One of the most significant challenges regarding DL is the immense diversity of perspectives about what digital is and what literacy implies. These issues have been mentioned in the various reviews included in this chapter. Therefore, facing DL as a multiple and diverse situated concept must be an achievable goal; trying to identify, more than a global definition of DL, a globally situated framework that would be localized on the different realities of people, as different authors suggest (Avello Martínez et al., 2013; Gonzalez-Martinez et al., 2019).

A common critique of many of the DL frameworks that have been developed so far, and that are included in this book chapter, is that they usually focus on the autonomous and universalist understanding of the DL. Under this perspective about DL, all learners are to be equipped with an uniform set of functional and technical skills so that they can start reading and writing in digital media (Manca et al., 2021). It seems essential to rethink DL frameworks from a more comprehensive perspective, considering the situated nature of DL and taking a proactive standpoint on the development of DL.

As Canchola-Gonzalez and Glasserman Morales (2020) assert, most conceptual approaches to digital fluency, competence, and literacy are from authors from North America and Europe. There are very few conceptual approaches from authors located in regions of Latin America or Africa. However, these regions have a high

level of interest in the topics. Still, nearly half of the reviews included in this chapter (15 out of 33) were led by Spanish-speaking authors, even if only four of the reviews were written in Spanish, and just two other reviews were originally written in Portuguese. This observation highlights an opportunity to open the perspective about DL and contribute to the discussion process and developing thinking regarding DL to integrate knowledge from different cultural and local realities where technology has a different process of implementation, participation, enactment, and appropriation (Manca et al., 2021).

In addition to this, digital practices are present in people's daily lives, especially in screen reading and writing, and in learners' academic lives. As a result, digital literacy can be considered a social practice linked to peoples' day to day lives (Cetindamar Kozanoglu & Abedin, 2020; de Paulo Moura, 2019). DL implies both the appropriation of new languages of the digital medium and related social practices, uniting various media, resources, interfaces, genres, and digital languages. Therefore, DL cannot be conceived just as an academic term to study or as a skill for children or young people, but rather as a reality that intervenes in the daily life of employees, adults, seniors, and families.

Because of its prevalence in everyday life, DL should actively included in the curriculum at every level, in an active way – not just in a transversal way (Hadjerrout, 2010). The approach to DL education must include not only the instrumental use of digital tools but also the use of digital languages and codes for communicating, for assessing, as well as for understanding the world (de Paulo Moura, 2019; Guardia et al., 2017; Littlejohn et al., 2012). Furthermore, it is important to remark the relevance of effectively integrating DL into different disciplines and subjects, to be able to adapt the DL education to different curricula and organization structures (Guardia et al., 2017), and guarantee the transference of digital capabilities among different contexts (Littlejohn et al., 2012).

In addition, DL is no longer considered an individual issue, rather it is viewed as a collective need. People work and learn in groups, with others, and DL must be a crucial component and an enhancing factor of this shared approach. Therefore, DL should not only be used to make the interaction more fluent but also as a collective competence for empowering groups (Manca et al., 2021). This more generic, but at the same time much more profound perspective, reinforces the significance of both literacy practices and pedagogical practices; both enable new power relations between subjects and with knowledge. Consequently, highlighting profound critical approaches to DL is important in order to emphasize the DL critical component, when understanding and addressing DL (de Paulo Moura, 2019; Kirchoff & Cook, 2017).

Another challenge concerns the interest in developing instruments for efficiently evaluating the DL performance, not just self-perceptions (Perdomo et al., 2020). Even though this lack of appropriate instruments to evaluate DL, the vast majority of authors agree that the greater number of studies are focused on defining the limits of DL to measure and evaluate it, rather than on developing it

(Cetindamar Kozanoglu & Abedin, 2020). Therefore, even though research focuses on the importance of effectively evaluating DL, and many authors are still collecting self-report data, especially from undergraduate students (Zhao et al., 2021). This situation represents a paradox given that authors agree that fostering DL is a highly important issue.

In the case of the approaches that try to improve the DL in institutions and at every educational level, the most common perspective is the understanding of DL as an individual quality that resides in the brain of people (Cetindamar Kozanoglu & Abedin, 2020). For expanding this individual and generalist notion of DL, theories such as the affordance theory or the socio-material theories regarding entanglements (Frauenberger, 2020) would be especially useful. The institutional improvement of DL is considered as something that depends only on the individual effort of the institutional members for improving their own DL. Consequently, the prevailing perspectives ignore the importance of the institutional conditions and resources for people that must be guaranteed to enact the DL; in other words, the relevance of the Agency regarding DL (Castañeda et al., 2022). Only some projects, such as the European project CUTE “Competencies for Universities using Technology in Education” (<https://cute.ku.dk/>), include the strategic approach to foster the DL as a crucial perspective for holistic development of DL in higher education institutions.

Probably one of the most obvious challenges regarding DL is the one concerning the digital divide. The COVID-19 crisis, and the lockdowns that closed on-site activity in educational institutions and jobs worldwide, faced every society with a desolating scenario of digital exclusion that is even more devastating in some zones of the world that are also traditionally excluded from the intellectual debates. The importance of opening the discourses about DL to voices from other realities that enrich the perspectives about what DL is and how it is developed over the world has been already mentioned. But it is not just a question of discourse and debate, one of the most problematic challenges regarding DL is how to increase DL around the world by being aware about the local approaches. Increasing DL everywhere, considering what citizenry means in each context; the empowerment of governments, societies, and people worldwide, for enacting the DL and maintaining their sovereignty to take decisions about the digital. Unfortunately, it seems that at the moment the only interested parties are companies that are investing a lot of money in implementing technology at some points, or for replacing the national educational systems with remote schools systems based on developing countries (Selwyn, 2018).

Finally, as DL evolves, the importance of understanding the ethical, political, and social dimensions of DL has increased. Renewed definitions of DL and digital competence (as the 2018 of the EU) highlight the importance of citizenship empowerment over the instrumental literacy approach. These new, more ethical approaches, are also being included in teachers’ DL frameworks that highlight the importance of the social commitment and the community empowerment as a desirable goal of DL in education (Castañeda et al., 2018).

## Conclusion

The world has increasingly become more digital. Indeed, some authors prefer to consider the current situation as a post-digital situation, where “digital” (tools, processes, influence) is everywhere and nothing is “normal” without being digital (de Laat & Bonderup, 2019). In this changeable scenario of the last 30 years, the ambition of DL, as a relevant notion within open, distance, and digital learning, has changed enormously, becoming ever more complex, precisely because the human relationship with technology is also much more complicated.

Technology is not just a set of tools for doing specific things anymore. Technology is a way of thinking, is an incredible market, is a scenario of political debate and fight, is a part of human nature, and is a reality that configures existence in many ways. Technology configures human physical reality to the realities of human relationships (families, love, friendship) until human realities as citizens. Therefore, the ambition of a DL that helps us enact participatory citizenship has changed. In sum, it is time to continue working on DL, especially to further explore how DL can be more fully integrated in teaching and learning contexts.

DL, with all of its different names (i.e., competence, fluency, and so on), has become one of the most transversal competencies. It is an area of increasing interest in open, distance, and digital learning research, as can be seen from the significant number of reviews on the topic. DL is necessary to support both communication and participation as a citizen in contemporary society. In this way, the following suggestions focus on the goal of increasing DL for everyone, with clear implications for open, distance and digital education. First, DL should reshape the contents, subjects, and organizations to the digital moment of schools and educational institutions. Second, at institutions and strategic bodies, a collective effort is needed to develop conditions and resources that support DL. The focus of these initiatives must aim beyond improving digital literacy among individuals, addressing how the education sector can foster the conditions for DL. Finally, for the DL field, the efforts must be concentrated on enriching the global discourse, encouraging diversity in debates, reshaping the contexts of discussions, and integrating minorities and nontraditional contexts and realities.

Above all, the ethical approaches to DL represent the next big step. In a world becoming increasingly datafied, where EdTech moves a billionaire market (Williamson & Hogan, 2021), the determination of how DL is defined, developed, and protected for the citizenry is more relevant than ever. This shift on the definition of DL highlights the importance of a multiple literacies’ conception rather than a monolithic one. In addition, this turn speaks to the significance of the critical vision about the human’s role in this new world with technology; it means not only how to participate/communicate but also how to enact the human role to its full extension.

## Abstract

In a rapidly changing world, the discussion on Future Skills is one of the most topical in educational research. The discussion on Future Skills has been going on for a long time (starting with studies on graduate attributes), is often intangible due to conceptual ambiguity about what skills actually are, and often only refers to digital Future Skills in a reduced way. The research presented here is based on a sound empirical approach, the multi-method, and multi-part NextSkills studies. The intention of the project is to explore the demand for specific Future Skills in more detail and then, in a second step, to substantiate them in terms of educational theory. These Future Skills are classified by the “Future Skills Triple Helix-Model of Capacity to Act in Emergent Practical Contexts.” More specifically, these are skills such as ambiguity competence, ethical competence, self-competence, and others.

## **Future Skills: Guiding Principles of a New Educational Concept for Higher Education Institutions**

In this chapter, we define Future Skills as competences that enable individuals to solve complex problems in a self-organized manner and to act (successfully) in highly emergent contexts. They are based on cognitive, motivational, volitional, and social resources, are value-based, and can be acquired in a learning process. In the public discussion on higher education concepts, they have meanwhile contributed to a decisive change, which we refer to here as the Future Skills Turn (Ehlers, 2020a, b). It is the subject of the research presented here to address and grasp its implications for the conception of future higher education. As a concept, Future Skills has gained an influence similar to that which emanated from concepts such as equal opportunities or science orientation in the 1970s. Such leading brands do not appear as precisely tailored and empirically operationalized concepts, but rather as conceptual condensations of broadly diversified bundles of arguments and objectives (Placke & Schleiermacher, 2018; Ehlers, 2020a, b).

The starting point for the enormous career of the concept of Future Skills is the diagnosis that current concepts of higher education do not confront the pressing challenges of our societies with convincing concepts for the future (Hippler, 2016; Kummert, 2017) – neither the sustainable design of our environment nor the related social or economic challenges. While societal problem situations are exacerbated by a constantly accelerating globalization process and ever faster digital progress, it is precisely here that we find the forces of enabling a multitude of new options for human development. In this situation of digital acceleration, the characteristic feature is that of uncertainty and the inescapable necessity is that of creative responsibility. For the future is unpredictable and we cannot forecast it, but we must be prepared to shape it.

Children who enter primary schools next year will go on to vocational training or higher education in 10–12 years and in 15 years will be the ones who begin to shape our society as young professionals. We know little about this future. In 2060–2065 they will in all likelihood stop working. We know nothing about this future. Our schools must prepare them for jobs that do not exist today, for technologies, apps, and applications that have not been invented today, for living in a society whose structures we cannot foresee today, and for dealing with challenges that are not yet apparent today. It is the responsibility of all of us to make the best of the possibilities and to find ways to deal with this uncertain future. This is about nothing more and nothing less than the preservation of our planet and our livelihoods.

Solving societal problems such as those associated with climate change, the challenges of migration that will increase in the future, the conflicts that arise from

populist concepts of society and politics, and the associated question of the future of democracy – all of this require the ability to develop new and previously unknown approaches, to take new paths and to relate previously unconnected things to each other in new ways. In education and science, this will only succeed if we work in the best sense of inter- and transdisciplinary ways to bring together, critically reflect on, and relate to each other the solution contributions of each discipline and science. Higher education institutions find it difficult to do this – because they all share a common handicap: the history of science, research, and thus also of higher education is a history of differentiation, specialization, and delimitation of disciplines. The almost 18,000 degree programs offered at German higher education institutions bear witness to this (Hachmeister, 2017). The institution of higher education is faced with the challenge of reinventing itself – at a time when it is undergoing an enormous growth process and a rate of 70 percent higher education students of one age cohort or more is predicted worldwide by the year 2050. That's a bit like having to change pilots in a car race, in the middle of a steep curve and during a dangerous overtaking maneuver. Higher education institutions must address the question of what Future Skills the graduates of tomorrow will need and how they can support them in acquiring them. To do this, it is first necessary to describe these Future Skills in terms of educational theory – and this can be done using the Future Skills Triple Helix Model, which was developed within the framework of the Next Skills Studies ([www.nextskills.org](http://www.nextskills.org)) (Ehlers, 2020a, b).

---

## Research Design

The research project NextSkills aims to analyze which skills are needed for a productive and proactive design of future work contexts in order to derive requirements for higher education institutions. To this end, Future Skills profiles were identified in a multi-step research process:

1. Identification of Future Organizations: In a first step, organizations were identified that already had explicit experience in the implementation of competence models, ideas about Future Skills, and a high degree of maturity in the design of future work contexts. For this purpose, so-called Future Organizations were identified as an empirical field, which had developed suitable contexts for the identification of Future Skills. The selection process took place in 2015 as part of a competition in which more than 8500 partner organizations of the Baden-Wuerttemberg Cooperative State University were contacted and given the opportunity to submit their human resources development concepts and, in particular, their concepts for the supervision and support of students. 124 organizations took part in the competition. All submitted concepts were evaluated in a criteria-based expert rating. The resulting ranking was then discursively validated in a discussion by 15 experts and 20 organizations and their competence concepts were selected for a shortlist. All 20 organizations were invited to participate in the next

step of the NextSkills study, 17 responded positively and were included in the interview study. The interviews took place between December 2016 and June 2017.

2. Interview study: Guiding questions were developed for the interview study, which were used for orientation within the framework of an open, semi-structured, problem-based in-depth interviews. Participants of the interviews were the HR managers of the organizations and partly also the students who studied there in the context of (dual) study programs. A total of 17 in-depth interviews were conducted, in which 20 people participated and which resulted in about 700 minutes of qualitative interview material. The interviews were transcribed verbatim and independently coded by two researchers using the inductive coding technique (Mayring, 1996; Thomas, 2006) using MaxQDA software (VERBI Software, 2017). Constructs were extracted from the interview data to reconstruct contexts, values as well as processes, and dependencies for skills considered important in the future for individuals.
3. International Delphi study: In order to further refine and validate the qualitatively acquired results, a Delphi study was conducted with an international panel of experts. The Delphi study (for Delphi methodology see Dalkey and Helmer, 1963) entitled “Future Skills – Future Learning and Future Higher Education” (Ehlers & Kellermann, 2019) comprised two rounds of interviews. Fifty-three international experts from different organizations and institutions were invited to participate in the study (ibid.).

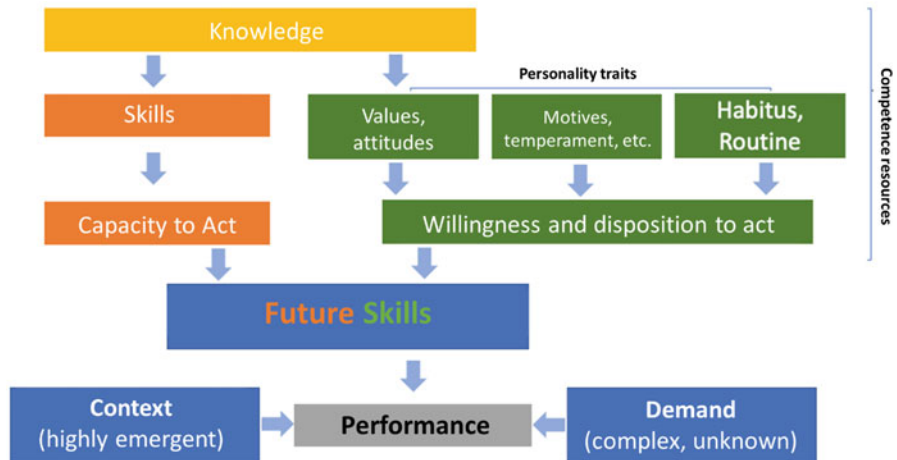

---

## Future Skills for the World of Tomorrow

The higher education of the future must be oriented toward teaching Future Skills. This is shown by the results of the NextSkills study. Based on the in-depth interviews and the assessment of the experts surveyed worldwide, 17 skill profiles were constructed that are important for future higher education graduates. Each skill profile consists of a bundle of individual competences, so-called reference competences. Skill profiles are clusters of future-relevant skills. They are in turn divided into three so-called fields of competence.

At the same time, the study forms the empirical basis on which the Future Skills Triple Helix Model of Capacity to Act in Emergent Practice Contexts was constructed. Future Skills are part of the competence turn, the Future Skills Turn, which is necessary at the higher education institutions of the future. They mark a turn toward higher education that no longer focuses on the function of preparing students through knowledge transfer, but rather supports them in developing Future Skills, i.e., dispositions and readiness to act in dealing with complex, unknown problem situations through reflection, values, and attitudes. Future Skills are defined as follows:

**Definition** *Future Skills are competences that allow individuals to solve complex problems in highly emergent contexts of action in a self-organized way and enable*

**Fig. 1** The Future Skills concept from a competence perspective © Ehlers

*them to act (successfully). They are based on cognitive, motivational, volitional, and social resources, are value-based, and can be acquired in a learning process.*

If we formulate Future Skills in terms of competence theory, it becomes clear that they are competence constructs with a special content profile (Fig. 1). They enable individuals to act in highly emergent contexts. From a competence-theoretical perspective, the ability to act (fed by knowledge and further developed into skills) comes together with dispositions and willingness to act, which is primarily fed by values and motivational and habitual factors – i.e., personality traits.

In terms and concept, Future Skills can be distinguished from those competences that are not particularly future-oriented. The concept of emergence is used as a differentiating dimension between current or previous competence requirements and those that are future-relevant: In particular, those contexts of action that show highly emergent developments of life, work, organizational and business processes require Future Skills to cope with the requirements. Emergence thus defines the dividing line that separates previous or traditional areas of work from future areas of work. Since this boundary is not clearly schematic but fluid, and many organizations are in transformation processes in which weakly emergent work contexts evolve into highly emergent work contexts, the need for Future Skills is also an evolving field and not a binary state of either-or.

Emergence versus submergence is therefore an important basic distinction for explaining the significance of Future Skills. The NextSkills study shows that low-emergent (stable) professional contexts of action change often, quickly and with high intensity toward high-emergent contexts of action. We speak here of the drift-to-self organization. This change corresponds to a change in the systemic state of organizations. It is triggered by changes in macro-, meso-, and micro-systems and reinforced by their interdependent entanglement. In the resulting new system state,

the system elements cannot be causally or linearly traced back to their previous state. The system condition of irreducibility and unpredictability applies.

The Future Skills profiles reconstructed in the NextSkills study on the basis of in-depth interviews are summarized in Table 1. Future Skills profiles consist of bundles of individual related so-called reference skills. A total of 17 such competence profiles can be reconstructed from the qualitative data (see Fig. 2), which are presented and described below. They are divided into the three competence fields of the Triple Helix model.

The division into three fields of competence follows the systematics of the Triple Helix Model for Future Skills. It is based on the idea that the skills necessary to cope with action requirements can be structured on the basis of three interacting dimensions, which are designated with specific terms in the Triple Helix Model:

1. Subject-development-related Future Skills, which refer to the ability to develop oneself, here called individual-development-related competences
2. Those Future Skills that relate to dealing with specific objects, work tasks, and problems, referred to here as object-related competences
3. Those Future Skills that relate to dealing with the social, organizational, and institutional environment, referred to here as organization-related competences

The individual Future Skills mentioned by the interviewees can be conceptually located within this three-dimensional space of action.

---

## Future Skill Profiles of the NextSkills Study

Table 1 provides an overview of the individual Future Skill profiles, the corresponding reference competences, and the descriptions of the competence fields.

---

## The Future Skills Triple Helix Model

Future skills can be further subdivided in terms of their internal structure. It must first be noted that skill is a term that always expresses a relation between a (requirement) context on the one hand and an action on the other. Ehlers (2020a, b) explains that not one, but three such relations can be reconstructed in the empirical data of the Future Skills study: An acting person can develop Future Skills in relation to him/herself, can develop them in relation to the handling of a task, a topic or an object he/she is working on, or in relation to the organizational environment, i.e., the social system (for a detailed description of the underlying epistemological position, see also Ehlers (2020a, b)). In the reconstruction of the data, we name these three relations as subject, object, and (social/organizational) world reference. A three-pole relation emerges, where each pole is in relation to the other. In relation to actions in highly emergent contexts, all three poles and their relationship to each other are thus always determining in any action. Because of the close interconnectedness of all

**Table 1** Future Skills: Competence clusters and profiles

ID	Competence cluster/ Future Skill profile/reference competences	Definition
<b>I</b>	<b>Subject development-related Competences</b>	<b>Subject development-related competences entail the ability to be able to act from within oneself and engage in self-directed learning and development activities within a professional context. Autonomy, self-competence, self-efficacy as well as performance competence play an important role in this context.</b>
1	Learning literacy	Learning literacy is the ability and willingness to learn in a self-directed and self-initiated fashion. It entails metacognitive skills as well.
2	Self-efficacy	Self-efficacy as a Future Skills Profile refers to the belief and one's (self-)confidence to be able to master the tasks at hand relying on one's own abilities and taking over responsibility for one's decisions.
3	Self-determination	Self-determination as a Future Skill describes an individual's ability to act productively within the field of tension between external structure and self-organization, and to create room for self-development and autonomy, so that they can meet their own needs in freedom and self-organization.
4	Self-competence	Self-competence as a Future Skill is the ability to develop one's own personal and professional capabilities largely independently of external influences. This includes other skills such as independent self-motivation and planning. But also, the ability to set goals, time management, organization, learning aptitude and success control through feedback. In addition, cognitive load management and a high degree of personal responsibility.
5	Reflective competence	Reflective competence as a Future Skill includes the willingness and ability to reflect, i.e., the ability to question oneself and others for the purpose of constructive further development, as well as to recognize underlying systems of behavior, thought, and values and to assess their consequences for actions and decisions holistically.
6	Decision competence	Decision competence is the ability to seize decisions and to evaluate different alternatives against each other, as well as making a final decision and taking over the responsibility for it.
7	Initiative and performance competence	Initiative and performance competence refers to an individual's ability to motivate him-/herself as well as to his/her wish of contributing to achievement. Persistence and goal-orientation form the motivational basis for performance. A positive self-concept also plays an important role as it serves to attribute success and failure in such a way that the performance motivation does not decrease.
8	Ambiguity competence	Ambiguity competence refers to an individual's ability to recognize, understand, and finally productively handle ambiguity, heterogeneity, and uncertainty, as well as to act in different roles.

(continued)

**Table 1** (continued)

ID	Competence cluster/ Future Skill profile/reference competences	Definition
9	Ethical competence	Ethical competence comprises the ability to perceive a situation or situation as ethically relevant, including its conceptual, empirical, and contextual consideration (perceive), the ability to formulate relevant prescriptive premises together with the evaluation of their relevance, their weight, their justification, their binding nature and their conditions of application (evaluate) and the ability to form judgments and check their logical consistency, their conditions of use and their alternatives (judge).
<b>II</b>	<b>Object-related competences</b>	<b>Individual object-related competences group together competences that refer to interacting with certain objects, topics, and tasks in a creative, agile, analytic fashion, and with a high degree of understanding of the system – also in highly uncertain and/or unknown environments.</b>
10	Design-thinking competence	The Future Skill Profile Design Thinking competence comprises the ability to use concrete methods to carry out creative development processes open-endedly with regard to given problems and topics and to involve all stakeholders in a joint problem and solution design process.
11	Innovation competence	Innovation competence as a Future Skill Profile includes the willingness to promote innovation as an integral part of any organizational object, topic, and process and the ability to contribute to the organization as an innovation ecosystem.
12	Systems competence	Systems competence as a Future Skill is the ability to recognize and understand complex personal-psychological, social, and technical (organizational) systems as well as their mutual influences and to be able to design and/or accompany coordinated planning and implementation processes for new initiatives in the system.
13	Digital literacy	Digital literacy is the ability and disposition to use digital media, to develop them in a productive and creative way, the capacity to critically reflect on its usage and the impact media have on society and work, both for private and professional contexts, as well as the understanding of the potentials and limits of digital media and their effects.
<b>III</b>	<b>Organization-related competences</b>	<b>A third group of Future Skills Profiles entails all those competences that refer to interaction of an individual with his/her social, organizational, and institutional environment. Among them are sensemaking and value-orientation, the ability to actively design future environments, collaborate and cooperate with others, be able to communicate in a certain way, and be open to criticism as well as to finding consensus.</b>
14	Sensemaking	The Future Skill Profile Sensemaking comprises the willingness and ability to construct meaning and understanding from the rapidly changing structures of

(continued)

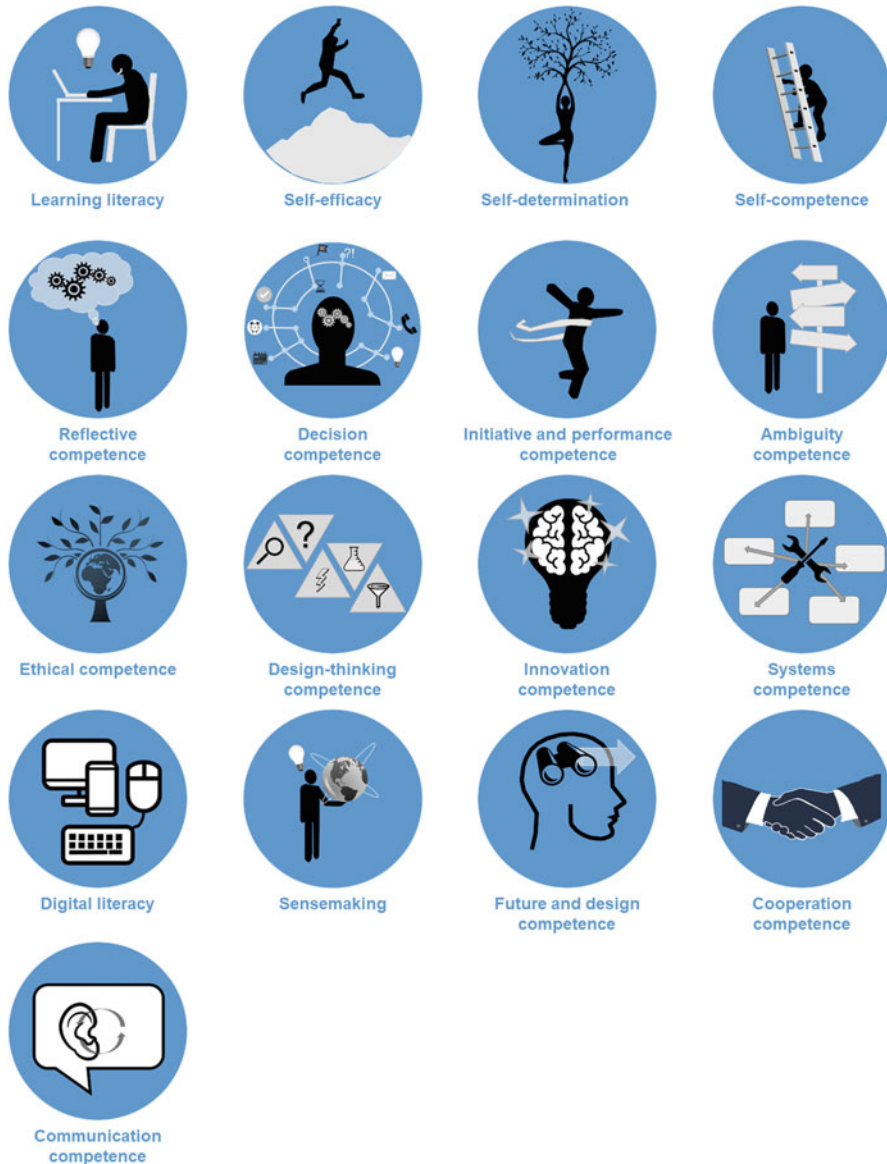

**Table 1** (continued)

ID	Competence cluster/ Future Skill profile/reference competences	Definition
		meaning within future work and life contexts, to further develop existing structures of meaning or to promote the creation of new ones where they have been lost.
15	Future and design competence	Future and design competence is the ability to master the current situation with courage for the new, willingness to change and forward thinking. To develop situations into other, new and previously unknown visions of the future and to approach these creatively.
16	Cooperation competence	Cooperation competence is the ability to cooperate and collaborate in (intercultural) teams either in face-to-face or digitally aided interactions within or between organizations with the purpose of transforming differences into commonalities. Social intelligence, openness, and advisory skills play a key role in this competence.
17	Communication competence	Communication competence as a Future Skill entails not only language skills, but also discourse, dialogue, and strategic communication aspects, which – taken together – serve the individual to communicate successfully and in accordance with the respective situation and context, in view and empathy of her/his own and others' needs.

three poles and their interrelated integration, we refer to this concept as the Future Skills Triple Helix Model. The resulting concept is suitable for the formal description of actions in highly emergent contexts. In answer to the question of whether it is rather a subjective ability related to oneself (e.g., self-directed learning, self-competence), an ability related to an object or a task, or an ability related to the social, organizational environment, the future skill constructs can be divided into three areas and internally differentiated. The classification criterion is the goal of the relation – whether it is related to a subject (individual to him/herself), object (individual to a specific object, for example a task) or the environment (individual to the social environment):

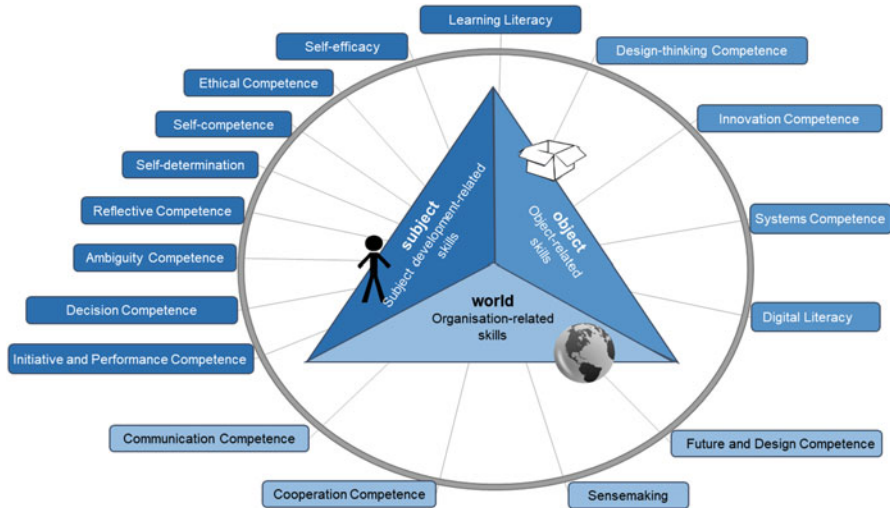

1. Relationship of an individual to him/herself in the present, past, or future (subject or time dimension)
2. Relationship of an individual to a particular object (object dimension)
3. Relationship of an individual to a person or a group in the world (social dimension)

This tripartite division is deeply rooted in the philosophy of educational science (e.g., Dewey and Bentley in their essay *Knowing the Known* (Dewey & Bentley, 1949)), but goes back significantly to Meder (2007; also Roth, 1971), who establishes a fundamental, constitutive structure for education as a structural tripartite

**Fig. 2** Overview of Future Skills Profiles © Ehlers

relationship. For the Future Skills concept, this results in a three-dimensional breakdown: Future skills thus refer (1) according to the time or subject dimension either to individually development-related aspects of the acting subject (e.g., the ability to self-reflect in relation to something experienced in the past or ethical competence) or refer (2) to dealing with a subject, an object, such as a topic or a

**Fig. 3** Future Skills overview – allocation to three dimensions © Ehlers

task (e.g., design thinking skills), or else (3) to the social environment or the organization in which the individual acts (e.g., cooperation or communication skills). Subject, object, or world/organizational reference thus span the competence fields in which Future Skills can be located. Figure 3 shows the breakdown of Future Skills into the different fields of competence.

All three dimensions are in turn interrelated and mutually influence each other. For example, the competence of self-reflection not only affects the subjective development of an acting individual, but also the ability to communicate and cooperate (social or organizational dimension) and in turn the system competence of an individual (object dimension). In this respect, different Future Skills are equally involved in every action. The three dimensions thus form the Future Skill Triple Helix DNA, in which the three skill dimensions interact in concrete actions (see Fig. 4). They enable a better understanding of the factors that define future action skills.

## Changing Contexts of Life and Work

Tracing Future Skills back to three constitutive components also allows us to clarify the causes that make Future Skills so significant. The empirical analyses of the interview data show that processes of change – referred to as shifts in the following – and movements are taking place in each of the three dimensions. It becomes clear that a clear change is emerging with regard to the nature of those skills that are significant for individuals and their ability to act in future work and life contexts. Future skill requirements can therefore be clearly distinguished from those of the past and also, to some extent, from those of the present.

**Fig. 4** The Triple Helix Model of Future Skills © Ehlers

### **Shift 1: From Standardization to Self-organization**

The theses of Voss and Pongratz (1998) on the labor force entrepreneur, of Hitzler and Honer on the craft biography (1994), and also of Ulrich Beck (1986) on the risk society suggest an ever-decreasing standardization of employment biographies. This results in a stronger self-control of the individual with regard to his or her employment biography. This self-control of navigating from one job to the next, but also from one position within an occupation to the next or from one occupation to the next is also evident in the Future Skills data at a micro level. At this level, skills can

be reconstructed for the internal demands within work processes, suggesting that there is a change that requires less prescribed work structures and more self-organization. This emphasis on self-competences is expressed in the reconstruction of the data, in which the interviewees emphasize that contexts of action in organizations are changing ever faster, both structurally (in the organization) and in terms of content (in the task area) and socially (in the environment). It becomes clear that individuals have to make ever greater individual adaptations to new contexts of action. These often arise in the context of emergent processes and are difficult to plan or predict. The necessary skills, which are demanded of the respondents as Future Skills, have the task of enabling this adaptive performance. It becomes clear that a productive-anticipatory approach to changing contexts of action is becoming increasingly important, so that the focus is not on compensatory measures that aim to restore the capacity to act in the event of a loss of capacity to act due to changing contexts of action. Rather, it is about enabling actors to productively shape new contexts of action already in the course of change processes. Future Skills have the task of enabling actors to be able to act in a self-organized way. So-called self-competences such as self-efficacy, self-determination, self-competence, reflection competence, and self-directed learning enable individuals to productively carry out the necessary adaptation processes in highly emergent contexts.

## **Shift 2: From Knowledge to Competence**

A second shift that emerges from the interview data is the change from the originally high importance of specialized knowledge to a more generic capacity to act. Following Erpenbeck (2012), we define capacity to act as the disposition to act in a goal-oriented manner in complex and unknown problem situations. Following Baake's (1991) dimensions of competence, which he in turn develops from the concept of communicative competence based on Chomsky (1981) and which he elaborates for the area of media competence, four dimensions are central, which can well illustrate the shift described here. The competence dimensions originally developed for the area of media competence and dealing with media (based on Baake, quoted from Vollbrecht, 2001, p. 56) are generally referred to the capacity to act in emergent contexts, as they can also be used to illustrate the shift in the understanding of competence:

- The knowledge dimension with an informative and an instrumental qualification dimension
- The dimension of usage with a more receptive and a more interactive component
- The design of something new with an innovative and a creative component
- The ability to criticize a knowledge base with an analytical, a reflexive (here self-referential), and an ethical component

Beyond the realization that Future Skills rather require the capacity to act and that pure technical knowledge is no longer sufficient, the model allows for a much more

precise reconstruction of which dimensions of competence are pronounced in the Future Skills model. In the interviews, it is clearly pointed out that Future Skills primarily require the development of the creative and critical dimensions of competence. In the past, individuals could limit themselves to applying knowledge, methods, and tools; in the future, however, it will become increasingly important to develop new knowledge, methods, and tools in an original and creative way.

### **Shift 3: From Hierarchical to Networked Organizations**

A third change refers to a generally changing organizational environment from hierarchical process organizations to networked and agile organizations. The change taking place here is clearly described in the interview data: While organizations in the past were organized in clear structures and management processes, the organizations of the future will be organized in more fluid structures that are subject to faster and more fundamental changes. In this context, competing poles face each other, where the previous structures and processes of clearly defined management structures are more likely to be replaced by agile processes and enabling management in the future. In the future, process organization will be characterized by networked structures in which clearly defined processes evolve more frequently and organizational charts and responsibilities change more quickly. Relationship management will become an increasingly important factor in this. The whole area of informal initiative is an important component of organizational success and an essential future skill without which the management of organizations will become inefficient in the future. The interviewees express that in future organizations central control approaches are less and less effective and instead participation-oriented goal-setting processes are becoming more and more important.

---

## **Conclusion**

With regard to Future Skills, the following points can be summarized:

1. Future Skills can be analyzed and described using a profile set that categorizes the 17 skills into three dimensions. Each of these dimensions contains a set of Future Skill profiles.
2. These skills can be described by two cornerstone characteristics: a strong, transversal, and well-developed capacity for self-organization, accompanied by the capacity to act in unpredictable contexts. These two elements thus advance to key components for professionalism – regardless of the respective professional field.
3. Future Skills can be described with a model that categorizes the 17 skills according to three dimensions: subjective – individual development-related skills, objective – task and topic-related skills, social – world/organizational skills. All

three dimensions are interrelated and should therefore not be thought of as mere expressions of isolated skill fields.

4. The future skill approach as presented here goes beyond a static model of pure skill enumeration and definition. Moreover, while the model assumes that digital or technical skills will undoubtedly be an important Future Skills ingredient in the future, it does not see these skills as sufficient on their own. The real value of these skills, therefore, lies primarily in the personal development of dispositions that can enable the individual to act in a self-organized way in a defined domain.

### Abstract

This chapter discusses different factors underpinning the development of online doctoral education and pedagogical concerns influencing the design of online doctoral programs. The rapid development of online doctoral education has been guided by recent changes in doctoral education and distance education contexts, both conceptually and empirically. To develop a comprehensive understanding of the nature of online doctoral education, 47 journal articles concerning the design of existing online doctoral programs were systematically selected and reviewed. The review results demonstrate that online doctoral education is a complex entity developed and influenced by a dynamic interplay among multiple factors relevant to different aspects of online higher education, professional doctoral education and internationalized education. However, there has been a lack of holistic research approaches to develop a comprehensive understanding of online doctoral education. In particular, literature grounded in online higher education and professional doctoral education scholarship has not been effectively integrated and synthesized, creating an unhelpful chasm. Within the chasm, a range of

pedagogical concerns and contradictions have emerged in online doctoral programs, which can be understood and addressed only when online doctoral educators have a holistic perspective bridging the two. Therefore, while the present review reveals valuable insights into online doctoral education research and practice, it also suggests that more research needs to be conducted using a more comprehensive theoretical understanding of online doctoral students and their experiences.

**Introduction**

This chapter provides a brief overview of the development of online doctoral education, both its scholarship and practice, by reviewing relevant literature. Compared to the long establishment of doctoral education practice, which was begun in the 1800s or even compared to the emergence of distance education dates back to the 1900s, online doctoral education has a relatively short history that has arisen with the advancement of information and communications technologies (Kumar & Dawson, 2018). For example, Sunderland (2002) is one of the first articles that discussed the use of email communication in a distance doctoral program offered, by Lancaster University in the UK, to academics at Romanian universities in 1997 and 1998. Crossman (2005) also reported that email communication is an innovative pedagogical tool for distance learners in doctoral programs in Australian universities.

Online doctoral programs (ODP) began to emerge between the late 1990s and the early 2000s. In the USA, for example, Regent University set up a doctoral program in Leadership Studies in 1996, where “with the exception of three brief summer residencies, all courses are designed and delivered primarily using [computer-mediated communication] or asynchronous instruction via the Internet” (Grooms, 2003, p. 3). The first fully ODP in Nursing was established at Duquesne University in the USA in 1997 (Milstead & Nelson, 1998), followed by several UK ODPs, including one in Business Administration set up at the University of Northumbria in 2000 (Combe, 2005). Currently, there are 259 ODPs in the USA, 187 in the UK, and 596 around the globe (Studyportals, 2022, September).

Although the wide dissemination of the Internet technologies is often referred to as the main contributor to the emergence of online doctoral education, the rapid development of OPDs in their current form is closely interlocked with recent changes in general doctoral education practice (Kumar & Dawson, 2018). Thus, it would be helpful to understand those changes and related debates to the growth of online doctoral education in the literature. The changes in general doctoral education practices across the 1980s and 1990s can be conceptualized as three related phenomena: i) moving from a traditional knowledge-oriented doctorate to a

training-based doctorate, ii) a decrease in traditional research students and an increase in researching professionals, and iii) a tightened public funding for doctoral studies with added pressure on improving student competition rates (Hockey, 1991).

These changes were not unique to the doctoral education context. Similar phenomena were observed across the higher education sector under the impact of neoliberalism and free-market fundamentalism (Giroux, 2014) and also noted in the open and distance education context (Lee, 2017). The idea of higher education as a public service began to be demolished, and subsequently, student fees, not only for campus-based programs but for distance programs, were rapidly increased or newly introduced in some countries (in the UK, for example). As doctoral studies were becoming an individual customer's choice, those interested in earning a doctorate for self-promoting purposes in the competitive market space signed up for doctoral programs.

These nontraditional (and fee-paying) doctoral students demanded a new, more convenient, and flexible way of engaging with doctoral education as they want to pursue a doctorate while maintaining their professional status and other social responsibilities. Also, the radical shift in the subject and purpose of doctoral education – *from* elite and “bright” student production of new knowledge *to* non-traditional and often “under-prepared” student participation in research training (Lee & Danby, 2012) – mandated universities and research institutions to change their doctoral education practices or at least to come up with different types of doctorates. Against this societal and economic backdrop, ODPs emerged as an alternative approach to doctoral education that could meet the growing needs of the new doctoral student group. That is where the affordances of information and communications technologies came to realize and accelerate the required changes in general doctoral education.

The development of the “contemporary” formats of online doctoral education has been influenced and enabled by the complex interplay between a range of social, educational, and technological changes in recent years. Subsequently, those factors have underpinned the design of ODPs, shaping student experiences in those programs. Therefore, the nature of online doctoral education is multifaceted and complex (Lee, 2020a). This chapter seeks a deeper understanding of the development of online doctoral education by reviewing diverse contributing factors to its development identified in the published literature. The chapter also discusses how those factors have guided the design of specific ODPs concerned in the same literature. 47 journal articles were systematically selected and reviewed to write this chapter, which will be detailed in the following section.

---

## Review Methods

This review employed a systematic scoping process (Arksey & O'Malley, 2005). The initial search was conducted on Scopus, the largest abstract and citation database of peer-reviewed literature (<http://www.scopus.com/>), using the following compound search terms:

("online" OR "distance") AND "doctor\*" AND ("program\*" OR "course\*" OR "stud\*")

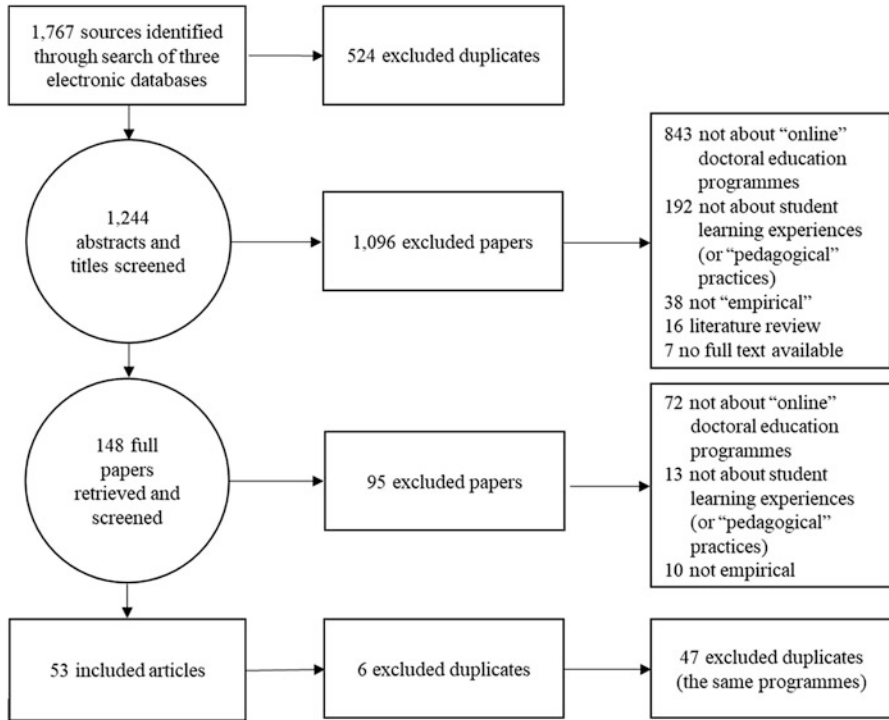

When conducted in March 2021 (without limiting the publication period), based on the title, abstract, and keyword of the literature, the initial search results included 1144 journal articles (written in English). Another search was undertaken on the Web of Science using the same search terms to ensure the completeness of the search outcomes. 623 journal articles were also included. All 1767 articles were imported to a reference management software, and 523 were excluded as duplicates.

The author screened the titles and abstracts based on the inclusion and exclusion criteria (Zawacki-Richter, Kerres, Bedenlier, Bond, & Buntins, 2020). To be included, filtered articles must demonstrate their focus on (i) an online doctoral program (the most part of the program should be conducted at a distance, except for a limited number of residentials), (ii) online pedagogical practice (rather than technological tools such as learning management systems), and (iii) an empirical case or existing doctoral program (rather than conceptual or theoretical discussions). That is, papers discussing doctoral students' experiences in a single online course or module in face-to-face doctoral programs were excluded alongside conceptual papers, including literature review articles. In addition, recent papers discussing online doctoral education practice during the COVID-19 pandemic were excluded to maintain the focus of the review on the contributing factors to the development of online doctoral education in normal circumstances. For this first step of the filtering process, sensitivity rather than specificity was adopted. For example, when the titles and abstracts did not include complete information required for the selection decision, the articles were included rather than excluded.

As the above flow chart (Fig. 1) suggests, after the first screening of 1244 articles, 148 papers were included for full-text screening. After the second round of inclusion and exclusion exercise, 53 papers were finally selected for the present systematic review. Additional six articles were excluded to avoid reviewing multiple papers describing the same doctoral program, with one exception. Kumar, Dawson, Black, Cavanaugh, and Sessums (2011), Kumar, Ochoa, and Edwards (2012), and Kumar and Dawson (2013) were all included in the present review despite their duplicated focus on the same online doctoral program. It was because each paper discusses a distinct aspect of the program, such as a theoretical underpinning of the overall design of the program (Kumar et al., 2011), the design of the specific information literacy and library instruction of the program (Kumar et al., 2012), and the impact of the program on the broader educational sector (Kumar & Dawson, 2013). Three research questions have guided the review process:

- (i) What are the stated reasons for the development of online doctoral education?
- (ii) What are the stated pedagogical concerns about online doctoral programs?
- (iii) What are the stated theoretical approaches to conceptualizing online doctoral studies?

Taking a grounded theory approach (Charmaz, 2014), I conducted an inductive thematic analysis of the selected 47 journal articles. More specifically, three steps

**Fig. 1** Systematic review flow chart

of the coding process were employed as suggested by Corbin and Strauss (2014) – open coding, axial coding, and selective coding.

Firstly, I read through each article in print and highlighted sentences or paragraphs discussing the factors contributing to the development of online doctoral education, pedagogical problems observed in ODPs, and the theoretical underpinnings to design the programs. Abstracts were excluded from the coding since most statements in abstracts were repeated in the main texts. The literature review section of each article was also excluded since statements appearing in the section are often not aligned with the authors’ broader arguments nor relevant to the particular doctoral programs concerned. Thus, coding and reading those statements in a decontextualized manner may reduce the accuracy and validity of the coding results. However, there were some exceptions. For example, Provident et al. (2015) utilize the literature review section to present their theoretical framework (i.e., transformative learning theory) and explain its implication for their online doctoral program. Jiang, Ballenger, and Holt (2019) also introduce their theoretical framework (i.e., Community of Inquiry) in the literature review section. In these cases, I selected and coded the relevant parts of the literature reviews.

Initial codes were identified and assigned to each of the highlighted meaning units – using critical notions in the research questions or the articles. Most articles

presented multiple developmental factors and pedagogical strategies. I also made notes of potential categories emerging from the highlighted parts in the margins of the articles. These initial codes were all entered into a qualitative analysis tool (i.e., Atlas.ti).

The second round of reading (i.e., axial coding) was undertaken using the tool, with the codes more carefully examined and compared with and against each other. An attempt to answer the research questions was made by selecting the codes that were ascribed more weight (e.g., appeared more frequently) within and across the articles or directly relevant to the research questions. The other codes that were less weighted or not directly connected to the research questions were removed at this stage. Those selected codes were logically organized and grouped into independent categories. These categories were shared and discussed with three online doctoral students conducting their thesis projects on online education supervised by the present author. Based on the conversations—a mechanism of utilizing the concept of critical friends (Lincoln & Guba, 1985) to increase the trustworthiness of the qualitative research outcomes—the categories with representative codes were checked and validated.

The final stage of analysis (i.e., selective coding) focused on generating themes to answer the three research questions. As a result, 12 themes have been drawn from the reviewed articles, which will be presented in the following section of this chapter.

---

## Findings and Discussions

### What Are the Stated Reasons for the Development of Online Doctoral Education?

There are at least five different reasons stated in the reviewed articles. Each article positions its rationale for the development of ODPs in distinctive educational and research contexts such as distance education, doctoral education, professional education, and international education. The review results clearly suggest a dynamic, interdisciplinary, multi-focal nature of the scholarship and practice of online doctoral education. Each of the five reasons will appear below in turn with a selected excerpt that illustrates how the concerned rationale is presented and discussed in the reviewed papers.

#### Growth in Online Higher Education

The most frequently stated reason for developing ODPs is the fast growth in online education. Many authors open up their articles by describing the contextual background of the growing numbers of online programs offered by universities and online students registered in those programs. The below excerpt effectively demonstrates how the rationale for online doctoral education is typically argued.

[W]e have witnessed the exponential growth of online education. According to Babson Survey Research Group, more than 6.3 million students in the U.S. took at least one online

course in Fall 2016. . . Internet and digital technologies. . . have dramatically transformed the way education is delivered. . . Such new tools have enabled online delivery of course materials to students outside of brick-and-mortar classrooms in an asynchronous manner. . . students with full-time leadership positions in public education benefit from online programs as they provide self-paced flexibility. (Jiang et al., 2019, pp. 296–297)

The exponential growth in online higher education, enabled and facilitated by the educational use of advanced communication technologies, is set as a benchmark for doctoral-level educational practice. The flexibility of online education that allows adult learners (often professionals with full-time work) to access university education is the key to this argumentation, which is applicable and translatable to other educational contexts, including doctoral education. Most of the articles starting from this context tend not to have any statements specific about doctoral education or doctoral studies.

### **Growth in Professional Doctoral Education**

The second frequently stated reason underlying the fast development of online doctoral education is situated in the context of professional doctoral education. A group of reviewed articles mention the recent changes in the doctoral education landscape, including the growing demand for a doctorate among professionals and the increasing diversity in doctoral provisions.

In recent years, there has also been an increase in professional doctorate awards in the USA, the UK, and Australia, accompanied by studies and discourse about their design and impact. . . Professional doctorates are designed in many ways and are offered as pre-service or in-service degrees. They range from doctorates that structure coursework and a discipline-specific dissertation to doctorates that are designed in collaboration with employers and include research that is conducted in the workplace and supervised by university faculty. (Kumar & Dawson, 2013, p. 165)

This set of literature tends to perceive online doctoral education as an effective means for professional development, supporting professionals to acquire up-to-date knowledge and integrate it into their workplace to improve their practice. Such an approach has shifted a traditional view on the purpose of doctoral education – from knowledge creation to knowledge acquisition (and application). Thus, although both Jiang et al. (2019, in the previous section) and Kumar and Dawson (2013) mention the fact that ODPs allow adult students to remain in their workplace while pursuing a doctorate as a starting point, where and how those doctoral programs will bring their students to as an ending point can differ.

### **Demands in the Professional Field**

Another frequently stated rationale for offering online doctoral education (more “academic” doctorates, including PhD) tends to be situated in urgent needs of specific professions and professional contexts such as nursing, educational leadership, and social work. Despite their apparent similarity with the previous point about the growing professional doctoral education, this set of selected statements provides an increased level of urgency and specificity to the discussion.

Increased numbers of doctorally prepared nurses are needed due to a demand for faculty, administrators, researchers, and theorists who possess a nursing doctorate, a demand that exceeds the supply. . . . However, when nurses make the decision to pursue a doctorate, they tend to be older than students in other disciplines, typically have established careers, have financial and family responsibilities, and unlike most other doctoral students, the majority of them work full-time and study part time. . . . In the United States there are only 88 doctoral programs in nursing. . . . finding one that is within commuting distance, not to mention consistent with the student's research interests, may be impossible. To address the barrier of proximity, nursing programs are offering distance learning options and they are becoming a common method of acquiring a nursing education. (Halter, Kleiner, & Hess, 2006, pp. 99–100)

As can be labeled as online “academic” doctoral education, the ultimate outcomes of the online doctoral education program in Halter et al. (2006) is meeting “a demand for faculty, administrators, researchers, and theorists.” Thus, the focused aim of the program is rather academic, which is distinguishable from the practice-oriented purposes of professional doctorates that mainly target improving professional practices and technical performances in the fields. The differences are, however, not always explicitly stated but implicitly assumed.

### **Internationalization of Education**

A few reviewed articles discuss the reason for online doctoral education within a dynamic interplay of the increase and decrease in international education (more specifically, internationalized education market). This line of argumentation tends to be merged into the marketization discourse, seeing online doctoral education as a competitive product which could attract a larger group of students worldwide. Authors with this perspective often explicitly refer to students as customers. For example, Combe (2005) argues:

International education has grown into a substantial worldwide industry. . . . However, there is some evidence to suggest that over the last three decades growth in international education has been slowing down. . . . This slowing of overall market growth may reflect a maturing industry and is likely to increase the level of competition between education service providers seeking to operate in international markets. . . . The development of e-learning technologies has presented providers with opportunities as well as challenges as they seek to positively enhance their educational value chain to effect lower costs, enhanced differentiation of products and reap the benefits of economies of scale and scope to create a competitive advantage. One way of achieving this is to target high value customers with access to advanced qualifications at Master's or Doctorate level. (p. 119)

Reading such statements as “the educational market has been saturated, and thus, educational providers need to find a niche market” may not be a total surprise given the neoliberal climate in the current higher education context. Internationalization discourse, providing a big picture, is compatible with other reasons mentioned earlier – the growth in online education and professional doctoral education. In fact, most of the reviewed articles stress the international nature of their focused ODPs where the diversity of students' ethnic and cultural backgrounds is apparent. Regardless of the fundamental financial interests in such internationalization among

doctoral institutions and programs, the international cohort community seems to have pedagogical merits.

### **Social Justice-Oriented Rationale**

The internationalization of education is not only (and always) driven by profit-oriented market principles. Despite the small number, several articles approach international online doctoral education with a social justice-oriented perspective from a vantage point of less developed countries (LDCs) lacking doctoral education opportunities available at the local level. In those articles, ODPs are usually offered by universities located in more developed countries, serving students located in LDCs. Syler and Venkatesh (2018) is a rare article that discusses doctoral education provisions in LDCs (i.e., Cameroon in Africa).

LDCs face various complex problems and needs, such as the availability of potable drinking water, eradication of infectious diseases, elimination of poverty, and availability of healthcare, that require well-developed and sustainable solutions. . . [LDCs] urgently need to develop intellectual capital internally in the form of scholars, leaders, and technicians. . . Doctoral programs in LDCs, for example, allow [researchers] to expand their knowledge and insights throughout the global information systems (IS) community. . . Such endeavors require the support and contribution of scholars in developed countries. (p. 2)

Although the concerned doctoral program in Syler and Venkatesh (2018) is mainly operated face-to-face on multiple campuses in Cameroon, Ghana, Uganda, and Nigeria, it also serves online students from various places in Africa, using video conferencing tools. The article describes the authors' unique experience of coordinating an online doctoral course with other educators and experts dispersed across the world. One of the authors clearly articulates their social justice-oriented rationale for online doctoral education as: "I decided to take on the course for a simple reason: to give back to the community in any way I could, which I feel is my true calling" (p. 3). Given that the authors themselves are also located in the United States – distant from the doctoral program – such teaching efforts could be only feasible through being mediated by communication technologies.

### **What Are the Stated Pedagogical Concerns About Online Doctoral Programs?**

There are multiple pedagogical concerns about online doctoral education discussed in the reviewed articles. Such concerns are primarily associated with the inherent nature of learning at a distance and the unique characteristics of adult students. The shared theme across those concerns is their double-edginess – those concerns are advantages and disadvantages of online doctoral education, at the same time. As discussed earlier, one of the rationales for developing ODPs is to meet the growing educational needs among adults with other responsibilities. A greater level of physical flexibility offered by ODPs enables those adults to begin their doctoral study in the first place; however, the same flexibility creates subsequent pedagogical

challenges such as a sense of isolation that often threaten successful learner engagement in ODPs. In addition, adult learners themselves walk into the programs with their own difficulties caused by their personal and professional circumstances.

The distinctive features of doctoral “level” of studies add additional academic challenges to adult distance learning scenarios. The following excerpt effectively captures the combination of the three: distance learning, adult learners, and doctoral studies.

Working students with families must balance career and home obligations with their academic responsibilities. Staying in contact with their doctoral advisor (chair) is more difficult for students at a distance. Another common problem for older students that have been away from school is the need to strengthen their academic writing and research skills. Weak writing skills result in more drafts, and poor research skills increase the time to complete the proposal and the data analysis. Students also find the transition from taking structured courses to writing the dissertation or doctoral study challenging because of the need to work independently. (Hogan & Devi, 2019, p. 61)

Previous research has attempted to address one or more of those challenges. There are at least four pedagogical concerns frequently addressed in the 47 reviewed articles.

### **Flexibility and Structure**

While ODPs provide a significant level of physical flexibility at the entry point, they tend to employ a more structured approach to their pedagogical design. Given that most doctoral students are experienced professionals who are “seeking to enhance their skills in research, education, and leadership in their respective professions,” ODPs tend to be structured “to improve the students’ abilities to educate and conduct research in their disciplines” (Cotter, Welleford, & Drain, 2008, p. 262). Especially in the European context, where doctoral studies mainly involve individual students pursuing their thesis projects with supervisory support, ODPs are often called “taught” programs, including tutor-guided coursework. In North American and other contexts where it is common for doctoral students to take courses, ODPs are still more structured than face-to-face ones. ODPs tend to offer a limited range of “pre-selected” online courses to make the program more structured and guided.

Within the structured taught part, however, these programs also attempt to provide pedagogical flexibility to adult students regarding when and how they engage with learning. With a small number of exceptions, most learning activities in online doctoral education are organized asynchronously, using lecture videos, independent readings, discussion forums, research projects, and reflective writings. In addition, most programs support students’ own choice of learning content and project topic, which are closely related to their personal interests and professional experiences:

In the DPHRS [Doctoral Program in Health-Related Sciences], another issue was evident in the development stage—students would be experienced health professionals and health professional educators, who, within their respective disciplines, had more extensive

knowledge than the instructors but were lacking in a formal didactic research and education framework. . . It becomes incumbent upon the DPHRS program and its instructors to facilitate the students' understanding of their respective learning styles, processes, and preferences. Thus, a learner-centered environment places the health professional student at the center of the course organization and processes. (Cotter et al., 2008, p. 264)

As Lee (2020a) observes, such part-timeness and practice-orientedness are the shared aspects of online doctoral studies, which are fundamentally grounded in the flexibility of ODPs. Martin and Noakes (2012) also report online doctoral students' appreciation of freedom of "learning by wandering" in their studies. At the same time, experienced professionals who begin their part-time doctoral studies after many years of a study break tend to lack study skills, habits, or time. Thus, an effective program structure with carefully designed learning activities and guidance is necessary for their successful doctoral journey. In a nutshell, online doctoral education literature focuses on finding and realizing an optimal balance between the seemingly contradictory principles of flexibility and structure.

### **Isolation and Community**

While structured flexibility is a vital design principle underpinning most ODPs, many articles note the issue of students feeling isolated and disconnected from their university. Although a sense of isolation is a common emotion that may be experienced by any distance learner, Sunderland (2002) has provided an in-depth and sophisticated explanation of a psychological gap experienced by educational professionals enrolled in an online PhD program in applied linguistics:

Together, these geographical and temporal gaps can be seen as creating "a psychological and communications gap, a space of potential misunderstanding between the inputs of instructor and those of the learner" . . . This suggests a consideration of the particular affective needs of the distance learner, as well as their pedagogic needs. However, the psychological gap may also be an effect of the complex identity of the distance student. They are likely, after all, to be working as a professional, possibly even doing the same sort of job as the teachers on their distance programme. And this psychological gap may not only be an effect of the relationship between student and the "distant" tutor, but also of the differences between the institution with which the student studies and that at which they work, the academic discourse practices by which they are characterized, and the political regimes which directly or indirectly govern these two institutions. (p. 234)

Many authors, including Sunderland (2002), perceive such a psychological gap as one of the major problems and drawbacks in online doctoral education, resulting in student mistrust and dissatisfaction with the program, loss of confidence and demotivation in their studies, and subsequently, poor academic progress and drop-out. To address this problem, authors have employed diverse community-oriented remedies. Therefore, developing student support networks in ODPs appears to be the most frequently researched topic in the reviewed literature. Common strategies employed to improve the community-aspect of online doctoral education include i) establishing a cohort-based program structure (e.g., Kumar et al., 2011; Provident et al., 2015), ii) facilitating synchronous online interactions (e.g., Hogan & Devi,

2019; Myers, Singletary, Rogers, Ellor, & Barham, 2019), and iii) organizing short face-to-face residentials (Cotter et al., 2008; Halter et al., 2006). Most ODPs adopt more than one strategy (often all three), which is clearly demonstrated in the following description of an ODP:

[W]ith a *cohort-based format* that includes online coursework and interactions with a one-week session on campus... We designed online courses in the program to include multiple forms of *synchronous and asynchronous interaction*... At the end of their first year, students took a summer seminar that consisted of online activities to prepare for the *one-week campus-based experience* and follow-up online assignments. Program faculty collaboratively led the campus experience, which was intended to help students get acquainted with the university through interactions with one another, faculty both in and outside the program, administrators, and librarians. (Kumar et al., 2011, p. 129)

Researchers have found that the sense of isolation and the sense of community are closely interlinked in online doctoral studies (Berry, 2017). It is critical to ensure that distance students feel that there is a strong academic community exists in their program and that they also belong to the community. The cohort-based program structure, where a group of 20 or 30 students start and progress through the program together at the same time, has proven effective – especially for the taught part of the program. Although having synchronous interactions (using telecommunication tools) and face-to-face residentials as mandatory components of ODPs may reduce the flexibility and accessibility of these programs, many students appreciate those community-building opportunities. Therefore, again, it comes down to the matter of finding the right balance between improving flexibility and a sense of community within a single ODP.

### **Technology Anxiety and Research Literacy**

While most articles (e.g., Jiang et al., 2019; Martin & Noakes, 2012) emphasize the potential of advanced communication technology for enabling adult professionals to pursue a doctorate and increasing a sense of belonging among those students, it is crucial to notice that online doctoral students also experience a range of technology-related difficulties. Another set of pedagogical concerns that emerged in the reviewed articles is closely related to a lack of technology and research literacy among online doctoral students. For example, Bolliger and Halupa (2012) report that online doctoral students tend to experience a high level of technology anxiety, “negative emotions associated with computer use” (p. 83), especially at the beginning of their program, and such anxiety strongly influences their overall learning experiences.

In a similar vein, several articles (e.g., Kumar et al., 2012; Tuñón & Ramirez, 2010) focus on a lack of information literacy among online doctoral students, exploring how to design and deliver effective library training to those distance learners. The reviewed articles stress the importance of an early introduction to a library system and solid orientation on using information technology for research purposes, which is an essential part of research literacy required for the successful completion of doctoral studies. It is further suggested that library training needs to be

effectively integrated into student coursework in an ongoing manner “beyond one-shot library training” (Tuñón & Ramirez, 2010, p. 989).

Of course, technology anxiety (or information illiteracy) is not always associated with particular learner groups or simply caused by a lack of technical skills. For example, online PhD students may experience a high level of technology anxiety at the beginning of their doctoral program even though they have technical skills required (Lee, 2020a). Encountering new people, new knowledge, and new practices at the same time “online” – such as engaging with a doctoral level of academic discussions online, whether synchronously or asynchronously, may cause a great sense of insecurity and anxiety among online doctoral students (also see Lee, 2021). That is, the notion of technology anxiety needs to be more holistically understood, which can be experienced when online doctoral students do not have a complete set of skills (online social and communication skills, academic and learning skills, etc.).

Nevertheless, some of the reviewed articles link those challenges to the particular characteristics of online doctoral students (Brahme & Walters, 2010). Bolliger and Halupa (2012) discuss the differences between doctoral students enrolled in online programs and those in traditional programs as:

[M]ost students in online doctoral programs are nontraditional students – many are between 45 and 60 years of age. . . These students did not grow up using these types of technologies and many obtained their undergraduate degrees 25 or more years previously, before online programs were available. In contrast, the median age of individuals awarded doctoral degrees was 33.0 years in 2004–2005 and 32.7 years in 2005–2006 (Snyder & Dillow, 2010). Because this segment of the population typically consists of older individuals who are returning to higher education to obtain a doctoral degree after spending a considerable amount of time in the field, returning graduate students may be less comfortable with the online delivery format than their traditional counterparts. (p. 82)

Unfortunately, the present review has failed to find literature that offers more recent perspectives about online doctoral student populations; thus, it is difficult to know how the populations have been changed in more recent years. Alternatively, it may be a fortunate and welcoming result that suggests the maturity of the scholarship of online doctoral education, moving away from the simple representation of the populations and their experiences.

### **Diversity and Inequality**

As discussed earlier, the internationalized education, often coupled with social justice-oriented agenda, is one of the stated reasons for the development of online doctoral education. Subsequently, there are a growing number of international students in ODPs, including those from less privileged backgrounds who cannot afford to the full-time doctoral studies on campus. Such a great diversity among online doctoral students in terms of their cultural and social backgrounds and professional and educational experiences presents both pedagogical advantages and challenges to online doctoral educators. For example, Roumell and Bolliger (2017) report the positive side of such diversity from the staff perspective as:

The most-often satisfying aspect mentioned by faculty was that the distance environment provides students with access to doctoral education who otherwise would not have the opportunity to pursue a doctorate. Another perceived benefit is that distance programs include more diverse students in regard to educational and professional background (and subsequently a variety of research topics), making the student body more diverse in terms of gender, race, ethnicity, and ability. (p. 88)

The social justice-oriented argument is also evident in Williams, Wall, and Fish (2019) that shows online doctoral education is more accessible to underserved students where more than 30% of students are the first generation of college graduates than traditional doctoral education (the average percentage of those students in science and engineering doctoral programs is 17%).

Berg (2016) similarly notes the advantages from the student perspective as:

Some [students] saw an advantage in the online format, especially for [underrepresented minority] students, as exemplified by one student: *As the majority of this educational journey has been online and therefore demographically blind, I do not believe my doctoral experience has been any different than most of my co-hort. I find that I am a student far more often than an “ethnic minority” student.* In a similar vein, students wrote about the large cultural diversity of the online classroom, which often includes international students, as a positive characteristic: “. . . meeting other learners from all nations.” (p. 231)

Nevertheless, the same authors also notice the unavoidable academic and socio-economic gap among the diverse population of online doctoral students. Williams et al. (2019) argue a high interrelationship between doctoral students’ academic persistence and their parental educational level. Although there is no direct impact, the social and economic circumstances of the first-generation students indirectly influence their learning abilities and attitudes – such that “the self-regulation behaviors learned early in life from the parents persist, apparently, even into mid-life” (p. 71). Berg (2016) also reports diverse academic and nonacademic challenges faced by the underrepresented minority students in ODPs and the crucial roles of academic supervisors in their degree completion. Beyond the problem of inequality among doctoral students, the diverse needs, learning preferences, personalities, and professional and personal situations of adult students all strongly impact their learning experiences and achievement in online doctoral education, which calls for more inclusive and sensitive pedagogical approaches of doctoral educators (see Lee, 2020b; Rovai and Grooms, 2004).

## **What Are the Stated Theoretical Approaches to Conceptualizing Online Doctoral Studies?**

This final group of themes analyzed in the review project is about how previous researchers conceptualize online doctoral studies to better understand student experiences in ODPs and address different pedagogical concerns discussed in the above section. As the development of ODPs is primarily grounded in the existing

practice and increasing demands in online higher education and professional doctoral education, there has been some theoretical resonance between online doctoral education and the two. In other words, the following three interlinked theoretical approaches, commonly appear in online higher educational and professional doctoral education literature, have been most frequently adopted by the authors of the reviewed articles. It is worth mentioning that a large number of these articles ( $n = 24$ ) neither include a theoretical framework section nor name any particular learning theory.

### **Constructivist Learning Theories**

Most articles with specific theoretical conceptualizations stress that online doctoral students are adult professionals who demand student-centered learning opportunities through which they are effectively guided to construct meaningful knowledge for their own professional practice and development. Thus, the authors of those articles have utilized different learner-centered learning and practice-oriented learning theories, which can be collectively called constructivist learning theories. The fundamental pedagogical principles drawn from constructivist learning theories underpin the design of several ODPs discussed in the literature. The following two excerpts clearly set the tone of such theorization.

[A] learner-centered environment is one in which students are partners in the learning, have multiple options for learning, work collaboratively, and help define the objectives and methods of the course. . . In a learner-centered environment, the students' struggle is a process that leads to improved outcomes (McKeachie & Svinicki, 2006). Learner-centered programs are organized differently to stress the student's responsibility for learning and teaching along with the development of a faculty perspective that moves from didactic, lecture-discussion to a facilitative resource exchange. (Cotter et al., 2008, p. 258)

Historically, a range of traditions related to progressive education and situated learning theories have contributed to research connecting learning and the workplace (Cobb, 2001; Kolb, 1984; Mezirow, 1991; Smith, 2003). Nevertheless, the literature suggests (Argyris & Schon, 1974) that workplaces and universities have traditionally been somewhat estranged though the emergence of student centred learning and the development of transferable skills has clearly kindled initiatives to seek common ground. (Crossman, 2005, p. 19)

### **Community of Inquiry and Community of Practice**

Within the broader constructivist learning paradigm, some articles zoom into more specific social aspects of online learning or professional learning processes and outcomes. These articles have conceptualized online doctoral studies as a dynamic process of creating a community of inquiry or participating in a community of practice. Earlier in this chapter, two interconnected phenomenal aspects of online doctoral education – online doctoral students feeling a sense of isolation and a sense of community – have been discussed as one of the common pedagogical concerns that have received ongoing scholarly attention from online doctoral educators. Those authors concerned about building a sense of community among doctoral students have utilized a community-oriented approach to conceptualizing online doctoral studies. The Community of Inquiry (CoI) framework is, in fact, the most frequently

used one among the community-oriented learning theories, providing valuable insights and guidance into ODP design.

The CoI framework consists of three elements (social, cognitive, and teaching presence) that takes place in the interaction of individual learners and their instructor, as well as the categories and indicators that are to define each presence and to code the transcripts. The element of social presence was defined by Garrison et al. (2000) as “the ability of participants in a community of inquiry to project their personal characteristics into the community, thereby, presenting themselves to others as real people” (p. 89). Effective communication, open communication, and group cohesion are three major aspects of social presence. To achieve educational goals, online course design should create the environment for inquiry to allow quality, open educational communication between learners and the instructor. (Jiang et al., 2019, p. 298)

Another community-oriented theory, which appears several times in the reviewed articles, is Community of Practice (CoP). While the CoI framework has its root in online learning, CoP theory is initially developed in the context of professional learning – more specifically, the apprenticeship context where a novice trainee develops into an expert member of a specific professional community through interacting with other members in the community. Greene, Cote, Koperniak, and Stanley (2021) conceptualize online doctoral studies as a process of participating in moving between multiple CoPs. Thus, doctoral students develop their professional and academic identities as members of different CoPs in their doctoral programs and professional settings. This line of theoretical discussion is particularly relevant to the idea of a professional doctorate, highlighting the immediate impact of doctoral studies on students’ professional development.

As individuals engage in a [CoP], they move from legitimate peripheral participation to full participation. Wenger (1998) came to see this process as an important factor in identity development. . . Wenger-Trayner and Wenger-Trayner (2015) zoom out to view [CoPs] in multiplicity on a landscape of practice. Through this lens, they explore implications of negotiating identity while navigating boundaries between a range of communities. . . It is these key concepts of accountability to a community, boundary crossing between communities, and inexpressibility of identity within a particular community that frame and organize our study. (p. 94)

### **Transformative Learning Theory**

Four articles focus on online doctoral students’ transformative learning experiences. Mezirow’s (1997) transformative learning theory, one of the prominent theoretical accounts of how adults learn and develop, is referenced in nine articles. ODPs provide structured opportunities for adult professionals to critically reflect on their “familiar” practices and systematically engage with relevant scholarship. The international nature of online doctoral communities also allows doctoral students to be exposed to diverse perspectives and rational discourses with students from different cultural and professional backgrounds. Through those intellectual and social engagements, doctoral students experience meaningful perspective transformations. Such perspective transformation is the ultimate goal of the professional learning process,

which involves adults' active engagement with constructive learning activities in a supportive learning community. The following excerpt effectively captures the essence of transformative learning experiences in ODPs.

[T]he student often experiences change as the result of a multiple step process frequently characterized by a disorienting dilemma, followed by the use of active learning, and reflection. The dilemma can serve as a catalyst for learners to examine their assumptions and beliefs through engagement in self-reflection and discourse with others related to changing their view. According to transformative learning theory, this process results in the reorganization of perspective with action to promote change (Santalucia & Johnson, 2010). The product is a learner who emerges with skills to effect broader change. The scientific literature includes outcome studies of *doctoral students' transformative learning experiences*. . . Trusting relationships and establishing support have been cited as important elements in facilitating *transformative learning processes in online environments*. (Provident et al., 2015, pp. 129–130)

---

## Conclusion

Although the emergence of online doctoral education is often discussed in the context of the advancement of the Internet and communication technologies, the present review demonstrates that its development is firmly rooted in at least two seemingly separate educational phenomena – the growth in online higher education and the growth in professional doctoral education. As briefed in the introduction of this chapter, the growth in both online higher education and professional doctoral education has complex societal backdrops. In addition, internationalized education context has added another layer of complexity to the online doctoral education practice. Although the detailed discussion on those backdrops for the fast development of ODPs falls outside the scope of this review, the review results provide online doctoral educators with several useful recommendations:

- Online doctoral educators need to have a holistic understanding of online doctoral studies: Most authors of the reviewed articles have not brought the complexity to their writings, exclusively focusing on one aspect of online doctoral education (e.g., online education, professional doctorate, and internationalized education). Consequently, there has been an inevitable chasm within the scholarship of online doctoral education – one emerged in online higher education contexts, and the other originated in professional doctoral education contexts (with a few exceptions found in international education settings). Given that the experiences of online doctoral students are constructed by multiple social and pedagogical characteristics of online doctoral studies (Lee, 2020a), such separation in the academic discussion limits our view of online doctoral education. This calls for integrated research efforts to construct a more comprehensive understanding of online doctoral studies and students.
- The design of ODPs is to find the right balance between multiple conflicting needs of online doctoral students: The complexity of online doctoral education is

inevitably manifested in the pedagogical tensions in many ODPs, as observed by most authors in this review project. For example, there is an ongoing tension between providing flexible learning opportunities to adult students with different learning needs and situations and offering well-structured guidance to support their learning experiences. Finding the right balance in the design of an ODP is critical for online doctoral students' retention and success. Also, many online doctoral students appreciate the accessibility of online programs, which enables them to maintain their professional and personal lives; however, many also suffer from a sense of isolation and disconnection created by the physical and psychological distance from tutors and peers (Byrd, 2016). To address such tension (and increase a sense of community among distance students), most ODPs employ a cohort-based structure and diverse community-based pedagogical strategies. However, it is essential to remember that such strategies could, in turn, reduce the accessibility and flexibility of the ODPs.

- There are critical but often neglected research topics in online doctoral education literature: The aforementioned concerns are similar to the common pedagogical issues observed in online higher education or professional learning settings. Most of the reviewed articles focus on those concerns – the flexibility (or structure) of ODPs and the sense of isolation (or community) among online doctoral students. Meanwhile, a relatively small number of articles concern other problems that tend to stem from the particular characteristics of adult learners (e.g., a high level of technology anxiety), doctoral studies (e.g., a lack of research literacy), and international education (e.g., diversity and inequality). Despite the importance of those issues for successful online doctoral studies, there has not been enough scholarly attention to those problems in online doctoral education literature.
- The online doctoral education scholarship can benefit from an integrated theoretical approach: The same pattern emerges from the analysis of theoretical approaches employed in the reviewed articles. Most of the reviewed articles use either online learning theories or adult learning theories to conceptualize online doctoral studies – as demonstrated by the four most commonly employed theories (i.e., constructive learning theories, Community of Inquiry, Community of Practice, transformative learning theory). As the number of ODPs and students enrolled in those programs grows across the globe, the program design improves and pedagogical practices in those programs mature (Holmes & Rockinson-Szapkiw, 2020). It is timely to reflect on the maturity of the scholarship of online doctoral education and the rigor of the current scholarly understanding and practice. While the present review reveals valuable insights into online doctoral education research and practice, it also suggests that more research needs to be conducted using a holistic perspective to develop a comprehensive understanding of online doctoral studies.

### Abstract

This chapter overviews the 14 chapters in Part 7 of the *handbook*, which are focused on the design, delivery, and assessment of open, online, and digital learning. While the chapters address a wide variety of factors relevant to ODDE, I discuss several common themes, including evidence for the effectiveness of ODDE, standards to guide effective ODDE design, assessment and credentialing of ODDE learning, and the need for future research to move beyond studying individual factors (micro level) in higher education. Finally, I conclude with a call to how we can design the future of ODDE, including first, seeking to understand systemic nature of learning; second, embracing the sociocultural nature of learning, and third, utilizing the full repertoire of diverse scholarship methods to develop knowledge in our field.

**Introduction**

A major challenge in the field of open, distance, and digital-based education (ODDE) has been the overemphasis of the role of technology in learning versus pedagogy, strategy, and design. To be certain, new technologies provide new affordances that can anchor new approaches to teaching and learning, and often-times, technological innovation precedes pedagogical creativity. However, when we focus too much on the technology implementation, we may miss the bigger concerns with how to design the context to benefit from the technology. In doing so, we may make the error of putting “new wine in old bottles” by resurrecting the “media vs. methods” errors of the 1980s/1990s in the new flasks of online and open education (Lockee, Moore, & Burton, 2001).

In fact, Honebein and Reigeluth ([in press](#)) have found that we often do exactly that – and may be going backwards as a discipline. In their analysis, they found that there is research to *improve* learning by focusing on strategy and research to *prove* one media-based approach is better than another through media comparison research. From 2010 to 2019, in their analysis of educational technology journals, they found “a significant rise of experimental, research-to-prove papers. These papers appeared to (1) confound media and instructional methods, (2) not include sufficient information about the instructional objective, (3) omit one or more of the effectiveness, efficiency, and appeal outcomes, and (4) not report whether or not the researchers conducted formative evaluation” (para. 35).

Because of the tempting siren song toward media comparison research, it is especially critical that scholars of open, distance, and digital learning focus on research to *improve* by emphasizing how we design, develop, and assess effective learning in these digital spaces. For this reason, this section of the *handbook* is the largest of the book, and focuses on the design, development, and assessment of learning in ODDE spaces.

---

**Organization of Section 7**

Topics for this section of the *handbook* were developed in consultation with the overall *handbook* editors and were an attempt to represent major theoretical thrusts in the discipline. Authors were encouraged to focus on the design, development, and assessment issues related to these topics, rather than on technological developments.

An attempt was made to find some of the most highly cited and respected authors in these areas while representing global diversity. In addition, an attempt was made to represent diversity by seeking some authors that were established experts as well

as some rising stars in their areas. I believe that the following chapters represent some of the best thinking and current practices that can guide the effective design of ODDE learning.

The section includes several chapters that overview the design of different kinds of distance learning. First, Graham and Halverson provide guidance on designing blended and flexible learning environments. Meanwhile, Martin and Bollinger lend their considerable expertise to understanding the design of online learning in higher education. In contrast, Borup and Archambault, former editors of the *Journal of Online Learning Research*, describe the effective design of online learning for children and youth. Similar overview chapters are also provided by Schrader on game-based learning and Ge and Huang on problem-based/inquiry-based learning.

After these more general chapters, there are additional chapters that probe strategies for the effective design of specific technology-afforded learning environments such as flipped classrooms (Lee), online learning communities (Cleveland-Innes & Hawryluk), MOOCs (Stracke et al.), and computer-supported collaborative learning environments (Hmelo-Silver & Jeong). Dron and Anderson, and Bozkurt et al. each provided valuable perspectives on informal learning and social media-based learning, respectively, while Bond and Bergdahl shares strategies for addressing one of the most often discussed challenges in ODDE (and any) learning environment – improving student engagement. Finally, assessment within ODDE environments is then discussed by Hickey et al. generally, and by West and Cheng more specifically in the area of open micro/alternative credentials.

Even though this section of the *handbook* is large, it is unfortunately not large enough. An entire handbook could be produced, and often has been, on each of these topics, and by limiting ourselves to only 14 chapters, there were many worthy topics that were excluded. Still, the authors in this section have provided, in my view, enough powerful and useful strategies and frameworks to improve the effective practice of ODDE learning by any scholar/practitioner who reads their chapters.

---

## Overarching Themes

While these chapters are individually diverse, there were a few interesting cross-cutting themes.

## Originary Theory to Guide ODDE Design

Graham and Halverson cited McDonald and Yanchar's (2020) description of two types of theory available to ODDE scholars/practitioners. The first is imported theory, transferred from other disciplines and applied to ODDE environments. Examples of imported theory could be the application of Flow theory, Self-determination Theory, Control-Value Theory, and the Player Experience of Need Satisfaction model, all of which Schrader demonstrated can effectively describe and inform game-based learning. Another helpful example is in Hickey et al.'s chapter,

where they describe how four main paradigms on learning theory (differential, cognitive-associationist, cognitive-constructivist, and situative-sociocultural) affect our understanding of effective and efficient online assessment. Finally, Bond and Bergdahl described how Astin's (1984) theory of community has helped to characterize a student's involvement, or engagement, in learning.

The second type of theory is originary theory, developed within a research discipline and specific to that discipline. Because ODDE learning is, and has been, changing rapidly, originary theory in our discipline is still more rare and underdeveloped. However, the authors of these chapters in this section identified several existing originary theory frameworks that can guide effective ODDE design. These include:

- The Community of Inquiry framework, cited by Graham and Halverson as the most referenced theory in blended learning and then discussed extensively by Cleveland-Innes and Hawryluk, as well as Bond and Bergdahl and Hickey et al. This theory illuminates the types of interactions and presence that members of an online environment can achieve.
- The Academic Communities of Engagement framework, cited by Borup, Graham, West, Archambault, and Spring (2020) and Graham and Halverson, which adapts ideas from the COI theory, as well as ideas from research into social learning and student engagement, to describe how personal and course communities interact to support student engagement, particularly for adolescents.
- Cognitive Theory of Multimedia Learning, cited by Schrader to explain how game-based learning affects cognitive processing, as well as by Lee.
- Czerkowski and Lyman's (2016) e-learning engagement design framework, Gao and Ji's (2019) Five-Star Teaching Cycle Framework of Online Courses, and Conole's (2014) 7Cs of Learning Design Framework, all cited by Martin and Bolliger.

In addition, several authors in this section proposed new originary theories, or at least descriptive frameworks, that provide new perspective to guide designers of ODDE learning. Among these new ideas include the following:

- Bond and Bergdahl's bioecological model of engagement, which places the student at the center of engagement, but affected by a microsystem, mesosystem, exosystem, and macrosystem of affecting factors. In addition, these authors described student engagement at the micro level as not only including the traditional descriptions of affective, behavioral, and cognitive dimensions, but also a social dimension – representing the important sociocultural perspective on learning that also affects students' engagement and motivation to learn.
- Dron and Anderson's conceptualization of dimensions of learning, including informal/formal, intentional/incidental, and self-directed/dependent – dimensions that can be helpful in defining and better conceptualizing informal learning.
- Ge and Huang's pedagogical framework that summarizes the four key aspects to designing online problem-based learning as preparation/planning for the PBL,

design and development, implementation and facilitation, and assessment (along with strategies and suggestions for each phase).

- Hickey et al.'s helpful organizing of assessment practices as assessment *of* learning, *for* learning, *as* learning, and then even how assessment is sometimes used *as compliance* or *as sabotage* – and then framing these assessment practices around various learning theories and assessment levels and formats.
- Hmelo-Silver and Jeong's organizing of the computer-supported collaborative learning literature into four different clusters representing different design approaches to CSCL learning, based on technologies, pedagogies, and collaboration modes used.
- Martin and Bolliger's support framework, which identified four types of support (based on a previous paper) that instructors need to be effective online: administrator, personnel, pedagogical, and technological support.
- West and Cheng's description of an open education infrastructure that focuses on open content, open practices, and open recognition (synthesizing previous ideas from Wiley, 2018).

### **The Need for Research to Expand Beyond Study of Individuals in Higher Education**

This *handbook* has adopted a 3M framework for considering research, first discussed by Zawacki-Richter (2009). West and Cheng further develop this framework in the area of open credentials by describing how the micro level of research focuses on individuals, while the meso level represents research on institutional impacts and macro level research studies impacts at the societal level. Authors in this section of the *handbook* identified several new areas for necessary research exploration, which can be organized within this 3M framework. For example,

- Bond and Bergdahl argued that student engagement includes a largely unresearched social dimension, particularly in ODDE settings, as well as the relationship between the bioecological levels in their model of engagement. In addition, they called for more research into disengagement as a separate construct from engagement itself.
- Graham and Halverson argued that blended learning research to date has focused on the individual, micro, level, and research at other levels is needed. They cite several emerging frameworks for understanding institutional adoption of blended learning that can guide future research, including suggestions about necessary blended learning competencies and professional development.
- West and Cheng similarly found that the research on the impacts of open credentials is focused at the micro/individual level, and is despairingly scant at other levels.
- Lee documented explosive growth in research into flipped learning, but mostly these studies have focused on university learners.

- Hickey et al. argued that while online learning has embraced situative/sociocultural perspectives on learning, there is little research consideration of how this theory affects assessment practices. They also caution against throwing out traditional assessment practices in favor of “authentic” assessment, when research is still needed into how all these manners of assessment can be useful in ODDE teaching.
- Martin and Bolliger stated that of Moore’s (1989) three types of interaction, learner-content interaction is surprisingly under-studied. Moving towards the meso-level of the 3 M research framework, they argued that the interaction between instructors and instructional designers within institutions is under-studied.

### **ODDE Learning Can Be Effective**

All learning environments can be either effective or ineffective depending on a slew of other variables such as personal investment, social learning factors, the design of the experience, and the learning strategies employed. However, the authors in this section were still able to document many positive effects from including that ODDE learning, including the following:

- **Provides more effective learning** (e.g., Hmelo-Silver & Jeong, Lee, Schrader).
- **Improves student communication/collaboration** (Bozkurt, Hmelo-Silver & Jeong). Similarly, Schrader explained the relationship in reverse, that student collaboration promoted the strongest learning in game-based environments.
- **Promotes student engagement** (e.g., Bond & Bergdahl, Bozkurt, Graham & Halverson, Hmelo-Silver & Jeong, Lee, Schrader).
- **Incorporates more active student learning** (e.g., Hmelo-Silver & Jeong, Lee).
- **Improves flexibility and individualized learning as well as more flexible teaching** (e.g., Bozkurt, Lee, Stracke et al., West & Cheng).
- **Improves student autonomy** (e.g., Schrader, West & Cheng).
- **Supports feedback to learners on performance** (e.g., Hickey et al., Hmelo-Silver & Jeong, Schrader, West & Cheng).

However, these effects, unsurprisingly, were very nuanced, and results varied depending on many variables including effectively matching the ODDE learning model with individual learners who would most benefit, utilizing effective design/teaching strategies, and employing strong learning activities.

### **Standards to Guide ODDE Design**

Several authors identified helpful standards frameworks that can guide our effective design and implementation of ODDE environments. For example,

- Florence and Bolliger identified eight different online course development rubrics or standards frameworks, both within the United States and internationally, for designing higher education online learning. They then synthesized these standards and rubrics to create the Online Course Design Elements instrument that identifies five categories of design elements that should be attended to in creating effective distance education courses.
- Similarly, Stracke et al. presented the Quality Reference Framework as synthesis of international standards in the form of seven dimensions for creating effective online learning, and in the case of their chapter, MOOCs.

## **How Assessment Supports Learning**

Three chapters in particular argue that rather than simply assuming that assessment follows the teaching/learning process, that effective and innovative approaches to assessment and credentialing can restructure and prompt changes in how we teach and “do” education. This is particularly true for ODDE environments where, as Hickey et al. argued, learning assessment takes on wholly new meaning because the signals for what we value are different. For example, as delivering content and participating in learning interactions became more flexible due to online technologies, instructional designers are increasingly moving away from seat time and credit hours as evidence of “learning” and focusing more on skills, performance, and abilities. But this requires new thinking when it comes to how we assess learning. In addition, the amount of time required for individual feedback in online interactions can be overly strenuous – again requiring creativity in how to provide feedback and assessment in efficient ways.

Similarly, Dron and Anderson argued that assessment and digital credentialing can be especially powerful in supporting informal learning, by providing a mechanism for recognizing the value of skills/knowledge gained in informal learning. This system benefits from the use of challenge assessments, decoupled from the learning itself, to allow for more learner flexibility. In addition, technological systems are developing – but need to develop more – to improve how we store, recognize, and share these credentials.

Finally, West and Cheng offered definitions to the complicated world of micro/open/alternative credentials, and review research findings about the impacts of these credentials at the micro/meso/macro levels of education. While acknowledging that the research on these types of credentials is small and emerging, the authors argued that the core ideas of transparency, openness, learner agency, and clear data representation are sticky ideas that will continue to impact education in one form or another.

---

## **Designing the Future of Open, Distance, and Digital Education**

During the COVID-19 pandemic, the world learned the value of instructional designers. As schools closed and laptops opened; parents, teachers, and students learned quickly the difference between well designed instruction and emergency

teaching (Hodges & Fowler, 2020). Instructional designers around the world were highly sought after to help soften the blow. This affirmed the value the discipline needs to play on the world stage, and the growth and maturity of the field over the last century.

The chapters in this section describe well this maturity. We have a solid foundation of theory and research to describe precisely how effective learning can be designed and assessed in many situations, levels, and subject areas. But once the foundation of a home is established, it is not the time to sit down in the recliner, but rather to continue building the walls upward.

So what are the next steps that will enable the field of open, distance, and digital learning to build upon its strong foundation? The chapters in this section suggest many ideas, and I conclude with the following overarching observations.

First, we understand well how to design and develop an effective product, curriculum, or training, but we need greater focus on understanding the systemic nature of learning. Much of the research in the field focuses, as mentioned above, on the micro level of the 3M framework. In addition, research tends to study single variables, and designs often hyperfocus on a single theory for explaining learning, and in both cases the complexity of the learning environment can be ignored. It is difficult to conduct studies sophisticated enough to understand the complex interconnection between all of the levels of the 3M framework. But we need to research and design the systems, in order to best affect the individuals.

Second, but similarly, we need research and design to fully embrace the sociocultural nature of learning. Social relationships affect how people learn (Cleveland-Innes & Hawryluk), how they collaborate (Hmelo-Silver & Jeong), how they get engaged in education (Borup et al., 2020) and how they should be assessed (Hickey et al.). When we talk about a systemic view of learning, a major and critical part of that system are the relationships learners have with each other, their teachers, and even their personal support systems (see Borup et al., 2020).

Third, we need research methods as rich and varied as the humans we study. While educational methodologists have developed increasingly more sophisticated methods for studying the complex process that is human interaction and learning, our research journals tend to remain unbalanced. Far too many published research studies re-examine research questions we already know the answer to, using methods we have already seen before. Other disciplines have pushed the edge of their expertise developing a wide variety of approaches to research, and we need similar variety in ODDE scholarship.

As I described in another article (West, 2020) there are different ways of creating knowledge and legitimate scholarship, and we need to appreciate and encourage, in our journals, publication of all these ways of knowing, including:

- Review scholarship that rigorously summarize what other studies have found.
- Conceptual scholarship that identifies and qualifies key concepts that characterize a phenomenon and model the relationships between items in a system.

- Theoretical scholarship that critiques existing ideas, establishes the boundaries of existing theory, and develops new paradigms that create possibilities for new thinking.
- Exploratory research that develops theory by exploring variables and their relationships through empirical observation and often bottom-up inductive thinking.
- Explanatory research that tests theory by objectively validating its generalizability.
- Critical research that explores what ideas and experiences mean to various groups, and how we can productively put theory into action.
- Design-based research and design cases that develop local and generalized theory by designing interventions for real learners in real contexts.

In the last 20 years, the world of open, distance, and digital learning has evolved dramatically, as social media (Bozkurt et al.), microlearning (West & Cheng), complex educational games (Schradler), MOOCs (Stracke et al.), and other technological innovations have changed the way we can teach and learn. It cannot be known what new technologies will be developed in the future to meet the needs of future learners, but only through a *systematic* understanding of learning, and especially the rich *sociocultural* layers that affect education, gained via a *variety of research methodologies* will we be prepared for this future. The chapters in this section provide the foundation, but now we need to push forward to finish the building.

Abstract

The strategic integration of online and in-person learning modalities (referred to as blended learning) is becoming increasingly popular in primary, secondary, post-secondary, and corporate contexts. Some have even called blended learning (BL) the “new normal” in education. This chapter addresses five important questions for scholars interested in contributing to research in this domain. First, how are scholars defining BL? Second, what are some of the common models of BL being used in higher education and K-12 learning environments? Third, what is happening with BL research and practice in different regions of the world? Fourth, what research frameworks have been developed by BL scholars and what are other common frameworks that scholars have borrowed from other

domains? Finally, the chapter overviews some of the current BL research around institutional, faculty, and student issues. The global pandemic from 2019 to 2021 has increased administrator, instructor, and student awareness and familiarity with many online learning options. It is likely that blended practices that combine both online and in-person instruction will become increasingly prevalent. Scholars will need to better understand how different blended models and pedagogical practices within those models work to improve learning outcomes, increase access and flexibility for learners, and impact cost efficiencies.

**Introduction**

The purpose of this chapter is to introduce you to current research and practice in the area of blended learning (BL), which has become widespread in secondary schools, higher education, and corporate training environments. Attempts to accurately quantify the growth of BL were frustrating because institutions lacked formal mechanisms for labeling and tracking BL in addition to the fact that much of the BL was being implemented by individual instructors without institutional oversight (Graham, 2019; Graham et al., 2007). However, some institutions like the University of Central Florida were early adopters of BL and have been tracking its growth and impact on student learning and satisfaction for decades (Dziuban, Graham, Moskal, Norberg, & Sicilia, 2018; Dziuban, Hartman, Juge, Moskal, & Sorg, 2006; Dziuban, Hartman, & Moskal, 2004; Dziuban & Moskal, 2011; Moskal, Dziuban, & Hartman, 2013). Despite the challenges with accurately quantifying all of the BL that is happening, it is clear that the combination of online and in-person learning is becoming the norm for many institutions. Therefore, it is important to understand the research being done in this area and where it intersects with and differs from research related to fully online and fully in-person learning contexts.

The chapter content will be organized around the following questions of interest to researchers who want to study BL contexts.

1. What is blended learning?
2. What are common models of blended learning?
3. What is happening with blended learning internationally?
4. What blended learning frameworks are being used by researchers?
5. What are some important areas of research in blended learning?

## What Is Blended Learning?

The term blended learning (sometimes also called hybrid learning) was popularized in the early 2000s. Since then, there have been many commentaries and academic discussions about how to define the term. In particular, a group of interested scholars associated with the Alfred P. Sloan Consortium (now the Online Learning Consortium) met repeatedly with the specific intent of creating a working definition that would help institutions of higher education and researchers navigate this new space between fully online learning and the in-person learning typically happening on campuses (Picciano, 2011). Definitional issues were complex because each institution seemed to have a slightly different model of what they felt was important for their own context and environment. At the same time, researchers trying to study this emerging phenomenon were interested in less ambiguity and clear definitions and descriptions of the boundaries of blended learning. Yet many were frustrated (Oliver & Trigwell, 2005). Many of the most popular definitions focused on issues related to the modality, media, and method of different blends (see Table 1).

Despite the conceptual fuzziness, the term “blended learning” continued to grow in popularity, but with a slightly different meaning for each institution. Hrastinski (2019) referred to it as an “umbrella term” while Dziuban and colleagues (Dziuban, Shea, & Moskal, 2020; Norberg et al., 2011) referred to the term as a “boundary object” that is “plastic enough to adapt to local needs and constraints of the several parties employing them, yet robust enough to maintain a common identity across sites . . . weakly structured in common use . . . strongly structured in individual site-use” (Star & Griesemer, 1989, p. 393). In previous publications, Graham (2006, 2013, 2019, 2021) argued for a broad definition of BL focused primarily on

**Table 1** Blended learning definitions media, method, and modality

3 Ms	Description	Examples
Modality	The physical instructional setting or environment	Definitions focused on a mix of online and in-person instruction. Often definitions tried to define percentage thresholds that would change an environment from “fully online” to “blended” in order to meet institutional needs (Allen & Seaman, 2007; Watson et al., 2010).
Media	Physical tools or technology used to deliver or mediate instruction	Definitions focused on using a combination of different technology tools like “the combination of different training ‘media’ (technologies, activities, and types of events) to create an optimum training program for a specific audience” (Bersin & Associates, 2003, p. xv).
Method	Teaching strategies and practices used in instruction	Definitions included pedagogical requirements by including things like “integrating . . . in a planned, pedagogically valuable manner” (Picciano, 2009, p. 10).

**Definition:** Blended Learning is the strategic combination of online and in-person learning.

**Fig. 1** Parsimonious definition of blended learning

combining modalities and allowing innovations in method and media to distinguish between the models and quality of the blends. Figure 1 shows this broad definition that will be used throughout the chapter.

---

## What Are Common Models of Blended Learning?

Early researchers in K-12, higher education, and corporate training sought to categorize and classify BL models that were observed in practice. Twigg (2003) identified higher education models such as supplemental, replacement, emporium, and buffet. Staker and Horn (2012) identified rotation, self-blend, enriched virtual, and flex models among others that have become popular in K-12 environments. Many of these classification models emphasize the physical features of the blend rather than the pedagogical features (Graham, 2021). For example, blends might focus on rotating between online and in-person instruction (rotation models) or providing both online and in-person instructional choices to students (buffet model) without specifying the pedagogical practices to be used in each modality.

More recent models developed have provided design guidance related to relevant pedagogical practices. For example, the Multimodal Model (Picciano, 2009, 2017) matches instructional approaches in different modalities with a range of pedagogical objectives, and Farmer (2020) recently identified six common models in higher education that add some high level pedagogical descriptions to the typical structural description of blends. In a recent research-driven planning guide for educators, Joosten et al. (2021), emphasized pedagogy as one of four important dimensions to consider in creating effective blends.

The 2019 global pandemic increased the number and variety of blends being explored at all educational levels. In order to keep operating, many K-12 schools and universities implemented technology-mediated forms of instruction with very limited faculty training and resources. Commonly referred to as *emergency remote teaching* (Hodges, Moore, Lockee, Trust, & Bond, 2020), many of the online practices attempted to preserve the more familiar synchronous nature of traditional teaching through the use of online conferencing systems. Therefore, in the last couple of years we have seen an increase in a unique form of BL sometimes referred to as blended synchronous instruction (Bower et al., 2015) or HyFlex (Beatty, 2019) that concurrently involves both synchronous online and in-person students in learning experiences (Irvine, 2020; Osguthorpe and Graham 2003). Additionally, the term “bichronous” online learning has surfaced as the combination of synchronous/asynchronous instruction (Martin, Polly, & Ritzhaupt, 2020). This is a form of *online learning* when both synchronous and asynchronous elements are fully online

and considered *blended learning* when the synchronous element takes place in-person.

Within the larger umbrella of BL, we see that there is a wide range of blended models that varies in *physical* and *pedagogical* dimensions. It is important for researchers to clearly specify both the *physical* structure and *pedagogical* elements of a blended model or design. Research that just looks at the physical structure of the blend as a treatment effect without considering the pedagogical dimension of the blend will have limited usefulness because there is a significant body of research that suggests pedagogy (method) is more influential than modality or media in terms of student learning (Dziuban et al., 2020; Clark, 1983; Clark, 1986; Cunningham, 1986; Kozma, 1991; Clark, 1994a, b; Kozma 1994).

---

## What Is Happening with Blended Learning Internationally?

Research published in 2012 (Halverson et al.) and 2013 (Drysdale et al.) showed very little international focus in the most frequently cited articles discussing BL, and in the theses and dissertations on the topic. In order to learn more about BL outside of North America, Spring and Graham (2017) investigated the most frequently cited articles on BL in each region of the world. They determined which articles from each region were the most cited, how the regions compare in terms of citations and which journals publish these highly cited articles. One of the authors' findings was a large disparity in citation patterns of BL research around the world, "a gap that was greater than expected" (p. 35): "North America exceeds the others, with twice as many citations than the next highest, Europe. Oceania (3rd) and Asia (4th) each garnered about half as many as Europe" (p. 31). The authors called for more in-depth research to be done in every region.

In the intervening years, BL research has advanced internationally. Galvis (2018a, 2018b) studied how Latin American universities were strategically developing virtual and BL environments. Using case studies of five countries, Galvis explored the challenges that institutions of higher education encounter when trying to adopt and specified guidelines for adoption, particularly in Latin American settings.

Research from the Asian and Pacific areas has particularly flourished. Tham and Tham (2013) investigated challenges to BL adoption and implementation in the countries of China, Japan, Singapore, and South Korea. Supported by UNESCO Bangkok, Lim and Wang (2016) gathered case studies throughout the Asia-Pacific region to "explore the potential of blended learning, including its impact on the role of teachers, the relationship between teachers and students, and the nature of educational institutions themselves" (p. xiii). UNESCO gave a regionally specific explanation for the view that BL was a valuable approach to promoting inclusive education: "especially important in Asia-Pacific – the world's most populous and most disaster-prone region – so that learners can continue to study without a physical classroom or campus" (p. xiii).

Lim and Graham's (2021) *Blended Learning for Inclusive and Quality Higher Education in Asia* expands upon the work done in Lim and Wang (2016). Motivated by the importance of equitable access to quality higher education for all, they argued that "institution-supported rapid innovation is more critical than ever" (p. v) and see blended and online learning as "a fundamental principle for action" (p. vi) in enabling this access. Using research from six Asian countries – Cambodia, China, Hong Kong, Korea, Malaysia, and Sri Lanka – they examined both university-level initiatives (examining the support mechanism for successful BL in Asian universities) and disciplinary-level practices (documenting promising practices and lessons learned). Disciplines included general education, English language, visual arts, linguistics, STEM, and teacher education, and topics researched included learning design, academic integrity, interactive BL, professional development, and augmented reality.

In the final chapter of *Blended Learning for Inclusive and Quality Higher Education in Asia*, Zaugg, Graham, Lim, and Wang (2021) evaluated the previous chapters according to a framework devised to guide higher education institutional strategic planning when driving, sustaining, and scaling up BL practices (Lim, Wang, & Graham, 2019). The framework itself is the result of collaboration across higher education institutions in the Asia-Pacific regions, and proposes seven strategic dimensions to be considered in institutional strategic planning, namely (1) curriculum; (2) vision and policy alignment; (3) infrastructure, facilities, resources, hardware and support; (4) professional development; (5) student learning support; (6) partnerships; and (7) research and evaluation. The authors synthesized the discussions of each previous chapter as they related to the dimensions of the framework. Finally, the authors identified gaps in the synthesis and made six key recommendations for universities in Asia to develop their capacity for BL. First, they argued, while Asian HEIs can learn from other BL research, many issues may be unique to the learning culture in Asia. Second, programs would benefit from better alignment between BL and current theories of learning. Third, HEI leadership and BL practitioners must together make concerted efforts to build congruence between institutional shared vision and individual practices of BL. Fourth, HEI's capacity building will benefit from prioritizing pedagogy and teacher professional development. Fifth, libraries can support the advancement of BL if HEIs re-envision their roles as support hubs and resources. And finally, sixth, HEIs can learn from the expansion of BL in and lessons learned from the K-12 sector while also providing resources for students, while still in high school, to earn advanced university credit or take apprenticeship instruction through blended opportunities.

---

## What Blended Learning Frameworks Are Being Used by Researchers?

McDonald and Yanchar (2020) identified two types of research frameworks: *original* and *imported*. Imported frameworks are borrowed from other domains (say psychology) for use within the domain. Original frameworks are developed

within or adapted for use within a specific research domain. Because BL as a domain is fairly young, there are a limited number of originary research frameworks available for researchers to use. BL models presented earlier in the chapter are a few examples of originary frameworks within BL. A recent model that has received significant attention during COVID has been the HyFlex model (Beatty, 2014, 2019) that provides design guidance for supporting student-directed learning paths across multiple modalities. Shea (2010) built on the “how people learn” framework (Bransford et al., 2000) to identify elements that influence decisions in a blended environment in order to provide design guidance for developing instructional strategies for particular learners in particular contexts. This section of the chapter will share a few additional originary frameworks used in BL. A more extensive coverage of BL research frameworks can be found in Graham (2021, in press).

By far, the most referenced framework in current BL research is the Community of Inquiry framework (COI; Garrison, Anderson, & Archer, 2000). The COI framework emphasizes the importance of cognitive, teaching, and social presence in building a powerful educational experience. Though this framework evolved from online work with text-based computer conferencing, it was quickly adapted to a BL environment (Garrison & Kanuka, 2004; Garrison & Vaughan, 2008; Vaughan, Cleveland-Innes, & Garrison, 2013). Hundreds of studies, including foundational work on the COI framework, are being archived by Athabasca University at <https://coi.athabascau.ca/>. Another framework related to blended teaching competencies is the Blended Teaching Readiness framework (Graham et al., 2019). This framework was developed initially to support primary/secondary education blended teaching professional development. It identifies and elaborates on four core blended teaching competency areas: (a) online integration, (b) data practices, (c) personalization, and (d) online interaction (Archibald, Graham, & Larsen, 2021; Graham et al., 2019; Pulham & Graham, 2018; Pulham, Graham, & Short, 2018).

One of the early areas where BL researchers have developed frameworks is related to institutional adoption and/or transition to BL. Many researchers have used imported frameworks such as Everett Roger’s Diffusion of Innovations (1962) or the Technology Acceptance Model (Davis, 1989). Others have tried to create frameworks more specific to institutional adoption of BL. The Framework for Institutional Adoption of Blended Learning (Graham, Woodfield, & Harrison, 2013) identifies three stages of institutional adoption: (a) awareness/exploration, (b) adoption/early implementation, and (c) mature implementation/growth. Indicators for each of the stages related to institutional strategy, structure, and support are described. The Framework for Transition to Enhanced Blended Learning (Adekola, Dale, & Gardiner, 2017) characterizes stakeholder roles, organizational preparedness areas, institutional considerations, and change agents to help institutions manage the transition to BL. Two other originary frameworks were developed at the systems level to help institutions plan for transitions to BL: the Framework for Strategic Planning of BL in Institutions of Higher Education (Lim et al., 2019) and the Framework of Complex Adaptive Blended Learning Systems (Wang, Han, & Yang, 2015).

Finally, student engagement has been an important area of research for traditional learning environments. It is natural that researchers would try to import and adapt frameworks from educational psychology research to blended contexts. Halverson and Graham (2019) developed a conceptual framework for blended environments with constructs and indicators for cognitive and emotional engagement. Borup et al. (Borup, Graham, West, Archambault, & Spring, 2020; Borup, Jensen, Archambault, Short, & Graham, 2020) recently developed the Academic Communities of Engagement framework intended specifically for looking at affective, behavioral, and cognitive dimensions of student engagement in blended and online learning environments. The framework posits that students have a zone of independent engagement that is extended through support from actors in personal and course communities. Support elements for each dimension of engagement can be distributed across different community actors and communities that mix virtual and in-person support.

---

## What Are Some Important Areas of Research in Blended Learning?

This section addresses some of the BL research related to institutional issues, faculty issues, and student issues.

### Institutional Issues

According to Smith and Hill (2019), BL research and practice has been, to this point, “predominantly an individual rather than an institutional endeavour,” with projects that are small in scale that provide a “snap-shot in time evaluation” (p. 391). This “methodological individualism” (Brown, 2016, p. 5) means that researchers are missing the “network of socio-technical interactions in higher education organizations [which] would get us closer to unpacking the black box of situated faculty decision-making” (p. 7). We need more research being done at the institutional level to unpack this “black box.”

Research on the nature of institutional BL adoption has begun to be done. Graham, Woodfield, and Harrison (2013) developed a framework (the Blended Learning Adoption Framework) identifying the three stages of institutional BL adoption, namely (1) awareness/exploration, (2) adoption/early implementation, and (3) mature implementation/growth. Later, Porter and Graham (2016) applied that framework to examine how institutional *strategy*, *structure*, and *support* decisions facilitate or impede BL adoption among higher education faculty. They found that faculty adoption was most influenced by the availability of sufficient infrastructure, technological and pedagogical support, evaluation data, and the alignment of faculty and administrators’ purpose for adopting BL. They followed this quantitative research with qualitative analysis in Porter, Graham, Bodily, and Sandberg (2016), where the authors explored how higher education faculty’s innovation adoption

category affected which measures facilitate or impede BL adoption. Additional research into institutional adoption of BL can complement what we are beginning to understand.

Research is also being done into the institutional support necessary for adoption of BL practices. Rasheed, Kamsin, and Abdullah (2020) noted that the biggest institutional challenges to adopting BL were technological provision challenges – the high cost of producing electronic content, the cost of online learning technologies, overly complex technology causing distractions to students, the creation of tools that are flexible and compatible with other systems, the complexity of technology, and the implementation of LMSs to suit student learning styles – as well as the need to train faculty in effective online and blended practices.

However, when focusing on low-budget institutions, Abusalim, Rayyan, Jarrah, and Sharab (2020) found that faculty training had a significantly higher influence on satisfaction with blending practices than did IT infrastructure. “Therefore,” the authors argued, “low-budget institutions should focus first on helping instructors shift to student-centred styles of pedagogies before making large investments in IT infrastructure” (p. 1203). Such training support was also deemed important by McGee, Windes, and Torres (2017), who found three kinds of support to be most influential to the development of the online expertise that is necessary to BL: Formal training of the instructor (including skills-based training, training in best practices, and course rubric strategies), provision of external supporting mechanisms (including instructional design help, external course review before implementation, opportunities to consult with others about online instruction, help desk availability for just-in-time support, and institutional recognition and/or rewards), and prolonged experience (including recognition and rewards for that experience). Further research into how to best support faculty in blended instruction can enrich our understanding of this important area.

## Faculty Issues

The expansion of technology’s usage in K-12 and higher education classrooms, whether through planned blended and online learning programs, or emergency remote teaching during the COVID-19 pandemic, has created new teacher training and professional development (PD) needs (Cavanaugh & Deweese, 2020; Philipsen, Tondeur, Roblin, Vanslambrouck, & Zhu, 2019; Short, Graham, Holmes, Oviatt, & Bateman, 2021). This is particularly true because teaching online requires new attitudes, knowledge, and skills for success (Salmon, 2011). Thus the 2016 National Education Technology Plan (U.S. Department of Education, 2016) noted that “effective use of technology is not an optional add-on or a skill that we simply can expect teachers to pick up once they get into the classroom. . . . Schools should be able to rely on teacher preparation programs to ensure that new teachers come to them prepared to use technology in meaningful ways” (p. 32). The 2017 National Educational Technology Plan (U.S. Department of Education, 2017) added that faculty need “continuous, just-in-time support that includes professional development,

mentors, and informal collaborations” (p. 28). Below we review some of the current research into teacher training and professional development for blended instruction.

Short, Graham, Holmes, et al. (2021) found few articles (7 of the 58 initially reviewed) and no systematic reviews of current peer-reviewed research on PD or training for blended learning teachers for primary/secondary age children. To fill this gap, their research reviewed works that focused on intentionally preparing these teachers for blended teaching. Articles on the topic proliferated in 2016 and thereafter. A significant portion of the results (40.9%) came from international contexts, an improvement from the finding in Halverson, Graham, Spring, Drysdale, and Henrie (2014) that BL research originating from regions other than North America and Europe were underrepresented in the most impactful BL publications. Short et al. (2021) also identified the most impactful articles and authors according to citation count, the most prolific journals publishing such research, and the most common research methods used in the studies. They also determined broad themes based on the articles’ research questions and findings. Those themes included articles which were reviews, models, and theories; articles focused on training through university coursework and PD; articles proposing competencies for blended teaching; and articles that provided metrics to evaluate readiness for blended teaching.

Practitioners and administrators seeking insights into what will help most in the classroom can look to Philipsen et al. (2019), who used a meta-aggregative approach to analyze qualitative research into faculty PD in blended and partially online settings. The authors identified six broad areas for creating successful PD. First, such PD should be crafted so that teachers receive just-in-time support, feedback, and clear pedagogical rationale across the entire professional development process. Second, faculty want training that takes into account their unique institutional context, through planning that acknowledges the institutional characteristics, existing programs, and any financial components. Third, successful PD for blended instruction recognizes and gives participants time to reflect upon the psychological or mental changes that these nontraditional methods of instruction can have upon one’s professional identity and educational beliefs. Fourth, faculty need clarity about the specific goals and procedures of the PD, and the relevance of that training to teachers’ own personal and professional goals. Fifth, successful PD uses strategies for reaching their overall goals, including encouraging teacher reflection, enabling teachers to experience blended and online instruction in an active way, inspiring teachers’ confidence and motivation, and facilitating peer support. Finally, PD should encourage knowledge-sharing within the institution as well as continuous evaluation of processes to best tailor further initiatives to existing contexts and needs.

Another important element for practitioners is to understand which competencies must be mastered for effective blended teaching. Short, Graham, Holmes, et al. (2021) found few peer-reviewed articles on the competencies in blended teaching (4 of the 58 reviewed) and mentioned the need to look beyond peer-reviewed articles to online resources and white papers from professional organizations in their analysis (Pulham et al., 2018; Pulham & Graham, 2018). Among the pertinent articles,

there does not appear to be agreement on what should constitute BT competencies. Some competencies adapted existing frameworks (Huett, Huett, & Ringlaben, 2011; Pulham & Graham, 2018), while others created entirely or partly new frameworks (Al-Doseri, Elgazzar, & Nouby, 2016; Bjekic, Krmeta, & Milosevic, 2010; Foulger, Graziano, Schmidt-Crawford, & Slykhuis, 2017). Research can be done to test the efficacy of these competencies in improving student learning in blended settings.

In addition to competencies, new research is emerging on how to evaluate teacher readiness for blended teaching. Graham, Borup, Pulham, and Larsen (2018, 2019) created and empirically validated instruments to measure K-12 Blended Teaching Readiness. Archibald and colleagues (2021) took the instrument one step further, validating its ability to show that the blended teaching readiness model and accompanying instrument are reliable for use with teacher candidates both before and after going through a blended teaching course. Graham, Borup, Short, and Archambault (2019) created a professional development guidebook organized around the K-12 Blended Teaching Readiness model. Short and colleagues have done further validation research around the readiness model with analysis of hundreds of artifacts used for K-12 blended teaching professional development as well as dozens of interviews with experienced teachers using blended approaches (Short, Graham, & Sabey, 2021; Short, Hanny, Jensen, Arnesen, & Graham, 2021).

## Student Issues

Many issues face students participating in BL, including motivation, self-direction, and time management as well as preparation in basic digital skills and sufficient internet service. But one of the most researched (Azevedo, 2015) relates to student engagement. Student engagement, or the involvement of the student's cognitive and emotional energy to accomplish a learning task (Halverson & Graham, 2019; Schunk & Mullen, 2012), correlates with important educational outcomes (Conrad, 2010; Wang & Degol, 2014). Such correlations have led some to refer to learner engagement as "the holy grail of learning" (Sinatra, Heddy, & Lombardi, 2015, p. 1). Spring, Graham, and Ikahihifo (2018) give a good introduction to the issues in the field.

Halverson and Graham (2019) reviewed models, definitions, and constructs of learner engagement, delineating challenges with prior research, including lack of clarity surrounding definitions (Fredricks, Blumenfeld, & Paris, 2004; Henrie, Halverson, & Graham, 2015), muddling of indicators and facilitators of engagement (Skinner, Furrer, Marchand, & Kindermann, 2008), and a focus on institutional rather than activity or course-level factors (Ainley, 2012; Wang, Bergin, & Bergin, 2014). The authors then suggested factors for a conceptual framework grounded in existing engagement literature and contextualized for blended settings, specifying cognitive indicators of engagement (attention, time on task, effort and persistence, cognitive and metacognitive strategy use, deep concentration or absorption, and individual interest or curiosity) and emotional indicators (enjoyment, happiness, confidence or self-efficacy, confusion, boredom, frustration, and anxiety). Follow-up research (Halverson, 2016) operationalized and tested this model of BL

engagement using exploratory and confirmatory factor analysis and developed a new instrument, the Blended Learning Course Engagement Survey, to take into account context (online or face-to-face) and the cognitive and emotional aspects of learner engagement in such settings. Results showed the related yet distinct nature of face-to-face and online engagement and that indicators of engagement considered behavioral in some alternative models of engagement are empirically indistinguishable from cognitive indicators.

Another attempt to expand the theory base in BL research includes Borup, Graham, West, Archambault, and Spring's (2020) investigation of the Academic Communities of Engagement (ACE) framework. The ACE framework suggests that a student's ability to engage is facilitated by support from both personal and course communities, which must function together to increase students' affective, behavioral, and cognitive engagement (Fredricks et al., 2004). Just as in Vygotsky's (1978) zone of proximal development, ACE proposes that a student's zone of independent engagement can be extended with support from the personal and course communities. The authors identify actors from these communities that provide such support. Martin and colleagues have also investigated the relationship between facilitators and student perception of engagement (Martin & Bolliger, 2018; Martin, Wang, & Sadaf, 2020).

---

## Conclusion

The 2019 global pandemic has increased the number and variety of blends being explored at all educational levels. By April 2020 some 190 countries across the globe closed their schools and universities. This forced an estimated approximately 90% of the world's learners (almost 1.6 billion) to stay at home (UNESCO, 2020). A year later, close to half the world's students still faced partial or full school closures (UNESCO, 2021). In order to keep operating, many primary/secondary schools and higher education institutions implemented technology-mediated forms of instruction with very limited faculty training and resources.

In the best cases, quarantine situations were accompanied by quality online learning and an excitement for the changes underway. As British professor of the philosophy of higher education Ronald Barnett stated in regard to the impact of the pandemic on higher education institutions, "Perhaps no-one institution is so interconnected with the world as the contemporary university," whose powers of self-reflection he felt would create of this interconnectivity a new emphasis on cross-disciplinary and even cross-national work. For Barnett, this result would be "nothing short of a completely new theory of the university" (Barnett, 2020).

Many, however, felt unprepared for the challenges, including but not limited to "creating content for online spaces, learning new delivery tools, understanding online pedagogy, engaging parents, addressing student mental health issues, and attempting various pedagogical strategies to address both synchronous and asynchronous teaching and learning" (Hartshorne, Baumgartner, Kaplan-Rakowski, Mouza, & Ferdig, 2020). As schools scrambled to adapt to the new situation,

teachers experienced “appreciably different learning and performance contexts” (Lockee, 2021, p. 17) depending on each nation’s, state’s, district’s, and school’s unique responses and solutions.

Cavanaugh and Deweese (2020) examined educators’ search terms and their use of support content during the initial weeks of the pandemic. From February to March 2020, they found, total content views on the educator support website <http://support.office.com/education> increased from 640,000 to 4,145,000 (a sixfold growth) while video views changed from 4000 to 120,000 (a 30-fold increase). Clearly educators were embarking on a learning curve. The authors feel that the preference for synchronous video “signals that educators sought quick and authentic instruction and demonstration of the skills they wanted to apply immediately in their teaching” (p. 235).

Nonetheless, the strategic blending of face-to-face and online that is seen as “the best of both worlds” (Bele & Rugelj, 2007) sometimes went missing during the pandemic’s emergency remote teaching (Hodges et al., 2020). One group of researchers described a particularly dystopian view of the “rushed online migration” (Watermeyer, Crick, Knight, & Goodall, 2021, 638). Their survey of 1148 academics working in universities in the United Kingdom reported that the COVID-induced changes to online education resulted in “a depressing abundance of afflictions” (639) exacted upon the educators. Their descriptors included: “hesitancy and suspicion,” “trauma,” “profound professional and personal disruption,” “vulnerability and helplessness,” “disempowerment, displacement and marginalisation,” and educators feeling “bruised” and “distrustful” (p. 637–638). “Overall, [their findings] suggest that online migration is engendering significant dysfunctionality and disturbance to their pedagogical roles and their personal lives.”

But there is an abundance of new research coming out of the vastly varied experiences of educators during COVID, and most research findings are not anywhere near as bleak. Ferdig, Baumgartner, Hartshorne, Kaplan-Rakowski, and Mouza (2020) published an e-book of 133 chapters and over 850 pages, divided into seven sections that address pedagogy, collaboration, field experiences, pre-service education methods, professional development, digital tools, and equity issues. Journals published special issues devoted to the issues of teaching during the pandemic (see, for example, Reynolds & Chu, 2020). Borup et al. (2020) investigated how the Academic Communities of Engagement framework might be particularly relevant during the pandemic. Two of the four major findings in Gillis and Krull (2020) focused on the importance of how instructional strategies and digital tools were implemented – in other words, on the pedagogical nuances – in determining whether students found those strategies to be effective, accessible, and enjoyable (p. 296). Oyarzun et al. (2019) similarly found that methods were more important than media.

Despite the wide variance in experiences with emergency remote teaching, it is likely that blended practices that combine both online and in-person instruction will become increasingly prevalent across all educational sectors. Scholars have an opportunity to help institutions, instructors, and learners to understand research that can guide and improve blended learning practices. Additionally, there is still

much research to do as we need to better understand how different blended models and pedagogical practices within those models work to improve learning outcomes, increase access and flexibility for learners, and impact cost efficiencies.

## Abstract

Flipped learning (FL) began as a local trial strategy in a US high school in 2012 and in less than 10 years has exploded in popularity, among both educational practitioners and researchers, and has now been extensively recognized and implemented at all levels of education across the world. This chapter will discuss what is known from current FL literature, what the practical implications are from this literature, what gaps exist within FL research and between FL research and practices, and how those gaps should be addressed. This chapter begins with the definition and continues discussing history and supporting theories of flipped learning and its effectiveness, affecting factors, challenges, and possible solutions

**Introduction**

Flipped Learning (FL) practice and research has recently grown extensively at all levels of education, prompting active discourse among researchers and practitioners. Although there still exist learners left behind by a lack of technological access, FL has certainly benefited from increasing access to digital technologies, resources, and broadband connectivity along with open course ware, open educational resources, massive open online courses, or YouTube clips, which has led to the easier and wider implementation of FL. Another reason for its increasing popularity is the movement by many educational institutions to improve the quality of education by incorporating FL to bring about learners' active engagement coupled with positive learning outcomes (Lee & Choi, 2019). This chapter will discuss the research into FL: what is known from current FL literature, what the practical implications are from the literature, what the gaps within FL research and between FL research and practices are, and how those gaps should be addressed. This chapter will begin by discussing the definitions, history, and theories underpinning FL followed by the effectiveness of FL, its affecting factors, challenges, and possible solutions and introduce a set of extended versions of FL model and future research directions.

---

**What Is Flipped Learning? The Definitions of Flipped Learning**

Flipped classroom, flipped learning, inverted classroom, or inverted learning are all terms used in connection with this instructional model. Originally called flipped or inverted classroom, these terms are being replaced by *flipped learning*, which will be used throughout this chapter with the abbreviation FL.

When defining FL, researchers have slightly differing perspectives regarding what is flipped and whether to include video-based pre-class learning. FL has been referred to as both flipping traditional teaching and flipping early forms of blended learning. Bergmann and Sams (2012) defined FL as an instructional strategy “where work that was traditionally done in the class is now done at home, and what was traditionally homework is now completed in class” (p. 13). An earlier definition by Lage, Platt, and Treglia (2000) similarly defined FL as happening when “events that have traditionally taken place inside the classroom now take place outside the

classroom and vice versa” (p. 32). Other definitions are to gain foundational knowledge before class and then actively apply it in the collaborative classroom (Brewer & Movahedazarhouli, 2018), individual learning as homework outside the classroom, and interactive group-based learning inside the classroom (Bishop & Verleger, 2013). With students learning and reviewing concepts at home, class time can then be freed up for active, collaborative activities within the group space and increased time with the teacher (Bond, 2020; Lo & Hew, 2017).

Some other definitions posit FL as flipping the early version of blended learning, i.e., a combination of face-to-face synchronous classroom lecture and online asynchronous text-based activities (Garrison & Kanuka, 2004). Incorporating the concept of online and offline learning, Lee, Lim, and Kim (2017) defined FL as “a newly emerging form of blended learning, where students individually watch online lectures prior to class and then engage in classroom learning activities interacting with peers and instructors” (p. 427). Chen et al. (2018) also defined FL as a hybrid approach, combining online learning and face-to-face classroom activities where, during online learning, students engage in content learning before class and thereby during face-to-face classroom activities students engage in maximized active learning.

There is yet another lack of consensus among researchers and practitioners on learning materials with different modalities for FL pre-class. Some use a broader definition of FL that includes not only video but also reading assignments, homework problems, and PowerPoint presentations as pre-class learning materials (Giannakos, Krogstie, & Sampson, 2018; Lai & Hwang, 2016; Lee & Choi, 2019). More cutting-edge materials like interactive simulations, animated readings, and intelligent tutoring systems were also reported as pre-class learning (Davies, Dean & Ball, 2013). The FL definition of Bergmann and Sams (2012) allowed videos and other forms of media for pre-class learning materials, and Brewer and Movahedazarhouli (2018) also delineated resources such as modules, videos, or readings.

Other researchers take a stricter approach to defining FL as only utilizing online video lectures as pre-class learning materials. Lo and Hew (2017), for example, defined FL as an instructional approach combining video-based learning outside the classroom and interactive group learning activities inside the classroom. In addition, Bishop and Verleger (2013) excluded from their definition implementations that did not employ pre-class lecture videos. A systematic review of 37 FL studies published during 4 years by Giannakos et al. (2018) revealed that over 80% of reported cases employed video lectures in practice. The reasons of this stricter FL approach can be summarized as follows: firstly, many believe students learn better with video lectures than reading assignments (Akçayır & Akçayır, 2017; Lo, 2020). Video lectures are believed to function better because it is easier to repeat, pause, fast-forward, or slow down the instruction to match the learner’s pace and make content accessible at any time (Bush, 2013); secondly, the emphasis on video may be because the original version of FL that Sams and Bergman tried in their high-school chemistry course and launched into the spotlight exclusively utilized prerecorded video lectures.

However, many educators are questioning whether video lectures can flexibly be replaced with reading assignments for FL pre-class learning (Lo, Hew, & Chen, 2017). This is related to the evolving nature of FL's definition as well as the effectiveness of learning resources with different modalities. The value of FL lies in enabling in-depth, learner-centered learning experiences by offloading content delivery onto pre-class online learning (Lee & Choi, 2019). Thus, despite the popularity of video lectures, other solutions for providing pre-class learning could also be valuable components of FL. One example could be, in a problem-based learning situation, having students explore and study out the situation individually before class, which may allow for more constructivist learning in-class within groups as they derive solutions to the problem (West, Tawfik, Gishbaugher, & Gatewood, 2020).

Synthesizing two approaches of its definition, FL can be defined as an instructional strategy or model that combines online pre-class self-paced learning for foundational knowledge acquisition with video lectures together with other equivalent solutions and offline in-class interactive learning activities for knowledge application facilitated by instructors.

---

## The History of Flipped Learning Practice

There are disagreements regarding when and where FL originated. Some point to Harvard's Eric Mazur, who, in the late 1990s, implemented a peer instruction method in his undergraduate physics course, having students prepare to learn outside class by doing pre-class readings and answering questions about those readings and then in class engaging students in discussing their answers with peers coached by instructors. He found that students learned better when instructors coached students' learning rather than directly instructing them. Although it resembles FL, it seems unwarranted to regard it as the origin of FL since it was not similarly named.

The term "classroom flipped" and "flipped class" then was initiated by Wesley Baker at Cedarville College in 2000. He had practiced FL in his graphic design course since 1995 using web course management software, where lectures were uploaded and asynchronous threaded discussions were hosted. In 2000, he mentioned FL made it possible for faculty to move from "sage on the stage" into "guide on the side" (Baker, 2000, p. 11). The term "inverted classroom" was then used by Maureen Lage, Glenn Platt, and Michael Treglia, who, in 2000 at Miami University, implemented FL in their economics course, putting a high value on the individualized approach of FL for accommodating different student learning styles.

While the concept and practices of FL had existed since 2000, sporadic reports and anecdotes were shared among limited groups of educators in the form of conference papers. The research contained limited empirical evidence on implementation and effectiveness (Cheng, Ritzhaupt, & Antonenko, 2019). Full-fledged implementation and development were then pioneered by high-school chemistry teachers John Bergmann and Aeron Sams. From 2007 and 2008, they recorded lectures for students who had missed their classes. Later, these teachers prerecorded

all of their chemistry lectures and utilized them in assigning student's homework, subsequently finding that students engaged in problem-solving and experiments during class more actively. After reflecting on questions like "when are students struggling and seeking help from their instructor or peers?" and "how can instructors help them while optimizing the technological benefits of an online learning environment and the in-person benefits of human interactions in the classroom?" (Lee et al., 2017, p. 428), the two then formulated their instructional strategy into the FL model and shared their experiences in a series of publications (Bergmann & Sams, 2012; Bergmann & Sams, 2014).

Since 2012, FL has gained widespread popularity, becoming extensively recognized and implemented at all levels of education across the world. In 2012, Sams and Bergmann started the nonprofit Flipped Learning Network™ (FLN) to provide educators with the knowledge, skills, and resources for successful FL implementation. From 2016, international and coalitional support for effective implementation of FL began to emerge (Birgili, Nevra Seggie, & Oğuz, 2021). In 2016, an FL global coalition, Flipped Learning Global Initiative (FLGI), was formed by researchers, practitioners, and technologists from 49 countries. In 2018, higher education institutions such as Harvard and Stanford and MEF University in Turkey, the first fully flipped university, took the initiative for the FL global movement and collaborated in publishing Flipped Learning 3.0 Global Standards that were curated from 187 FL best practices worldwide (Flipped Learning 3.0 Global Standards Summit, 2018).

---

## Theories and Research Evidence Supporting Flipped Learning

With its widespread implementations and reported anecdotal success, researchers have sought to stipulate theoretical rationales or evidences for FL and provide FL practitioners with suggestions for best practices. Related theories can be the didactical 3C model of Kerres and de Witt (2003) in the area of blended learning theories; the media synchronicity theory of Dennis, Fuller, and Valacich (2008) in the area of media and communication theories; the cognitive load theory from a group of studies initiated by Sweller, Merrienboer, and Paas (1998), and the schema theory of Bartlett (1995) and subsequent studies in the area of cognitive psychology theories.

Since FL is under the big umbrella of blended learning, designing FL entails designing the optimal blend between two modes of learning, i.e., online pre-class and offline in-class learning. Blended learning (BL) integrates classroom face-to-face learning experiences with online learning experiences (Garrison & Kanuka, 2004; Garrison & Vaughan, 2008). Within this framework, BL practitioners have sought to design a better blend, one of the theoretical endeavors being the didactical 3C model of Kerres and de Witt (2003). The model specifies three components that all types of BL should have: Content, Communication, and Constructive components. In this model, educators designate the relative proportion of each component and then decide a corresponding delivery format. The Content component is factual learning content that needs to be available to learners; the Communication component is interpersonal interactions between instructor and learners or among learners

for more arguable learning tasks; and the Constructive component is activities that facilitate learners' more cognitive engagement in most complex learning tasks. In FL contexts, the theory supports FL having all of the 3C components: the Content component for factual learning, which is implemented with FL pre-class, and the Communication and Constructive components for more cognitively engaging learning interacting with instructor and peers, which are implemented with FL in-class. The model suggests the proportion of components should be designed considering learning objectives and learning contexts. Once the proportion of each of three Cs has been decided, the delivery method is then chosen from the variety of technologies and communication tools offering different affordances.

Several media and communication theories inform how the components of the 3C model can best be arranged using available media. Media synchronicity theory (MST) is one of the theories informing FL design, which argues that the fit between information processing needs and the affordances of the media used to support synchronous communication determines the quality of communication performance (Dennis & Valacich, 1999; Dennis et al., 2008). MST views communication as a series of tasks to achieve shared understanding, where a task consists of two cognitive processes – conveyance and convergence. Conveyance focuses on transmitting large amounts of new information followed by receivers internalizing that information to construct their own mental models. Convergence focuses on verifying, adjusting, or negotiating participants' mental models, enabling shared understanding. MST proposes that tasks with conveyance focus can be better supported by synchronous media, whereas tasks with convergence focus may be supported by asynchronous media. In FL contexts, pre-class learning aims at conveyance, i.e., transmitting new information and the learner internalizing that information to construct his/her mental model, for which asynchronous media such as learning materials posted online should be selected. In-class learning aims at convergence, i.e., approaching to shared understanding by interacting with instructor and peers, for which synchronous media such as face-to-face class should be selected.

The importance of FL pre-class learning and pre-class mini-lectures is supported by cognitive load theory and schema theory, which concern the role of prior knowledge or expertise of learners. Cognitive load theory (CLT) states that learning can be hindered if learner's cognitive resources and working memory are overburdened, and learning should be designed so that learner's cognitive load is reduced, saving capacity for more meaningful and higher-order learning tasks. CLT classifies the load into three types: intrinsic cognitive load, which is the inherent difficulty of the learning content; extraneous cognitive load, which is the load caused by the way the content is presented; and germane cognitive load, which is efforts required for integrating new information, the creation and modification of schema (Sweller et al., 1998).

Leaving extraneous cognitive load that is associated with learning materials aside, one way to reduce cognitive load is constructing and making accessible one's cognitive schemas, for which the learner's level of prior knowledge or expertise is a critical factor (Bartlett, 1995). A learner's level of prior knowledge or expertise relating to the topic can determine the comfort with which complicated learning

tasks can be processed simultaneously in working memory without burdening cognitive overload. Learners with more prior knowledge can have more cognitive resources available to actively process learning tasks at hand, whereas learners with less prior knowledge need more cognitive resources and thus can choose superficial learning strategies. In the context of FL, locating individualized pre-class learning that can provide background knowledge for collaborative in-depth in-class learning activities prior to FL in-class is for activating cognitive schemas to reduce intrinsic cognitive load prior to FL in-class. Ultimately this allows more resources for germane load that require more complex schema constructions during FL in-class learning.

## Growth of Flipped Learning Research

With the popularity of FL practice, FL research has grown exponentially. A systematic search, as of June 26, 2021, using the keywords “flipped learning” or “flipped class\*” or “inverted learning” or “inverted class\*” in titles of peer-reviewed journal articles throughout the four databases of ERIC, Scopus, Web of Science, and Medline, found in total 1,629 publications. As shown in Fig. 1, the volume of FL peer-reviewed journal articles jumped significantly from 5 in 2012 to 372 in 2020. In less than 10 years, FL research has achieved tremendous quantitative growth, and this trend is expected to continue.

FL literature is presently dominated by investigated FL cases and FL effectiveness (Lundin et al. 2020). As Lundin et al. (2020) found, in the initial years of FL research, descriptive case reports on FL implementation were dominant, but these studies were mainly limited to reporting the experimental process and results of adopting FL in individual courses or subjects at individual schools. There have also been studies with reflection or opinion-based arguments around FL and with a theoretical approach discussing relevant educational theories supporting FL (Lundin

**Fig. 1** The quantity of FL publications since 2012 as of June 25, 2021 ( $n = 1629$ )

et al., 2020). For this reason, the study design lacked rigor with lower levels of evidence. As educators and researchers asked for compelling evidence on the effectiveness of FL, studies have tried to assess its effectiveness with higher levels of evidence – mostly done through meta-analyses.

This exploding body of empirical literature has also led to an increasing number of review studies such as systematic reviews, scoping reviews, and meta-analyses (Birgili et al., 2021; Hew et al., 2021). Systematic syntheses of the state of research can provide researchers and practitioners with knowledge on the integrative effectiveness of a certain approach of learning design (Zawacki-Richter, 2020). With the systematically synthesizing endeavor, we can “look at the body of evidence rather than looking at any study in isolation” (Nordenbo, 2010, p. 22) and stay reflective about future research, education practices, and policies. The growing number of FL review studies reflects a scholarly and practical need to understand the FL outcomes across studies.

Effectiveness research investigates the learning outcomes achieved by FL, by either comparing FL to traditional lecture-based learning or comparing the start and end of FL using pre-post designs. The learning outcomes analyzed have been mostly academic achievement, measured by score or grade, and occasionally motivational or attitudinal outcomes such as engagement, perceptual change, and satisfaction (Brewer & Movahedazarhouli, 2018; McLaughlin et al., 2014). Among the 25 meta-analyses, all reported that FL had higher learning outcomes, among which 24 were statistically significant and 18 reported with medium to large effect sizes. The full list of FL meta-analysis studies can be accessed in Data 1. The full list of FL review studies can be accessed in Data 2.

According to recent systematic review studies on FL, the greatest proportion of FL studies have been conducted with undergraduate students in higher education institutions, with a far smaller proportion with K-12 contexts (Akçayır & Akçayır, 2017; Cheng et al., 2019; Lundin et al., 2020). The areas reported as having implemented FL were diverse, but higher education and STEM education were two main areas (Bond, 2020). Asia and the USA were geographically dominant in FL research (Lundin et al., 2020). In this chapter, I will now discuss the practical implications from the literature, including the gaps within FL research and between FL research and practices.

---

## Flipped Learning Benefits

The majority of studies investigating the effectiveness and benefits of FL have reported that FL promotes improvements in student academic performance mainly measured by test scores or course grades. The systematic reviews and meta-analyses synthesized this dominant cognitive outcome of FL. Recent meta-analyses with relatively large samples of studies— for example, a meta-analysis of 203 studies published between 2012 and 2019 (Tutal & Yazar, 2021), of 95 studies published between 2013 and 2019 (Zheng, Bhagat, Zhen, & Zhang, 2020), and of 198 studies published between 2012 and 2018 (Strelan, Osborn, & Palmer, 2020) — reported

positive cognitive learning outcomes, i.e., growth in academic performance or outperformance by FL over traditional approaches. Twenty-four of the 25 FL meta-analysis studies in Data 1 investigated either academic performance or cognitive achievement.

The next most commonly investigated outcome of FL is student motivation or engagement, measured, for example, by the amount of discussion participation. Related outcomes were positive attitudes or perception toward FL, which were measured usually by self-report survey. Other outcomes investigated include a self-regulated learning or study habit, competency in problem-solving and social or collaborative learning, digital competency, academic efficacy and changes in behaviors, changes in professional practice, or changes in actual outcome such as patient recovery. Four out of 25 studies reported course satisfaction or motivation as FL outcomes (Data 1).

There are many other potential positive benefits of FL that have been explored. One is that it can enable flexible, individualized learning with pre-class resources at students' own pace at any time, and they can repeat or learn additional content as they want (Birgili et al., 2021; Brewer & Movahedazarhouli, 2018; Cheng et al., 2019; Hew et al., 2021; Lo & Hew, 2017). The benefit of flexible individualized learning can lead to learners' self-regulated and self-directed learning by properly scheduling their time to learn pre-class assignment and ultimately being accountable for their learning (Lee, Park, & Davis, 2022). Kostaris, Sergis, Sampson, Giannakos, and Pelliccione (2017) showed that FL brought learners' growth in their digital competencies while accessing and managing digital learning resources.

Another compelling benefit of FL is that it facilitates learner's active and interactive learning. FL design is ultimately for securing active learning time by offloading knowledge delivery pre-class, allowing in-class time to be utilized in engaging learners in interaction between instructor and students and between peers (Birgili et al., 2021; Bond, 2020). FL can benefit large college courses such as introductory basic science courses, where learner engagement is traditionally minimal (Brewer & Movahedazarhouli, 2018) and where the benefit of active and interactive learning leads to enhanced engagement.

Lastly and most critically, most FL studies have agreed that FL can promote meaningful and constructivist learning by involving learners in knowledge construction assignments and activities both in and out of the classroom, thereby developing higher-order thinking competencies such as critical thinking or problem-solving skills (Brewer & Movahedazarhouli, 2018).

---

## Factors Affecting Flipped Learning Effectiveness

While the majority of studies have trumpeted positive benefits of FL, some studies have reported no significant difference between FL groups and non-FL groups. A few further studies reported FL impaired student learning. One possible solution to the muddy picture of FL effectiveness is to explore factors affecting FL's effectiveness and investigate into what context and in what ways FL can be effective, as

intended. FL is not a panacea and might not be effective in certain contexts or for a particular learner group. Educators' decision-making would benefit greatly from knowing how and where FL should be implemented and which particular groups would gain maximum benefit.

Educational level has a bearing on the effectiveness of FL. According to Cheng et al. (2019), 55 publications, published from 2000 to 2016, reported the overall effects of FL on K-12 and college undergraduate students' learning outcomes and its moderating variables and concluded that FL outperformed the traditional lecture method. However, for graduate students, the traditional way of teaching and learning was more effective than FL, which was explained by the fact that the usual format of graduate education is already similar to FL and discussing and analyzing scholarly works are their main activities.

The subject or area of learning can influence the effectiveness of FL. Arts and humanities courses benefited more from FL than did mathematics courses, perhaps because some subject areas are difficult to learn independently and students could be overwhelmed by the FL pre-class learning (Cheng et al., 2019). Learning objectives and assessment method also can be affecting factors. In the course for skill acquisition assessed by OSCE (Objective Structured Clinical Examination) or knowledge retention/comprehension assessed by multiple-choice questions (MCQs) (Chen et al., 2018; Hughes & Lyons, 2017), FL showed mixed result or no significant advantage over a non-FL approach.

One of the most critical affecting factors is learner's pre-class learning. The influence of pre-class learning on final FL success has been empirically shown to be both significant and strong. As the proportion of students who do not complete the assigned pre-class work is reported as quite substantial (Heitz, Prusakowski, Willis, & Franck, 2015) and pre-class is the opening move to the benefits of FL, completion of pre-class assignments has a drastic effect on the differential effectiveness of FL. Typically video materials induce higher academic performance than reading materials (Lee & Choi, 2019), but the quality of video materials can be also crucial to the success of FL, implying a need to produce or prepare high-quality video materials that are attractive and not overly long. Although video materials certainly have unique and optimal features for FL pre-class, it is the quality of learning content and instructional design that those video materials deliver that matters, as explained in the classic debate raised between Richard Clark and Robert Kozma on the role of media in learning in the early 1990s. As an instructional strategy to promote students pre-class learning, quizzes at the start of an in-class session can be employed. Hew and Lo (2018) found that the use of verification quizzes for testing learner's understanding on pre-class learning significantly influenced the effect of FL.

Learner factors, academic capability, attitudes toward FL, and their technology competency also can be significant factors as shown in Table 1. As educator factors, their pedagogical approach, such as their recognition of FL as a learner-centered approach, their empowering, engaging and encouraging students and commitment can be a critical affecting factor in the effective implementation of FL (Brewer & Movahedazarhouli, 2018; Shi et al., 2020). Institutional support and professional

**Table 1** Factors potentially affecting FL effectiveness

Factors	Sub-factors	References
School or course factors	Educational level	Cheng et al., 2019; Lundin et al., 2020
	Subject area	Birgili et al., 2021; Cheng et al., 2019
	Learning objective	Chen et al., 2018
	Assessment method	Chen et al., 2018
Fl implementation factors	Students' completion of pre-class learning assignment	Lee & Choi, 2019
	Kinds of learning material	Lee & Choi, 2019
	The quality of video materials	Moraros et al., 2015; Akçayır & Akçayır, 2017
	The use of the verification quizzes	Hew & Lo, 2018
Learner factors	Learners' academic capability	Cheng et al., 2019
	Attitudes toward FL	Akçayır & Akçayır, 2017; Lee et al., 2022
	Technology competency	Akçayır & Akçayır, 2017
Educator factors	Pedagogical approach	Brewer & Movahedazarhouli, 2018; Shi et al., 2020
	Institutional support	Brewer & Movahedazarhouli, 2018
	Professional development	Brewer & Movahedazarhouli, 2018

development may be another factor in the same vein (Brewer & Movahedazarhouli, 2018).

## Remaining Challenges and Possible Solutions

FL research conducted so far has provided practical implications for FL implementations, but there remain challenges that research has not yet fully addressed. Lo and Hew (2017) classified those challenges into three: student challenges, educator challenges, and technical challenges.

Challenges related to students are mostly related to their pre-class learning issues and also general unfamiliarity and an unreceptive attitude toward a new approach to learning. Student unpreparedness of pre-class assignments is seen as the biggest challenge of FL due to lack of either motivation or of self-regulation, and overcoming this is critical because FL pre-class learning is positively and strongly correlated with FL learning outcome and nearly twice that of in-class learning (Lee & Choi, 2019). Underprepared learners are clearly an obstacle to the intended benefits of FL. Students' disengagement from the pre-class learning, due to their natural vulnerability to distraction while watching online lectures, and helplessness during pre-class learning when they are unable to understand the materials and want to ask

questions during the pre-class can be also pre-class-related challenges. The general unfamiliarity and unreceptive attitude toward FL can be another type of challenge. Students can feel uncomfortable and nervous in the new format and further resist FL in the initial stage of implementation (Brewer & Movahedazarhouligh, 2018; Giannakos et al., 2018), which can be even worse for older learners (Birgili et al., 2021).

Student challenges naturally become educators' challenges. Significant start-up effort is required to design both pre-class and in-class sessions, tightly linking the two. Pre-class video requires levels of instructional and technical qualities attractive enough to engage reluctant students in self-regulated learning and prevent distractions. The length and load must also be appropriate. The production of a 10-min video is known to require nearly 2–3 h work, and according to McLaughlin et al. (2014), an FL educator has to spend 1.27 times more time in developing and managing an FL course as compared to a traditional course. Preparing in-class session also requires great deliberation in order to provide the necessary active learning experiences. Educators whose courses were mostly lecture-based may be bewildered as to what to prepare for the in-class time. Most importantly, educators need to create a tight link between pre- and in-class learning so that the two complement each other, which may ultimately involve redesigning a course (Lee & Choi, 2019).

Another fundamental educator challenge is the need to shift their pedagogy and philosophy about teaching and learning to minimize the knowledge deliverer's role and maximize the facilitator's role. However, in reality many educators resist this change and prefer traditional lecture-based teaching (Hew et al., 2021). Since FL requires a fundamental conceptual shift in thinking about teaching and learning, this challenge must be tackled strenuously.

Lastly, there are technical challenges in terms of infrastructure, devices, and technology skills, for both students and educators. Educators must constantly be aware of any learner left behind by such issues.

Research has provided some possible solutions to these challenges, as shown in Table 2. For student pre-class learning issues, strategies such as the checking of students' pre-class learning written notes, online quizzes or video-embedded quizzes, pre-class assignments, in-class quizzes, and study schedule can be provided to support student self-regulation (Cheng et al., 2019). Educators must help students recognize that FL pre-class learning is a crucial component of FL, not a supplementary task. Regarding unfamiliarity and unreceptive attitude toward FL, course orientation with clear explanations about the FL concept and teacher's expectations of students' responsibility can be provided (Lee et al., 2017). For the educators' video production challenge, educators can deliberately select and use the vast number of preexisting video learning materials (e.g., OER, MOOCs) provided by institutions and refer to production guidance on how to create high-quality video.

For educators who usually deliver knowledge during class and do not know what to do during FL in-class, designing in-class learning activities can be a big challenge. Studies suggested a set of in-class activities such as discussion, small

**Table 2** FL challenges and possible solutions

FL challenges		Possible solutions
Student challenges	Unpreparedness for pre-class assignment Disengagement from the pre-class learning Helplessness during pre-class learning	<ul style="list-style-type: none"> <li>✓ Checking students' written notes of pre-class learning</li> <li>✓ Online quizzes</li> <li>✓ Video-embedded quizzes</li> <li>✓ Pre-class assignments</li> <li>✓ In-class quizzes</li> <li>✓ Provide study schedule</li> <li>✓ Help student see the importance of pre-class learning</li> </ul>
	Unfamiliarity and unreceptive attitude toward FL	<ul style="list-style-type: none"> <li>✓ Course orientation</li> <li>✓ Reflection on opportunities to reinforce FL concept throughout the course</li> </ul>
Educator challenges	Significant effort for pre-class video production	<ul style="list-style-type: none"> <li>✓ Use preexisting resources (e.g., OER)</li> <li>✓ Provide guidance on how to create high-quality video</li> </ul>
	Significant effort for in-class activity preparation	<ul style="list-style-type: none"> <li>✓ Adopt TBL or PI</li> <li>✓ Discussion, small group activities, feedback, problem-solving, Q&amp;A</li> </ul>
	Resistance against shifting their pedagogy and philosophy about teaching and learning	<ul style="list-style-type: none"> <li>✓ Professional development</li> <li>✓ Educator community peer consulting</li> </ul>
Technical challenges	Technical accessibility in terms of infrastructure, devices, and technology skills	<ul style="list-style-type: none"> <li>✓ Institutional support</li> <li>✓ Professional development</li> </ul>

group activities, feedback, problem-solving, Q&A or exercises, group projects, gaming activities, personal projects, and peer assessment. Other instructional model such as team-based learning (TBL) (Michaelsen, Knight, & Fink, 2004) or peer instruction (PI) (Mazur, 1997) can also be implemented, each of which has a structured procedure. For example, TBL starts with (1) individual readiness assurance test (IRAT), followed by (2) team readiness assurance test (TRAT), (3) appeal (the opportunity to appeal that their answer choice is better), and (4) instructor feedback, and finally ends with (5) application-focused exercises. These steps can guide FL educators when designing and implementing FL in-class learning.

---

## Fully Online Flipped Learning, Bichronous Online Learning, and HyFlex Learning

The COVID-19 pandemic, causing offline in-class sessions to be cancelled, has naturally called for a modified FL model implemented in fully online contexts. A few studies (e.g., Stöhr, Demazière, & Adawi, 2020; Jia, Hew, Bai, & Huang,

**Fig. 2** Fully online FL in comparison with original FL and traditional learning

2021) reported the experiences when implementing the fully online FL model. The fully online flipped learning converts offline in-class learning into online in-class learning using video conferencing tools. Face-to-face classroom learning is replaced by synchronous virtual class learning as in Fig. 2. Video conferencing enables real-time interaction with nonverbal communication cues, such as facial expressions and body language, which offer high levels of immediacy and student engagement (Jia et al., 2021). Stöhr et al. (2020) and Jia et al. (2021) investigated whether fully online FL is as effective as the original FL and found no statistically significant difference in average academic performance between the two. However, Stöhr et al. (2020) cautioned that fully online FL led to a polarized larger spread in performance, indicating some students perform better, while others struggle even more.

Although no specific prescriptions for what should be done during each mode of learning exist, the blending of both asynchronous and synchronous online learning has recently been christened with the name of bichronous online learning by Martin, Polly, and Ritzhaupt (2020). Bichronous online learning can be a broader concept than the fully online flipped learning model. In the former model, students participate in their learning anytime, anywhere, during the asynchronous parts of the course but then participate in real-time activities for the synchronous sessions, whereas in the latter model, the way of blending both asynchronous and synchronous online learning is the same, but it specifies that knowledge delivery should be done during the asynchronous part, and collaborative constructive learning activities should be conducted during the synchronous part. Further variation is the hybrid flexible (HyFlex) approach suggested by Abdelmalak and Parra (2016), where students choose how to participate in the course or session, either online or offline, synchronously or asynchronously, over the course and from session to session, depending on which works best for them.

## Future of Flipped Learning Practices and Research

In this chapter, I have reviewed the definition, history, supporting theories, research status quo, modified versions, and future research issues of FL.

FL review studies have given many recommendations for future research, with the following four being most often mentioned. Firstly, while some FL studies have provided rich accounts of design features and associated implementation, more have not. Future studies should provide details on specific course design, materials used, pedagogical strategies, learning environment, and context for both pre-class and in-class learning. In addition, there have been calls for the research to be more rigorous and theoretically grounded. Secondly, research should explore the contexts in which FL works best, i.e., for whom, when, under what circumstances, and in what ways. Thirdly, although most meta-analyses show that FL is better than the traditional approach in terms of academic performance, studies comparing the two in terms of higher-order learning outcomes are limited.

Fourthly, a small number of studies into long-term implementation of FL have been conducted. In addition, as some studies stressed that FL involves a shift in thinking about teaching and roles of teachers, and its successful implementation requires cultural shifts, further studies on cases of a whole FL school or multiyear FL implementation would reveal whether such a pedagogical or cultural shift was induced by FL.

FL started as a local trial strategy in a US high school and in less than 10 years exploded in popularity, having been extensively recognized and implemented at all levels of education across the world by researchers. Behind this popularity is a global desire to improve the quality of education through putting learners in the center of their learning. The contributions of FL in improving educational practices thus far cannot be ignored. However, in practice, educators have to remember that flipping, per se, cannot guarantee its effectiveness but can be the catalyst to reflecting and redesigning the entire learning experience. FL research should rigorously listen to and support practical needs in order to have the FL model properly and effectively implemented and further extended.

### Abstract

In this chapter, we discuss open recognition as a key part of the digital learning/open education revolution, and open microcredentials a method for open recognition to disrupt traditional educational practices surrounding how we recognize and certify learning. We begin with definitions of open microcredentials, badges, verifiable credentials, and similar concepts. Then, we discuss the potential of open microcredentials to impact teaching and learning at the micro-, meso-, and macrolevels. We then conclude with recommendations for practice and the suggestion of a framework to guide research.

## Introduction

A benefit of the twenty-first century digital education revolution has been the increased access to education provided by digital technologies. This interest in improving access has led to the growth of the open educational movement and an explosion of openly accessible and/or openly licensed resources for education such as Massively Open Online Courses (MOOCs), textbooks, and other open educational resources. However, learning is more than content, and consequently open education must include more than just open educational resources (OER). As Wiley (2018) has argued, we need to talk about an open education *infrastructure* that includes open content, competencies, assessments, credentials, and even pedagogy. We further synthesize Wiley's ideas and propose that an open education infrastructure for the twenty-first century should include methods, technologies, and plans for:

1. Open practices (e.g., open pedagogy, open research, and open sharing/collaboration of ideas).
2. Open content (e.g., MOOCs, OER, open textbooks)
3. Open recognition of learning (e.g., open assessments, data, standards, credentials, transparency of trust around recognizing learning)

While open content has been discussed for 30 years and is the most well-known, open practices and recognition have been largely ignored. However, new technologies have emerged to support open recognition and practices in the last 8 years. In particular, technologies supporting how we assess and recognize acquired knowledge, skills, and abilities are becoming increasingly popular.

One emerging innovation to support how we assess and recognize learning is digital microcredentials, also known as open microcredentials, open badges, or alternative digital credentials. While there are nuances in how these terms are used, they are often used interchangeably in the literature. These credentials have exploded in popularity in recent years with 45 million open badge credentials having been issued since their creation in 2012 (source: IMS Global). While some are concerned that breaking education down into microbits appropriate for microlearning would be detrimental, others argue that they instead present an enticing opportunity for educational innovation by playing a complementary role, creating the building blocks for more affordable degree programs, and promoting greater transparency for educational outcomes (Gallagher, 2019).

Rather than sweeping away degrees, new types of online credentials — various certificates, MicroMasters, badges, and the like — are instead playing a complementary role, creating the building blocks for newer, more affordable degree programs. ... The growing digitization of credentials also heralds a new era of greater transparency for educational outcomes — providing more and better data on which corporate leaders can make hiring decisions. (para 9, 14)

In this chapter, we will focus on open recognition as one aspect of the open education infrastructure, and in particular open microcredentials due to their ability to disrupt

traditional educational practices surrounding how we recognize and certify learning. In keeping with the spirit of the handbook, we will discuss the potential of open microcredentials to impact teaching and learning at the micro-, meso-, and macro-levels, concluding with recommendations for both practice and research.

---

## Definitions

One challenge in discussing the literature on open badges/microcredentials is that the terms have been used very differently by different professionals and overlaps with other, similarly micro, open recognition technologies. For that reason, we begin our chapter by briefly defining the terms.

First, it is important to distinguish between *open* and *controlled* credentials. Open credentials use technology that openly distributes the role of assessing and credentialing learners among various institutions and persons. Meanwhile, controlled credentials are issued and controlled by a small group of persons or institutions. For example, the number of institutions that can issue a university degree is relatively small – only 3700 such institutions in the United States (National Center for Education Statistics, 2020).

In contrast, an open credential, by nature of the technology supporting it, cannot be controlled but could be issued by anyone. Because open credentials are based on common, open technology (such as the Open Badge Infrastructure, maintained by IMS Global, see <https://www.imsglobal.org/activity/digital-badges>), these credentials can be exported and imported freely between institutions – putting the learner in control. In this way, open credentials, as Hickey and Chartrand (2020) argued move us away from accrediting institutions towards endorsing actual learning.

Second, we distinguish between micro- and macrocredentials. Macrocredentials, such as degrees, diplomas, and professional learning certificates, represent a culminating recognition of program completion – such as the end of a university degree. Microcredentials, instead, do not signal the end of learning, but rather small steps on a learning trajectory, representing acquisition of a single skill, ability, or bounded set of knowledge. Because these credentials represent smaller pieces of education, they can be combined to form unique learning pathways.

The terms *open badges* and *open microcredentials* can describe either the same thing, or sometimes very different things – often with open badges representing smaller pieces of learning, or with microcredentials representing traditional university credit options but on a microscale, while badges represent noncredit, informal learning. Sometimes, however, the difference could be as simple as a difference in culture – for example, whether a particular society has a history of boy or girl scout merit badges for youth learning. However, in the end, both terms represent credentials supported by the Open Badge Infrastructure and are thus equivalent technologies. We will refer to these both as *open microcredentials* when talking about them generally, and in reviewing the work of others, we will use whatever specific term the authors use.

Key affordances of open microcredentials that we identify include their capabilities to: (1) recognize accomplishments at more granular level, (2) demonstrate mastery in a particular area, (3) provide verified and endorsed certifications, (4) serve as a lifelong portfolio that captures both formal and informal learning, (5) store rich formats of metadata to serve different purposes, and (6) be shared among different stakeholders.

Finally, there are other emerging credential technologies that use different open technology standards but share similar affordances. For example, *verifiable credentials* use open source technology maintained by the World Wide Web Consortium (<https://www.w3.org/TR/vc-data-model/>) and *comprehensive learner records* (or *extended transcripts*) which are a comprehensive record of all of a learner's accomplishments in school, on the job, or within communities – a record that can follow the learner wherever they go. This technology standard is also maintained by IMS Global (<https://www.imsglobal.org/introduction-extended-transcript-et>).

We believe that this concurrent push to develop comprehensive learner records, verifiable credentials, and open microcredentials is representative of the same underlying desire to create credentials that can be openly shared among institutions, controlled by learners, and representative of both small and large pieces of learning.

---

## What Research on Open Microcredentials Has Taught Us

We will divide our discussion of the research findings into those related to micro-levels of education (effects on teachers and learners and their perceptions of open microcredentials), mesolevels (effects on institutions), and macrolevels (effects on society), in keeping with the theme of this handbook.

### How Do Open Microcredentials Affect Learning in the Microlevel?

#### Learner Perceptions on Open Microcredentials

Most learners hold positive attitudes towards the use of microcredentials (Başal & Kaynak, 2020; Malczyk, 2019). These learners suggested that the use of digital badges provides several advantages, such as promoting learning engagement and motivation, providing external rewards, providing feedback (Santos-Díaz, Hensiek, Owings, & Towns, 2019), triggering a sense of enjoyment or accomplishment, enhancing learner autonomy (Iwata, Wang, & Clayton, 2019), developing positive attitudes towards learning (Watson, Ann, Arabia, & Watson, 2020), and enhancing learner autonomy (Iwata et al., 2019). However, these perceptions can be heavily influenced by their perceptions of the course and engagement in it (Higashi & Schunn, 2020).

In contrast, other research showed that microcredential users may hold mixed perceptions on the adoption of this technology. For example, freshmen education majors have held some mixed attitudes (Beilstein et al., 2019) and considered microcredentials less prestigious than a certificate of completion (Dyjur &

Lindstrom, 2017) despite being an innovative idea. Also, students with prior experiences earning a microcredential have perceived microcredentials as more beneficial compared to students with no prior experiences before (Hartman & Andzulis, 2019).

While these studies looked at the perceptions of learners using open microcredentials, other studies have looked at their actual impacts in various areas, including student motivation, learning performance, personalization of learning, and self-regulated learning.

### **Open Microcredentials and Student Motivation**

Open microcredentials can promote motivation, encouraging participation, and engagement (Facey-Shaw, Specht, van Rosmalen, & Bartley-Bryan, 2020; DeLello, Hawley, McWhorter, Gipson, & Deal, 2018; Başal and Kaynak, 2020). Learners given the opportunity to earn microcredentials find it motivating because credits were given to recognize their efforts and devoted time. With rich metadata, microcredentials can communicate different types of learning data, such as interactive activities and multimedia instructional materials. For example, digital badges can motivate online tutors to improve their online tutoring skills, monitor the quality of their work, and encourage them to reflect on their tutoring process (Hrastinski, Cleveland-Innes, & Stenbom, 2018). Skills-based digital badges helped middle and high school learners ( $N = 72$ ) become more motivated, as evidenced by significantly higher self-efficacy and self-regulation ratings (Elkordy, 2014). Moreover, learners who worked with digital badges at a secondary special education school in North Holland ( $N = 34$ ) showed a significant increase in their intrinsic motivation (Bareño, 2021).

However, this research on the potential impact on motivation from using microcredentials has been mixed (Roy & Clark, 2018), with some studies finding they can decrease motivation (Chou & He, 2017; Reid, Paster, & Abramovich, 2015; Tomić et al., 2019). Contradictory results can even be found in different methodological sections within the same study. For example, in a quasi-experimental study conducted in an introductory programming course ( $N = 362$ ), the survey results suggested no impact of digital badges on learners' intrinsic motivation, while in the focus groups and interviews, learners using digital badges expressed motivation to learn programming (Facey-Shaw et al., 2020). Other research showed that the use of microcredentials had different impacts on different types of learning, improving motivation for extrinsic learners but not intrinsic ones (Sullivan, 2013).

### **Open Microcredentials and Student Learning**

While the effects on learner motivation are mixed, and to date still uncertain, it has been argued that microcredentials can influence learning performance and skill development. For example, Newby and Cheng (2019) found that preservice teachers who learned with digital badges outperformed those who learned with traditional projects in an undergraduate-level educational technology course. Also, the preservice teachers in the badge group reported more gains in their technology integration ability than those in the nonbadge group. Similarly, researchers found that the elementary students who earned digital badges for reading outperformed those who

did not earn badges in reading acquisition tasks (Collins, Grroff, Mathena, & Kupczynski, 2019).

Microcredentials have also helped K-12 educators learn twenty-first century skills of collaboration, communication, critical thinking, and creativity. Microcredentials help them become more goal-oriented and reflective on their learning and effectively communicate their conceptual understanding of the learned skills with each other (Yanek, 2021). Theoretically, microcredentials can also support inquiry-based learning through outlining prerequisite knowledge, chunking the problem into manageable subproblems for novices, and providing criteria and evidence for flexible assessment (West, Tawfik, Gishbaugher, & Gatewood, 2020). In addition, student achievement in reading and writing about literature was found to be positively correlated with their engagement in a course embedding soft skills badging (Naimark, 2021).

### **Open Microcredentials and Personalized Learning**

Microcredentials may also support personalized learning, or instructional and learning approaches based on the needs of individual learners, which can spark curiosity of students through active engagement with the learning environment (Hughey, 2020). Microcredentials can support this personalized learning by first breaking content into small modular units, so learners can create their own learning pathways (Erickson, 2020; McGovern & Gogan, 2021).

Second, open microcredentials are typically associated with individualized portfolios, documenting earned skills and knowledge for lifelong learning (Amano et al., 2019) and recognizing accomplishments (Wolfenden et al., 2020; Leaser, Jona, & Gallagher, 2020; Zhou, Chen, Fan, & Ji, 2019) so that learners can “use the terminology and examples that the gatekeepers of higher education would recognize and value” (Martin, Gutierrez, & Muldoon, 2020, p. 20). With microcredentials, learners can easily communicate their accomplished skills and knowledge in a more granular level and gain the flexibility to hop on and off “the formal education bus” when needed (Ryken, 2006). For example, in the CHAMPIONS NETWork program, Chicago high school students could earn seven digital badges of online experiences on health advocacy to prepare them for future health professionals. Students could then share earned badges with employers and colleges (Heinert, Quasim, Ollmann, Socarras, & Suarez, 2020). In this way they could take better advantage of employment opportunities at current skill levels and resume the degree completion path when new skills and knowledge are needed (Pearea, 2020).

Third, microcredentials can support personalized learning by providing specific and prompt feedback (Besser & Newby, 2020) as well as instructions with details, explanation, hints, and examples (Besser & Newby, 2019; Hensiek, 2018). While digital badges may serve as a fine-grained and an informational feedback tool, they only become effective when students acknowledge the value of using this type of feedback and show an expectancy for learning, as Reid et al. (2015) argued.

### **Open Microcredentials and Self-regulated Learning**

Finally, research about how microcredentials might affect learners has also explored the impact on self-directed or self-regulated learning. For example, in a study of

college graduates studying self-directed e-learning content, researchers found that the badge group reported higher levels of autonomous regulation than the nonbadge group, indicating that the use of digital badges had a positive impact on learners' self-regulation (Agola, 2020).

As widely acknowledged, self-regulated learning is a goal-oriented process, that is, self-regulated learners are intentional about information needed and take steps to master this information to achieve a desirable goal using strategies and responsive feedback (Zimmerman, 1990). Microcredentials can support learners' goal-setting process to enhance self-regulated and self-directed learning (Cheng et al., 2020; Cheng, Watson, & Newby, 2018) via a couple of mechanisms – for example, by helping to set explicit goals. In two studies conducted by Morris, Dragovich, Todaro, Balci, and Dalton (2019), no difference was found on learning performance across four groups, badges only, goal only, badge+goal, and control group, indicating that badges serve a similar role as goals in supporting learning.

Second, open microcredentials could theoretically help in establishing the necessary background knowledge and pathways. With microcredentials, learners could earn prerequisite credentials that prepare them to enter a complex problem-solving realm with sufficient background knowledge (West et al., 2020).

Third, these credentials help in optimizing goal-effects on learning (Cheng et al., 2018, 2019). Four specific functions of digital badges had been found in prior research on facilitating learners' goal setting process: connecting multiple goals, affecting goal commitment, scaffolding complex tasks, and providing personalized feedback. With the support of digital badges, learners can more easily connect learning goals, professional goals, and lifelong learning goals to optimize the effect of goal-setting on learning and professional development. Digital badges also influence learners' commitment to a goal as learners may devote more time and effort to achieving a badge (goal). Many digital badges not only serve as a pure extrinsic reward or recognition of accomplishment, but also bear different metadata including interactive instructional strategies and activities. Each digital badge also serves as a steppingstone that scaffolds a learning process towards achieving a complex objective. In addition, both the badge visual itself and the embedded feedback could provide learners with both summative and formative personalized feedback (Cheng, Richardson, & Newby, 2019).

## **How Can Open Microcredentials Support Learning in the Mesolevel?**

Thus far, most research on open microcredentials has focused on the microlevel of individual learners, teachers, and experiences. Adoption of an innovation at the level of an institution, organization, or system is much more difficult, requiring policies and practices to be rewritten. Perhaps because of this, Borrelli and Tateo (2021) observed that it has been difficult to fully evaluate the benefit of open microcredentialing compared to traditional credentials as limited pedagogical models are available to consider. In this section, we review existing research, organized into a few common themes.

### **Microcredentials Can Communicate Pathways Towards End Goals**

Some organizations have explored how to organize microcredentials into pathways, stacks, or playlists that represent an educational journey. Communicating these feasible pathways of learning is especially important for community colleges and other institutions working with students who may feel disoriented or less confident in their educational goals. Perea (2020) argued that stacking microcredentials allows learners, especially underrepresented population and individuals who are vulnerable, in persisting in ambiguous and poorly designed degree programs, to be able to “have multiple on and off ramps at certain milestones in a pathway towards degree completion and take advantage of employment opportunities at their current skill levels, and then later resume the degree completion pathway without starting anew” (p. 23). Perea then shared three case studies of community colleges stacking microcredentials in ways that guided students towards degrees while also recognizing their progress along the way and empowering them with credentials that could benefit them in the short and long term (see Table 1).

### **Microcredentials Can Communicate Their Value and Make Organizational Goals Visible**

While at the individual level, this helps students “see a pathway toward higher level credentials, toward progressively higher levels of workforce skills” (Perea, 2020, p. 23), at the institution-level, this can help with establishing shared expectations, vision, and goals. For example, digital badges can make library learning goals visible (Ekordy, 2014) or provide a record of granular and traditionally undocumented teaching skills (Spencer & Bussi, 2020).

In fact, Carey and Stefaniak (2018) found that this visibility and transparency of organizational goals is not only a great benefit, but a necessary precondition for using open microcredentials. They further argued in a different paper that microcredentialing systems must effectively communicate their value to learners for the system itself to be adopted successfully, because most learners will not be motivated to pursue these credentials without understanding their value. As Stefaniak and Carey (2019) stated, “badge participants emphasized the importance of creating badges with internal and external value to maximize buy-in. The recommendations also emphasized the importance of a comprehensible purpose for the badges” (p. 15).

It is also important to communicate the value of open microcredentials to employers and other end consumers of these credentials. For example, Randall and West (2020) surveyed potential employers in the field of education and found that employers often did not know what badges were, but if they did, they valued them. Similarly, Perkins and Pryor (2021) surveyed 73 employers and found 93% were unfamiliar with open badges. However, they wanted to understand the credentials better. This indicated that educational entities need to better partner and communicate with employers about these credentials: “Such synergies are crucial to address the changing skills agenda, to prepare students to thrive in physical and virtual work environments” (p. 24).

**Table 1** Three cases from Perea (2020) of community colleges stacking microcredentials

Case title	Goal	Action	Outcome
Tennessee Transfer Pathways project	Facilitated transferring from community colleges to universities within the state	Provided professional microcredentials	Student enrollments increased 44% and completion rates tracked at 85% at one college
Colorado Industry-Demanded Credential Initiative	Provided industry-demanded skills and credentials while still guiding students on a path towards degree completion	Offered digital, competency-based badges matched to industry technical standards and being embedded within manufacturing and applied degree pathways	It enabled students to complete the degree at multiple points to apply their skills in the workforce successfully and additionally helped employers be able to articulate what kinds of skills they needed for specific positions
Basic Health Care Certificate initiated by Rogue Community College in Oregon	To address dual concerns of a lack of entry-level skilled workers in healthcare and the lack of young people entering the field	The standalone Basic Health Care Certificate was interweaved in 11 different programs with a diverse set of electives – preparing students for five different entry-level positions	Students can use it to build credentials horizontally within an occupational field or to ladder up vertically within a professional healthcare career or degree completion pathway

**Microcredentials Can Widen Participation in Higher Education**

In addition to providing vision to students through potential stacks and pathways, microcredentials can widen student participation and persistence in higher education. The UK Open University, for example, has offered MOOC courses on basic skills. This project aims to develop students’ confidence and skills as a “personal ‘journey from informal to formal learning’ (or JiFL)” in a way that creates “a steppingstone into accredited education” (Hills & Hughes, 2016). They found that 28% of learners “clicked-through” to learn more about enrollment in regular OU programs.

Similarly, Carnevale, Garcia, Ridley, Quinn, & Georgetown University (2020) reported that students in certificate programs at Georgetown University are more likely to be minority or older – in other words, nontraditional. In total, they found that in the United States, 50% of students in undergraduate coursework were enrolled in certificate or associate’s degree programs. They argued “the middle-skills pathway—between a high school diploma and a bachelor’s degree—is often overlooked.” (pp. 3–4). However, they caution that to date, “not enough is known about the risks and rewards” of these educational paths, a gap we also identified in the literature.

However, one potential benefit that badges/microcredentials can play with this segment of students is in helping them communicate their skills for these “middle-skills” careers. Martin et al. (2020) found that “programs need not only to help participants gain knowledge and skills, but also to give them tools for communicating their accomplishments to college and career gatekeepers” (pp. 16–17) – something they believed digital badges could do as tangible representations of learning.

### **Microcredentials Can Be Interwoven with Traditional Credentials**

Some may view microcredentials as competitors to traditional degrees, but there are many documented cases of micro- and macrocredentials being interwoven (or latticed, as Perea, 2020, described) together. Doing so can “break down the silos between workforce development education and transfer education and provide learners with flexibility in meeting both education and career goals” (Perea, p. 23). Indeed, because microcredentials require thoughtful design and consideration of assessment, evidence of learning, and supportive resources, creating a micro-credentialing system can cause teachers and institutes to reflect and rethink teaching practices and curriculum. Eaton, Rauseo, d’Entremont, and Dziorny (2019) found this in their evaluation of the Boston After School and Beyond and the Providence After School Alliance programs and reported that providers, “did not realize that the deep work involved in aligning programmatic activities with the pilot’s skill-building goals would strengthen the quality of their own programs” (p. 6).

One example of interweaving open microcredentials with traditional academic credit was described by Randall et al. (2013). They designed over 40 skill-specific open badges available within a preservice, grade-based educational technology course. Students could elect to earn credit towards a degree, and if they wished, they could also earn as many open badges as they wanted to demonstrate mastery of specific skills. While finding this to be an effective method to support personalized learning in the course, one challenge was the burden of additional assessment/grading (also identified by Stefaniak & Carey, 2019), as well as the time required to create new microcredentials to support every potential personalized learning pathway. As Stefaniak and Carey (2019) explained, “It takes time to pitch, design, develop, promote, implement, and manage a badge program” (p. 14).

One solution employed by Randall and colleagues was to train students – peers of the target learners – as evaluation and design assistants to help develop new badge credentials and assess/issue credentials to other students. By comparing the quality of design from these student assistants to established experts, they found the student assistants to produce badge rubrics of equal quality, if they had received sufficient training (Randall et al., 2019), indicating that organizations seeking to integrate open microcredentials into traditional educational systems can do so through trained student assistants, alleviating some of the burden on faculty to run the system.

### **Microcredentials Can Assist Employers in Tracking/Providing Professional Learning**

Employers are key end consumers of microcredentials, and the most successful credentialing systems design credentials that benefit employers as well as students.

But what aspects of a microcredential are most important to employers? In one study of educational principals and hiring personnel, Randall and West (2020) found that employers saw the most value in achievement and capability badges, in comparison with participation/attendance or other types of badges. In particular, the employers valued the evidence link and endorsements from established professional organizations. Most employers in this study believed badges would be useful in the hiring process, but they worried about having too much data and being able to sift through the information effectively. Thus, microcredentialing systems and technologies may consider developing better ways of helping these end consumers parse, aggregate, and filter the data available in digital credentials.

Besides interpreting badges/microcredentials on resumes as part of a hiring process, employers have developed microcredentials as part of their own staff training programs. For example, Clements, West, & Hunsaker (2020) described the successful design of a gamified employee skill tracking and professional development system using open badges for employees of a multimedia center in a university library. In this case, the badges were developed to help the supervisor know who was qualified to teach certain workshops and also to establish regular goals and reward opportunities for employees continuing to develop their skills.

Similarly, Copenhaver and Pritchard (2017) reported on a microcredentialing program at Eckherd College Library to train student employees due to the lack of satisfaction with the previous program, which did not fully meet learning outcomes nor engage the employees. In particular, students had difficulty connecting library work to career development. In redesigning the training as modules with open badges, they found they covered more material in greater depth and had better employee retention and learning.

Similarly, National Instruments designed an open badging system mainly to train customers of their products in professional skills for using the products in their own workplaces. Young, West, and Nylin (2019) found that learners felt the badges were helpful and they were likely to repeat the training program to earn additional ones and were likely to recommend the program to peers. For both the badge earners and National Instruments the company, the value seemed to come from the ability to share the microcredential, which helped the earner in progressing their career and applying for new positions, but also provided marketing benefits to the company.

Similarly, IBM developed a robust badging system (first piloted in 2015) to recognize professional learning by its employees and others (Leaser et al., 2020). Results were staggeringly positive, as attendance increased 125% and course completions increased by 226%. In 2017, IBM partnered with Northeastern University to convert these badges into academic, graduate-level credit. As the authors put it, “This type of partnership provides a blueprint for how colleges can collaborate with businesses to improve the job market alignment of their academic credentials in a way that delivers more value for students and employers” (p. 40). By 2018, IBM had issued more than a million badges to 400,000 people in nearly 200 countries.

From this robust implementation of employer-based badges came a few insights documented by Leaser, Jona, and Gallagher. First, that community colleges should focus on areas in-demand by industries and create badging programs aligned to those

needs. In fact, issuing badges, they argue, can provide a powerful feedback loop to universities about what skills and abilities are “hot” in the market. Second, they argued that these partnerships between employer badging systems and universities work best in online programs. Third, faculty engagement is essential. Fourth, robust communication and marketing is important to articulate the opportunities to learners. Fifth, the digital badges/credentials must provide very clear specifications and criteria to make it easy to understand what competencies they recognize. Sixth, they argue for the need to develop new and robust policy that understand partnerships between academia and industry and articulates where – and how much – academic training can be provided by industry.

## **How Can Open Microcredentials Support Learning in the Macrolevel?**

Although limited in empirical research, there have been many discussions on the societal and cultural aspects of open microcredentials. Many believe that open microcredentials may help break the boundaries of education by connecting formal and informal learning, enhancing lifelong and community-based learning, as well as building a new network of trust. In addition, different regions and cultures have found the use of open microcredentials valuable in different ways.

### **Connecting Formal and Informal Learning**

Open microcredentials earned in informal educational experiences could be used in and transferred to different parts of formal education, such as college admissions (Gutierrez & Martin, 2021), university transfer decisions, career development, and cross-institution credits transfer. This can help connect formal accredited schooling, informal interest-driven learning, and any other recognition of learning accomplishment (Casilli & Hickey, 2016). The documentation of both formal and informal learning enabled by microcredentials is adjustable and responsive to situational needs and economic demands (Jirgensons & Kapenieks, 2018). For example, many out-of-school-time (OST) programs, such as the Design League program offered by Parsons School of Design, have helped learners in disadvantaged backgrounds communicate informal learning accomplishments to formal educational institutions like college and potential employers. These OST programs leverage digital badges as alternative credentials by recognizing and valuing the shared values among the involved organizations and institutions (Martin et al., 2020).

Similarly, in the Informal Ed to Higher Ed (IE2HE) workshop, different stakeholders including microcredential developers, educators, and faculties from two- and four-year institutions worked with informal learning providers from New York and Pennsylvania to help low-income high school youth enter STEM programs. This partnership could easily yield future work, leveraging community colleges to build cross-institution relationships (Gutierrez & Martin, 2021). To be successful, though, the value of using microcredentials needs to be recognized by different stakeholders in informal, formal, and higher education before microcredentials can truly serve as

important alternative credentials (Itow & Hickey, 2016; Martin, Gutierrez, & Muldoon, 2020).

Although much of the research literature in education focuses on formal (e.g., in structured courses) and informal (e.g., self-directed, unstructured) learning, new semiformal educational spaces have arisen in the twenty-first century, where learners can self-direct their learning through structured, but unaccredited and lightly assessed, learning opportunities. One example could be MOOC courses such as those offered by the Open University, mentioned above. These courses allow anyone to enroll and participate at any time, but without direct interaction with the teacher or designer of the course.

### **Enhancing Lifelong and Community-Based Learning**

These semiformal spaces open up the possibility of lifelong learning options, and open microcredentials could help to acknowledge lifelong and lifewide knowledge (knowledge learned from a variety of contexts and environments (Reischmann, 1986), skills, and accomplishments by “unbundling” degrees into small components, recognizing granular accomplishments (Cummings, 2021). With open microcredentials, learners can simultaneously pursue both degrees and workforce credentials (Derryberry, Everhart, & Knight, 2016) and design individual development pathways across K-12, higher education, professional development, and different careers throughout one’s lifetime.

A robust microcredential system is also valuable in helping connect school communities, such as local educational institutions, historical sites, and habitats. For example, community-based organizations with afterschool and summer learning programs in both Providence and Boston have piloted the use of digital badges to certify courses offered in the Expanded Learning Opportunity (ELO), an after-school program. With these digital badges, learners can showcase all of their learning, not only the components that show up in a grade point average or a standardized test score (Eaton, 2019).

Microcredentials have also been used in developing community-based research. For example, in Aboriginal communities in northern Australia, indigenous researchers take contracting work to earn a salary within flexible working hours while living in their home communities. Microcredentials were designed to help these researchers recognize intercultural research skills, playing an important role in promoting community-based research services and reforming education services offered by universities (Spencer, 2020). Microcredentials may also be used to connect community colleges with four-year colleges, acting as a bridge to build cross-institution relationships (Gu & Martin, 2021).

### **Improving the Credibility of Credentialing**

Educational assessment at its core is an act of communicating – communicating to the learner or to potential employers or important peers – about what the learner knows and can do. We are accustomed to verifying a person’s knowledge, skills, and abilities through degrees and certificates. However, there are concerns about how to trust these credentials and improve their rigor (West & Randall, 2016). With the

increasing need of recognizing on-demand and informal accomplishments, how to increase the security, verifiability, and transparency of different credentials remains a challenge (McGovern, 2020).

Like all credentials, open microcredentials function best in society when they can be trusted. However, the basis for this trust is substantially different than with traditional credentials. Instead of basing this trust in the accreditation and the authority of the issuer, the trust shifts to open transparency about the explicit criteria and evidence for earning the credential. In contrast with commercial networks of recognition such as LinkedIn, which use endorsements to promote a proprietary network, the open nature of open microcredentials allows the development of trusted networks as other open education resources (e.g., Wikipedia) and provides participants with free and open options of accomplishment recognition services (Cummings, 2021).

Establishing this trustworthiness of open microcredentials will be essential to their adoption. For example, Erickson (2015) interviewed 20 Minnesota hiring directors and found they are interested in open digital credentials because this tool may help increase the potential hiring pool. However, they emphasized that to trust these credentials, standards should be established and recognized by the stakeholders (Fishman et al., 2018), and this recognition process requires negotiation, translation, and partnership among stakeholders across formal and informal educational institutions (Itow & Hickey, 2016).

From a technical perspective, open microcredentialing systems could also be integrated with blockchain technologies to offer a trustworthy credentialing network. For example, in the QualiChain project to support learners' lifelong learning journey and their career trajectories, open badges were integrated with blockchain technologies to make the issuing, storing, and transitioning of open badges more transparent and reliable, providing transparent and reliable accreditation services (Mikroyannidis, Third, Chowdhury, Bachler, & Domingue, 2020). Also, many European countries had been experimenting with educational blockchains to create an infrastructure to document, store, and manage credentials in a permanent, transparent, and sustainable manner while providing learners a lifelong record of achievements (Jirgensons & Kapeniaks, 2018).

### **Open Microcredentials in Different Cultures**

These issues of how to develop trust in microcredentials may vary across cultures. Open microcredentials originated with the Mozilla Foundation in the United Kingdom and quickly spread throughout Europe and North America. Today, microcredentialing is still more common in some cultures than others, in part due to differing expectations for what an educational credential should be, look like, and communicate. In addition, there are different connotations for words such as *credential* and *badges* in different cultures. However, increasingly, many varied regional and cultural contexts have found the use of this new technology valuable (McGovern et al., 2021), and new research is emerging from these additional cultures. For example, open microcredentials are especially appealing to Kyrgyzstan teachers because this technology aligns well with

Krygyzstan's nomadic culture, which praises individualized learning, instant reward, constructivist-based instructional methods, and learning flexibility (Gwin, 2021).

In many regions with different cultures, open microcredentials have been applied as an effective approach to support teachers' professional development (Erickson, 2020). For example, in Southeast Asia, microcredentials were used to provide an extensive range of digital professional learning experiences that enabled educators to learn on-demand skills related to their pedagogical practice, student needs, or school-wide collective goals (Casey, 2019). The Information Communication Technology for Rural Education Development (ICT4RED) initiative in Cofimvaba, Eastern Cape Province of South Africa, also used digital badges to reward teachers participating in professional development training. This project was so successful that later the University of Koblenz-Landau in Germany learned from this experience and adopted it in an online Master's Degree course and designed a multichannel open badge system with an advanced validation system (Niehaus et al. 2017).

Microcredentials were also adopted in teachers' professional development in other countries such as Canada (Dyjur & Lindstrom, 2017), Tanzania (Ghasia, Machumu, & DeSmet, 2019), and Finland (Brauer, Kettunen, & Hallikainen, 2018). In China, digital badges were used as learning modules in Moodle to teach Chinese college students multimedia animation design and production. Students can earn different digital badges, such as participation and completion badges, assessment badges, knowledge talent badges, independent learning badges, and communication badges (Zhou et al., 2019).

---

## Conclusion

In this chapter, we have discussed our analysis of the research literature on open microcredentials/open badges according to the 3 M framework of micro-/meso-/macroeffects. While the research literature in this area is thin, limited to certain contexts, and sometimes contradictory, there have been interesting case examples and research findings documenting benefits of open microcredentials. Because the technology supporting these credentials has existed for only the past decade, it will be important to continue future research into their potential positive and negative effects on learners and educational systems. In addition, important questions remain, such as: How do we recognize learning? What kinds of learning recognitions do we trust? And what role does learning recognition play in the overall teaching and learning process?

Open microcredentials may be one way of exploring the answers to these questions, but other possibilities exist, including verifiable credentials, comprehensive learner records/wallets, and other technologies. Common among these tools is a focus on data representation, openness and transferability, and learner agency. These are sticky ideas and ones that we are excited to see explored in current as well as future technological innovations.

## Abstract

Design is critical in online learning. This chapter reviews research and practice on designing effective online courses in higher education. Firstly, the importance of design in online learning is described including asynchronous, synchronous, and bichronous delivery methods, as well as the significance of course organization and meeting learner needs in online courses. Secondly, we provide a brief overview of online course design research in higher education. Thirdly, standards and rubrics for online course design from US colleges and universities as well as professional organizations across the world are reviewed. Fourthly, we describe a research-based and validated online course design element rubric, which includes overview, course presentation, interaction and communication, assessment and evaluation, and student support. Fifthly, the chapter describes how instructors can

be prepared for and supported in online course design, incorporating administrator support, pedagogical support, technology support, and personnel support. Sixthly, the role of instructional designers in online course design is described. The chapter concludes with recommendations for instructors and designers and topics for future research.

**Introduction**

Design is critical in online learning. Online course design is described as “a context-specific form of instructional design oriented to online learning spaces. Therefore, online course design includes both the features of the online course, and the processes and procedures used to create that online course” (Martin, Ritzhaupt, Kumar, & Budhrani, 2019a, p. 35). According to Martin et al. (2019a), online learning includes three critical phases: design, facilitation, and assessment and evaluation. This chapter reviews research and practice on the first phase or “designing effective online courses” in higher education. It will first describe the importance of design in online learning and provide a brief overview of research on online course design in higher education. It will then describe standards and rubrics used for online course design and introduce the online course design elements (OCDE). Furthermore, it will describe how instructors can be prepared for and supported in online course design and discuss the role of instructional designers in online course design. The chapter concludes with recommendations for instructors and designers and future research.

---

**Importance of Design in Online Learning**

Online courses are no longer an innovation but have become mainstream in higher education. This was particularly the case when the COVID-19 pandemic disrupted the entire educational system worldwide and education shifted from traditional learning to emergency remote and online learning. Online courses provide flexibility because learners are able to participate in learning from anywhere. There are three types of online courses that institutions may offer: asynchronous, synchronous, and bichronous online learning. Asynchronous online learning is anytime, anywhere online learning where students have the ability to participate in courses at their convenience and work at their own pace. This format, however, tends to have limited interaction with peers and instructors due to the lack of real-time communication and immediacy. Synchronous online learning is anywhere online learning but requires

real-time sessions. Students are able to log in through a synchronous tool and communicate with their instructors and peers at the same time. Bichronous learning, although a recent coined terminology, includes the blending of both asynchronous and synchronous online learning (Martin, Polly, & Ritzhaupt, 2020a).

Kuo, Walker, Belland, and Schroder (2013) found that learner-content interaction was the strongest predictor of student satisfaction in online courses. If the course organization is not clear to online learners, it is difficult to retain them in the course. Taking content from an on-campus course and uploading it to a learning management system or delivering content via synchronous lectures does not make an online course effective (Ko & Rossen, 2017). In traditional, on-campus courses, learners have information on how to navigate to their physical classrooms and know what to do once they arrive, which is different from online courses where instructors need to provide enough information on how to get them started and “to get students through ‘the door’ to the content” (Baldwin, 2019, p. 202).

Another important aspect of designing online courses is meeting the needs of learners. The needs of online learners can be different from on-campus learners because many online students are adult learners who have a variety of responsibilities such as jobs, family, and other duties. Therefore, courses need to be designed considering students’ prior knowledge, time constraints, and desired competencies.

---

## A Brief Overview of Online Course Design Research in Higher Education

There are numerous research studies investigating various elements of online course design with a variety of methodologies and methods, study participants, variables, and so forth. It would be impossible to provide a comprehensive review of all of these investigations. However, we would like to highlight a few areas of research such as how instructors design online courses, instructor and student perceptions of online course design elements, other recent developments, and models and frameworks that have been used in online course design research.

**Instructors as designers.** Recent research has focused on how university instructors approach the design of online courses for adult learners. When Martin et al. (2019a) interviewed eight award-winning online instructors, they found that expert instructors used a systematic approach in their design of the courses, alignment of learning outcomes with content, and chunking of course content. These experts were considerate of online learners’ needs, created opportunities for student interaction, integrated a variety of assessments, and used rubrics to grade activities and assignments. Interviewees also mentioned that consistent course organization is critical in online courses.

Baldwin (2019) found that instructors used similar approaches to course design in face-to-face and online courses. Instructors reported they used approaches and strategies that worked in face-to-face courses to design online courses. Baldwin, Ching, and Friesen (2018a) found that instructors did not use instructional design models; however, they followed a similar process as illustrated in instructional

design models. Instructors who were interviewed developed learning objectives; searched for existing resources and evaluated them; structured courses based on semester length, class size, and content; aligned topics by modules or weeks; uploaded instructional material in learning management systems; and revised courses based on student feedback. In order to assure quality in online course design, some institutions and programs have invested in faculty training for peer assessment (Gibson & Dunning, 2012; Hollowell, Brooks, & Anderson, 2017).

**Faculty perceptions.** Limited research has been conducted to include the voices of online faculty regarding good quality online course design. Some of these studies investigated practices by instructors (Lenert & Janes, 2017), quality elements and effective online assessment strategies (Gaytan & McEwen, 2007), and faculty perceptions of facilitation and engagement strategies (Martin & Bolliger, 2018; Martin, Wang, & Sadaf, 2020b). Gregory, Rockinson-Szapkiw, and Cook (2020) focused in their study on how faculty perceptions of the Quality Matters™ rubric, which includes online course design standards, changed after participation in a professional workshop.

**Student perceptions.** There is a plethora of literature on students' perceptions of good quality online course design. Researchers have focused on useful course design elements (Crews, Wilkinson, & Neill, 2015; Fayer, 2014), quality indicators and effective assessment strategies (Gaytan & McEwen, 2007), effective instructor facilitation or engagement strategies, and skills students need to successfully complete online courses (Bolliger & Martin, 2018; Crews et al., 2015; Young, 2006). Other areas that have been examined are student perceptions of outcomes such as student satisfaction with online learning and perceived learning (Bolliger & Halupa, 2012; Bolliger & Martindale, 2004; Kuo et al., 2013; Paul, Swart, Zhang, & MacLeod, 2015; Swan, 2001).

**Other research.** Additionally, research has been conducted to examine relationships between online course design elements and outcomes using existing data and self-designed checklists. For example, Jaggars and Xu (2016) studied how online course design elements influenced students' grades using a self-developed course assessment tool, course evaluations, and students' grades. Shin and Cheon (2019) used a similar approach to determine student satisfaction with online course design elements by evaluating courses using a self-designed checklist (based on the Quality Matter's rubric) and student course evaluations.

**Models and frameworks.** While several instructional design models have been used for the design of in-person instruction, many models can also be used for the design of online instruction (Dick, 1997; Morrison, Ross, Morrison, & Kalman, 2019). Some traditional frameworks that have been used in online course design research are Chickering and Gamson's (1987) Seven Principles for Good Practice in Undergraduate Education (see Crews et al., 2015; Grant & Thornton, 2007), Moore's (1989) Interaction Framework (see Bernard et al., 2009; Karataş, Yılmaz, Dikmen, Ermiş, & Gürbüz, 2017), and Moore's (1991) Transactional Distance Theory (see Paul et al., 2015) and the Universal Design for Learning framework developed by the Center for Applied Special Technology in 2008 (n.d.) (see Rao,

Edelen-Smith, & Wailehua, 2015). However, there are a few specific frameworks used to design online courses. For example, Czerkowski and Lyman (2016) developed an e-learning engagement design framework that included four essential components: instructional needs, instructional objectives, learning environments, and summative assessment. The learning environment aspect included components specifically relevant to the online environment such as the development of interaction and collaboration strategies, design of facilitation strategies and feedback, and selection of media and instructional resources. Gao and Ji (2019) created the Five-Star Teaching Cycle Framework of Online Courses which is based on Merrill's (2002) *First Principles of Instruction*. The authors focus on a problem-centered approach that is structured. The framework includes the following steps: problem-centered, problem progression, activation, demonstration, application, and integration. For each stage, instructional design activities are suggested, and interaction activities – when appropriate – are included. Conole (2014) introduces the 7Cs of Learning Design Framework which was developed in partnership with the Open University and University of Leicester to meet the needs of today's learners who has a multitude of digital media and tools at their fingertips. It was conceptualized because it includes the following elements: conceptualize, capture, create, communicate, collaboration, consider, and consolidate. All these models and frameworks emphasize the importance of following a systematic process to design effective instruction.

---

## Standards and Rubrics for Online Course Design

In order to assist practitioners in their efforts to design high-quality online courses, several organizations in the USA have created online course development rubrics. Some of these rubrics include Blackboard's (2020) Exemplary Course Program Rubric and the Quality Matters' (2019) rubric. Several rubrics were developed at universities or colleges in the USA: the California Community Colleges' (2016) Course Design Rubric for the Online Education Initiative, the Illinois Online Network's (2015) Quality Online Course Initiative, the Open SUNY Course Quality Review Rubric (Online Learning Consortium, 2016), and the California State University's (2015) Quality Online Learning and Teaching assist with online course design.

Outside of the USA, there are a few standards such as the Open eQuality Learning Standards (Joint eQuality Committee, 2004) created by the European Institute for e-Learning, the quality assurance framework of the Asian Association of Open Universities (2020), and the Benchmarks developed by the Australasian Council on Open, Distance and e-Learning (2014). Some of these rubrics and standards focus entirely on design, whereas some of them have a broader focus but include some elements pertaining to design. These rubrics have a different number of standards (Table 1); however, all of these rubrics can be used by instructors or instructional designers to guide their design of online courses.

**Table 1** List of online learning design rubrics and number of standards

Rubric or standards	Number of standards
Blackboard's (2020) Exemplary Course Program Rubric	17
Quality Matters' (2019) rubric	42
California Community Colleges' (2016) Course Design Rubric	56
Illinois Online Network's (2015) Quality Online Course Initiative	
OSCQR Course Design Review (priorly known as Open SUNY Course Quality Review Rubric)	50
California State University's (2015) Quality Online Learning and Teaching	57
Open eQuality Learning Standards (Joint eQuality Committee, 2004) from the European Institute for e-Learning	25
Asian Association of Open Universities (2020) Standards	54
Benchmarks developed by the Australasian Council on Open, Distance and e-Learning (2014)	64

## Online Course Design Elements (OCDE)

Building on six of these rubrics, Martin, Bolliger, and Flowers (2021) created and validated the online course design element (OCDE) instrument. This was an extension of a study by Baldwin, Ching, and Hsu (2018b) who identified 22 standard online design elements after analyzing several rubrics including the Blackboard's (2020) Exemplary Course Program Rubric, California Community Colleges' (2016) Course Design Rubric for the Online Education Initiative, Illinois Online Network's (2015) Quality Online Course Initiative, Open SUNY Course Quality Review Rubric (Online Learning Consortium, 2016), California State University's (2015) Quality Online Learning and Teaching, and Quality Matters' (2019) rubric. Martin et al. (2021) extended this analysis through the review of the literature on online course design and an expert panel review. The OCDE instrument includes five categories (Fig. 1) and 38 items (see Table 2).

**Overview.** An overview to the course assists the online learner in beginning the course. Online learners can benefit from a “getting started” or “start here” module including overview elements such as a student orientation, course goals, student expectations for communication, participation, and assignments. This section can also include the instructor's biography, contact information, availability for office hours, response times, and various policies for the online course.

Research has shown the importance of including a course orientation in online courses (Jones, 2013) for students to be better prepared. Instructional design models and research emphasize the importance of providing course goals and setting expectations. It is also a good practice for the overview module to include the instructor biography and different ways for online learners to contact the instructor (Price, Whitlatch, Maier, Burdi, & Peacock, 2016). Figure 2 includes a sample overview page from an online course with a number of items that students are required to review and complete at the beginning of a course before instructional

**Fig. 1** Online course design elements

content is introduced. Online learners can also benefit from an overview of various course projects and the course grading and feedback information.

**Content presentation.** As part of the content presentation, objectives have to be clearly defined, instructions need to be clearly written and chunked, and activities need to be aligned with the objectives. Online courses have the advantage of including content in various modalities at the same time as maintaining instructional rigor. With this opportunity, however, comes the responsibility of maintaining accessibility for students with disabilities. Most learning management systems (LMSs) have functionalities included to create modules or units and then chunk information based on the course organization (Ko & Rossen, 2017). It is important for content modules to begin with clearly defined course objectives that are aligned with course goals (Czerkawski & Lyman, 2016). Instructional material can be presented in various formats. Figure 3 shows a screenshot of a sample module introduction page which lists the alignment of weekly objectives with course goals in parenthesis and illustrates the alignment with weekly activities.

As mentioned previously, online courses can be delivered asynchronously, bichronously, or synchronously. It is important for the course to include instructor-generated videos or other instructional materials to establish instructor presence. When videos are created, it is helpful to make them reusable (Martin & Betrus, 2019). There are a number of lecture capture tools (e.g., TechSmith Capture™, Camtasia®, Kaltura, etc.) instructors can use to easily record videos in order to integrate them in online courses. These videos can include still pictures or slides,

**Table 2** Online course design elements

OCDE categories and items (Martin et al., 2021)
Overview
1. A student orientation (e.g., video overview of course elements)
2. Major course goals
3. Expectations regarding the quality of students' communication (e.g., netiquette)
4. Expectations regarding student participation (e.g., timing, frequency)
5. Expectations about the quality of students' assignments (e.g., good examples)
6. The instructor's contact information
7. The instructor's availability for office hours
8. A biography of the instructor
9. The instructor's response time to e-mails and/or phone calls
10. The instructor's turnaround time on feedback to submitted assignments
11. Policies about general expectations of students (e.g., late assignments, academic honesty)
Content presentation
12. A variety of instructional materials (e.g., textbook readings, video recorded lectures, web resources)
13. Accommodations for learners with disabilities (e.g., transcripts, closed captioning)
14. Course information that is chunked into modules or units
15. Clearly written instructions
16. Course activities that promote achievement of objectives
17. Course objectives that are clearly defined (e.g., measurable)
Interaction and communication
18. Opportunities for students to interact with the instructor
19. Required student-to-student interaction (e.g., graded activities)
20. Frequently occurring student-to-student interactions (e.g., weekly)
21. Activities that are used to build community (e.g., icebreaker activities, introduction activities)
22. Collaborative activities that support student learning (e.g., small group assignments)
23. Technology that is used to promote learner engagement (e.g., synchronous tools, discussion forums)
24. Technologies that facilitate active learning (e.g., student-created artifacts)
Assessment and evaluation
25. Assessments that align with learning objectives
26. Formative assessments to provide feedback on learner progress (e.g., discussions, practice activities)
27. Summative assessments to measure student learning (e.g., final exam, final project)
28. Assessments occurring throughout the course
29. Rubrics for graded assignments
30. Self-assessment options for learners (e.g., self-check quizzes)
31. Opportunity for learners to give feedback on course improvement
Learner support
32. Easy course navigation (e.g., menus)
33. Consistent course structure (e.g., design, look)
34. Easily viewable media (e.g., streamed videos, optimized graphics)

(continued)

**Table 2** (continued)

---

 OCDE categories and items (Martin et al., 2021)
 

---

 35. Media files accessible on different platforms and devices (e.g., tablets, smartphones)
 

---

 36. Minimum technology requirements (e.g., operating systems)
 

---

 37. Resources for accessing technology (e.g., guides, tutorials)
 

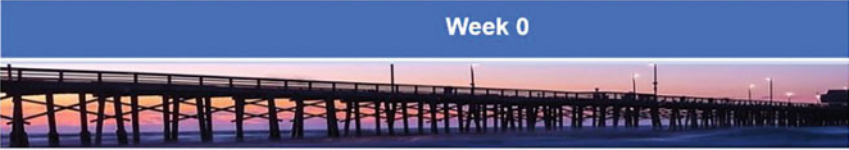

---

 38. Links to institutional support services (e.g., help desk, library, tutors)
 

---

*Note:* Items “Content presentation,” “Interaction and communication,” “Assessment and evaluation,” and “Learner support” were excluded because they were short-answer, write-in questions

## Week 0 Overview

This week we will spend time reviewing and completing a number of activities to assist you to get started in the course. While several links are for you to review, the other links are for you to complete. Below is a quick list but click on the "Next" button to get to the various items. You can also access this by directly clicking on the modules menu.

---

**To Review**

1. Course Orientation
2. About the Instructor
3. Course Syllabus
4. Course Schedule
5. Course Projects
6. Grading and Feedback
7. Course Map
8. Student Resources
9. Course Design Project Introduction

---

**To Complete**

1. Getting Started Quiz
2. Introduction Discussion by Voice Thread or Text
3. Signup/Instructions for Facilitating Discussions
4. Online Course Readiness Survey
5. Configuring your canvas profile

**Fig. 2** Sample overview page from an online course

Week 1

### Know your Learner (Jan 25 to Jan 31)

In this first week, you will be introduced to characteristics of your learners. The objectives in this week focuses both on characteristics and learning strategies of the 21st century learners which includes Gen X, Y and Z learners.

The instructional material to achieve these objectives include three articles and each one focuses on Gen X, Y and Gen Z learners which assists you in meeting your objectives. The reading from Wilson describes effective elements of teaching millennials (Gen Y students) and the reading from Mohr introduces you to the digital natives (Gen Z students) and the reading from Brown review Gen X students. The elesson that follows the readings summarizes the characteristics and learning strategies used by these learners.

The readings and the elesson assist you to be prepared for your discussion where you reflect on characteristics and strategies that you use as a learner and that your students use.

---

#### Weekly Objectives (WO)

By the end of this week, you will be able to:

1. Review characteristics of 21st century learners (CG2)
2. Describe teaching and learning strategies that work for millennial and digital native students, Gen X, Gen Y and Gen Z (CG2)

---

#### Tasks

1. Read the articles and review the resources
2. Watch the Elesson
3. Participate in the Discussion

---

#### Readings and Resources

1. Teaching, Learning and Millennial Students [\(PDF\)](#)   
Wilson, M. E. (2008). Teaching, learning and millennial students. *New Directions for Student Services*, 2004(106), 59-71.
2. Understanding Gen Z Students [\(PDF\)](#)   
Mohr, K. A. (2017). Understanding generation Z students to promote a contemporary learning environment. *Journal on Empowering Teaching Excellence*, 1(1), 9.
3. New Learning Strategies Gen X [\(PDF\)](#)   
Brown, B. L. (1997). New Learning Strategies for Generation X. ERIC Digest No. 184.

---

#### Activities and Assessment

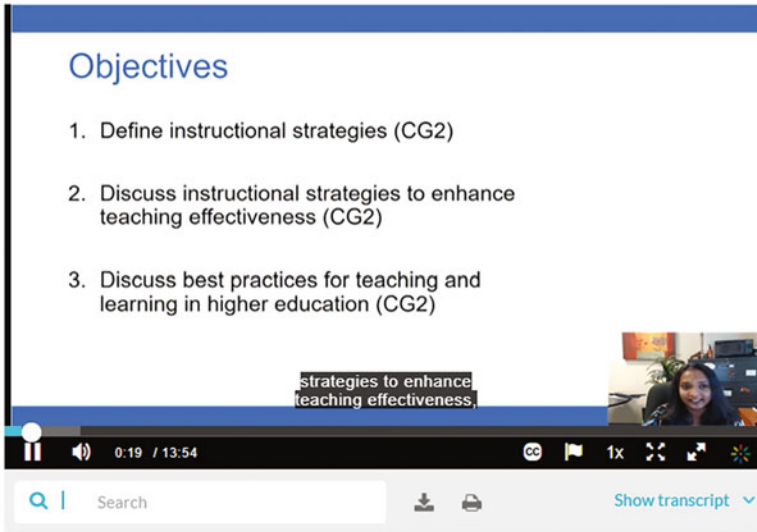

1. Participate in the discussion 1 (measures WO1 and WO2)

**Fig. 3** Module introduction page

video files, motion video capture of the instructor's screen, and the instructor's voice. While external video creation tools are available, some LMSs include video recording functionality. Figure 4 shows a short video recording that was created using Camtasia and uploaded using Kaltura into Canvas, an LMS. It also includes closed captioning to support learners with special needs.

Experts recommend keeping instructional videos relatively short – less than 10 min – to hold students' attention. More complex or complicated topics that require more time to discuss can be broken down into smaller segments (Haley & Heise, 2008). Audio files or podcasts can also be easily created and shared on a variety of learning platforms. Another option includes the integration of open educational resources which may add valuable instructional content to a course without having the need for instructors to generate personal content (Colvard, Watson, & Park, 2018).

**Interaction and communication.** Student interaction is an essential component in online courses. In online education, teaching and learning takes place in different

**Fig. 4** A short video recording of an instructional lesson

spaces. In other words, online learners are physically separated from their instructors (Moore & Kearsley, 2012). Therefore, it is important to engage learners by creating opportunities for student-student, student-instructor, and student-content interaction. The online course should include opportunities for all three types of interaction (Moore, 1989). These elements focus on the importance of collaborative activities, building and sustaining community, and using technology to enhance interaction and communication.

While various strategies can be used for interaction and communication in an asynchronous online course, synchronous sessions assist in building community and provide immediacy. In an asynchronous online discussion, it is important to provide clear discussion prompts, required number of posts, and due dates. Additionally, it is helpful for learners to include a discussion grading rubric (see Fig. 5).

Some additional ways to enhance learner-instructor interaction and communication include providing periodic announcements, reflection opportunities, and timely feedback. Different ways to provide opportunities for learner-learner interaction include peer review, peer facilitation, group projects, a virtual student lounge for informal conversations, icebreaker discussions, student presentations, etc. (Martin & Bolliger, 2018).

Synchronous sessions can enhance both learner-learner and learner-instructor interactions. The use of various synchronous features, such as text, audio and video chat, polling features, white boards, and screensharing functions, can assist in enhancing interaction with students. Lowenthal, Dunlap, and Snelson (2017) examined the importance of live integrated web meetings, which could reconceptualize virtual office hours. Some of their design recommendations for synchronous sessions included providing a schedule, an orientation to live sessions,

**Discussion 3 - Discussion 3 1** Jan 29 at 2:10pm 13 / 30

From 202110-ADMN-8695-080-ADMN-8695-090-XLSCX202110\_Combined

**By Thursday, February 18th, 11:59 pm.**

Post responses to the following questions with a **minimum of 300 words**. Use **APA references** from readings and resources to support your post.

1. Identify a course that you might teach in the future. Describe the course.
2. Describe at least five of the different instructional strategies and best practices that you might be able to use in this course.

**By Sunday, February 21st, 11:59 pm.**

Read through a sampling of the postings of your colleagues, focusing particularly on those to which you can add relevant or insightful comments that expand the Discussion. Respond to at least two of your colleagues' postings.

**Discussion Board Grading Rubric**

Discussion Board Grading Rubric			
Response	0	5	10
<b>Posted Discussion</b>	Post was not relevant to course content or no post was submitted.	Posting reflects only a basic understanding of course readings and content, and/or summarizes only basic information that does not support their message.	Student posted thoughtful discussion on time. Posting clearly reflects an understanding of course readings and concepts and uses appropriate terminology and quotes to support the message.
<b>Peer Discussion</b>	Students did not respond to two or more peers.	Responds predictably to other posts, adding little to the discussion and/or references interactions within their reflection but does not provide evidence of learning.	Actively seeks to add depth to the discussion, reflection or critique, providing quality analysis of content.

**Fig. 5** Asynchronous online discussion with a grading rubric

and agenda for each session, selecting an inviting title, sending reminders, and sharing a recording of what to expect. When scheduling live sessions, it is important to consider different time zones, vary day and meeting times, and identify important events in the semester. Other recommendations include providing learners with reasons for the sessions and alternative learning experiences for those who are unable to attend, adding incentives for attendance, and engaging students in learning activities during the session. The authors emphasized the importance of including icebreaker activities, involving students in activities, scheduling formal and informal interactions, and modeling the level of interaction.

**Assessment and evaluation.** Assessments in online courses can look differently from in-person courses. The importance of aligning assessments with objectives is emphasized along with including formative and summative assessments. Frequent, smaller assessments should be spread out throughout the course instead of including high-stake assessments at the end of the course. Instructors should provide periodic feedback on learner progress, an opportunity for learner self-assessment, and an evaluative feedback option on course improvement.

Martin et al. (2019a) determined that assessment and evaluation are important components of effective online courses. Award-winning online instructors who were interviewed recommended the inclusion of a variety of course assessments,

traditional and authentic assessments, and grading rubrics for all assessments. Self-assessments enable learners to measure their progress in achieving learning and course outcomes (Gaytan & McEwen, 2007). For course evaluations, they recommended participation in a high-quality assurance process in which instructors receive feedback on course design and facilitation from both students and peers.

**Support.** Learner support is also an important online course design category. This category includes easy and consistent course navigation, consistent course structure (e.g., templates), easily accessible and viewable media (e.g., streaming video with closed captioning), minimum technology requirements for learners (e.g., hardware, software), resources for accessing technology such as online guides or tutorials, and links to support services offered by the educational institution (e.g., help desk, library resources).

Swan (2001) emphasized the importance of consistent design and easy navigation. When these components are missing, then it is easy for students to get frustrated (Graf, Liu, & Kinshuk, 2010). It is important for all media files to be easily accessible and viewable for all learners. These are essential principles of universal design for learning for content presentation and learner engagement and interaction (Dell, Dell, & Blackwell, 2015; Rose & Meyer, 2006). Coombs (2010) also emphasized the importance of making documents accessible for online learners. Because online learners rely heavily on technology to participate in the course, they need to be aware of minimum technology requirements for them to be successful in the course. Mobile interfaces have been designed for LMSs in order for learners to access courses and content with various devices such as tablets and smart phones (Ssekakubo, Suleman, & Marsden, 2013). Additionally, resources for accessing instructional technologies utilized within the course and support information should be available in case learners encounter challenges. Moore and Kearsley (2012) pointed out that students who learn at a distance need different types of support than on-campus students.

---

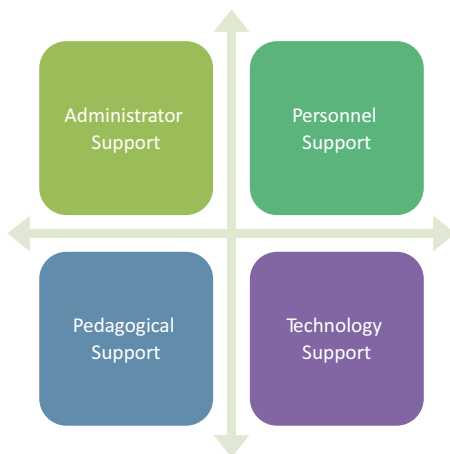

## **Instructor Preparation and Support for Online Course Design**

Not all instructors who begin teaching in higher education are trained to design and deliver online courses. Many doctoral programs focus mainly on content with little consideration for preparation for academic teaching. However, there has been a steady increase in the number of distance or online courses over the past 20 years at higher education institutions. In Fall 2016, over six million students (31.6%) were enrolled in at least one course delivered via distance (Seaman, Allen, & Seaman, 2018).

With the onset of the COVID-19 pandemic, almost all instructors at higher education institutions in the USA were forced to shift from on-campus teaching to emergency remote or online teaching due to campus closures in March of 2020 for several months (Martel, 2020). However, the literature shows that quality online course design requires lead time for instructors, professional development, and instructional design support to assist instructors with the transition from face-to-

**Fig. 6** Support for faculty for online course design and teaching

face or blended teaching to online teaching. Martin et al. (2021) determined during the validation of the OCDE instrument that self-reported level of expertise was related to the use of elements listed in the OCDE, whereas years of experience were not.

There are several ways in which instructors can be prepared for and supported in designing online courses. Martin, Wang, Budhrani, Moore, and Jokiah (2019b) found there are four critical areas of support for faculty: administrative, personnel, pedagogical, and technology (Fig. 6).

**Administrative support.** Some requests from US instructors to their administration included more preparation time; reduced class sizes, including course development into teaching load; and recognizing quality in online courses (Major, 2010). Some institutions are able to provide incentives to faculty who participate in professional development or training pertaining to online course design or who are involved in the design and development of online courses. Although faculty consider supporting their students as the main reason for teaching online, administrators believe providing incentives to faculty is critical (Herman, 2013).

**Personnel support.** Faculty who are expected to design online courses also have personnel support needs (Martin et al., 2019b). These personnel include design and development support staff such as instructional designers, technicians, graphic designers, multimedia designers, or coders/programmers. Instructional designers are becoming more common in higher education as instructional design needs are growing due to the number of online courses that institutions are offering (Beirne & Romanoski, 2018; Chen & Carliner, 2021). Instructional designers are trained to systematically design instruction for various delivery methods, including blended and online courses. Quite often they are housed in centers for teaching and learning, distance education centers, libraries, or information technology units (Intentional Futures, 2016). Other personnel who can support instructors includes faculty or peer mentors, members of a learning community, and student teaching assistants.

**Pedagogical support.** Instructors can benefit from learning about online teaching strategies by participating in training to teach online and having access to instructional resources (Martin et al., 2019b). Training programs can be webinars, one-on-one consultations, formal and informal workshops, department workshops, and opportunities for practice. Most centers for teaching and learning at universities offer professional development workshops for instructors who are new to online course design or want to advance their skills. Instructors can also participate in online course design workshops offered by professional organizations such as the Online Learning Consortium or Quality Matters. Doctoral students who wish to be instructors and faculty new to teaching online can enroll in a graduate-level course at their institutions.

**Technology support.** Technical support for online instructors is critical. This includes access to help desks with knowledgeable staff during the design and delivery phase of online courses. Instructors also requested software for video creation and hardware such as cameras, headsets, and microphones (Martin et al., 2019b). While many universities in North America have access to an LMS, several universities across the world do not use one. This was one of the biggest challenges in course design for universities during the COVID-19 pandemic.

---

## Role of Instructional Designers in Online Course Design

According to Ko and Rossen (2017), many instructors develop courses on their own. However, many institutions have implemented a team approach in an effort to standardize or streamline online courses. Teams may consist of a faculty member and instructional designer or other members such as project managers and instructional technologists. It is estimated that approximately 13,000 instruction designers work at US higher education institutions (Intentional Futures, 2016). Instructional designers are often involved in supporting faculty with the design and development of online courses because instructors may be overwhelmed with other tasks or do not have the skills to develop high-quality online courses (Chen & Carliner, 2021).

In this collaborative process, instructional designers who have been trained in the systematic design of instruction can support instructors in the analysis, design, development, implantation, and evaluation of instruction, whereas instructors serve as content experts and clients (Kumar & Ritzhaupt, 2017). This process is what Chen and Carliner (2021) term an “assignment” role. Other roles include facilitator of workshops and consultants to faculty members who need input on a particular issue. Quite often, instructional designers manage the process of others such as faculty, the university’s administration, information technology personnel, and other instructional designers (Intentional Futures, 2016). Chen and Carliner found that when instructional designers and instructors work together, they usually utilize instructional design models; modified, customized models; and “quality standard tools” (p. 481). Richardson et al. (2019) found that in order for collaborations to be successful, both parties – instructional designers and instructors – need to have the ability to establish connections; build trusting and respectful relationships; take the

time to listen without necessarily providing answers right away; remain open and flexible, particularly when projects shift into a different direction; and be aware of differences pertaining to culture, including the culture of disciplines or organizations.

---

## Recommendations for Instructors and Designers and Future Research

Online course design is critical to the success of online courses. Below are some practical recommendations for instructors and designers for online course design:

- Participate as a student in an online course before you design and/or teach an online course.
- Participate in training before you design online courses.
- Use a framework to guide the design of online courses.
- Review other online courses to get ideas on course design.
- Utilize quality course standards or validated course design rubrics.
- Collaborate with instructional designers.
- Use peer mentoring.
- Use a peer review/observation process.
- Include an overview or getting started module in the online course.
- Include various aspects of course presentation (e.g., media files).
- Interaction and engagement are key to effective online courses.
- Build in learner support structures.
- Provide students with an opportunity to provide continuous feedback.
- Fine-tune your skills by participating in professional development opportunities.

All three types of interactions in online courses (Moore, 1989) are important because they affect student learning (Bernard et al., 2009). However, learner-content interaction even though critical in learning has not been investigated much, and there is a need for more research to examine this type of interaction (Xiao, 2017). Other areas of needed research are the use of online assessments in various contexts (Gaytan & McEwen, 2007), collaboration between online instructors and instructional designers (Chen & Carliner, 2021), and policies for online course design (Meyer, 2002).

## Abstract

The technology used by Open, Distance, and Digital Education (ODDE) to deliver educational content includes social media (SM), which provides many opportunities to support learning in ODDE processes. This book chapter explains the use of SM in educational processes and the use of SM as a web-based educational technology, focusing specifically on the development of web technologies and SM from the perspective of ODDE. Furthermore, the chapter explores the affordances and limitations of SM through theoretical/conceptual lenses to better understand social media and its use in ODDE. In examining the research patterns on SM, four themes emerged, suggesting SM supports ODDE learning through: (1) social communication, interaction, and collaboration in online learning communities, (2) improved engagement, motivation, and satisfaction of learners, (3) functionality as an alternative learning management system for blended courses in higher education, and (4) facilitation of networked

**Introduction: ODDE as an Emerging Field**

Over the course of its history, Open, Distance, and Digital Education (ODDE) has evolved in line with educational technology as a field (Moore & Kearsley, 2012). As such, ODDE practices and educational technology development converged (Bozkurt, 2019, 2020), and ODDE emerged as a part of mainstream education (Bozkurt & Zawacki-Richter, 2021). Like many of the technologies that have come to mark the twenty-first century, social media (SM), as a service empowered by online web technologies, has had a major impact on many areas of life, including ODDE practices and theory. Features of SM such as easy access, online interactivity, instant communication, establishing and maintaining social relationships, and forming communities require a closer look at the potential for supporting ODDE.

---

**Web Technologies: Collective Intelligence and the Global Brain**

Web technologies have been revolutionary for humankind in many aspects of life, especially education. The potential of these web technologies emerged from their ability to enhance two-way communication and interaction, their participatory nature, the opportunities they provided learners to produce and consume information, and, most importantly, their power to build communities that exhibit the social characteristics of humans. Through successive generations of web technologies, online networks enhanced human capabilities, offering a new online ecosystem, where the boundaries of the offline physical world were extended to virtual online digital worlds.

The first-generation Web 1.0 was static, read-only, and based upon hypertext technology (Barassi & Treré, 2012). Upon the emergence of Web 2.0 in the early 2000s (O'Reilly, 2005), which was followed by Web 3.0 (Barassi & Treré, 2012), social networking sites became popular and attracted millions of users worldwide. Web 2.0 technologies are based on the architecture of participation and motivated by harnessing “the collective intelligence of crowds to create value” and transform “the web into a kind of global brain” (O'Reilly, 2005: p. 25). While Web 2.0 is based on users' participation, Web 3.0 (also known as the Semantic Web) is based on users' cooperation. The changes marking the stages of the evolution of the web are

numerically labeled (e.g., 1.0, 2.0, and 3.0) and indicate that it is an emerging, evolving space that must be regarded as a growing and living entity. In line with the idea that technology is an extension of the human body (McLuhan, 1964), Fuchs et al. (2010) highlighted that the different generations of the web require us to consider it as an integrated socio-technical system and that its value lies in its ability to enhance human cognition, communication, and cooperation.

Despite there being critical discourse arguing that there are two sides to the web, negative and positive (Barassi & Treré, 2012), the web is clearly a space that enables information flow across networks and thereby has potential for education. The opportunities provided by web technologies, specifically the second and third generations, point to the social characteristics of these spaces and suggest that these spaces are more than synthetic structures built by binary codes but rather have value waiting to be discovered and harnessed for teaching and learning. Thus, it is difficult to design ODDE learning environments without some understanding of social networks, social media technologies, and their application.

---

## **Social Media: Revisiting Its Definition and Concepts that Make It Popular**

Despite the clear application of social media to ODDE, the concept of what constitutes social media is sometimes murky and should be defined. A network is a structure, a system that connects different identities. It can be visible (e.g., railway networks) or invisible (e.g., kinship), human-made or naturally emerging. The most basic, albeit significant, value of networks is their ability to connect entities through different channels or links and facilitate communication and interaction between and within the networks or the entities that are connected to these networks. In this regard, networks have always been vital in the evolutionary progress of human beings, insofar as they enable communication and interaction, both of which are crucial elements of being social and fostering socializing.

Referring to Wellman's (1988, p. 37) argument that the world is "composed of networks," McLuhan (1964) asserted the notion that technology is an extension of the human body and increases human capability, from which it can be claimed that SM is a virtual online extension of our networks that exist in the physical offline world. SM (also known as social networks or social networking sites) refers to a variety of online platforms and is used for many purposes, such as socializing with friends and family, romance and flirting, job seeking and professional networking, doing business, and teaching and learning (Aichner, Grünfelder, Maurer, & Jegeni, 2021). The wide spectrum of SM use indicates that these media are not merely online platforms but, rather, projections of many human practices.

SM is defined as "Web-based services that allow individuals to construct a public or semi-public profile within a bounded system, articulate a list of other users with whom they share a connection, and view and traverse their list of connections and those made by others within the system" (Boyd & Ellison, 2007, p. 211). Likewise, Kaplan and Haenlein (2010, p. 61) defined SM as "A group of Internet-based

applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of user-generated content.” In another definition, SM is defined as “Personal and personalisable spaces for online conversations and the sharing of content based typically on the maintenance and sharing of profiles, where individual users can represent themselves to other users through the display of personal information, interests, photographs, social networks and so on” (Selwyn, 2009, p. 157). Lastly, Dabbagh and Kitsantas (2012, p. 1) defined SM as “A variety of networked tools or technologies that emphasize the social aspects of the internet as a channel for communication, collaboration, and creative expression.”

All these definitions point out the opportunities that SM provides individuals to present themselves, build or join networks, and communicate and interact socially. In this context, users’ online profiles are especially important because their profiles not only present the facts of their life, but also (and perhaps even more importantly) how they want to be perceived by their social environment (Maranto & Barton, 2010). However, it is important to note that there is a continuum between actual and idealized self (Higgins, 1987) and that identity presentation is a performance (Goffman, 1959), meaning that what is presented on SM might be, in many cases, idealized selves (Manago, Graham, Greenfield, & Salimkhan, 2008) rather than actual selves with real identities. However, regardless of whether individuals choose to present their idealized or actual identities, they nonetheless are socially present in online spaces, which, in effect, is the true power of SM.

SM’s ability to nurture its users’ connections and make them visible and accessible is responsible for its growth in popularity (Greenhow & Robelia, 2009) and for encouraging billions of people to form a digital identity (Bozkurt & Tu, 2016), that is, to create a profile and be socially present online by building relationships and communities (Thurlow, Lengel, & Tomic, 2004). According to Social Capital Theory (Bourdieu, 1983), SM enables the bridging, bonding, and maintaining of social capital (Ellison, Steinfield, & Lampe, 2007). Equipped with all these features, SM has become the *normal* of the online-technology-centric twenty-first century.

The number of people who use SM demonstrates that SM goes well beyond merely being online platforms but, rather, is part of our daily lives and routines. Accordingly, as of 2021, the total population of the world is around 7.83 billion, and approximately 4.66 billion people are Internet users, of which 4.20 billion people are SM users (We Are Social, 2021). These figures suggest that SM has great potential as an educational technology, as it is already being used by nearly half of the world population.

---

## **Educational Affordances and Limitations of Social Media**

In the online digitally intensive twenty-first century, radical transformations have taken place that have been driven by the massive increase in the diffusion of information facilitated by technological developments (Fischer & Konomi, 2005). This period of time has seen a high demand for information and lifelong learning (Fischer & Konomi, 2005), whose characteristic features are communication,

collaboration, community, creativity, and convergence (Friedman & Friedman, 2008). Since its inception, there has been increasing interest in benefitting from social dynamic characteristics of SM (Barrot, 2021). SM can be used in online educational processes to meet learners' needs for more autonomy, connectivity, and socio-experiential learning (McLoughlin & Lee, 2007) by sharing, creating, and remixing information to create affinity spaces (Gee, 2004).

Earlier systematic studies have reported that SM can be used for online and blended courses to enhance learning outcomes and face-to-face courses, foster learning communities, understand student perceptions of tool affordances, and increase student engagement with SM by supporting educational processes with social elements such as self-presentation, instant and rich communication, multiple interaction points, and ability to collaborate (Sharma, Tohill, Tietjen, & Akgun, 2018). The opportunities provided by SM have been formed by their ability to enable individuals to communicate, interact, and collaborate through self-driven motivation in socially enriched online spaces that extend beyond formal learning settings (Kimmerle, Moskaliuk, Oeberst, & Cress, 2015). Even in cases where SM does not play a part in learning processes, learners themselves can use SM to build their personal learning environment where learners can create, organize, and share their learning content (Dabbagh & Kitsantas, 2012; McLoughlin & Lee, 2007) and thus build bridges between formal, nonformal, and informal learning spaces (Greenhow & Lewin, 2016). Moreover, as an alternative learning management system (LMS), SM has the potential for blended learning in higher education (Giannikas, 2020).

In addition to the above advantages, SM played a vital role in sustaining education (Cavus, Sani, Haruna, & Lawan, 2021), especially collaborative learning, during the Covid-19 pandemic (Khan, Ashraf, Seinen, Khan, & Laar, 2021). For educational institutions that were not prepared for the sudden shift to emergency remote online education, or which could not afford to invest LMS due to high costs, SM was an effective and working solution (Nadeak, 2020). Likewise, countries that could not afford LMS due to their high costs used SM to sustain and deliver education during the pandemic (Sobaih, Hasanein, & Abu Elnasr, 2020). In this regard, it can be argued that SM proved its value in a time of crisis and may lessen inequities and social injustice derived from the digital divide on national, institutional, or even individual levels.

However, while SM offers many advantages, there are still some limitations to consider. For instance, some faculty may resist adopting SM for delivering educational content and communication with learners (Willems, Adachi, Bussey, Doherty, & Huijser, 2018). Also, some instructors (Veletsianos & Kimmons, 2013) or learners (Poellhuber, Anderson, & Roy, 2011) might be unwilling to integrate SM into their learning processes, and for some students, SM can be an online distraction (Hollis & Was, 2016). How to ensure integrity of SM into education is still an open-ended question for many educators (Moran, Seaman, & Tinti-Kane, 2011), and there are concerns about user-generated data (Krutka et al., 2019), which potentially recognizes learners as products and SM learning processes as a market. Besides, algorithmic bias (Boratto, Fenu, & Marras, 2019) is an issue and less is known regarding on its effects on learners' well-being. In addition to these points, the issues of cyber

bullying (Clark, Werth, & Ahten, 2012) and how digital footprints and data privacy could compromise the value of SM in ODDE if normative, ethical, and legal measures are not taken (Buitrago-Roper, Ramírez-Montoya, & Laverde, 2020). Moreover, students could experience conflicts when they shift from their private social identities to their learner identities (Dennen & Burner, 2017).

---

## **An Examination of Social Media in Terms of the Theoretical Underpinnings of ODDE**

To better understand the value of SM, it is necessary to examine it from the perspectives of the theoretical bases of ODDE. In this regard, this section will first focus on the Community of Inquiry (CoI) model. According to the CoI (Garrison, Anderson, & Archer, 1999), teaching (design and organization and facilitating discourse direct instruction), cognitive (triggering event, exploration, integration, and resolution), and social (open communication, group cohesion, and personal/affective) presences lead to meaningful learning experiences in an online learning environment. Among these presence types, social presence is defined as the degree of salience of the other person in the (mediated) interaction and the consequent salience of the interpersonal relationships (Short, Williams, & Christie, 1976). In other words, the degree to which it is being perceived as real (Gunawardena, 1995). The value of social presence in online learning environments lies in the ability to help participants be seen as real and social in these environments (Kilgore & Lowenthal, 2015).

Intimacy and immediacy are two important concepts of social presence, and as such, are related to social context, online communication, and interactivity (Tu, 2000). In this sense, SM plays a pivotal role in not only sustaining social communication and interaction but also in increasing the social aspects of learners and learning by supporting their social presence and making them visible through real-life projected digital identities.

Another significant theory underpinning ODDE is the Community of Practice (CoP) model (Wenger, 2010), which highlights the importance of identity formation, joining a community, and initiating interaction for self and professional growth. CoP further suggests that learning does not occur only in formal spaces, arguing that when learners participate in self-emerging communities, informal learning may also occur. However, the development of CoP can be a challenge in online learning spaces (Brook & Oliver, 2003) owing to spatial and temporal distances (Moore & Kearsley, 2012). By virtue of their nature and features, SM platforms offer learners the opportunity to join an existing community or to build their own communities (Holcomb & Krüger-Ross, 2013) via socially empowered networks, where they can connect, network, communicate, and interact (Brady, Holcomb, & Smith, 2010). As a space that has the prerequisite features of building and developing a community, SM provides educational opportunities not only for formal learning but also for nonformal or informal learning.

Spatial and temporal distances are common features of ODDE (Moore & Kearsley, 2012), however, rather than narrowing these distances, it is more important to lessen the gap in transactional distance (Moore, 1993), that is, psychological and communicational distances. Transactional distance involves dialogue and structure (Moore, 1993), where the former reduces the transactional distance and the latter increases it. Tools and services like SM enable learners to meet, discuss, and engage with the learning content more actively, which reduces factors that increase transactional distance (Dron & Anderson, 2014). SM, in this regard, has the potential to lessen transactional distance by loosening the structure and facilitating different dialogue channels (Huang, Chandra, DePaolo, & Simmons, 2016; Quong, Snider, & Early, 2018). Recent studies confirm that SM enhances learners' interaction, and engagement along with their social presence results in increase in dialogue and reduce in transactional distance (Quong et al., 2018).

While interaction is a significant component of all educational processes, it is even more important for ODDE learners due to the limitations stemming from spatial and temporal distances. In this regard, three types of interaction—learner-learner, learner-instructor, and learner-content interaction—have been proposed as essential interaction types (Moore, 1989) that contribute to the satisfaction and academic achievement of learners (Bernard et al., 2009). However, fully online courses that use LMS may fail to completely provide learner-learner and learner-instructor interaction because they are primarily designed to deliver content. SM, which was originally developed to build and sustain social communication and interaction, can be adopted in ODDE to augment communication and interaction between learner-learner and learner-instructor.

In summary, SM can be a social glue for learners who are separated by time and space and isolated from their peers and instructors in cases where they do not have the tools to communicate and interact in online spaces. As explained in the above sections, SM is especially effective in supporting theoretical assumptions of ODDE (e.g., CoI, CoP, transactional distance, and interaction types). The empirical evidence presented in the related literature shows that SM can be used to support some, but not all, components of ODDE practices. The trick is to get the right mix (Anderson, 2003) to ensure meaningful equivalent learning experiences (Simonson, 1999) and facilitate interaction and communication by effectively using the capabilities of SM.

---

## Reflections and Insights from Research on Social Media

This section provides a snapshot of the research that has been conducted on SM by examining articles and proceeding papers ( $n = 215$ ; Articles: 99, Proceedings: 116) published in the Scopus database between 2001 and 2021. The research corpus was built in June 2021 by using predefined search strings (see "Appendix A"). Text-mining (Feldman & Sanger, 2007) and social network analysis (Hansen, Shneiderman, & Smith, 2011) were used to analyze the papers and identify research patterns. In the text mining process, the titles and abstracts of 215 papers (40,840

total words and 4,213 unique word forms) were analyzed to identify lexical patterns. A thematic map was then created to visualize these patterns (Fig. 1). In the social network analysis, from among the 575 keywords identified, a total of 91 with a minimum occurrence of two were included in the analysis, and a network graph was created to visualize the results (Fig. 2). The analysis identified the following four general themes by triangulating paths in Fig. 1 and nodes in Fig. 2. In other words, the data revealed through the text mining (Fig. 1) and social network analysis (Fig. 2) merged to identify the thematic research patterns and reach a broader perspective.

**Social media supports social communication, interaction, and collaboration in online learning communities** (see path on Fig. 1 *communication, social, interaction, learning, online, communities, CoP, CoI*; see nodes on Fig. 2, *social learning, communication, interaction, collaboration, participation, learning communities, communities of practice, computer-supported collaborative learning, online learning community, online social network*).

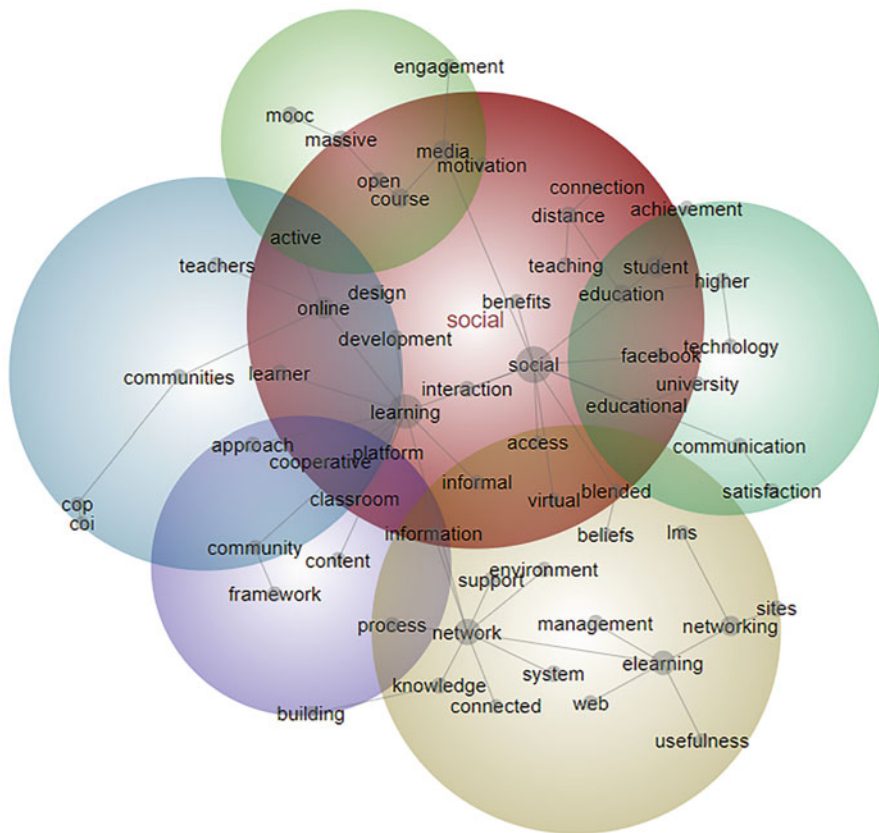

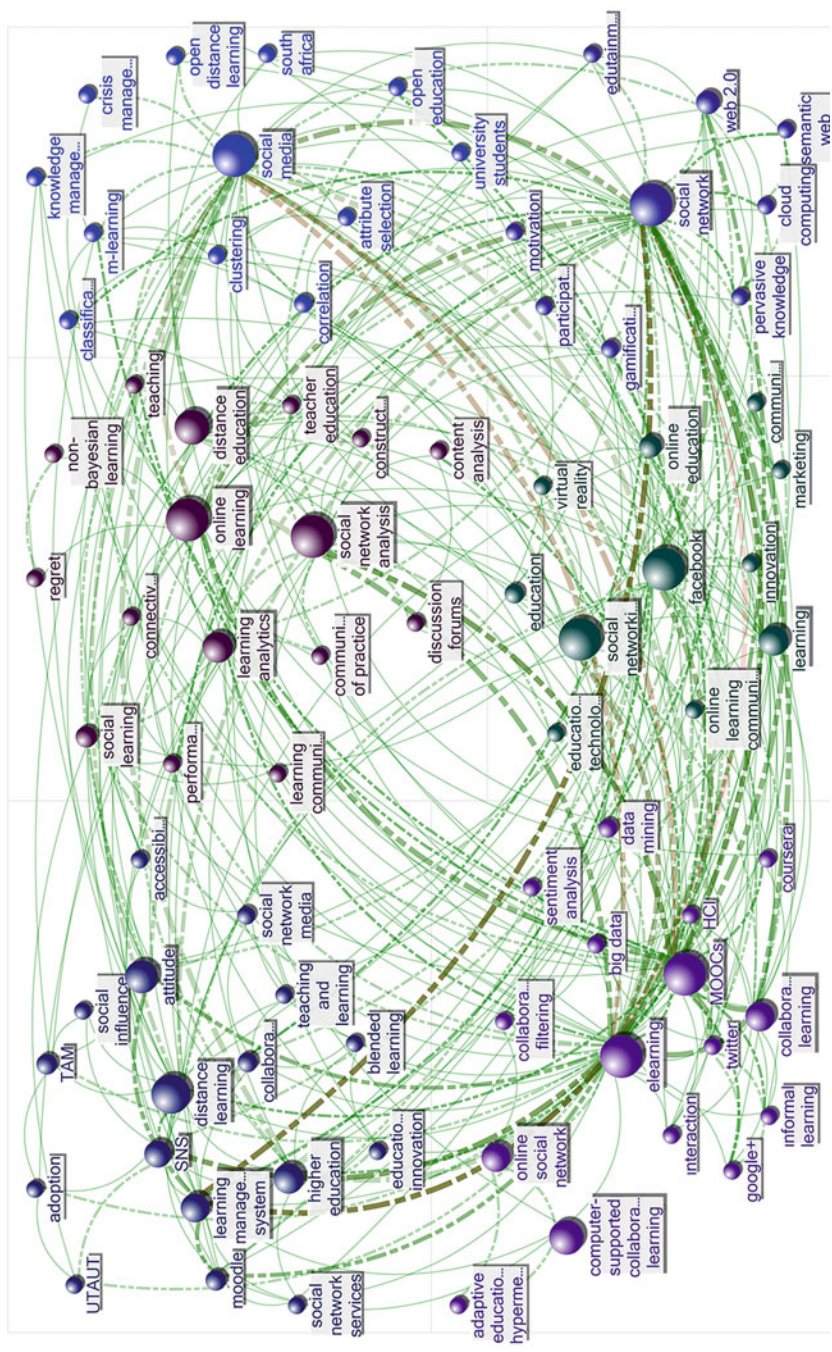

Fig. 1 Text-mining of the titles and abstracts of the papers on social media

**Fig. 2** Social network analysis of the keywords from the papers on social media

The ODDE practices aim to promote social elements of learning and apply a pragmatic approach to the use of education technology. As explained earlier, meaningful learning through different presences (Garrison et al., 1999) and interaction (Moore, 1989, 1993) in a learning community (Wenger, 2010) is essential in ODDE practices. SM, in this context, mitigates many of the limitations that emerge with the spatial and temporal distances (Moore & Kearsley, 2012).

What is more promising, learning communities formed on SM contributes to learners' interaction (Nunes, Palomino, Nakayama, & Silveira, 2016), and these communities can last after the course and provide opportunities to learners to further collaborate and sustain their scholarly discussions beyond course boundaries (de Lima & Zorrilla, 2017). The text mining and social network analysis indicate that the value of SM lies in its ability to promote participation and collaboration, both of which are desired in ODDE and all educational processes.

**Social media supports engagement, motivation, and satisfaction of learners** (see path on Fig. 1, *satisfaction, communication, social, media, motivation, engagement*; see nodes on Fig. 2, *motivation, social influence, teaching, and learning*).

The existing literature indicates that SM promotes student engagement and motivation (McLoughlin & Lee, 2007; Rueda, Benitez, & Braojos, 2017; Sharma et al., 2018), both of which can affect student learning satisfaction and success on account of the participatory nature of SM and learners' willingness to use these platforms. However, it is important to remember that SM was primarily developed for personal use and that despite the many advantages and opportunities afforded by SM, not every learner will voluntarily adopt SM in their learning process (Poellhuber et al., 2011).

**Social media serves as an alternative learning management system for blended courses in higher education** (see path on Fig. 1, *LMS, networking, e-learning, management and technology, higher, education, social, blended* and MOOC, massive, open, course, media, social, educational, university; see nodes on Fig. 2, *blended learning, Coursera, distance education, distance learning, educational technology, e-learning, Facebook, higher education, learning management system, m-learning, MOOCs, online education, online learning, open and distance learning, social network sites, university students*).

LMS are limited in how they support the social aspects of learning (Sharma et al., 2018). Learners might prefer SM as an alternative to traditional LMS considering that they are more user friendly and always-on and provide opportunities to shift learning experiences between formal and informal online learning spaces (Andrews, Tynan, & Backstrom, 2012). Blended/hybrid modes of learning are becoming increasingly popular (EDUCAUSE, 2021), and as noted by Sharma et al. (2018), SM is mostly used for blended courses and can be a cost-effective, socially forged alternative type of LMS in higher education. Empirical studies confirm that learners demonstrate positive attitudes for the use of SM as a supplement in higher education, and learners find SM more attractive than conventional LMSs (Giannikas, 2020) owing to cost and accessibility opportunities (Perguna, Apriyanti, & Kurniasih, 2021).

**Social media facilitates networked and connectivist informal learning** (see paths on Fig. 1, *informal, learning, online, active and connection, distance, education, social, media and connected, network, knowledge, building*; see nodes on Fig. 2, *connectivism, constructivism, informal learning, learning, online social networks, social network, social networking, social media, web 2.0*).

The advent of online networks and SM not only provided new educational opportunities but also led to the emergence of new pedagogical approaches, such as networked learning (Gourlay et al., 2021) and connectivism (Siemens, 2006). Connectivism argues that networking is critical for accessing current information by building or nurturing connections. Networking through SM allows learners to communicate in and out of the formal learning environments (Alzain, 2019) by ensuring the continuity of the learning and moving learning beyond the course objectives by facilitation informal learning opportunities.

Networked learning requires collaborative, cooperative, and collective inquiry, and, in this sense, SM can play a pivotal role. Learners are able to present themselves through SM profiles and increase their social presence in online networks. Moreover, online networks are not limited to formal learning opportunities but rather have a chaotic, complex, emergent, dynamic, open, self-controlled, self-maintained, and self-organized nature that extends the boundaries of online learning to formal, nonformal, and informal learning.

Reflections and insights from research on SM confirm earlier research themes and further indicate the potential of SM in terms of self-presentation and social presence not only for formal educational processes but also for informal educational processes such as networked and connectivist learning. The prevalence and use of SM by too many people can be a good opportunity to further explore how SM promotes communication, interaction, and collaboration and how SM contributes to engagement, motivation, and satisfaction of the learners in ODDE and education in general. The social features of SM support ODDE by default, but it's not just about its social features but also how we design learning processes and integrate SM.

---

## Conclusion and Suggestions

SM, an innovative technology that defined the twenty-first century, has features that enrich and augment socializing in online networks and as such, and it has attracted the attention of all segments of society. It can be argued that the web, online network technologies, and SM have radically transformed how individuals interact and connect. They have also forced education to change and have shaped education based on the realities of the online and digitally intensive twenty-first century.

SM is inherently designed for private use, not for educational purposes. However, currently, it is being seen as an alternative or supplement to traditional LMS. Therefore, educators and learning designers must address certain questions surrounding this new phenomenon, such as: Why is SM seen as a supplement or an alternative? Why do educators design learning platforms that are isolated from the

social characteristics of learning? Why is LMS seen as a means to delivering educational content rather than as a means to facilitating and fostering learning?

As argued in theories of ODDE, learning is about eliminating barriers, situating the content of learning in a social context, and facilitating learning through communication and interaction, all of which leads to increased motivation, engagement, and satisfaction of learners. In brief, human learning is social and largely involves socializing the processes involved in learning.

The research on SM demonstrates that SM technologies can be useful in supporting social communication, interaction, and collaboration in online learning communities. The nature and characteristic features of SM support the engagement, motivation, and satisfaction of learners in ODDE. Hybrid and blended modes of education are growing in popularity, and SM appears to be a ready-made alternative or supplement for LMS in some situations. Also, online networks and SM are well tailored for collaboration, participation, and community formation, which can increase their value as a social LMS in online learning. In many cases, learners use SM as a personal learning environment, meaning that their learning experiences are not confined to a single mode. In contrast, by taking advantage of SM, learners can easily shift between different learning modes (e.g., formal and informal learning). Lastly, since SM is controlled and formed by the users, it gives agency to learners to identify their own learning needs and to self-regulate, self-manage, and self-direct their learning processes. Taking into account these features, SM can be effective in networked and connectivist learning processes and empowering learners to engage in informal learning.

In the postmodern world, the borders between formal, nonformal, and informal learning are blurring. Information is distributed across networks, and learners traverse between different modes of learning to meet their learning needs. Given these new circumstances, how can ODDE adopt and position itself in the changing world, and how should learning be designed in the realm of online networks and networked society? It is also important to keep in mind that SM should not necessarily be placed at the center of the learning process but instead should be used to assist learning by facilitating discussions, sharing information, and weaving networks and can be used to bridge formal and informal learning.

Although SM offers many advantages for learning, and most educators are drawn to the features of SM, these socially enhanced technologies may not be as innocuous as they seem, as these technologies were originally meant for profit making and therefore should be approached with caution. Moreover, there are still many areas of concerns about the use of SM, such as data privacy, use of algorithms, ethics, and cyber bullying, which means that learning designers should be careful and find the right mix when they adopt SM in ODDE processes.

Based on the insights gained from the reviewed papers and analysis conducted to identify the recent main research themes, the following suggestions can be taken into consideration for future research directions.

First, SM has already been used by individuals, and it has many potentials to support ODDE, but this requires careful and purposeful instructional design to enable and ensure the participation, collaboration, and community formation. In this regard,

instructional designers can focus on how to integrate SM to the curriculum and learning activities. Because some learners only use SM for private use, this still can be a challenge, but learners can be motivated to use SM for educational purposes. Second, conventional LMS can be improved by integrating social features of SM that can lessen the sense of being isolated from the real world. Additionally, another approach can be integrating SM into LMS tools so that learners can optionally present themselves with the digital identities they created. This can be important because profiles in LMS are generally composed of photos and basic personal information; the digital identities in SM can include the real-life connections and reflect real-life backgrounds of learners. As such, the degree of learners being perceived as real can be increased, and their social presence can be strengthened. Third, educational institutions can focus on how to best harness the capabilities of SM and use it beyond formal education. For instance, orientations or courses on SM literacy, how to best use SM in learning processes and how to protect themselves from the side effects can be an effective strategy in a long run. Such an approach can increase the awareness on SM in education and can further empower and give agency to learners. Finally, there is a need to develop regulations and policies to protect learners in case of cyber bullying, misuse of private data, and unethical use of digital footprints.

## Abstract

This chapter summarizes theory and empirical research concerned with the use of serious games and game-based learning in educational contexts. Relevant characteristics and theoretical foundations of the value of games are assessed. The reviewed empirical findings indicate a strong effect of serious games and game-based learning on learner motivation, affect, and cognitive outcomes. However, the direction of their impact is not always straightforward as it depends on the interplay of conditions including the game type, design features, learner characteristics, and learning activities. This chapter suggests that developers and educators take this interplay into account to ensure optimal learner experiences when developing or choosing serious games or game-based learning approaches for educational purposes.

## Introduction

Serious games and game-based learning are popular methods for teaching and learning. While the value of games and play for learning has a long history in classroom-based contexts, the interest in games for digital and distance education has emerged over the last decade. Based on the enthusiasm this generation's students exhibit for games, they appear to have high motivational value, but in the context of teaching and learning, they are recognized as being much more than motivational tools. To a certain extent, games are argued to support the development of knowledge and skills that are otherwise hard to teach. They allow educators to virtually model real-world tasks in which students are able to interact, which gives students a sense of learning by doing or, in the case of games, learning by playing. Games further encourage students to take risks and to try different ways of learning and thinking with lower consequences of failure (Gee, 2003). Games' immediate response to actions might offer the kind of feedback mechanism to students that digital and distance education sometimes require, so that students can reflect on their difficulties.

Based on these advantages, games are intended to be useful learning tools by engaging learners on cognitive, affective, motivational-behavioral, and social levels (Plass, Homer, Mayer, & Kinzer, 2020; Prensky, 2001). Thus, the current tendency to integrate game-based learning approaches in digital and distance education acknowledges the emergence of new learning experiences that games may offer in order to enhance learning.

In this chapter, the understanding and the role of serious games and game-based learning are analyzed and discussed. The theoretical foundation for the success of games is outlined, and current empirical contributions are reviewed. Essential design features that impact the learning effectiveness of serious games and game-based learning are highlighted. Finally, this chapter closes with a reflection on the value of games for learning and directions for future research.

---

## Definition and Characteristics of Serious Games and Game-Based Learning

Games can be defined as "a system in which players engage in an artificial conflict, defined by rules, that results in a quantifiable outcome" (Salen, Tekinbaş, & Zimmerman, 2004, p. 5). Digital commercial games were developed primarily for fun, entertainment, and recreation. In contrast, the objective of serious games and game-based learning is to use the entertaining quality of games for the purpose of learning (Connolly, Boyle, MacArthur, Hainey, & Boyle, 2012; Michael & Chen, 2006; Wouters, van Nimwegen, van Oostendorp, & van der Spek, 2013). While it can be argued that any game provides learning opportunities, such as gaining technical knowledge and developing motor skills (i.e., the development of body movements related to balance), the explicit function of serious games and game-based learning is to help students (1) acquire new knowledge and skill about an

important subject matter, (2) practice existing knowledge and skills, (3) develop learning and innovation skills, and/or (4) prepare for future learning (Plass et al., 2020).

The term “serious game” has a long tradition, starting with Abt (1987), and includes digital and non-digital games in various contexts such as business, industry, marketing, healthcare, and education (Michael & Chen, 2006). With the growing development of technology, however, the understanding of serious games is mostly from a digital point of view, in which they are defined as examples of interactive learning technologies that offer learning experiences through fully animated elements that are under learners’ control (Rieber, 2005). The term “serious game” is often mentioned in the literature as synonymous with the term “game-based learning.” Game-based learning, however, can be seen as an approach to teaching in educational contexts (Becker, 2021). With a specific learning goal in mind, a learning task is redesigned to make learning more interesting and more effective. This involves the use of serious games in the learning process, seen as a tool of game-based learning.

Common to both the use of serious games in specific contexts and the game-based learning approach in general is the use of games’ inherent entertaining characteristics to deliver specific goals, outcomes, and experiences. Games provide rich sensory experiences through combinations of text, graphics, dynamic animations, audio, and haptics. Many games contain a story narrative with characters that involve the players. They consist of a constructed competitive setting with an incentive structure following a clearly defined goal that challenges the players (Graesser, Chipman, & Leeming, 2009). The most commonly cited entertaining characteristic of a game is its interactive nature. A game’s story only evolves through interaction with the player’s behavior. Therefore, as described in the input-process-output game model (Garris, Ahlers, & Driskell, 2017), feedback is half of the interactive game cycle, as the player’s input and the game’s output assert reciprocal influence. For example, games use visual and auditory feedback to let players know if certain actions have succeeded or failed.

---

## Theoretical Foundations

The theoretical foundations of what makes the use of serious games and game-based learning psychologically successful can be described from motivational, affective, cognitive, and sociocultural perspectives.

**Motivational perspective.** The need to motivate learners to stay engaged over long learning periods has been often used in the literature as the main and most important argument for the use of games in educational contexts (Plass, Homer, & Kinzer, 2015). A number of theorists (e.g., Malone & Lepper, 1987; Rigby & Ryan, 2011) have proposed explanations for why games should be motivating, mostly through the inherent game characteristics described above, which apply a range of existing motivational approaches. For instance, the interactive and competitive nature of games increases motivational constructs such as interest, intrinsic

motivation, and what Csikszentmihalyi (e.g., 2008) has described as a state of flow, i.e., an extended time spent on a task with intense concentration in a way that perception of time and fatigue disappear. Ideally, the provision of challenge at the zone of proximal development (Vygotsky, 1978), i.e., the matching of challenge difficulty to student ability, satisfies the specific intrinsic needs of competence, autonomy, and relatedness. These three physiological needs comprise the major components of the Player Experience of Need Satisfaction model (Rigby & Ryan, 2011), which has been developed in order to identify game characteristics that are most satisfying. From the perspective of self-determination theory (Deci & Ryan, 1985; Ryan & Deci, 2002), the fulfillment of these learner needs is essential for intrinsic motivation and self-efficacy and leads to action-related behavior in terms of learning.

**Affective perspective.** By exploring what make games fun, Loftus and Loftus (1983) stated that active player engagement, associated with the right balance in challenge as described above, may also affect players' emotions. Ravaja, Saari, Salminen, Laarni, and Kallinen (2006) found enjoyment related to an exchange between success (acquiring in-game goods) and failure (such as falling over the edge of the game board). This result can be explained through the control-value theory (CVT) of achievement emotions (Pekrun, 2006; Pekrun & Perry, 2014): An optimal challenge (rather than being too hard or too easy) might foster perceived controllability, which, in turn, is linked to positive emotional experiences. Moreover, described in the literature as emotional design (Plass & Kaplan, 2016), a strong narrative and aesthetic visual and auditive design are examples of game features that influence emotions. (For a detailed overview of affective foundations of game-based learning, see Loderer, Pekrun, and Plass (2020).)

**Sociocultural perspective.** Social learning theories (e.g., Bandura, 1977; Piaget, 1964; Vygotsky, 1978) posit that learning consists of the construction and application of knowledge through direct experience of success and failure and through interaction with others, both of which are characteristics of games. For example, the game *Mad City Mystery* immerses students in an authentic scientific inquiry of a mysterious death, where teams of students experience social practices of being investigators by actually "practicing inquiry and argumentation skills" (Squire & Jan, 2007). The possibility to interact with the game system, with in-game characters, or with other students integral to the learning process helps to develop skills for collaboration and cooperation – skills which are seen as necessary for the twenty-first-century workforce (De Freitas, Rebolledo-Mendez, Liarokapis, Magoulas, & Poulouvassilis, 2010).

**Cognitive perspective.** By virtue of their motivational, affective, and sociocultural properties described above, games have been intended to foster learning. In the overall context of multimedia learning, both motivation and emotions have been found to be important prerequisites for and mediators of cognitive processes and outcomes (Astleitner & Wiesner, 2004; Leutner, 2014; Moreno & Mayer, 2007; Plass & Kaplan, 2016). Fostering motivational concepts and inducing positive emotions through certain game mechanics could serve as facilitators for cognitive generative processing during learning, including the selection of relevant learning information, its arrangement into a coherent structure, and its integration with prior

knowledge relevant for the academic content conveyed through a game (Mayer, 2014).

Based on this overview of different but related theoretical perspectives, it is clear that high expectations exist for games to foster motivation, positive emotions, and deeper learning through their inherent characteristics (Habgood & Ainsworth, 2011). The next section reviews whether games could fulfill these expectations, based on empirical findings from game research.

---

## Empirical Contributions

The research literature that investigates the effects of game-based learning (including computer and video games for learning, serious games, and the concepts of gamification and play) can be organized into cognitive consequences research, media comparison research, and value-added research (Mayer, 2014, 2020). Based on empirical studies using one of the three research approaches, a number of meta-analyses and empirical reviews have been conducted of the effects that game-based learning could have, particularly on motivation and on cognitive learning outcomes (e.g., Clark, Tanner-Smith, & Killingsworth, 2016; Connolly et al., 2012; Sailer & Homner, 2020; Wouters et al., 2013). A meta-analysis (Sailer & Homner, 2020) synthesizing 38 studies that use a consequence research approach by focusing on the effect of gamification for motivation, learning processes, and outcomes demonstrated a positive impact of gamification on cognitive learning outcomes, whereas the effect on behavioral outcomes (i.e., technical, motor skills, performance on specific transfer task) and on motivational variables (i.e., (intrinsic) motivation, preferences, attitudes, engagement, confidence, and self-efficacy) was less stable.

By determining whether there is evidence that learning from games can be more effective than learning from conventional media, in a meta-analysis of 65 studies that used a media comparison approach, Sitzmann (2011) found a positive effect of simulation games on self-efficacy and on conceptual, declarative, and procedural knowledge for the specific group of adult workforce trainees compared to alternative nongame instruction media. The meta-analysis of Wouters et al. (2013) identified 39 studies that investigated the effect of serious games on motivation and on learning outcomes for a wide range of age groups, from children to adults. No significant difference in motivation was found, but there was a positive impact of serious games compared to other more conventional instructional media such as lectures, reading, drill, and practice or hypertext-learning environments on learning outcomes including retention and cognitive skills. However, there was a wide-ranging effect size indicating that in some cases, games can be as effective and in other cases more effective than learning with conventional instruction media. Given two examples of inconclusive results in the context of higher education, Ebner and Holzinger (2007) examined motivation, enjoyment, and learning outcome between the use of the online game *Internal Force Master (IFM)* and traditional teaching in a math lecture on structural concrete at Master's level, involving 121 seventh-semester students. The results showed that the use of the game fostered motivation and enjoyment.

However, the student group who learned with the online game did not receive higher learning outcomes compared to the group who learned structural concrete in the traditional math course. Nonsignificant differences in learning outcomes between the two groups were found. In contrast, Crocco, Offenholley, and Hernandez (2016) reported an increase in motivation, enjoyment, and an improvement in learning of 440 undergraduate students who learned with games in English and science courses. Especially in science, games have been demonstrated to foster higher learning outcomes compared to conventional media (Mayer, 2020).

Overall, these contradictory findings from research using either a cognitive, affective, and motivational consequences approach, or a media comparison approach, suggest that there is no single and clear answer to the question of whether games positively influence motivation, affect, or cognitive outcomes. A discussion of games' effectiveness seems to be complicated by the fact that empirical studies in the context of serious games, gamification, and game-based learning vary in study populations, game type, academic content, and learning goals.

The inconclusive results further may refer to another problematic aspect discussed by Mayer (2020), who adapted the cognitive theory of multimedia learning (Mayer, 2009) and cognitive load theory (Sweller, Ayres, & Kalyuga, 2011) to describe how learners learn academic content when using digital games. Games have the potential to promote learner motivation, reflected in learners engaging with the material, which can foster generative processing. At the same time, however, they may create extraneous processing caused by the distracting features, even though these help learners to maintain a high level of motivation. Given the limited cognitive capacity of the human information processing system, as result of extraneous processing, there may be no cognitive capacity left for essential and generative processing which is needed for meaningful learning. Therefore, when designing games, there is a need for a balance of features that foster motivation but do not increase irrelevant extraneous processing (Mayer, 2020). This statement is supported by Clark et al.'s (2016) meta-analysis of 69 studies of the learning effect of digital games, which illustrated that only considering the genre of a learning environment is not sufficient to understand its impact on learning. Rather, more closely investigating instructional design features in interaction with learner characteristics may help to improve games' learning effectiveness and may guide game designers. Thus, besides research based on a media comparison or a consequence approach, a different line of research, i.e., value-added research, focuses on the question of how and what kind of design features in games may influence motivation, affect, and learning outcomes. The following section provides an overview of this question.

---

## **Design Features Influencing Motivation, Affect, and Learning Outcomes in Games**

There have been a few theoretical attempts to summarize typical game design features and their interplay with relevant aspects of learning. In terms of how to improve motivational aspects of learning, the instructional design approach

suggested by Malone and Lepper (1987) and the attention, relevance, confidence, and satisfaction (ARCS) model (Keller, 1987; Keller & Suzuki, 2004), for example, have been adapted to the context of gamification (e.g., Hamzah, Ali, Saman, Yusoff, & Yacob, 2015). In their integrative model of emotional foundations of game-based learning, Loderer et al. (2020) used the basic structure of the CVT in order to systematize and describe affective functions of certain game-based learning features such as aesthetic design, narrative, incentives, or feedback. A theoretical attempt that maps these game features onto theoretical components of motivational, emotional, cognitive, and social aspects of learning is the integrated design framework for playful learning (Plass et al., 2015).

While a detailed description of each of these attempts is beyond the scope of this chapter, particular game design features that the value-added research has shown to influence the effectiveness of games will now be briefly summarized.

**Mode of play: competition and collaboration.** In their comprehensive literature review of the effect of design features of game-based learning, Clark et al. (2016) found competition to be more effective when it is augmented with social interaction of learners. In other words, when learners collaborated in groups to compete against the gaming system, the learning outcome was higher compared to those games using single competitive game designs. Similar results were found in the review of gamification conducted by Sailer and Homner (2020). These findings overwhelmingly demonstrate the effectiveness of collaboration and cooperation over exclusively competitive game settings, which might cause social pressure and have a destructive effect on participation.

However, competition has also been shown to potentially increase enjoyment, situational interest (Plass et al., 2013), intrinsic and extrinsic goal orientation (Vandercruyssen, Vandewaetere, Cornillie, & Clarebout, 2013), and positive attitudes toward the academic content (Ke & Grabowski, 2007). The outcome of competition might vary for different types of learners depending on prior knowledge and preference to compete (Riemer & Schrader, 2020). While some students will see that they have no chance of achieving a high ranking and become demotivated, others may be motivated to climb the leaderboards (Abu-Dawood, 2016).

**Learner control.** As part of interactivity, learner control refers to the potential of a game to allow the users to handle flexibly the technology or the gaming systems (Bryant & Love, 1996). It includes the extent to which users are allowed to manage directions of gameplay activities, adjust task difficulty, or customize an avatar. In addition to the concept of control being an attribute of the game itself, it can also be defined as a psychological factor, which reflects the user's perceived competence to influence or master certain aspects of the gaming system (Klimmt, Hartmann, & Frey, 2007). Schrader and Nett (2018) designed *Liver Defense*, a serious game in which the learner must successfully defend the human liver from incoming substances such as ammonia, alcohol, and pharmaceuticals, by creating liver cells and enzymes that are specialized to break down each substance. The goal of the game is to help students to learn about functionalities of the human liver. By comparing three different levels of task difficulty, students reported higher perception of being in control, higher enjoyment, and lower frustration when learning with both low and

moderate difficulty levels compared to high difficulty. This finding can be linked to CVT, which predicts that the experience of enjoyment is supported if learners perceive an activity as being controllable. In turn, if activities cannot be handled successfully, frustration might be experienced. However, as also shown by Schrader and Nett (2018), the differences in control perception and in emotions between the three difficulty versions disappeared with increased practice time, yielding nonsignificant results in both affective and cognitive outcomes. Based on this finding, it can be noted that games should become complex as players may welcome gradual increments in the difficulty level. This is also an integral part of flow theory, indicating that the challenge should constantly match learner's ability (Abuhamdeh & Csikszentmihalyi, 2012; Nebel, Beege, Schneider, & Rey, 2020). To fulfill this recommendation of adaptivity, there is a need for continuous measurement of learner experience during gameplay; this is discussed as a methodological challenge for further game research.

**Aesthetic and narrative design.** A number of universal aesthetic characteristics specifically linked to learner's affect and motivation can be adapted to game-based learning. These include the visual aesthetic design and auditive design. Research on the effects of colors and shapes in games on learners' affect, for example, showed that warm colors and round shapes induced positive emotions (Um, Plass, Hayward, & Homer, 2012). Research investigating the effect of music in games has shown that a musical score positively impacts motivation and enjoyment (Lipscomb & Zehnder, 2004). However, there are mixed results regarding students memorizing facts in a virtual learning environment with and without background music (Fassbender, Richards, Bilgin, Thompson, & Heiden, 2012).

In terms of narrative design, the inclusion of a narrative for situating and anchoring learning in context has been demonstrated to lead to increased positive arousal compared to games without a narrative (Echeverria, Barrios, Nussbaum, Améstica, & Leclerc, 2012; Schneider, Lang, Shin, & Bradley, 2004). The design of human-like game characters with which players identify further leads to positive emotions during play (Hefner, Klimmt, & Vorderer, 2007).

While aesthetic design and strong narratives foster emotional and motivational aspects, Clark et al. (2016) found in their meta-analysis that an aggregate contextualized variable created from visual and narrative game features had a small but significant negative impact on learning outcomes. This result refers to the design problematic designers and educators are challenged with: Visual and auditive complexity and rich narratives might foster motivation and positive emotions that are important for learning. However, these might also distract learners, require nonessential cognitive processing, and hinder learning. Therefore, game design should balance motivating elements and align these with content and learning goals in a manner that does not unnecessarily add to the learner's cognitive load.

**Feedback and support.** Feedback and support are pedagogical components implemented in games. Feedback is instantly and immediately provided as learners see the outcome of their actions, often in the form of scores, experience points, badges, or power-ups. Examples of support include the provision of explanations in feedback; navigation through the game via on-screen messages, hints, or prompts; or

feedback via an avatar (Arroyo, Muldner, Burleson, & Woolf, 2014; Leemkuil & de Jong, 2011; Mayer & Johnson, 2010). All of these features encourage learners to reflect upon and re-evaluate their in-game behavior and strategies.

There is significant evidence suggesting that the implementation of feedback and support is necessary to foster motivation and learning (e.g., Erhel & Jamet, 2013; Rieber, 2005; Yaman, Nerdel, & Bayrhuber, 2008). However, there is a large discussion on how to design and how to integrate feedback and support in order to support students most effectively. Rigby and Ryan (2011) found that feedback that informs about progress during gameplay is more motivating than feedback that only indicates success and failure by the number of points and rewards. The meta-analysis of Clark et al. (2016) found feedback in games especially useful for learning outcomes when it was individually adaptive. Mayer and Johnson (2010) found that integrating support via additional on-screen explanations resulted in greater transfer of the learned academic content.

However, the frequency and amount of feedback and support may determine learner motivation. The addition of frequent support may disrupt game flow and might result in a loss of perceived autonomy and control (Vrugte & de Jong, 2011). For learners with extensive prior knowledge who could succeed with little to no support, it might have a detrimental effect (Tobias, Fletcher, Dai, & Wind, 2011). Thus, support should be carefully incorporated into the environment based on student prior knowledge (Mayer, 2020). Approaches that adapt support to the individual learner by intervening only where necessary may help to avoid loss of the motivational qualities of a game-based learning approach (Janning, Schatten, & Schmidt-Thieme, 2016).

---

## Conclusion

A game-based learning approach, including the use of serious games, is a powerful driver to motivate students rather than just providing them with information. Given the importance of motivation for learning outcomes, the use of games for education and their value for digital and distance education is currently generating much discussion.

This chapter has described theoretical foundations for the potential of games from motivational as well as affective, cognitive, and sociocultural perspectives. This highlights that games need to be understood from many interrelated views. The empirical literature, including media comparison research; cognitive, affective, motivational, and sociocultural consequence research; and value-added research, was reviewed. Based on value-added experiments that aim to identify which design features improve game-based learning and which do not, future design issues that educators should consider when choosing or developing games for learning were highlighted. Although promising, there are neither concrete design feature characteristics nor a combination of features that will always result in optimal learning under every condition.

Future research needs to determine conditions under which games are effective in order to strengthen the evidence for their positive value. For example, research that goes beyond short-term laboratory studies and actually integrates serious games and game-based learning approaches into naturalistic educational contexts (including their embedment in diverse learning activities) to study their effects over a longer time might contribute to a deeper understanding. What is more, research should be expanded to assess not only the final outcomes of learning with games.

Relatively, little attention has been paid so far to actually investigate in the development of learner-relevant factors such as motivation and affect during playing, their interplay, and their mediating role to cognitive processes. This presupposes also methods to detect changes in learner-relevant factors during learning. Emerson, Cloude, Azevedo, and Lester (2020) demonstrated that a multimodal learning analytic approach that incorporates student gameplay, eye-tracking, and facial expression data could predict student interest and performance outcomes. The possibility of continuous assessment of student behavior during gameplay without interrupting the gameplay holds significant promise for detecting suboptimal learning experiences in order to provide adaptive support on time.

## Abstract

Problem-based learning (PBL) represents an instructional approach through which learning is gained by investigating, negotiating, and resolving meaningful problems. PBL can be challenging to implement, and the online learning ecology adds another layer of challenges as it demands effective interactions between pedagogy and technology. To inform the design of online learning environments to support PBL, this chapter presents a practical pedagogical framework to support four key aspects of PBL implementation: (1) preparation and planning, (2) design and development, (3) implementation and facilitation, and (4) assessment. Strategies, tools, and examples were drawn from the literature to address each aspect.

**Introduction**

Problem-based learning (PBL) has been widely acclaimed as a powerful pedagogical approach to develop learners' twenty-first century skills such as real-world problem-solving, reflective thinking, and self-directed learning (Kek & Huijser, 2017). Research over the past two decades has documented effective strategies, tools, and resources to support PBL. However, most research on PBL has focused on the in-person context, and there has been scant research about designing and facilitating PBL in the online learning environment. With a global trend of moving learning and instruction online, particularly after the COVID-19 pandemic, there has been an increasing demand for a pedagogical framework to guide the design and facilitation of online PBL, which can take an asynchronous, synchronous, or blended format.

PBL educators often encounter challenges in various aspects of PBL in the classroom context, and adapting PBL to an online learning environment presents further challenges to educators. On the other hand, online or hybrid learning environments have the advantage of integrating emerging technologies as cognitive tools (Lajoie, 2000) to scaffold learners' PBL experiences. While pedagogical principles should remain the focus in designing online PBL (Brush & Saye, 2017), Uden and Beaumont (2006) argued that the characteristics of PBL make it a particularly suitable environment in which to blend technology, thus affording the possibility to integrate pedagogy and technology seamlessly to the best effect (Savin-Baden, 2006).

The purpose of this chapter is to present a pedagogical framework based on a synthesis of the literature to help online PBL designers and educators in their practice. We start by introducing the essentials that characterize PBL, followed by a discussion of four key aspects in conducting online PBL: preparation and planning, design and development, implementation and facilitation, and assessments.

---

**The PBL Essentials**

PBL was first created as a pedagogical approach in the 1960s to address the disconnection between theories and clinical applications in the medical education curriculum. From the perspective of cognitive psychology, PBL creates conditions to facilitate the processing of new information and retrieval of information from long-term memory (Schmidt, 1983). While working in small groups on a problem, students need to analyze the situation and provide an explanation to the symptoms or phenomena that underlie the causes of the problem. They collect additional information and formulate learning objectives in order to define the problem. The analysis of the problem calls for a careful examination of the known information,

activation of prior knowledge, and development of initial hypotheses. The groups of students will then come up with learning objectives, prioritize tasks, identify relevant resources, and collect information that will help them achieve the learning objectives. As a result, the PBL activities and processes help learners to analyze clinical cases, synthesizing and testing the newly acquired information.

From a sociocultural perspective, PBL is highly contextualized and situated problem-solving. Learners are engaged in the professional activities that enable students to identify with the professionals (Lave & Wenger, 1991). Through community-based learning, students learn not only from peers but also from experts who model their thinking that is made visible to the students and scaffold student learning. The students' learning activities are enculturated in the professional activities, which motivates their learning and makes learning more meaningful to them. In the process of developing their knowledge and identity, students develop self-directed learning skills, communication, and collaboration competence while the instructors serve as tutors or experts to provide facilitation as learners work independently and collaborate with other group members.

A wealth of literature (e.g., Barrows, 1994; Hmelo-Silver, 2004; Norman & Schmidt, 1992) suggests five essentials that characterize PBL: (1) *authentic and complex problems* allow students to simulate real-world reasoning and problem-solving experiences, which affords a learning context that activates students' prior knowledge; (2) learners engage in *information seeking and inquiry* to analyze problems, acquire new information, generate solutions, and develop new understandings; (3) through *communication and collaboration*, learners work together to brainstorm causes of problems, share new information, present multiple perspectives, and negotiate solutions; (4) learners apply and further develop *self-directed learning (SDL)* to identify and bridge their knowledge gaps both within the PBL context and beyond in lifelong learning; and (5) learners take advantage of the skillful *tutoring and facilitation* provided by PBL tutors or computer systems to guide their problem-solving process through modeling, scaffolding, feedback, and gradual withdrawal of support as their competence grows.

---

## A Pedagogical Framework for Online PBL Design

Guided by the PBL essentials, we present a pedagogical framework in this section to support online PBL focusing on four key aspects: (1) preparation and planning, (2) design and development, (3) implementation and facilitation, and (4) assessment. For each aspect, we draw from the literature specific strategies, learning activities, digital tools, and online resources for optimizing the learning experience.

### Preparation and Planning

Planning is particularly important for online PBL that integrates PBL and online instruction in one learning experience (Savin-Baden, 2007). The literature suggests

four planning considerations. The first consideration is the *scope*: Is the online PBL intended for part of a course, an entire course, or a program? Does it involve a single or multiple instructors (Grant & Glazewski, 2017)? A one-time implementation within a course may require less time and effort, but as the scope increases, more time and efforts are necessary for planning. Since program-level PBL involves comprehensive curriculum planning, we choose not to focus on it in this chapter. On the other hand, we suggest that online PBL should build on the experience gained from previous in-person PBL implementations.

With a determined scope, an important next consideration is the *learning goals* – that is, what learners are expected to achieve from the online PBL. The formulation of learning goals is no different between online and in-person PBL. As such, readers are referred to Savin-Baden (2007) for a discussion of PBL learning goals. Of particular note is that learning goals should take into account the context where learners will act as members of a community of practice (Lave & Wenger, 1991) and aim for developing learners' strategic and metacognitive knowledge, which would contribute to SDL and lifelong learning (Brush & Saye, 2017).

Another important consideration is the *delivery format* of the online PBL. Will it be completely online or blending some in-person components, and will it be mostly synchronous, asynchronous, or blended? Blended can be blending of online and in-person learning, or blending of synchronous and asynchronous online learning, namely, bichronous online learning according Martin (2021). Some PBL programs are carried out completely online in a synchronous format. For example, an international online PBL enabled medical students from Canada and Hong Kong to work together synchronously (Lajoie et al., 2014). The COVID-19 pandemic also forced many in-person PBL into online synchronous sessions (Coiado, Yodh, Galvez, & Ahmad, 2020; Murata, Moss, Wright, & Pardi, 2021).

Other PBL programs are asynchronous, where the instructor and students do not participate concurrently. For example, the aforementioned international online PBL was later changed to the asynchronous format to address the challenge of meeting synchronously from different time zones (Lajoie et al., 2020). In many asynchronous online courses, PBL is often conducted asynchronously as part of a course (e.g., Huang, Ge, & Law, 2017).

Still, other PBL programs blend online sessions with in-person meetings. For example, in a dental education online PBL program in Saudi Arabia, students met on the first day to clarify terms, identify the problems to work on, and formulate learning objectives, followed by online asynchronous discussions to share, debate, refine, and reach common understandings. After the asynchronous online phase, students had another in-person meeting to synthesize and wrap up their learning (Saqr, Nouri, Vartiainen, & Malmberg, 2020).

While different programs choose different delivery formats out of their needs, contexts, and constraints, it appears that a blended approach has the potential to harness the benefits of different formats: in-person or synchronous meetings can help students and the facilitator to know each other, promoting a sense of social presence (Garrison, 2007; Lajoie et al., 2020), while the asynchronous modality affords in-depth and thoughtful interactions, permanently accessible discussion records,

and the possibility to ensure that all students respond to a given topic (Lajoie et al., 2020).

Lastly, another important planning consideration is *technology readiness*. When it comes to the adoption of technology for online PBL, it is critical that technology should serve pedagogical purposes (Uden & Beaumont, 2006). Many educational institutions now use a learning management system (LMS) for online education, and online PBL often makes use of the same platform with its suite of tools. In other cases, some PBL programs adopt technology to support specific learning activities. For example, online conferencing tools such as *Zoom* and *Skype* are particularly helpful for synchronous online PBL (Savin-Baden & Bhakta, 2019). Some programs conduct online PBL in immersive virtual worlds such as *Second Life* or *Terf* (Araújo, 2019). Of particular note is Maastricht University's experiment with a MOOC PBL (Verstegen et al., 2019). There are also tools developed specifically for PBL such as *STEP* for case-based teacher education (Derry, Siegel, Stampen,, & the STEP team., 2002) and *Compsoft* for PBL in medical education (Kaufman, Ireland, & Sauv e, 2009). Regardless of the tools adopted, the planning should ensure that both instructors and students have adequate access and support for using the tools.

In addition to access to technology, a consistent challenge in online PBL is the instructor's use of technology, especially sophisticated tools such as simulations (Brown, Lawless, & Boyer, 2015). Instructors should be well versed in not only the tools per se but also supporting students' use of the tools in their PBL inquiry. Sufficient time, training, and resources should be allocated to prepare instructors' technology readiness (Savin-Baden & Bhakta, 2019).

## Design and Development

Following the preparation and planning, the design and development phase plays a key pedagogical role in online PBL. This phase involves, in a sense, another level of planning, which is the design and development of the problem, learning resources, and inquiry activities *before* the start of online PBL. Throughout this phase, technology continuously plays a critical role in supporting and augmenting pedagogical decisions.

**The problem.** Online PBL similarly to traditional PBL holds the problem as the linchpin that drives, structures, and inspires learning (Barrows, 1994; Hung, 2019). Guidelines for designing the problem in traditional PBL apply equally to the online counterpart. Readers are referred to the 3C3R framework (Hung, 2019) for designing effective problems that offer sufficient content coverage, support the development of problem-solving skills, and maintain learner motivation. Of particular note is 3C3R's emphasis on affective factors, problem difficulty, and teamwork functions in problem design. For instance, instilling different roles in a problem is likely to promote teamwork (Hung, 2019). As an example, in Brown et al.'s (2015) web-based PBL, middle-school students acted as science advisors representing different countries to negotiate issues and develop policies related to science-based global concerns.

The online modality of PBL offers unique advantages for the design and presentation of the problem. The availability of different media types can offer rich contexts to enhance the authenticity of a problem. On the “low-tech” end, a slideshow that presents a patient case can incorporate photographs, patient diaries, and journal entries to depict rich narratives about the case (Bizzocchi & Schelle, 2009; Chen, 2016). At a more advanced level, Derry et al. (2002) used classroom video cases to present problems to preservice teachers.

Compared with texts, video problems have a few advantages: they offer nonverbal cues which, in medical education, can help learners develop more personalized perceptions of real patients and their problems (Bizzocchi & Schelle, 2009); video cases also contribute to a higher level of problem exploration activities in situated contexts (Chan, Lu, Ip, & Yip, 2012). At an even more advanced level, problem scenarios in virtual worlds such as *Second Life* offer immersive experiences that allow learners to manipulate and interact (Savin-Baden & Bhakta, 2019).

In designing problems for online PBL, one often does not have to start from scratch. Online databases such as *PBL Clearinghouse* and *National Center for Case Study Teaching in Science* can be good places to start. In developing video problems based on written cases, Bizzocchi and Schelle (2009) suggested the consideration of several narrative components: language, audience, point of view, time frame, crisis point, dialog, and character development. While video problems can be powerful, the quality of a video can affect its effectiveness, and PBL educators are recommended to collaborate with learning technologists to produce videos (Bizzocchi & Schelle, 2009; Savin-Baden & Bhakta, 2019).

**Learning resources.** Along with the problem, resources are also essential in the design and development phase of online PBL. We refer to resources as any information, data, or tools that learners will use to explore the subject matter of the problem. Online PBL makes it convenient to provide or access online resources. The resources can be adopted, adapted, or created by the instructor, ranging from assigned readings, mini-lectures, websites, databases, simulations, invited speakers, or other tools. For example, Saye and Brush (2017) provided more than 1,000 multimedia artifacts to secondary students’ historical inquiry PBL.

In STEM education, computer-based modeling and simulations such as *Excel*, *NetLogo*, and *Python* serve as unique resources for learners to explore and test their hypotheses (Morge, Narayan, & Tagliarini, 2019). Organization of learning resources is particularly important for online PBL, especially when a large volume of resources is provided. In the case of Saye and Brush (2017), more than 1,000 multimedia resources were organized into a chronological and conceptual architecture to facilitate students’ exploration. Appropriate scope is also necessary for resources to avoid being too overwhelming to students (Saye & Brush, 2017). In addition to instructor-provided resources, learners can also make use of the vast resources online to locate information pertaining to the problem.

**Inquiry activities.** Another important consideration is the design of inquiry activities for online PBL. Saye and Brush (2002) distinguished hard and soft scaffolds to support learning. While soft scaffolds offer dynamic and situation-specific support, hard scaffolds provide static support that can be anticipated and preplanned.

In the PBL context, hard scaffolds are preplanned activities and assignments. Savin-Baden (2007) used a table to illustrate the systematic planning of inquiry activities: the rows represented activities at different stages, while the columns specified details of each activity including necessary time, corresponding learning intentions, locations, and available resources. For online PBL, the design of learning activities cannot be separated from consideration of the *location*, or the online space where an activity takes place.

The selection of the location should take into account not only the nature of a PBL activity but also necessary group communication and collaboration in carrying out the activity. Ryberg (2019) classified four types of PBL-related activities: inquiry and exploration, resource management, dialogue and communication, and production. The locations and associated cognitive tools for each type can be planned in advance. *Inquiry and exploration* of the problem space can take place in a database provided by the instructor or in library databases, search engines, or even academic social networking sites, such as *Twitter* or *ResearchGate*. *Resource management* can take place on note-taking platforms, such as *Evernote*, social bookmarking sites such as *Diigo*, bibliographic reference managers such as *Zotero*, file sharing services, such as *Google Drive*. For multimedia resource management in particular, annotation tools and embedded notebooks can be helpful for interpretation and analysis (Lajoie et al., 2020; Saye & Brush, 2017). The third type, *dialogue and communication*, can take place synchronously via audio conferencing, online chat, or interactive whiteboard, or asynchronously on discussion boards, social media channels, or mobile apps, which were found to promote reflective thinking, information sharing, and social knowledge construction (Lan, Tsai, Yang, & Hung, 2012). The last type, *production activities* such as sharing and collaborating, can take place on collaborative writing sites such as *Google Docs* and wikis.

In online PBL, predesigned activities and assignments, which serve as hard scaffolds, often appear to students in the form of guidelines. These guidelines are particularly important for asynchronous online PBL because an “adjust as you go” approach would not work well (Caroni & Nikoulina, 2021). The guidelines organize the complex PBL process into different stages, which become the vehicle leading students to the creation of problem solutions (Childs, van Oostveen, Flynn, & Clarkson, 2015). The stages can be organized by cognitive processes of problem-solving (e.g., problem representation and solution generation, Ge, Law, & Huang, 2016) or activity phases (e.g., research, interaction, and debriefing, Brown et al., 2015).

In designing the guidelines, it is important that directions, deliverables, and expectations are clearly outlined and communicated to students (Caroni & Nikoulina, 2021; Huang, Lee, & Dugan, 2017). The guidelines should offer a tailored yet flexible structure (An & Reigeluth, 2008). Further, appropriate scaffolds should be provided to help students produce deliverables, especially targeting student weaknesses. For example, noticing that students often did not attend to competing narratives in historical inquiries, Saye and Brush (2017) designed an argumentation storyboard to intentionally scaffold students’ presentations. Ge and

Land (2003) used a template with guiding questions to support students' problem representation and solution formulation.

## Implementation and Facilitation

With the completion of planning, design, and development, students are ready to participate in online PBL. Similar to the design phase, the implementation and facilitation phase plays an important pedagogical role. This phase, on the other hand, is challenging due to its fluid and interactive nature. Key aspects in this phase include student readiness and instructor facilitation.

**Student readiness.** One cannot assume that students are ready to participate in PBL at the beginning. The success of online PBL hinges on students' readiness in at least three areas: the PBL pedagogy, the online platform and tools, and group formation. Online PBL is often implemented in one course or as part of a course while the rest of learning is more lecture-based (Savin-Baden & Bhakta, 2019). To prepare students for PBL, students should be clearly told their roles and expected quantity and quality of contributions (Valaitis, Sword, Jones, & Hodges, 2005). Further, students are often unfamiliar with the online platform and related technologies. They prefer an orientation that introduces only the essentials (Chen, 2016).

Lastly, students need to form small groups. Web-based sticky notes, such as *Linoit*, can facilitate online group formation. Students can share their background and interests on a sticky note and post it near peers' notes similar to theirs. The instructor can then finalize the group formation based on student input (Huang, Lee, & Dugan, 2017). In online PBL, smaller group sizes were found to positively correlate with student performance (Saqr, Fors, & Nouri, 2018). Once groups are formed, an informal in-person meeting or online icebreaker activity can help students to know each other while establishing common understandings of their roles and rules for group communication and collaboration (de Jong, Krumeich, & Versteegen, 2017; Versteegen et al., 2019).

**Instructor facilitation.** After students have been working on PBL tasks over a period of time, ranging from one to several class sessions or weeks, the predesigned hard scaffolds (guidelines for inquiry activities and assignments) can be offered to guide students through the key problem-solving stages. Meanwhile, the instructor's key role at this stage is to provide soft scaffolds throughout the stages of inquiry, both synchronously and asynchronously. The facilitation focuses on three intertwining aspects: (1) collaboration and communication among students, (2) the problem-solving process, and (3) the social-emotional aspect.

**Facilitation of collaboration and communication.** The facilitation can be different between synchronous and asynchronous PBL. In synchronous sessions, structure and clarity are important in maximizing efficiency, helping students to focus on PBL tasks, and avoiding unnecessary cognitive demand. Students should be asked to review the problem before a session begins (Savin-Baden, 2007). During the session, the instructor should manage the time by being explicit about the stages in the session, the current stage, allocated time, and goals for each stage (Chen, 2016).

Sufficient time should be allocated to the research stage to allow for adequate information retrieval and critical appraisal of information (Chen, 2016). Ground rules and etiquettes should be clearly established for communication and discussion (e.g., students should take turns to speak to avoid multiple individuals speaking at once, de Jong et al., 2017; Nagge, Killeen, & Jennings, 2018). In communicating directions and expectations to students, the instructor should be clear and specific to overcome any ambiguity or misunderstanding (de Jong et al., 2017).

In addition to structure and clarity, instructors should also be aware of various issues or patterns typically found in synchronous communications: There can be audio delays (Chen, 2016); students are comfortable with longer periods of silence (Nagge et al., 2018); there tends to be fewer side conversations; quieter students may participate more (Chen, 2016); students are less aggressive and show more mutual respect compared with in-face sessions (Lajoie et al., 2014); the pace can be slower to allow people to speak; slow typing may affect synchronous chat (Valaitis et al., 2005); and students tend to be distracted with increased screen time (Coiado et al., 2020).

The instructor should also model and encourage students to take advantage of different synchronous communication and collaboration tools. In addition to audio conversations, text chat affords thoughtful comments or questions, digital whiteboard enables students to visualize and share their thinking (Chen, 2016), file sharing tools allow students to share useful resources, and collaborative writing tools help groups to document progress and record ideas. In fact, tutors found that students' use of online file sharing and collaborative notes contributed to smoother synchronous sessions that required fewer interventions (Ng, Bridges, Law, & Whitehill, 2013).

A variety of strategies and tools can help engage students and facilitate collaboration in synchronous PBL. Students can be assigned to breakout rooms to meet in small groups and engage in critical thoughts around class topics (Chen, 2016). Online polling keeps students actively engaged while seeing how others approach the same questions. Private chat allows the instructor to provide immediate feedback regarding participation, roles, performance, and behaviors (Coiado et al., 2020).

To improve collaboration, An and Reigeluth (2008) suggested that the instructor should help groups divide tasks properly for members to collaborate rather than mostly working on their own parts. *Google Docs* or other collaborative task management tools can document each member's charges and timeline for completion. Role assignment is another strategy to engage students in synchronous sessions. For example, Coiado et al. (2020) required students to rotate eight different roles: leader, innovator, searcher, scribe, reader, synthesizer, inquisitor, and AV-tech. A unique challenge for PBL instructors in synchronous sessions is the additional tasks of offering technology support to students while attending to multiple communication channels such as text chat or whiteboard (Chen, 2016; Ng et al., 2013). A support person would be very helpful in monitoring communications and pointing the instructor to issues that need attention (Lajoie et al., 2014).

For asynchronous sessions, the facilitation of communication and collaboration shares many similarities to the synchronous format. It is equally important to communicate expectations clearly to students. Take asynchronous online

discussions, for example – the instructor should make clear the requirements of the discussion and specify student contributions in terms of quantity, timing, and expectations. On the other hand, asynchronous sessions are more paced, which offers more time and space for instructor’s management and intervention. Further, the variety of collaboration tools (e.g., blogs, wikis, chats, group emails, tasks, and discussions) makes students’ thinking visible to the instructor (Ertmer & Glazewski, 2019). It should be noted that the instructor does not have to participate in all discussions. Instead, facilitation is achieved through accessing ongoing discussions and intervening as needed (Savin-Baden & Bhakta, 2019).

**Facilitation of the problem-solving process.** In addition to facilitating communication and collaboration, instructors should focus on facilitating students’ problem-solving process to help them engage with the disciplinary knowledge and the self-regulative processes of problem-solving. The preplanned hard scaffolds offer a level of support but are not sufficient. Appropriate soft scaffolds are necessary to offer flexible guidance and support at different PBL stages. Instructors should maintain a balance between being overly silent and overly directive (Savin-Baden, 2006). Three areas of facilitation are necessary: the problem-solving stages, deep learning and engagement, and metacognition and self-directed learning.

Ge et al. (2016) stipulated that problem-solving involves two iterative stages: problem representation and solution generation. Naive problem solvers often spend little time on problem representation or lack necessary iterations between the two stages (Huang, Lee, & Dugan, 2017). To ensure that students develop adequate problem representations, mindmap tools can help students illustrate their understanding of the problem, which can provide the instructor a clear knowledge about students’ problem-space coverage (Imafuku, Kataoka, Mayahara, Suzuki, & Saiki, 2014). The instructor can also prepare a set of questions to prompt students to consider what is known and unknown and what information they need to seek further.

To encourage meaningful iterations between the two problem-solving stages, the instructor can prompt students to critically examine their emerging solutions to determine if further revisions or iterations are necessary. Synchronous online sessions can dedicate a time period for students to consider the prompts. In asynchronous PBL, these considerations can be facilitated with an online discussion board. In either case, as students record their ideas and reasoning with digital tools, the instructor is afforded a “window” to observe their problem-solving process and intervene as necessary. Such facilitated discussions could lead to greater and deeper problem space coverage than non-facilitated ones (Ertmer & Koehler, 2015).

In addition to facilitating students through problem-solving stages, the second aspect of facilitating the problem-solving process is to promote students’ deep engagement in the process. In both synchronous and asynchronous PBL, students often go through the motions while not developing a deep understanding (Erickson, Neilson, O’Halloran, Bruce, & McLaughlin, 2021; Hmelo-Silver, Bridges, &

McKeown, 2019). Their inquiries often stay at the exploration stage while not reaching the resolution level (Garrison, 2007).

In game- or simulation-based PBL, measures must be taken to prevent PBL from becoming a mere game without any educational dimension (Brown et al., 2015). To promote deep engagement in online discussions, Lan et al. (2012) emphasized justifications in their guidelines for students: “(1) finding learning resources, (2) making logical inferences, (3) offering opinions with reasons, (4) comparing and evaluating evidences, (5) asking relevant questions and seeking answers, (6) making criteria-based judgments, (7) making evidence-based decisions, and (8) reflexivity” (p.1125). Jolly, Brodie, and Jolly’s (2011) analysis of tutor interactions in PBL identified desirable tutor patterns that promote deep engagement (pointing out problems, questioning, confirmation, prompting learning behaviors), as well undesirable patterns (prompting students to include certain content in their work, directly giving content to students). Readers are referred to Kanuka, Rourke, and Laflamme (2007) and Gilbert and Dabbagh (2005) for more strategies to promote quality online discussions.

The third and final aspect of facilitating the problem-solving process is the facilitation of students’ development of SDL and metacognitive skills. When students feel overwhelmed by a vast amount of online information, it is necessary to support their information seeking. Providing guiding questions and helping to clarify the goal of inquiry can help students focus on their information search, identify relevant information, and evaluate and integrate different sources of information as a group (Jeong & Hmelo-Silver, 2010). Problem-solving requires the self-regulative processes of planning, execution, and reflection, but students often lack skills in planning and reflection (Ge et al., 2016). The instructor should explicitly emphasize planning and reflection through planning worksheets and reflective prompts. Well-guided debriefing activities, such as sharing group solutions online and private reflective writing, can help to promote reflection, metacognition, and transfer after the conclusion of a PBL (An & Reigeluth, 2008; Brown et al., 2015; Lajoie et al., 2020).

***Facilitation of social, emotional, and motivational aspects of PBL.*** While the cognitive and metacognitive aspects of PBL have been extensively studied, the social, emotional, and motivational aspects have received much less attention, especially in online PBL. Students may be disinterested in the PBL topic, perceive little value in the PBL approach, not feel competent in performing PBL tasks, or feel overwhelmed by the uncertainties in PBL inquiries. The online setting presents additional challenges, such as a lack of peer response (Valaitis et al., 2005) and difficulties in rapport building (Erickson et al., 2021). Instructors also find it hard to establish a social presence in online PBL (Fonteijn, 2015).

While the literature offers few suggestions for online PBL, online networking sessions, weekly hangouts with the instructor, or the use of emoticons can help to build social presence in online PBL (Verstegen et al., 2019). The instructor should maintain a continuous and active presence for both cognitive and emotional benefits of students. While not intended for online PBL, readers are referred to Belland, Kim,

and Hannafin (2013) and Ge and Chua (2019) for strategies such as helping students establish perceived task value and promoting mastery learning goals.

## Assessment

Assessments are an integral part of PBL and have been discussed extensively in the research literature. Assessments should align with PBL learning intentions and can be done individually or by groups, based on products, processes, or a combination of multiple artifacts (Grant & Glazewski, 2017). Assessments for online PBL can take a variety of formats, such as team presentations, essays, portfolios, or peer assessment (Savin-Baden, 2007). This chapter does not intend to give an exhaustive account of assessments in online PBL, but instead focuses on two aspects, namely process-oriented assessment and analytics-supported assessment.

**Process-oriented assessment.** In online PBL, students' problem-solving processes are recorded in different digital media (e.g., synchronous meeting videos, online discussions, group blogs and wikis, whiteboards, chats). Thus, the instructor should take advantage of the rich online records to incorporate the PBL processes in the assessment (Childs et al., 2015). The instructor can "prime" the PBL process by assigning a considerable portion of the grade to the problem-solving and learning process (An & Reigeluth, 2008), and by emphasizing desirable process performance in the assessment criteria. For example, in a rubric assessing case discussions, Murata et al. (2021) emphasized such qualities as evaluating evidence, organizing and prioritizing hypotheses, and making logical inferences.

**Analytics-supported assessments.** This type of assessment has received much attention in recent years. Through mining and analysis of analytics data generated in PBL, a variety of processes can be formatively assessed to inform instructor facilitation. Lajoie et al. (2020) described an example platform, *HOWARD*, which was intended to scale up costly small-group PBL tutoring to be able to monitor and scaffold multiple PBL groups asynchronously. The system can analyze discussion boards and interactive whiteboards and generate visual indicators of students' participation in group discussions, progress on tasks, group cohesion, and interaction patterns. Based on the visual displays, the instructor can recognize when group interactions go awry and facilitate accordingly. Similarly, Saqr et al. (2020) used social network analysis to examine the relationship between students' interaction variables and PBL performance, which can inform analytics-supported formative assessments and facilitation.

By now we have presented a pedagogical framework focusing on four key areas based on a critical and thorough literature review. The framework has been discussed with specific details focusing on the strategies and rationales for planning, designing, developing, implementing, facilitating, and assessing online PBL. For the convenience of processing and retrieving the information represented by the framework, the pedagogical framework is summarized and displayed in Table 1.

**Table 1** A pedagogical framework for online PBL environments

Key aspects	Areas of consideration	Suggestions
Preparation and planning	Scope	Consider the scope (module/course/program; single/multiple instructors)
	Learning goals	Consider professional context Aim for developing SDL
	Delivery format	Adopt in-person and synchronous formats to promote social presence Use asynchronous online format for thoughtful interactions and permanently accessible records Use blended format to harness the benefits of both in-person and asynchronous formats
	Technology readiness	Ensure access to all technology for PBL pedagogy Ensure instructor readiness for pedagogical use of technology
Design and development	The problem	Present with low or advanced technology Use videos to depict nonverbal cues and complexity of situations to promote problem exploration Adapt from existing resources
	Learning resources	Adopt, adapt, created by instructor, or identified by learners Keep resources organized Avoid too big a scope
	Inquiry activities	Delineate stages of inquiry and plan specifics for each stage Select online “locations” for each inquiry stage based on types of inquiry activities Predesigned activity guidelines serve as hard scaffolds Provide clear guidelines (directions, deliverables, and expectations) and address known student weaknesses
Implementation and facilitation	Student readiness	Communicate student roles and expectations Orient learners to online platform and technology with only the essentials Take advantage of online tools to form and prepare groups
	Instructor facilitation	Facilitate collaboration and communication: Communicate with structure and clarity Model and encourage the use of tools for communication and collaboration Prepare for unique communication patterns and use a support person in synchronous sessions Monitor student interactions in asynchronous PBL; intervene as needed Facilitate problem-solving process: Use dedicated time/location in synchronous/asynchronous PBL to facilitate each problem-solving stage

(continued)

**Table 1** (continued)

Key aspects	Areas of consideration	Suggestions
		Emphasize justifications; employ strategies to promote deep learning and engagement Support information seeking; use well-guided debriefing to facilitate SDL Facilitate social, emotional, and motivational aspects Use online networking sessions, weekly hangouts, and emoticons Maintain a continuous and active presence
Assessment	Process-oriented assessment	Take advantage of rich online records to examine PBL processes Assign a considerable portion of grades to problem-solving and learning processes
	Analytics-supported assessment	Use mining and analysis of analytic data to generate visual performance indicators Use formative assessment to inform instructor facilitation

## Conclusion

Through this chapter, we have shared examples, strategies, rationales, and considerations for designing online PBL environments. Although online PBL shares many similarities with in-person PBL, it has its unique challenges. The existing literature helps us to put together a pedagogical framework for designing online PBL environments. Despite the limited empirical findings to test this framework, this chapter offers helpful and practical guidelines to design and facilitate various aspects of online PBL.

This chapter is intended to lead to a productive discussion and empirical research to refine the pedagogical framework. There are many research questions to be empirically investigated using various research methods. Priorities should be placed on testing the validity of the framework by using practical research methods, such as design-based research. Research is also needed for examining each of the PBL phases indicated in the framework; for example, comparing different delivery modes for different scope, goals, and PBL activities, examining the effects of students' or instructor's technology readiness on students' online PBL experiences, investigating effects of various facilitation strategies in online PBL. In addition, we can also use social network analysis to examine the relationship between students' interaction variables and PBL performance.

At the conclusion of the chapter, we offer a few suggestions that are not unique to online PBL but general to online learning. Because multimedia is an essential part of online PBL, their successful use for PBL learning purposes depends on the effective management of learners' cognitive load. Multimedia learning principles should be followed in the design, development, and use of multimedia in online PBL (Chen,

2016; Mayer, 2014). Further, best practices for online learning apply equally to online PBL. The navigation, structure, and organization of the PBL resource site should be easy for learners to navigate and locate content and materials. This is especially important when an online PBL adopts an asynchronous format.

## Abstract

Students at the primary and secondary levels are increasingly enrolling in online courses either to supplement or completely replace their in-person courses. While there are benefits to learning online, they come at a cost, and students are less likely to pass their online courses compared to their in-person courses. In this chapter, we share two frameworks. We share the 4Es framework that highlights how online courses should be designed to enable, extend, engage, and elevate student learning. However, a well-designed course is not enough, and most students will require support from others to be successful. For this reason, we also share the Academic Communities of Engagement (ACE) framework that

highlights the supports that can increase a student's affective, behavioral, and cognitive engagement. The ACE framework identifies actors within the student's personal community and course community who can provide students with the support that they require.

## Introduction

Over the last 20 years, primary and secondary students have increasingly enrolled in online courses (Taie & Goldring, 2019). For instance, in North America, most students have easy access to online learning options at low or no cost to the student (Digital Learning Collaborative, 2019). Most of these students choose to enroll in one or two online courses to supplement their in-person coursework. By taking online courses, students can access classes that may not be offered locally, recover previously failed credits, and/or learn during times that are more convenient for them. Full-time online learning options, commonly called cyber schools, are also increasing in popularity for those students who require high levels of flexibility due to other pursuits such as competitive athletics. They may be pivoting from home schooling but still want to learn from home or are leaving in-person schooling due to health, safety, or personal reasons (Evergreen Educational Group, 2017).

Growth in online course enrollments at the primary and secondary levels has varied greatly across counties (Barbour, 2018). For online enrollments to increase, there needs to exist government and public support, along with access to adequate Internet (Palvia et al., 2018). Although Internet access and telecommunication infrastructures have rapidly grown and strengthened to make online learning possible, the lack of government and public support has limited or even completely prevented actual online course enrollments from occurring in many countries. However, in an attempt to slow the spread of COVID-19, countries throughout the world, including those who were previously resistant to online learning, closed their school buildings and shifted to learning online. While researchers have correctly pointed out that this emergency remote learning is not the same as preplanned online learning (Hodges, Moore, Lockee, Trust, & Bond, 2020), it is likely this experience will have a lasting impact on government and public support for online learning throughout the world.

There are potential benefits to learning online, but those benefits also come with associated challenges. For instance, research has repeatedly shown that students are less likely to pass online courses compared to in-person courses (Freidhoff, 2021). High attrition rates can be attributed to low learner engagement and lack of support (Borup, Graham, West, Archambault, & Spring, 2020). While students and their parents are drawn to online learning, they are often ill-prepared for its difficulties.

Learning online can be especially challenging because students not only need to learn the course material online but also need to learn how to learn online (Lowes & Lin, 2015). Just as teaching demands different skills than in-person teaching (Pulham & Graham, 2018), learning online requires different skill sets than what is required to learn in person.

Primary and secondary online course providers need to carefully consider both how the courses are designed and the supports that are provided to teachers and students. In this chapter, we first share the 4Es framework that can help in the design and evaluation of effective online learning activities and courses. Following, we use the Academic Communities of Engagement (ACE) framework to discuss how online students' engagement in online learning activities can be supported by their course community (e.g., teachers, mentors, peers) and personal community (e.g., parents, family, and friends).

---

## Online Courses and Design Models

The beginning of online learning can be marked in the 1990s when the Internet became easily navigable and affordable for many households. However, the roots of online learning are firmly grounded in the much deeper history of distance education. Distance education began over a century ago as correspondence courses where students were mailed paper packets of content and activities that they completed and mailed back to the instructor for grading. Radio, television, and then computers allowed students to learn with richer content, but individualized interaction with their instructor was limited, and they had little or no communication with other students in the course. Dial-up Internet in the 1990s with email, discussion forums, and basic learning management systems (LMS) allowed students to have more communication than ever before. Today, faster Internet speeds and the advent of new technologies have allowed for new forms of content, communication, collaboration, and creation (for a more detailed history of primary and secondary distance and online learning, see Barbour, 2019).

Often K-12 online learning programs are categorized by their comprehensiveness (supplemental vs. full-time), their reach (global, national, multistate, state, multi-district, or single district), or the body that has operational control (independent vendor, state, university, regional authority, consortium, local board, private school, public school) (Watson, Murin, Vashaw, Gemin, & Rapp, 2011). However, these categorizations provide little insight into how the courses are actually designed. As a result of shifting to remote learning due to COVID-19, many teachers found themselves in the role of instructional designer, asking themselves, “what should be included in my online class? how should I organize and present them in the required online learning platform?, how should I teach remotely? and how do I know my students are learning?” (Wang, 2021, p. 9). In response, the Content, Activities, Facilitation, and Evaluation (CAFE) model was created to help elementary and secondary teachers transition their instruction online. It asks teachers to organize their instructional content in a systematic way (Content), design and develop various

**Fig. 1** CAFE for Design Online Instruction. (Adapted from Wang, 2021)

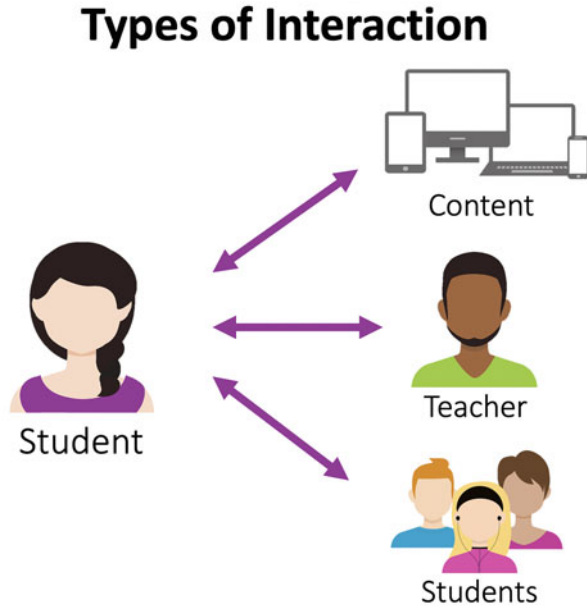

activities (Activities), facilitate online learning interactions (Facilitate), and then evaluate learning performance/outcomes (Evaluate) (Wang, 2021) (Fig. 1).

As described by the CAFE model among many other instructional design models, one of the key elements is learning interactions. Graham (2006) explained that learning interactions can be categorized based on the flexibility in time and place that students participate. Most course designs provide students with a high degree of flexibility with respect to the time of day that they complete learning activities with optional supplemental synchronous sessions (Digital Learning Collaborative, 2019). Similarly, course providers tend not to place any restrictions on where students participate in learning activities. However, at the local level some schools restrict students' flexibility by requiring them to attend a specific class time in their local brick-and-mortar school. This additional structure appears to help some students to participate in learning activities more consistently (Borup & Stimson, 2019).

Interactions that make up the course design can also be categorized by what or who the student is interacting with. For instance, Moore (1989) identified the following three types of interaction that act as the primary building blocks when designing learning experiences: student-content, student-teacher, and student-student interactions (see Fig. 2).

Despite the ability to have rich human interactions, a large portion of the K-12 online courses are actually designed as if they were high-tech correspondence courses, rich in media and learner-content interaction but lacking regular interactions with the teacher and others in the course. These courses can also focus on scalability by replacing some subjectively scored assessments such as projects that require teacher grading and feedback with objectively scored assessments that can be graded using technology.

**Fig. 2** Three types of interaction. (Created by Jered Borup, CC BY)

Teachers in these independent study programs are made available for students to contact for help but tend not to proactively contact students or attempt to develop close relationships with them (Oviatt, Graham, Borup, & Davies, 2018). These courses tend to have high attrition rates (Hawkins, Graham, Sudweeks, & Barbour, 2013), and student success often depends on their local support systems. These flexible courses are especially common in supplemental online programs where students follow a variety of different school calendars for their in-person courses. However, even cyber schools where students take most or all of their courses online and could follow a common calendar tend to follow an independent study model (Woodworth et al., 2015). Full-time cyber schools' focus on flexible pacing and independent study is particularly concerning because students could graduate from secondary school without any experiences collaborating with peers. Other programs emphasize developing close caring relationships between students and teachers, where teachers provide students with high levels of personalized feedback and encouragement. Despite their physical separation, teachers can successfully form caring relationships with students that allow them to better meet their students' needs (Velasquez, Graham, & West, 2013).

---

### **The 4Es: Goals when Designing and Assessing Learning in Online Environments**

Regardless of the course model, to build a quality online experience, it is necessary to focus on specific goals when it comes to designing and assessing learning. Building on previous research and frameworks such as David Merrill's (2009) e3

**Fig. 3** The 4Es. (Created by Jered Borup, CC BY)

and Liz Kolb's (n.d.) Triple E frameworks, Borup, Graham, Short, and Shin (2021) identified the following four goals when designing and evaluating online learning activities and assessments: enable, extend, engage, and elevate (the 4Es; see Fig. 3). Specifically, the 4Es framework asks if the online course activities:

- **Enable** new types of learning activities?
- **Engage** students in meaningful interactions with others and the course content?
- **Elevate** the learning activities by including real-world skills that benefit students beyond the classroom?
- **Extend** the time, place, and ways that students can master learning objectives?

## Enable

Instructors and designers may be tempted to replicate the in-person learning experience online. For instance, Woodworth et al. (2015) examined full-time cyber schools and stated:

Some [online] schools may function exactly like the traditional brick-and-mortar school. They may require all students to log in at specific times to receive instruction with the only difference from a traditional brick-and-mortar school being that the students are in different physical locations. (p. 42)

The attempt to digitize the in-person learning experience was also evident when social distancing requirements required primary and secondary schools to close their

buildings and rapidly move online. Understandably, many teachers and administrators began using synchronous webinar platforms in an attempt to replicate what they would have done in-person (Lowenthal, Borup, West, & Archambault, 2020).

While some aspects of teaching and learning appear to transfer well from the in-person to the online environment, others can become more challenging and frustrating. One example is establishing social presence in an online setting. Social presence encompasses fostering a trusted community in the online setting including developing interpersonal relationships, connecting to learners, and helping them to feel comfortable in the online environment (Garrison & Arbaugh, 2007). Developing strategies that promote social presence in online settings may be foreign to teachers, particularly when they are separated from students in space and/or time.

Instead of simply digitizing in-person activities, a better approach is to carefully consider the possibilities of the online environment and then leverage those possibilities to design online learning activities and assessments. In doing so, online technologies and learning environments can unlock and enable activities that teachers and students would not be able to do, or at least very difficult to do, without online technology.

## Engage

Learner engagement is frequently credited for learning success, and its absence may be blamed for education's ills. While learner engagement is far from a panacea, research has confirmed that online learner engagement is an important factor in several learning outcomes including performance, pass rates, and sense of community (Avcı & Ergün, 2019; Heyman, 2010; Shackelford & Maxwell, 2012). Sustained learner engagement is so valuable and elusive that Sinatra, Heddy, and Lombardi (2015) referred to it as the "holy grail of learning" (p. 1). Course design can play an important part in both the levels and forms of learner engagement that are required.

One challenge of sustaining learner engagement is that the research community has yet to produce a widely accepted definition (Halverson & Graham, 2019). The research community does agree that engagement is a complex, multidimensional concept. The primary disagreements occur when identifying and defining the dimensions of engagement (Bond & Bedenlier, 2019; Redmond, Heffernan, Abawi, Brown, & Henderson, 2018; Rodgers, 2008). Within the context of online learning, researchers tend to focus on the following three dimensions of engagement:

- Behavioral – the physical energy that students exert when completing learning activities. The PIC model categorizes activities as either passive, interactive, or creative.
- Affective – the emotional energy that is present when completing learning activities.
- Cognitive – the mental energy that students exert to learn the course content and develop new skills (Borup, 2018; Borup et al., 2020).

**Fig. 4** Dimensions of student engagement (created by Jered Borup, CC BY)

Teachers commonly refer to these dimensions when they talk about engaging students' hands (behavioral engagement), hearts (affective engagement), and heads (cognitive engagement) (see Fig. 4). The three dimensions of engagement also influence each other. For instance, too often students are not affectively engaged in their learning because they are given passive learning activities. If technology is used in ways that encourage students to be more active participants, it can increase their enjoyment and affective engagement. At the same time, if students are tasked with engaging behaviorally but lack cognitive and affective engagement, the task will be viewed as "busy work."

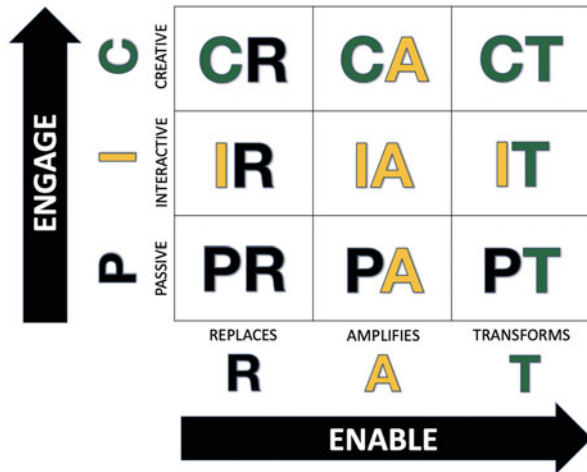

One framework that helps to categorize students' behavioral engagement in learning activities and examine learning activities in comparison with what could be done without technology is called the PICRAT framework (Kimmons, Graham, & West, 2020). The PICRAT framework is particularly useful when designing learning activities for the online learning environment. Specifically, PIC describes students' behavioral engagement as one of the following:

- **Passive:** students learn by consuming presented information but do not control or contribute to what is presented (e.g., reading an article, listening to a podcast, watching a video).
- **Interactive:** students exert some control over their learning by being an active participant in communications with others (e.g., discussions, peer reviews, study groups) or by interacting with content that is responsive or adaptive to student behavior (e.g., educational games, simulations, adaptive learning software).
- **Creative:** students learn or demonstrate their learning by creating original materials and artifacts using technology (e.g., writing a report, editing a video, creating a digital poster).

The RAT element then articulates how learning activities use technology. Specifically, it categorizes the use of technology as one of the following:

- **Replaces** – online technology sustains current practice without making meaningful changes to learning activities.
- **Amplifies** – online technology incrementally improves learning activities in ways that may result in some improvements in learning outcomes.

**Fig. 5** The PICRAT framework matrix. (Based on Kimmons et al., 2020; graphic created by Jered Borup, CC BY)

- Transforms – online technology fundamentally changes learning activities in ways that may result in significant improvement in learning outcomes.

While the PIC and RAT frameworks can each stand alone, Kimmons et al. (2020) combined them to form the PICRAT framework matrix. The matrix allows instructional designers and teachers to describe both student behavioral *engagement* and how the online environment and technologies *enable* learning activities (see Fig. 5).

It is important to note the PICRAT matrix by itself does not measure the worth of a learning activity. There are times when a passive activity that simply replaces a traditional in-person environment (PR) is a good and perhaps the best activity possible. That said, an issue arises when students engage in too many passive learning experiences that go on for too long. Even in an in-person classroom, learning experiences can be too passive, but it is particularly concerning when there are too many passive learning experiences online because they require the student to maintain focus – a difficult task when students with low self-regulation skills are not under the direct supervision of the teacher and can access countless online distractions (Pettyjohn, 2012). As a result, some online tools can help to make passive learning activities such as watching a video more interactive by periodically requiring students to answer questions regarding what they are learning.

## Extend

The distributed nature of online learning extends learning opportunities to students regardless of their location so long as students have an Internet-connected device. The extension in students' place of learning focuses on access to learning opportunities, but online learning can also be extended in ways that improve how and even

what students learn. For example, online learning can extend the time when students complete learning activities. While some online programs require regular synchronous class sessions, online courses are offered largely asynchronously that may be supplemented with optional synchronous sessions.

This extension of students' learning time also affords students some flexibility and control in their pace of learning. The one-size-fits-all approach to public education has long been highlighted as a limitation (see Skinner, 1958). Assignment deadlines (or the lack thereof) largely determine the pace of instruction, but even when courses establish weekly deadlines, students have flexibility to pace their learning during that week. Even with flexible timelines, ultimately online students will require support and feedback to help them to progress through learning activities. Not all feedback is equally valuable (Hattie, 2008). Feedback is best when it is timely, friendly, and specific (Borup, West, & Thomas, 2015). Teachers' content and pedagogical knowledge makes them an especially important source of feedback. However, providing detailed feedback can be time-consuming, making it challenging for teachers to provide timely feedback to all of their students. As a result, some online programs use technology such as adaptive learning programs and artificial intelligence to provide students with in-the-moment feedback, but these types of feedback should not replace teacher feedback (Amro & Borup, 2019; Amro & Dabbagh, 2020).

The extension of students' learning time can also have important benefits in online discussions. Certain types of students tend to struggle in synchronous discussions. For instance, students with learning disabilities, introverted tendencies, or those not proficient in the language can all struggle for different reasons to participate in fast-paced discussions and benefit when the discussion is extended to allow for extra time to reflect and form responses (Borup, West, & Graham, 2013). While these asynchronous discussions are most commonly text-based, discussion platforms are increasingly allowing for asynchronous audio and video communication. Allowing students some choice in their mode of communication will likely result in more equitable participation.

Lastly, online courses can be designed to extend the ways that students reach and demonstrate mastery of the learning objectives. This type of extension can occur to different degrees. For instance, students may be provided two options (e.g., read this article or watch this video, write a report or make a video). Students can also be provided with a choice board listing a variety of learning activities for students to choose from. At times teachers may also work with students to help them to develop their own learning goals and path to reach those goals (Arnesen, Graham, Short, & Archibald, 2019).

When students decide how their learning is extended, it is called personalized learning (Arnesen et al., 2019). While providing students with choice can potentially have positive impacts on student engagement, there are important drawbacks to allowing online students to extend and personalize their learning time, pace, and ways of learning. When students are provided with a high degree of choice in their learning time, pace, and ways of learning, it is possible to have each student completing different learning activities at any point in time, which can eliminate

certain communication- and collaboration-based learning activities that require students to be working on similar tasks at similar times.

This dilemma has created a tension between interactive learning and the flexibility in pace that has helped to make online learning so popular (Borup, 2016b). Richard Cullatta, the former director of the US Department of Education, explained that learning is inherently social and issues arise when online technology is used to isolate students (Davis, 2017). As a result, courses should be carefully designed so that students have some choice in the time, pace, and ways that they learn while still allowing for meaningful opportunities for student-student communication and collaboration.

## Elevate

There is also an opportunity to use online technologies and learning environments to help elevate learning activities to include higher-order and twenty-first-century skills such as communication, collaboration, critical thinking, and creativity skills. Effective online activities should promote deeper learning. The 4 Shifts Protocol outlines four shifts toward more relevant, personalized learning across grade levels and content areas (McLeod & Graber, 2019). First, deeper learning is promoted by a focus on higher-level thinking such as problem-solving and creativity rather than lower-level thinking such as factual recall. Second, student agency takes a larger role in deeper learning such that students have more ownership and control over what and how they learn, offering more personalization. Third, authentic work offers students the ability to participate in meaningful learning communities that are interdisciplinary in nature and relevant to local, national, and international contexts. Fourth, deeper learning includes the strategic infusion of technology to be able to effectively mobilize shifts toward higher-level thinking, student agency, and authentic work. It is this connection to “authentic work” where online activities can elevate the learning process. Authentic intellectual work (AIW), as originally described by Newmann and Associates (1996), contains the following four key indicators: higher-order thinking, deep knowledge, substantive conversation, and connectedness to the real world (Table 1).

AIW extends students’ learning by building new understandings and going beyond prior knowledge, valuing knowledge that extends beyond basic factual recall. It pushes students to support their new understandings through evidence (Newmann & Associates, 1996; Saye et al., 2018). These components have been correlated with the development of complex problem-solving and higher-order thinking skills (Saye et al., 2018).

AIW is frequently accomplished by using technology to situate learning tasks into “real-world” problems and projects. This can help increase elements of authentic pedagogy, including higher-order thinking skills and connections to students’ lives through engaging with meaningful, real-world problems through disciplined inquiry. Given its focus on observations, data collection, and drawing conclusions, science is full of real-world applications for students. For example,

**Table 1** AIW indicators

Indicator	Description
Higher-order thinking	Occurs when students combine facts and ideas to synthesize, generalize, explain, hypothesize, or arrive at some conclusion or interpretation
Deep knowledge	Concerns the central ideas of a topic or discipline because such knowledge is judged to be crucial to a topic or discipline. Mastery is demonstrated by student success in producing new knowledge by discovering relationships, solving problems, constructing explanations, and drawing conclusions
Substantive conversation	Discussion centers on the subject matter in the discipline and includes higher-order thinking and is shared (is not scripted or dominated by one party) and builds on student ideas to promote collective understanding of a theme/topic
Connectedness to the real world	Occurs when students recognize the connection between classroom knowledge and situations outside the classroom that create personal meaning and significance for the knowledge

*Note.* Adapted from Saye & Associates (2015, p. 67)

students can participate in citizen science projects that are organized online and allow them to collect and interpret data that have an impact on solving real-world problems such as biodiversity research. One such opportunity is Project Noah <https://www.projectnoah.org>, which allows students to learn about and identify various species of wildlife, create their own online nature journal, follow naturalists, and connect with experts in the field. Many other such projects exist and can be explored at <https://www.commonsense.org/education/top-picks/real-world-science-resources-for-students>.

Online activities can be structured so they allow students to engage in disciplinary literacies (Lent, 2015) that provide opportunities to read, write, and think like historians, scientists, mathematicians, and writers. For example, in social studies, they may create interactive timelines with associated narratives along with relying on valid primary and secondary sources for support. In language arts, students might write on relevant topics affecting them and the world. They may work to determine credible research on the issue and use it to support or refute claims, reflecting on multiple texts to guide their writing. They may even reach out with questions to a particular writer or researcher. Math provides the opportunity to connect to everyday life including budgeting and money management, investment and financial planning, building and engineering concepts that allow students to use information to come to a solution, calculating figures using mathematical principles, finding patterns, and estimating/generalizing. Students can use technology to communicate in authentic ways with each other but also with researchers, scientists, and other experts. Given the vast amount of information that is available online, together with the ability to communicate and collaborate with others, this provides students an avenue to engage with content in a real-world manner that includes higher-order thinking, deep knowledge, and substantive dialog to enhance learning in a meaningful way.

## ACE: A Framework for Supporting Online Student Engagement

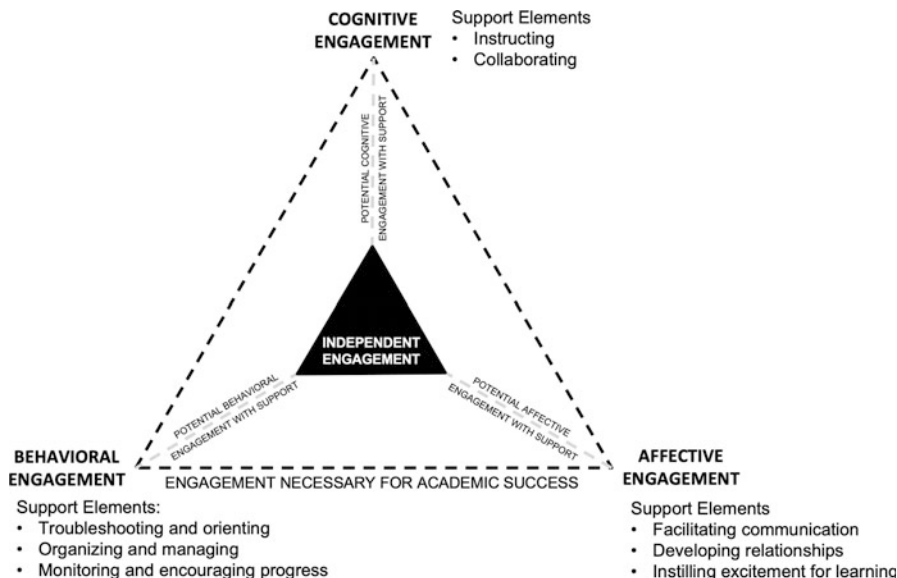

Designing and developing meaningful online learning activities following the 4Es is important, but many students will still be unable to fully engage in the activities without support from others. In fact, some students need so much support that they are told not to enroll in online courses. Rose, Smith, Johnson, and Glick (2015) explained that restricting online learning opportunities to those with low support needs results in inequitable access. Rather online programs should carefully consider the supports that are required for each student and then work to offer that support.

Support and scaffolding has long been viewed as an important part of learning, and Vygotsky (1978) argued that what students “can do with the assistance of others might be in some sense even more indicative of their mental development than what they can do alone” (p. 85). Building on Vygotsky’s zone of proximal development, Borup et al. (2020) argued that each student varies in their ability to independently engage in learning activities behaviorally, affectively, and cognitively. Students’ ability to independently engage in learning activities is dependent on different facilitators such as the learner’s background and characteristics as well as the learning environment and the students’ personal environment (see Fig. 6). Of the four highlighted facilitators of engagement, instructors have the most control over the learning environment and the support that they directly provide to students. However, teachers and programs can also have an impact on support that is provided by those within students’ personal environments (Hoover-Dempsey et al., 2005).

The ACE framework identifies the support elements that can narrow or bridge the gap between learner independent engagement without support and the level of engagement that is necessary for academic success (see Fig. 7). Cognitive engagement can increase when students receive instructing and collaborating support. Behavioral engagement can increase when students receive the following types of support: (a) troubleshooting and orienting, (b) organizing and managing, and

**Fig. 6** Facilitators of engagement. (Created by Jered Borup, CC-BY)

**Fig. 7** The gap between a student's independent engagement (black triangle), the engagement necessary for academic success (dotted triangle), and the listed supports required to bridge the gap

(c) monitoring and encouraging progress. Affective engagement can increase when students receive the following types of support: (a) facilitating communication, (b) developing relationships, and (c) instilling excitement for learning.

The ACE framework also identifies two support communities that can provide students with the support that they require: the student's course community and student's personal community (see Fig. 8). Actors within students' course communities can include teachers, other students in the course, facilitators/mentors, aids, and other support staff. In many cases, the course community actors have no relationship with the student prior to the course. In contrast, actors within students' personal communities can include parents, guardians, friends, coaches, and members of community who have developed relationships with the student outside of and prior to the course with some relationships beginning at birth. As a rule, actors in the course community will have greater knowledge of the course content and procedures, but actors in the personal community will have greater knowledge of the student's background, interests, tendencies, strengths, and limitations.

Parents, guardians, and/or caretakers are likely to be the most important actors in a student's personal community. While they can likely provide their primary students with content-related support, it becomes more difficult once students are in secondary school. As a result, parental support (which can be provided by a parent, guardian, or close family member who serves as a caretaker) tends to focus more on affective and behavioral engagement and less on cognitive engagement (Borup, 2016a; Borup, Stevens, & Hasler Waters, 2015). However, the amount of

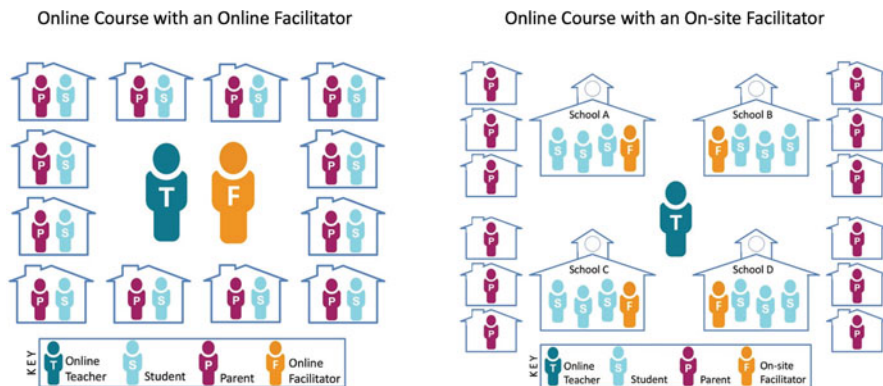

**Fig. 8** The ACE framework with support from the course and personal communities

time invested in providing parental support can vary greatly. Hoover-Dempsey et al. (2005) identified several obstacles that parents encounter when providing students with support including how they have constructed and perceived their roles, parent self-efficacy that their efforts will actually impact student performance and behavior, and demands on their time. They also found that parents were more likely to provide support when they received specific invitations from teachers and their students.

Teachers are an important actor within the course community and can develop caring relationships with students while providing them with high levels of support (Velasquez et al., 2013), often their high student loads and physical separation from students may prevent them from providing each student with the level of support that they require (Hawkins, Barbour, & Graham, 2011, 2012). As a result, online programs are increasingly providing students with online or in-person facilitators (see Fig. 9). These facilitators do not replace the instructor and typically are not experts in the course content. Instead facilitators work to develop caring relationships with students and support their efforts to learn how to learn online (Borup, 2018). Teachers and facilitators can also provide students with opportunities to support each other. For instance, teachers established a student-student tutoring program at a cyber charter school (Borup, 2016b).

**Fig. 9** Online courses where students receive support from the online teacher and a facilitator

## Implications

When designing online learning for youth and children, we need to consider not only how the courses are designed but also how to develop support systems so that students are able to succeed. The 4Es framework and Academic Communities of Engagement (ACE) frameworks have important implications for steps we need to take in order to improve online students' engagement in online learning activities and how these activities can be supported by their course community and personal communities. These include the need for additional learning opportunities and professional development for practicing teachers as well as for those who are becoming teachers as part of their teacher education programs.

## Need for Additional Learning Opportunities/Experience for Teachers

Current and future educators need guidance, support, and practice in designing and implementing online/blended activities. First, school districts should support teachers with learning opportunities specific to designing effective lessons for the online/blended setting. This support may include release time for the creation and sharing of lessons and approaches, peer review of created materials, and coaching/support from skilled professionals. In addition, districts should provide the latitude for teachers to try new approaches and make adjustments as they go, including opportunities to design materials to enable new types of learning activities; engage in meaningful interaction with one another and with the content; elevate activities with authentic, real-world applications; and extend flexibility for mastering learning objectives/outcomes.

When applying design principles to online learning, teachers need professional development opportunities that are well-designed and effective. To accomplish this

goal, professional development should be ongoing, be content-focused, and involve teachers as active learners (Birman, Desimone, Porter, & Garet, 2000). It should be job-embedded, meaning that it involves “systematic, planned, intentional and regularly scheduled efforts to embed teacher learning with teachers’ daily lives” (Dawson & Dana, 2018, p. 248).

In addition to designing activities, teachers may need specific professional development geared toward working with students’ personal and course communities as well as developing their teaching and social presence so that they are better equipped to cultivate critical relationships with students in online settings. These relationships can result in an increased sense of belongingness, connectedness, engagement, academic achievement, participation, and motivation (Cohen, McCabe, Michelli, & Pickeral, 2009; Miller, Riley, & Slay, 2021) – all important elements for success in the online classroom. There are a number of open educational resources, such as this volume as well as others, including those found at <https://edtechbooks.org> centered on blended learning approaches that may prove to be helpful when it comes to pragmatic approaches to designing online and blended learning activities.

## Teacher Education Programs

In addition to professional development opportunities for current teachers, future teachers also need preparation for designing online learning for online and blended learning environments. However, historically, teacher education programs have offered limited opportunities for future teachers to create/implement online or blended lessons (Archambault, 2011; Archambault et al., 2016; Kennedy & Archambault, 2012). As a result, teacher education programs should recognize the importance of embedding coursework and practical experiences for future educators. It is important that the first-time teachers are exposed to creating online learning activities prior to their first teaching experience.

There are a number of actions teacher preparation programs can pursue to address this issue. First, programs should consider a dedicated instructional design course to teach future educators strategies for enabling, extending, engaging, and enhancing online learning activities as well as exploring uses of technology that are creative and transformative. In addition, effective technology use should be integrated throughout pedagogical and content-related coursework to ensure that future teachers can experience its modeling as a teaching tool. Often programs select one approach or the other. However, future teachers need to experience not only principles of effective lesson design but also the implementation and evaluation of such lessons and strategies for blending in-person and online instruction. Also, the inclusion of an online or blended field experience could help future teachers gain valuable experience when it comes to building comfort and capacity in an online setting. As a result of COVID-19 along with how quickly society is changing due to the connected nature of modern-day living, the need to be able to design and implement effective online lessons is more evident than ever.

## Conclusion

As online offerings continue to expand at the primary and secondary levels for a variety of reasons, teachers and course providers need to be equipped with ways to help improve the design of effective online learning activities. The 4Es framework provides a structure for considering important design elements when it comes to online activities. Relatedly, the ACE framework shows how students' course and personal communities can support their engagement when it comes to online learning. Both are important and useful tools for those involved with creating and designing quality online learning experiences for children and youth.

## Abstract

Engaging students in their learning, and within their learning community, is a key goal of educators. However, ongoing discussions about its nature, conceptualization, and measurement have led to a diffusion of the concept's understanding, and ability to apply it within both research and practice. This chapter draws on theoretical and empirical primary and secondary ODDE research, and provides an overview of student engagement and disengagement, particularly as they relate to educational technology. The four dimensions of behavioral, affective/emotional, cognitive, and social (dis-)engagement are presented, alongside example indicators. In addition, a bioecological model of student engagement is explored with explicit links to digital learning. The chapter concludes by providing open questions and directions for future research, including further emphasis and

## Introduction

Engaging students in learning is a key goal of educators, especially as disengagement has been found to profoundly affect students' cognitive development and learning outcomes (Ma, Han, Yang, & Cheng, 2015), and is a predictor of student dropout in both secondary and higher education (Finn & Zimmer, 2012). As such, student engagement has received increasing attention over the past decade (Aparicio, Iturralde, & Maseda, 2021), suffering from ongoing criticism about its continued fuzziness as a construct (Trowler, Allan, Bryk, & Din, 2021), and being described in various ways in the literature.

There has also been widespread discussion about the nature, conceptualization, and measurement of engagement, as well as the level of theorizing being undertaken, in the field of open, distance, and digital education (e.g., Bergdahl, 2020; 2022c, Bond, 2020b; Henrie, Halverson, & Graham, 2015). While research has found that using educational technology can lead to improved self-regulation and self-efficacy (Alioon & Delialioğlu, 2019), increased participation (Northey, Bucic, Chylinski, & Govind, 2015), and increased involvement in the wider educational community (Junco, 2012), educational technology research has often lacked theoretical guidance (Bergdahl, Nouri, Karunaratne, Afzaal, & Saqr, 2020; Bond, Buntins, Bedenlier, Zawacki-Richter, & Kerres, 2020; Hew, Lan, Tang, Jia, & Lo, 2019). Given the difference between on-site/learning and learning undertaken in ODDE contexts, particularly within the current climate of remote and hybrid learning, it is crucial that further attention is given to understanding the complex interplay of digital learning environments and emerging educational modes (Bergdahl, 2022b), teacher-student relationships (Bergdahl & Bond, 2021), and learning activities (Bergdahl, 2022a).

This chapter, therefore, draws from and builds on the doctoral work and ongoing research of Bond (2020a) and Bergdahl (2020), and provides an overview of the concept of student engagement, particularly as it relates to educational technology. It will then briefly outline recent student engagement and ODDE research, provide implications for practice, and suggest future research directions.

---

## What Is Student Engagement?

The concept of student engagement arose out of a range of previous theories, which has led to discussions centering around the depth and breadth of its operationalization (e.g., Eccles, 2016; Lawson & Lawson, 2013). There is, however,

widespread agreement as to its multifaceted and complex nature (Appleton, Christenson, & Furlong, 2008; Fredricks, Blumenfeld, & Paris, 2004; Kahu, 2013), with Azevedo (2015, p. 84) declaring that it is

one of the most widely used and overgeneralized constructs found in the educational, learning, instructional, and psychological sciences.

Similarly, Kearsley and Shneiderman (1998) developed a framework for technology-based teaching and learning, based on the principles of “Relate, Create, and Donate,” calling it Engagement Theory. For them, engaged learning involved active cognitive processes, such as problem-solving and decision making, based on meaningful and authentic collaborative activities.

The Community of Inquiry framework (Garrison, Anderson, & Archer, 2000) furthered understanding of these collaborative activities that promote engagement, by describing the importance of teacher presence, social presence, and cognitive presence in facilitating effective educational experiences. Community Theory (Rovai, Wighting, & Lucking, 2004; Wenger, 2008) also influenced student engagement theorizing, with its emphasis on active participation, a sense of belonging and/or a feeling of membership, and the development of trust in self, peers, and the teacher. While Self-Determination Theory (Deci & Ryan, 1985) recognizes the role that teachers and peers play in influencing levels of intrinsic and extrinsic motivation, motivation is instead seen as an antecedent to engagement, as the intent that energizes behavior (Lim, 2004; Reeve, 2012; Reschly & Christenson, 2012). However, students can engage in learning without waiting to be motivated (Reeve, 2012). Even though teachers can influence engagement directly (Bergdahl & Bond, 2021), they often try to influence engagement indirectly via motivation and risk overlooking how their learning designs facilitate engagement or trigger disengagement (Bergdahl, 2022c, d). While the constructs are related, motivation alone remains insufficient for students to engage (Bergdahl, 2022c, d).

Astin’s (1984) theory of involvement was instrumental in furthering understanding of engagement. He defined involvement as the “physical and psychological energy that the student devotes to the academic experience” (p. 518), occurring along a continuum, with particular focus on active participation, interaction with peers and teachers, time-on-task, and effort, as well as their subsequent relation to satisfaction and overall achievement. Engagement can be approached as a manifestation of energy and effort in action (Filsecker & Kerres, 2014). Based on these ideas, we define student engagement as

the energy and effort that students employ within their learning community, observable via any number of behavioral, cognitive, or affective indicators across a continuum. It is shaped by a range of structural and internal influences, including the complex interplay of relationships, learning activities, and the learning environment. The more students are engaged and empowered within their learning community, the more likely they are to channel that energy back into their learning, leading to a range of short and long-term outcomes, that can likewise further fuel engagement. (Bond et al., 2020, p. 3)

While it may seem that engagement is defined vaguely, several reviews have revealed that engagement research is consistently strongly correlated with academic

success, and thus remains a core concept in educational research (Alrashidi, Phan, & Ngu, 2016; Henrie et al., 2015; Nkomo, Daniel, & Butson, 2021). It should also be pointed out that, in order for a theory to develop, an understanding of any phenomenon cannot be fixed or cemented. Thus, it should never be a vision to determine a fixed position, but rather to contribute to further understanding.

Contributing to further conceptual understanding, Wang, Fredricks, Ye, Hofkens, and Linn (2017) explored the relationship between engagement and disengagement, and concluded that these should be considered as two separate, but distinct constructs, each with its own continuum; a position supported here and discussed in greater depth within The Microsystem Level section in this chapter. When applied as a meta-concept, researchers might be less prone to explore the dimensions or the relations between the indicators of the dimensions. However, what the relationship between engagement and disengagement is at a microlevel, remains an important one to explore.

Bond (2019) proposed a bioecological model where engagement can be approached at the macro-, meso-, and microlevel, and later Bergdahl (2022b) explored engagement at the microlevel. Both articles assume that learning exists in a social reality. We therefore start by positioning engagement in a sociocultural context.

---

## Sociocultural Positioning of Student Engagement

Student engagement does not occur within a vacuum; it is influenced and impacted by many contextual factors (Kahu, 2013; Quin, 2017). By considering the wider sociopolitical context influencing student engagement, a clearer and more holistic understanding of students and their learning can be gained (Appleton et al., 2008). Following an extensive review of student engagement literature, both theoretical and primary/secondary empirical research (Bond, 2020b; Bond & Bedenlier, 2019; Bond et al., 2020), and through conducting empirical studies (e.g., Bond, 2019), a bioecological model of student engagement was developed (see Fig. 1), based on Bronfenbrenner and colleagues' model of child development (e.g., Bronfenbrenner, 1979). This model places the student at the center of the microsystem, nested within a system of intertwined milieus; the mesosystem, representing interactions between the micro- and exosystems, as well as between microsystems; the exosystem, including wider social structures impacting on the learner; and the macrosystem, encompassing the wider political, cultural, economic, and legal systems, in which all systems are located. The remainder of this chapter will focus on the meso- and the micro-system.

---

## The Mesosystem Level

The mesosystem level represents a student's social milieu and background, as well as their location and socioeconomic status. In some (dis-)engagement research, the reasons that students disengaged were sometimes identified in the meso-level – for

**Fig. 1** Bioecological model of student engagement (Bond, 2020a, 2020b)

example, socioeconomic factors and the stress level in the family (Alexander, Entwisle, & Kabbani, 2001), the number of siblings in the family (Chiu, 2010), and parental engagement (Bond et al., 2021). Economic factors can impact on the ability of families to afford devices (Warschauer & Xu, 2018), as well as access to the internet (Bond, 2019). Despite access to technology continually growing, issues of a digital divide persist, even in countries that are considered wealthy (Bond, Bedenlier, et al., 2021; Bond et al., 2021).

With multiple influential aspects in an increasingly digital context (dis-)engagement is subject to negotiation (Bergdahl & Bond, 2021). A learning context may be comprised of the educational mode (blended, hybrid, distance, or f2f), classroom leadership (including teacher self-efficacy), student self-perceptions and profile, and the available digital and analogue resources (ibid.), which create conditions under which engagement is affected. For example, distance education with mainly asynchronous elements has been found to primarily facilitate cognitive engagement,

whereas distance education characterized with mainly synchronous elements, relied on social engagement (Bergdahl & Gyllander Torkildsen, 2022). Both of these modes of education challenge the teacher to not simply roll with what is easiest to enable in that particular mode, but what benefits learning most.

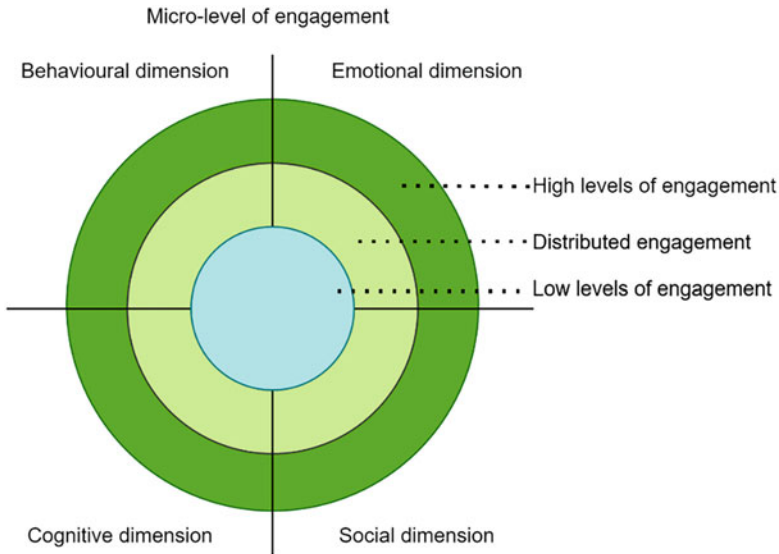

Conducting a needs analysis of digital device access at the beginning of a course is therefore vital, especially in ODDE, as this can help deepen understanding of any real or potential barriers to engagement (Goodall, 2018). It is also important to be cognizant of student ownership and use of devices that are not compatible with those used by the institution, as this can impact participation and engagement (Bond, 2019), as can rules at institutions for using certain apps within courses, especially in light of the GDPR in Europe (Bond, Marín, Dolch, Bedenlier, & Zawacki-Richter, 2018). Approaching this level could, for example, be beneficial when evaluating a mode of educational delivery, or institutional interventions aimed at increasing engagement and redeeming disengagement for specific groups of students.

---

## The Microsystem Level

The microsystem includes the students' immediate setting, for example, home or the classroom, and includes interaction with teachers, peers, authentic and worthwhile tasks (Kearsley & Shneiderman, 1998; Lim, 2004), the institution, family, and technology (Willis, Povey, Hodges, & Carroll, 2018). These external factors play a vital role in students' ongoing sense of connectedness, well-being, engagement, and success (Aldridge & McChesney, 2018). It is also important to consider the internal psychosocial influences on engagement, including motivation, skills, self-efficacy, well-being, and self-regulation (Bandura, 1995; Reschly & Christenson, 2012; Zepke, 2014), alongside their prior experiences with and level of acceptance of technology (Moos & Azevedo, 2009). This is also true of both teachers (Marcelo & Yot-Domínguez, 2018) and parents (Ihme & Senkbeil, 2017), whose attitudes to and skills with using technology can influence students (Krause, 2014).

There are (at least) two ways of approaching engagement within the microsystem level: a general level of engagement and momentary engagement. Sometimes, the general level is referred to as a macro-level (but this should not be confused with levels in the bioecological model above cf. Symonds et al., 2021). The general level (or macro-level) uses one data-point to reflect engagement in all subjects or across a full semester. The momentary (microlevel) engagement is used to reflect engagement in situ, and to capture fluctuations of student engagement in learning by comparing engagement on a day-to-day, lesson-to-lesson or activity-to-activity basis. A micro-level of engagement is useful when understanding how learning activities engage students, evaluate the effectiveness of learning designs, and can inform variations of engagement throughout the day, week, or across subjects. Conducting a Mixed Method Grounded Theory (MMGT) study, Bergdahl (2022c) approached teachers who regularly taught remote, hybrid, and distance courses across K-12 and adult learning. The teachers used a diary to reflect on students' level of engagement (by using a 1–5 scale, where one was low level and five was a high level of

**Fig. 2** Microlevel of engagement (Bergdahl, 2022c). Model viewed from above

engagement), as well as how they experienced student engagement online. Following an analysis of teacher perceptions of online engagement, a model of microlevel engagement was suggested (see Fig. 2).

Figure 2 suggests that there are qualitative aspects to engagement online, i.e., a student can display more engagement or less engagement (Bergdahl, 2022c). The highest level of engagement is visualized as three green layers. When engagement decreases, students rely on less engagement to succeed with their learning. As engagement decreases, the model reflects this with decreased green layers, for that dimension of engagement. For example, removing the outer layer in the cognitive dimension could manifest as attention being distributed (or shared) between listening to the teacher and focusing on non-learning-related activities. The teachers suggested that qualitative aspects include a degree of immediacy and responsiveness, ambivalence, having fragmented attention, and shallow learning (as opposed to deep learning). Ideally, all four engagement dimensions should be (fully) activated when immediacy and responsiveness are displayed. For example, students could be well-prepared with required equipment and materials, having completed their homework (behavioral dimension), exert the effort to master the subject, stay focused (cognitive dimension), display curiosity and aptitude to learn (emotional/affective dimension), as well as invite peers to share their reflections and contribute to a positive learning climate (social dimension). If engagement decreases in one dimension, the outer layer becomes inactive. If it decreases more, another layer is deactivated. When the inner layer is the only layer reflecting active engagement, then engagement levels are at their lowest. While students may have a desire to engage, they no longer participate in the learning activity, but may be fully engaged in

something else that is not education related. The engagement ‘in something else’, has led to disengagement from learning. It is also important to note that each indicator of disengagement may not have a natural opposite on the engagement scale (and vice versa) (Skinner, Kindermann, & Furrer, 2009); that is, disengagement is more than the lower levels of engagement in ODDE.

One problem with disengagement is that it may spiral into withdrawal, truancy, and dropping out of education (e.g., Tomaszewska-Pękała, Marchlik, & Wrona, 2020). Overlooking disengagement may lead to a failure to uncover critical insights that could redeem disengagement and support students to re-engage (Bergdahl, 2022d). If school students’ disengagement spirals into absenteeism and school dropout, for example, it has been shown that they have a hard time reentering and pursuing higher education (Department for Business Innovation and Skills, 2014).

While researchers have suggested that students could be engaged and disengaged at the same time (Fredricks, Reschly, & Christenson, 2019), further insights were needed. Building on the teachers’ diaries and interviews in the MMTG study, Bergdahl (2022c) then explored how disengagement and engagement indicators co-occurred when students were reported to engage at different levels (using the 1–5 scale) (see Fig. 3). Students estimated to engage at level 1 and level 5 do not necessarily express this in the same way. For example, students at level 1 were reported to display either disengagement behavior or a combination of indicators or engagement and disengagement. The combinations varied between the estimated levels of engagement (Fig. 3 visualizes level 1 and level 5).

The following abbreviations are used in Fig. 3: Beh, Cog, Emo, Soc for behavioral, cognition, emotion, social dimensions of engagement, and D is used to indicate disengagement: i.e., DBeh for disengagement behavior.

**Fig. 3** Teacher reported co-occurrence of engagement and disengagement indicators at levels 1 and 5 (Bergdahl, 2022c)

## Indicators of Student Engagement in ODDE

Each dimension of student engagement comprises many indicators (or facets) of engagement (see Table 1, adapted from Bergdahl et al., 2020; Bergdahl & Hietajärvi, 2022; Bond, 2020a, 2020b), as well as disengagement (see Table 2, adapted from Bergdahl et al., 2020; Bond, 2020a, 2020b), experienced as two related but distinctly separate constructs (Wang et al., 2017). Although many studies use three dimensions of student engagement— affective/emotional, cognitive, and behavioral (e.g., Fredricks et al., 2004) — we contend that social engagement plays an important role in student learning (Bergdahl, 2020; Bergdahl, 2022c, Bergdahl & Hietajärvi, 2022; Bond et al., 2021). Individual learning can be reflected using behavioral, cognitive, and emotional engagement, however, there is both individual and social knowledge-building (Stahl, 2006), as “social interaction provides essential cognitive resources for human cognitive accomplishment” (Paavlova et al., 2004, p. 546). As shown above, the MMGT study (Bergdahl, 2022c) identified quite other combinations of engagement co-occurring for highly engaged students. These could include immediacy (cognitive engagement), dedication beyond what was expected (emotional/affective engagement), and social withdrawal (emotional/affective disengagement). Social engagement was also particularly important during the COVID-19 pandemic (Bond et al., 2021) and should now be considered a critical fourth dimension of engagement (Finn & Zimmer, 2012; Linnenbrink-Garcia, Rogat, & Koskey, 2011; Wang et al., 2017), especially in ODDE contexts (Bergdahl, 2022c).

**Table 1** Example engagement indicators

Behavioral engagement	Cognitive engagement	Affective engagement	Social engagement
Effort	Critical thinking	Enthusiasm	Collaborating and interacting with peers
Study habits/homework completion	Self-regulation	Interest	Collaborating and interacting with teachers
Attending live lessons	Reflection	Satisfaction	Shared knowledge building
Assuming responsibility	Deep learning	Pride	Asking for help
Participation/involvement	Focus/concentration	Excitement	Caring for others

**Table 2** Example disengagement indicators

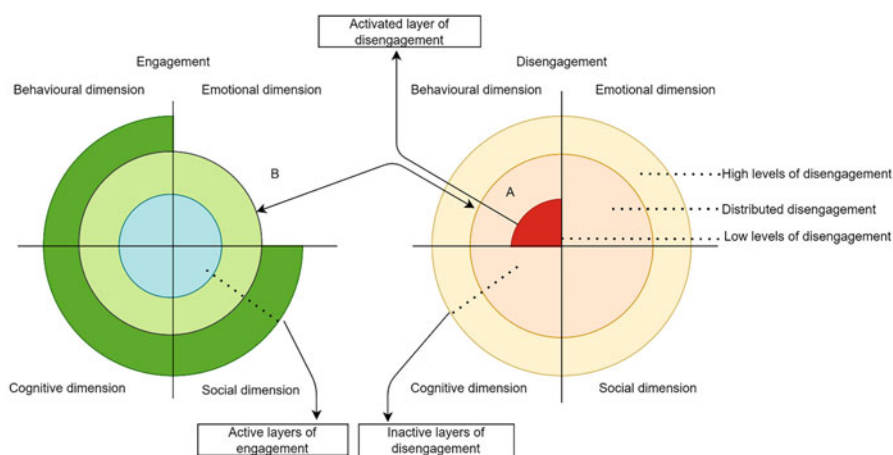

Behavioral disengagement	Cognitive disengagement	Affective disengagement	Social disengagement
Procrastination	Unwilling	Boredom	Feeling isolated
Absence	Apathy	Anger	Not feeling cared for
Giving up	Opposition/rejection	Dislike	Withdrawing
Poor conduct	Avoidance	Disinterest	Social anxiety
Task incompleteness	Unfocused/inattentive	Frustration	Indifferent or negative to interaction

Social engagement relates to students’ positive interaction with teachers, the learning environment, and peers, whereas affective engagement relates to students’ enthusiasm, satisfaction, and enjoyment in their learning, as well as their interest and sense of belonging. Behavioral engagement relates to positive conduct, such as attending synchronous lessons, and participating in discussion forums, completing work, and persistence, whereas cognitive engagement relates to deep learning strategies, self-regulation, and understanding.

Behavioral engagement is arguably the easiest domain to measure, as these are observable indicators, such as homework completion. However, a recent scoping review of 243 studies, focused on student engagement while using educational technology in higher education (Buntins, Kerres, & Heinemann, 2021), found that behavioral learning processes were measured as the second most frequent (36.6%,  $n = 90$ ), behind affective learning processes (57.3%,  $n = 141$ ). Nkomo et al. (2021) also argued that measuring only one or two dimensions of engagement in isolation prevents a more holistic and nuanced understanding of student engagement to occur. Engagement is influenced by – and within – the social context it occurs (Bergdahl & Bond, 2021). Thus, engagement is situation-specific, proactive, and reactive to external and internal stimuli and influence. When students display engagement and disengagement simultaneously (Bergdahl, 2022c; Fredricks et al., 2019), cognitive and affective/emotional dimensions of engagement may drive behavioral engagement (Reschly & Christenson, 2006). Bergdahl (2022c) suggested that there seems to be complex intra- and interdimensional influences between all engagement and disengagement dimensions, which seem to affect each other (see Fig. 4).

Figure 4 reflects how an external trigger activates one dimension of disengagement (in the figure, the behavioural dimension is activated) (Bergdahl, 2022c). Even though engagement and disengagement may co-occur, full engagement cannot coexist with full disengagement. Thus, an activated section of disengagement triggers deactivation of an engagement section. For example, an easily distracted

**Fig. 4** Interdimensional influences on student engagement

student enters class with an open mind and willingness to learn (emotional/affective engagement) but gets distracted by a mobile phone notification. Here, the student could display behavioral and cognitive disengagement (i.e., by actively choosing to engage in unauthorized uses of digital technologies). In other situations, students could withdraw from interaction and collaboration (social disengagement) due to social insecurities (emotional/affective disengagement).

The empirical results (Bergdahl, 2022c) support previously forwarded suggestions: that emotional/affective states can trigger engagement (Reschly & Christenson, 2006) and that student engagement is “non-linear reactions and pro-actions to internal (e.g., rising and falling fatigue, interest, hunger) and external (e.g., peer comments, teacher instructions) events” (Symonds et al., 2021, p. 14). Importantly, social insecurities were identified as preventing high levels of engagement, even for students who were identified as normally being highly engaged. It is proposed that the teacher’s social engagement with the (socially insecure) student could be a way forward to redeem social disengagement in class (Bergdahl, 2022c). After all, it has been found that indicators of engagement are not necessarily the ones that are significant when exploring disengagement, with the validation of a survey (Bergdahl et al., 2020) uncovering that social engagement, and social disengagement, were found to have the highest factor loadings (explanatory values) of all dimensions: indicating that the social dimension is critical for students in general, but disengaged students in particular.

---

## Open Questions and Directions for Future Research

This chapter explored how engagement can be approached at different levels, by providing examples of engagement at the meso- and microlevel, as well as how both the emotional/affective and social dimension of engagement are critical for student success. Considering the tradition of exploring engagement as a three-dimensional construct, we strongly encourage researchers to include the social dimension in future research, particularly as it relates to blended and online uses of synchronous and asynchronous collaboration tools, social networking tools, and assessment tools, which are areas that have been less researched in recent years (Bergdahl, 2022b, 2022c; Bergdahl & Gyllander Torkildsen, 2022; Bond et al., 2020, Bond et al., 2021). To further develop engagement theory, the relationship between bioecological levels, for example, how the social dimension of engagement relates to student sociocultural context, and the intra- and interdimensional dynamics between and within engagement and disengagement, across modes of online delivery, need to be further clarified.

We have also discussed how engagement is easier to identify than disengagement. However, one reason for this might be the amount of previous research that has focused on engagement, as opposed to disengagement, which would then have an influential effect on further research. Disengagement can both be used to describe maladaptive behavior and to measure what does not happen, and when learning online, disengagement may be challenging to observe. For example, measuring the

time to initiate work in an LMS has been shown to indicate procrastination, and decreased results and completion (Saqr et al., 2019). However, merely leaving the computer or not logging in, could also mean the computer was not working, or that the student collaborated with a peer and used another account. More research on student disengagement in online learning, that is not unidimensional, is therefore needed. Further to this is the effect of the mode of delivery (synchronous or asynchronous) in ODDE, which has been shown to affect how teachers facilitate student engagement (Bergdahl & Gyllander Torkildsen, 2022).

While we have proposed some entry points for future direction, we would also like to underline that much of the existing research has been conducted in higher education settings, while other educational settings (e.g., hybrid solutions for younger learners, blended learning in primary school, online learning in high school subjects other than STEM) remain largely overlooked (Bergdahl et al., 2020; Bond, 2020b; Bond, Bedenlier, et al., 2021; Bond et al., 2021). Further primary and secondary research that can shine a light on how engagement can be enhanced in these ODDE settings, and how disengagement can be realigned, is much needed.

## Abstract

This chapter considers the assessment of learning in open, distance, and digital education. To add new insights to the extensive body of relevant prior research literature, the chapter uses two “dimensions” of assessment to summarize and extend this work. The first dimension is assessment *function*. This includes traditional *summative* functions (“assessment of learning”), modern *formative* functions (“for learning”), and contemporary *transformative* functions (“as learning”). This also includes recently introduced *conformative* functions (“as *complianc*ance”) and *deformative* functions (“as *sabotage*”). The second dimension is *theory of learning*. This includes *differential*, *cognitive-associationist*, *cognitive-constructivist*, and *situative/sociocultural* theories. This chapter pays particular attention to how these dimensions interact with each other in complex (and often unanticipated) ways, and briefly considers how they interact with two other

## Introduction

Learning assessment takes on new meaning in open, distance, and digital education (ODDE). When education moves from classrooms to online settings, many traditional signals for what is valued are eliminated or transformed. Furthermore, as Conrad and Openo (2018) point out in the introduction to *Assessment Strategies for Online Learning*, assessment has become increasingly critical as all education (and particularly postsecondary education) increasingly moves away from credit hours and toward learning outcomes. Similarly, the introduction of open distance learning led to a paradigm shift away from grading and certification and towards performance-based assessment and learning outcomes. These developments have helped online designers, educators, and administrators appreciate how challenging and laborious it is to enact high-quality assessment in online settings.

In transitioning to online instruction, many educators and designers struggle to transform their informal assessment of classroom discourse to the discussion forums that are the primary form of interaction in many online classes. Likewise, many educators find that when offering formative assessment (i.e., assessment “for” learning), their relatively efficient whole class feedback sessions are supplanted by laborious individualized private feedback. When administering online summative assessments, (i.e., assessment “of” prior learning), many educators struggle to replace secure “closed-book” tests. Even when using expensive and intrusive digital proctors or requiring students to come to campus or a testing center, the nature of the Internet and the proliferation of so-called “homework help” websites raises suspicions about test scores in many online educational contexts.

This chapter is intended to help readers understand these and related issues and begin to address them in specific educational contexts. The chapter builds on two dimensions of assessment discussed in a prior consideration in Hickey and Pellegrino (2005). The first dimension is assessment *purposes/function* (e.g., *formative* vs. *summative*) while the second dimension is *learning theory* (i.e., *differential*, *cognitive-associationist*, *cognitive-constructivist*, and *situative/sociocultural*). Particular attention is paid to how the two dimensions interact with one another in online and open contexts; the chapter also briefly considers how these dimensions interact with item *format* (e.g., *selected response* vs. *constructed response*) and assessment *level* (i.e., *immediate*, *close*, *proximal*, *distal*, and *remote*) in online settings, as elaborated in Hickey, Harris, and Lee (in review). This consideration of assessment includes the entire range of fully online and open learning environments. This

includes massive open online courses (MOOCs) and other open courses as well as conventional for-credit online courses. This also includes both synchronous online formats, as well as cohorted “semi-synchronous” formats and fully asynchronous self-paced formats. This chapter does not consider assessment in traditional non-digital “correspondence-courses” using mail, broadcast radio, or television. And while developments such as computer-adaptive testing and new measurement models (e.g., Mislevy, 2018) are certainly relevant to this chapter, these are entire topics unto themselves that quickly move beyond the scope of the chapter. This chapter also does not directly consider online testing independent of online education (e.g., as in commercial achievement tests and tests for college admissions and professional licensure).

Given space limitations, this chapter does not attempt to exhaustively review the existing prior relevant research literature (sometimes characterized as “e-assessment”). Readers may wish to consult Mawhinney’s (2013) systematic review, which uncovered four main themes across 10 articles including perceptions, validity and reliability, student support, and benefits of e-assessment. Covering some of the same terrain, Wei, Saab, and Admiraal’s (2020) systematic review of the assessment of cognitive, behavioral, and affective learning outcomes across 65 studies uncovered 25 different approaches. Xiong and Suen (2018) reviewed the research literature on assessment in MOOCs, with a particular focus on the differences between the associationist “xMOOCs” and the connectivist “cMOOCs” described below.

---

## Assessment Purposes/Functions

Assessment scholars have traditionally focused on the intended *purposes* of assessment. For example, the 2001 expert consensus report from the US National Research Council distinguished between the familiar *formative* (“assessment for learning”), *summative* (“assessment of learning”), and *evaluative* (“assessment of programs”) purposes and cautioned against using assessments for multiple purposes (primarily because summative and evaluative purposes undermine formative purposes). Most considerations of assessment in online and open learning embrace these distinctions, and many embrace this concern.

The research literature on online formative assessment (sometimes “OFA”) is particularly vast. The integrated narrative review of higher education research by Gikandi, Morrow, and Davis (2011) uncovered themes such as Vygotsky’s zone of proximal development (ZPD) underpinning authentic OFA, OFA for individuals, peers, and teachers, threats to validity and reliability, and interactive formative feedback. Explicitly building on Gikandi et al., McLaughlin and Yan’s (2017) narrative review included 32 more recent studies, uncovered expanded delivery formats, detailed cognitive and emotional benefits of OFA, and expanded into K-12 contexts. The systematic review by Mahanan, Talib, and Ibrahim (2021) included 10 studies in higher STEM education and uncovered evidence of the tools used, themes used, outcomes assessed, practical skills, and assessment format. As discussed in Arnold (2016), one important issue in formative assessment is the

likelihood and consequences of cheating; Hickey and Harris (2021) argued that carefully “aligning” formative and summative assessments can discourage such practices by convincing students that completing formative assessments as intended is an ideal way to prepare for summative assessments.

Naturally, summative purposes are central to many of the considerations of assessment in online and open learning. Russell (2019) discussed the role of digital technologies in summative assessment in general while Russell (2018) discussed crucial issues of accessibility in this context. As elaborated in Hickey and Harris (2021) and Stadler, Kolb, and Sailer (2021), time limits are an important issue in online summative assessments. To reiterate, online test proctors are expensive and intrusive; they can also be bypassed by workarounds that proliferate online.

Meanwhile, numerous studies have shown that, despite honor-codes, many students will cheat on online assessments (e.g., LoSchiavo & Shatz, 2011); cheating is particularly likely when students assume that their classmates are doing so (Lang, 2013). Furthermore, the profusion of online “homework help” sites means that students can directly locate the answers to many items drawn from textbook publishers’ item banks (sometimes, thanks to the power of modern search engines, even after such item stems and answers are reworded). With all assessment formats, using time limits and ensuring that items are not directly searchable can maximize the validity of summative assessment scores as estimates of likely transfer of that knowledge to subsequent educational, professional, and personal contexts. With selected response format, including challenging “best answer” items or ensuring that students would have to search starting from the item responses (rather than the item stem) can further enhance the trustworthiness of scores on time-limited summative assessments.

While the evaluation of courses and programs is mostly outside of the scope of this chapter, summative assessment of learning certainly plays a role in doing so. Notable consideration of using assessment in evaluations is included in many of the chapters in Azevedo and Azevedo (2018).

## **Conformative, Deformative, and Transformative Assessment Functions**

Rather than assessment purposes, Hickey and Pellegrino (2005) argued instead for a sociocultural focus on assessment *functions* and a broader range of “learning” beyond the familiar individual behavioral or cognitive outcomes. As elaborated below, this makes it possible for a single assessment to serve multiple complementary functions. This also directs additional attention to the *consequences* of assessment practices.

To reiterate, the lack of classroom interaction means that assessments typically have a greater influence on the culture of education delivered online. Torrance (2012) demonstrated how a sociocultural perspective draws additional attention to the unintended consequences of assessment. Torrance insisted that “all assessment is formative, for student dispositions and self-identities as learners, as well as

knowledge and understanding, but not necessarily in a positive way” (p. 325). In addition to the three conventional functions above, Torrance acknowledged three additional functions, each of which takes on added meaning in online and open education. *Conformative* functions occur when instruction is overly aligned to narrow curricular aims that can be readily assessed. This concern is captured by Preston’s (2017) argument that competency-based approaches and the associated “mastery learning” movement of the 1980s was suppressed by the widespread embrace of constructivist theory in the 1990s, only to later resurge as “an existential threat to human learning” in the context of online education and training. Relatedly, Torrance cautioned about *deformative* functions, whereby assessment feedback and particularly low marks or scores undermine students’ affinity for and identity with the assessed knowledge.

Finally, Torrance (2012) encouraged the recognition of *transformative* functions, whereby the entire assessment practice and the social construction of judgment is made transparent and used to serve broader educational goals. Arguably, Torrance’s extensions shed new light on considerations of transformative functions. For example, Chaudhary and Dey (2013) discussed a “paradigm shift” away from content-based tests for grading and certification and towards a range of problem-based assessments following a broader governmental shift; for some, this is precisely the concern over conformative functions raised by Preston (2017). Alternatively, Ehlers (2013) discussed how new assessment practices might support “open learning cultures” via self-assessment, peer-assessment, “social information retrieval,” e-portfolios, and rubrics. Arguably, such discussions must be informed by explicit consideration of one’s underlying theory of learning, as discussed below.

## **Prior Learning Assessment**

Within summative functions, another prominent assessment function in online and open education is *prior learning assessment and recognition* (PLAR and sometimes just PLA) whereby assessments and/or work samples or other evidence are used to award course credit. The practice is particularly prominent in continuing education contexts and is particularly relevant for older students. Conrad’s significant contributions here should be noted, including two handbook chapters (2008a, 2008b), a special issue (2011), and an exploration in the context of MOOCs (2013). Other noteworthy considerations of PLA/PLAR are represented by the various chapters in Stevenson (2021). While not specifically about online and open learning, the journal *PLA Inside Out* was launched in 2012 and includes many relevant contributions.

---

## **Learning Theory**

Theories of learning are really theories of knowing, as one’s theory of learning must account for the nature of the knowledge that is learned. Together, assumptions about knowing and learning have profound implications for assessment. It is worth noting

that different considerations of learning theory use different labels and categories. The influential 1996 handbook chapter by Greeno, Collins, and Resnick contrasted *behavioral/empiricist*, *cognitive/rationalist*, and *situative/pragmatist-sociohistoric* perspectives, the US National Research Council (2001) contrasted *differential*, *behaviorist*, *cognitive*, and *situative*, while Hickey and Pellegrino (2005) contrasted *empiricist*, *rationalist*, and *socioculturalist* perspectives. These categories refer to “grand theories” (or “perspectives”), with each including more specific theories. Expanding beyond theory, Conrad and Openo (2018) summarized seven “philosophical orientations” in assessment, including *liberalism*, *progressivism*, *behaviorism*, *humanism*, *radicalism*, *cognitivism*, and *constructivism*, though without directly linking those philosophies to assessment practices. For reasons elaborated below, we have chosen to organize our discussion around *differential*, *cognitive-associationist*, *cognitive-constructivist*, and *situative/sociocultural* theories.

It is also worth noting that many practitioners and scholars pragmatically combine the second and third categories into an encompassing framework of “cognitive science” (e.g., Mayer & Wittrock, 1996) and that others similarly combine the last three (e.g., NRC, 2001). As elaborated below, we contend that working with different theories in the context of assessment calls for caution and careful consideration. Space limitations preclude elaboration beyond our points of departure from prevailing considerations; readers are referred to Conrad and Openo’s (2018, Chap. 4) and the NRC’s (2001, Chap. 3) extended discussions of learning theory and educational assessment.

## Differential Theories

Differential theories emerged in the early twentieth century within efforts to uncover stable intellectual traits like IQ. Differential theories eventually came to be seen as theories of measurement rather than theories of learning, because they assumed that knowledge is whatever tests measured. These theories were gradually supplanted by behaviorism (mostly in the USA) and Gestalt theory (mostly in Europe) and now sometimes go unacknowledged (e.g., Greeno, Collins, & Resnick, 1996; Hickey & Pellegrino, 2005). While differential theories of learning and the associated theory of knowledge transfer (i.e., general transfer of general skills) live on in “classical” education, such approaches are usually delivered in traditional classroom or home-school settings (though the curricula and assessments are increasingly distributed and accessed online). However, the elaborate statistical machinery that the development of differential theories left behind lives on in modern standardized tests (NRC, 2001). While such tests have greater consequences for K-12 and professional education than for higher education and open education, they are still quite influential.

We contend that differential theories live on in an additional way that may have even larger consequences for assessment in online and open education. Bruner (1996) convinced many that a great deal of teaching was driven by *folk pedagogy*, educators’ lay theories, or tacit assumptions about how students learn. While Bruner

identified four distinct folk pedagogies, he was referring mostly to K-12 educators (who have almost always had some formal preparation in pedagogy and usually some exposure to scientific theories of learning). Arguably, there are many educators and designers in online and open higher education who came to their role via disciplinary expertise and who have little or no training in scientific theories of learning. In our experience, many such educators embrace a theory of learning that is loosely consistent with differential theories. This is represented in tacit assumptions that (a) their assessments capture meaningful knowledge, (b) higher scores are better, and (c) higher scores are better by any means necessary absent cheating.

Our sentiments in this regard are captured nicely in the title of the study of computing education literature by Sanders et al., (2017), Boustedt, Eckerdal, McCartney, & Zander (2017) entitled “Folk Psychology: Nobody Doesn’t Like Active Learning.” We share their concern that higher education has broadly and enthusiastically embraced “active learning” (as well as “student-centered learning”) as a description of an instructional technique rather than a characterization of student learning. We also share their concern that many believe all active learning techniques are equally effective. As online and open learning are increasingly oriented to specific, measurable competencies, the way those competencies are gained in relationship to the way those competencies are assessed becomes more and more important.

To illustrate this nuanced difference, we invite readers to imagine two students who earn equivalent scores on performance assessments in an introductory online course. One student was taught by a part-time instructor whose evaluations (and continued employment) were based entirely on scores on assessments (whose coverage is known to the instructor) and student course evaluations. Such an instructor is likely to focus primarily on the content on those assessments to support high marks (and presumably stronger evaluations) while skimming or bypassing other content. In contrast, the other student was taught by a tenured faculty member who was more concerned with preparing students for subsequent courses and was not terribly concerned with student course evaluations. Such a faculty member would be inclined to cover all course topics equally and treat the performance assessments as “snapshots” of what the students learned. The second student likely learned more (and possibly a *lot* more), but that knowledge is not captured in the assessment scores. Our point here is that educators and assessors whose practice is not grounded in a viable scientific theory may tacitly embrace a “folk-differential” theory and assume that “learning” is whatever their assessments capture.

## **Cognitive-Associationist Theories**

Cognitive-associationist theories are rooted in and sometimes equated with behaviorism. But outside of K-12 education of students with special needs and the education of adults with profound disabilities, behaviorist theories have relatively little influence in contemporary education. Cognitive-associationist theories emerged when some leaders of the “cognitive revolution” (e.g., Anderson, 1980)

retained the core assumption of behaviorism that knowledge consists of organized structures of many small associations. This assumption and the corresponding concern with cognitive load support traditional “mastery learning” approaches and more contemporary “expository” approaches (i.e., expose students to content, give them practice, and test that knowledge). These approaches are widely used in MOOCs (typically with video and automated quizzes) and are sometimes referred to in that context as “instructivist” theories (e.g., Falkner & Sheard, 2019). Indeed, the term “xMOOC” (after the popular edX MOOC platform) was coined to distinguish instructionist MOOCs from the “cMOOCs” described below. Associationist theories underpin most (but not all) “competency-based” approaches that are widely used in online and open education, and which have significant implications for assessment in these contexts (e.g., Aram et al., (2019), Mödritscher, Neumann, & Andergassen, 2019).

Significantly for open and online learning, cognitive-associationist theories underpin most intelligent tutoring systems (ITSs). As illustrated by de Boulay (► Chap. 7, “Artificial Intelligence in Education and Ethics,” this volume), and Drachler (► Chap. 60, “The Rise of Multimodal Tutors in Education,” this volume), ITSs and artificial intelligence more generally have a prominent role in open and online learning. Associationist assumptions allow ITSs to use assessment evidence to maintain and constantly update a model of what each learner knows at a given time. When paired with a model of how learning about the topic typically/optimally progresses, ITSs are able to deliver instructional content that learners are presumably most ready to learn.

Because these theories assume that specific associations transfer relatively easily to new settings where they might be used, assessment of associationist learning is relatively unproblematic. In particular, selected-response items can be used to quickly and automatically assess whether students have formed those associations. But many assume that such item formats can *only* capture evidence of these more specific associations (e.g., Hirumi, 2014). However, selected response items, particularly when developed and vetted by professionals, can require relatively sophisticated understanding and reasoning to consistently answer correctly. This issue quickly exceeds the scope of this chapter (but see Mislevy, 2018). The key arguments for the purposes of this chapter is that (a) the relationship between theories of learning and assessment format is not as straightforward as many assume, (b) the concerns over selected-response formats primarily reflect cognitive-constructivist theories of learning, and (c) the efficiency and automation afforded by selected-response formats offer advantages that should not be ignored.

## Cognitive-Constructivist Theories

As argued in Greeno et al. (1996) and others, cognitive-constructivist theories are largely antithetical to associationist theories. Rather than specific associations, constructivist theories assume that knowledge consists of higher-order conceptual “schema” that the human mind (uniquely among animals) constructs when making

sense of the world. Constructivist theories (a) became prominent in the 1980s, (b) are still widely embraced by many cognitive scientists and educational psychologists, (c) encompass numerous more specific theories including socio-constructivist theories, (d) have long been a driving force in calls for “alternative” assessments and assessment reforms (e.g., Wolf et al., (1991), Bixby, Glenn III, & Gardner, 1991), and (e) motivated much of the explosion of interest in formative assessment ignited by Black and Wiliam (1998/2000). Arguably, this class of theories was tacitly embraced and taken for granted by many until situative/sociocultural theories started becoming prominent around 2000.

A great deal of the discussion of assessment in open and online education embraces cognitive-constructivist and/or socio-constructivist theories. In particular, the influential community of inquiry (CoI) framework “embraces deep approaches rather than surface approaches to learning and aims to create conditions to encourage higher order cognitive processing” and “represents a process of creating deep and meaningful (collaborative-constructivist) learning experience through three interdependent elements—social presence, cognitive presence, and teaching presence” (Garrison & Akyol, 2013, p. 106). Drawing directly from CoI and constructivist theory, Conrad and Openo (2018) devoted an entire chapter to defining constructivist “authentic” assessment. They speak for many when they assert that:

Authentic assessments, especially in blended and online learning contexts, encourage students to take a deep approach to learning, provide necessary alignment for faculty to better determine the quantity and quality of student learning, and provide institutions with the evidence necessary to respond to external pressures regarding their ability to measure student learning outcomes. (p. 55)

Furthermore, many agree with Conrad and Openo’s characterization of all selected response formats as “inauthentic” and likely to encourage cheating (p. 101).

It is important to note that measurement theorists (e.g., Messick, 1994) have long pointed out that authentic and alternative assessments are “task-driven” (rather than “construct-driven”). This means that they may introduce “construct-irrelevant easiness” and “construct-irrelevant variance” which introduce significant threats to the validity of the resulting evidence to support claims of achievement and expertise. Such assessment may be capturing evidence of what students “did” rather than what they will be able to “do” in subsequent contexts. Put differently, such assessments may inadvertently capture evidence of “near-transfer” or even “zero-transfer” rather than actual transfer of problem-solving skills or “far-transfer.” In terms of assessment “levels” described in Hickey and Pellegrino (2005) and Hickey et al. (in review), special interpretive care is needed to ensure that performance assessments are functioning at the *proximal* or *distal* level rather than the *immediate* or *close* level and that portfolio assessments are assigned, completed, and scored in a manner that provides valid evidence of future performance.

Pragmatically speaking, so-called “authentic” online assessments (both formative and summative) often call for relatively extensive individualized private feedback. This is in part because it is challenging to replace the traditional “whole class”

feedback session that can be quite efficient in physical settings. Furthermore, the subjective nature of scoring such assessments can lead to corrosive arguments with students over grades and marks. This feedback and these arguments can take away precious instructor time for more efficient public instructor interaction and are sources of online instructor “burnout” (see Conceição & Lehman, 2011). As illustrated by the computer-adaptive assessments developed by the *Smarter Balanced Assessment Consortium* (SBAC, 2021), new psychometric models and technologies (e.g., Mislevy, 2018) now allow automated multi-part performance assessments. Nonetheless, such assessments require specialized expertise and are extremely expensive to create. While such investment may be manageable at the massive scale of MOOCs, these approaches are likely beyond the reach of most online educators for the foreseeable future.

### **Situative/Sociocultural Theories**

This fourth category of theories is rooted in the work of the early Soviet theorist Vygotsky (1934/1987). We emphasize the situative strand of this broader class of sociocultural theories to highlight the perspective that emerged from the Institute of Research on Learning in Palo Alto, CA, from 1986 to 2000 (e.g., Greeno, 1998). We do so to distinguish this category of theories from the work of many socio-constructivist assessment theorists who also reference Vygotsky (e.g., Conrad & Openo, 2018) and have helped popularize situative/sociocultural theories among proponents of open and online education. While not explicitly citing the influence of situative theories, Siemens’s (2005) new theory of *connectivism* embraces many of the same assumptions while also addressing the massive influence of the Internet on the very nature of knowing and learning. The large influence of connectivism in open learning was signaled by the introduction of the term “cMOOC” to distinguish this approach from the more expository xMOOCs described above.

According to Greeno et al. (1996), assessment within this category of theories means “assessing participation in inquiry and social practices of learning,” “student participation in assessment,” and “design of assessment systems” (p. 39). Some considerations of e-portfolio assessment explicitly embrace situative theories (e.g., Batson, 2011; Habib & Wittek, 2007). From our perspective, the most important implication of situative theory is the way Greeno’s (1998, p. 17) “situative synthesis” reconciles the difference between individual activity and social activity. Cognitive-associationist and cognitive-constructivist theories reconcile these differences by characterizing social activity as aggregations of individual activity. However, this results in two incompatible characterizations of social activity, neither of which are capable of capturing the manner in which situative theories assume that knowledge is fundamentally “distributed” (i.e., “situated”) in social, cultural, and material contexts. In contrast, the situative synthesis uses a “dialectical” approach to resolve the difference between individual and social activity. From this perspective, the way that the human mind processes information (as in associationist theories) *and* the

way that humans make sense of the world around them (as in constructivist theories) are both “special cases” of socially situated activity.

As argued in Hickey and Pellegrino (2005) and Hickey (2015), applying the situative synthesis to assessment and testing similarly makes it possible to characterize the entire range of assessment practices as special cases of socially situated activity. Doing so makes it possible to frame formative and summative educational assessment as specialized forms of discourse between educators and students and to frame external achievement tests as a specialized form of discourse between disciplinary experts and test takers. While these forms of discourse are certainly peculiar (if not downright bizarre), they serve narrow and potentially necessary functions in many if not most educational ecosystems. As outlined in Hickey and Harris (2021), this also provides a coherent framework for “aligning” formative and summative functions across increasingly formal levels of assessment and makes it possible to coherently assign formative and summative functions to the same assessment. This means, for example, close-level assessments can serve a summative function for prior engagement while also serving a formative function for the same learner’s understanding of targeted concepts.

---

## Conclusion

In summary, this chapter organized selected research relevant to assessment in open and online education around the dimensions of purpose/function and learning theory. We acknowledge that this is a novel way of organizing research and insights about assessment. We further acknowledge that this organization is rooted in our underlying embrace of situative theories of knowing and learning. We contend that this organization reveals crucial interactions between these dimensions that may undermine more specific goals of assessment practices as well as the broader enterprise of education. While situative theories of knowing and learning are widely appreciated by many in open and online learning, there is relatively little consideration of them within considerations of assessment beyond the work summarized above. Our arguments about the situative synthesis are not widely known or appreciated in the assessment literature more broadly.

The primary implication of our position is one of caution regarding constructivist arguments in support of “authentic” summative assessment formats and against “traditional” selected-response formats. Summative performance and portfolio assessments can generate unsustainable demands for private instructor-student interaction and take time away from more effective formative assessment and more efficient public instructor interaction. We suggest that selected-response assessments that are well-constructed, time-limited, non-searchable, uncompromised, and automatically scored can efficiently provide valid estimates of the extent to which learning in online and open courses is likely to transfer to subsequent educational, personal, and professional contexts. We close by suggesting that this argument presents a particularly promising direction for future research on assessment in open and online education.

## Abstract

Higher education course design is moving increasingly toward constructivist, collaborative approaches for higher-order learning. A community-based approach to learning fits both this type of pedagogy and preferred learning outcomes related to critical thinking and metacognition. This is particularly necessary when moving such learning online, and the need for a community is even more important for engagement and motivation than in-person learning, where community and connection is often created organically. Online learning communities can be effectively created using the community of inquiry theoretical framework, as it intentionally makes space for learners to express their teaching, social, and cognitive presences. To support the design of effective online learning experiences, how each presence fits into the constructivist and inquiry-based approaches is explained in this chapter. As well, applications are suggested. Finally, assessment approaches are provided that are in line with the tenets of constructivism, inquiry-based learning, and hence the community of inquiry.

**Introduction**

This chapter provides an overview of a community-based, learning-focused approach to the design, delivery, and assessment of online learning. This learning focus is supported by creating a learner-centered environment, offering dedicated support to those wishing to learn, and motivating those feeling less willing and/or less able to learn. One way to create such a learning environment is by creating community through strong facilitation and engagement processes, supported by effective information and communication technologies.

According to Bolliger, Shepherd, and Bryant (2019), faculty report that a sense of community in online courses drives both student engagement and satisfaction. Findings from 344 survey responses identify that 88% strongly agreed that community was important, 66% said community extends beyond classes, and only 37% said that there was a system in place at their institution to help online students build community (Berry, 2019). This gap for building effective community online can be filled by the most researched approach to online learning in community: the community of inquiry (CoI) theoretical framework for online and blended learning (Garrison, 2016). The CoI is now supported by two decades of research and practice and provides guidance and direction to create community that promotes not only engagement and satisfaction, but also higher-order learning, as is needed in higher education. Using constructivist, collaborative processes, this framework has been identified, of all the new techno-pedagogical education delivery models, as the model that has yielded the greatest impact in the field of distance education (Bozkurt, 2019). As the latest UNESCO report indicates, to impact the current global human rights issues, pedagogy must be rooted in cooperation and solidarity, with participants collaborating to meet this challenge (International Commission on the Futures of Education, 2021).

---

**The Roots of Online Learning**

Emerging technologies have changed the ways in which we bridge the distance between teacher and learner. From a distance education perspective, these changes also carry forward from earlier generations of distance education the unique roles for learners and teachers, broader opportunities for access to learning, and additional requirements for learner self-direction (Cunningham, 2010; Shearer et al., 2020). These enduring characteristics of distance education create a type of online learning that is pedagogically distinct from more traditional, lecture-based teaching delivery in universities. This pedagogical distinction is discussed later in this chapter in reference to the community of inquiry theoretical framework (see Fig. 1), which is

**Fig. 1** The community of inquiry model. (Attribution to D.R. Garrison, University of Calgary, M. Cleveland-Innes, Athabasca University, N. Vaughan, Mount Royal University.)

used to guide the creation of high-quality, engaging online, and blended learning environments.

The following suggestions for online design describe what is required for active, engaging online learning activities (Ward, Peters, & Shelley, 2010). This applies whether the course is moving online from traditional, lecture-based, in-person delivery or arising from open and distance education. The differences, then, exist in the needed transition from current delivery models to high-quality, technology-enabled online and blended learning (Cook, 2020), described briefly at the end of this chapter, and discussed in detail other places in this book.

According to Hodges, Moore, Lockee, Trust, and Bond (2020), “what we know from research is that effective online learning results from careful instructional design and planning, using a systematic model for design and development” (p. 4). This can be considered as the central imperative of quality learning experiences in any online learning design. Broadly defined, quality sets out what counts as excellence in reference to preidentified standards. What counts as quality in a

complex, community-based, online learning environment often depends upon professional subjective interpretations of these standards, rather than empirical evidence (Bektashi, 2018; Nolan-Grant, 2019; Ossiannilsson, 2020; Rovai, 2002).

Further, online quality standards rest on the definitions of community and pedagogy. Where social learning theories are seen as foundational, required, and/or an enhancement to online learning, the development of online learning communities are part of a high-quality online learning experience (Zimmerman, Altman, Simunich, Shattuck, & Burch, 2020). This community-based experience moves the online course (and program) experience beyond mere content instruction and achievement of predetermined learning outcomes. Attempts to create this experience online occurs through supported and facilitated activities such as social interaction, meaningful engagement, and shared metacognition. These aspects of online learning design were well represented in Garrison's (2016) model of online and blended communities of inquiry.

---

## The Community of Inquiry Theoretical Framework

Originally created in the late 1990s in support of early online design with text-based discussion (Garrison, Anderson, & Archer, 2001), the community of inquiry (CoI) theoretical framework shone significant light on the need for interaction, collaboration, and connections online. Significant developments have occurred in distance and online education since the original conception of the CoI. Over the last two decades, the CoI framework has been tested, applied, and adjusted for use across delivery methods and disciplines (Befus, 2016; Bozkurt, 2019; Castellanos-Reyes, 2020). The CoI framework is known to be (1) highly effective in the learning environment for which it was originally designed; (2) a good fit with further developments through emerging technologies for learning; and (3) compatible with blended as well as online learning (Le Roux & Nagel, 2018).

**Explaining the CoI framework.** The CoI framework “represents a collaborative approach to inquiry that fuses personal reflection and shared discourse for a deep and meaningful learning experience” (Garrison, 2016, p. 53). The framework rests on the assumption that engaging, meaningful, educational experiences, leading to deep learning outcomes, occurs at the convergence of three presences: *cognitive*, *teaching*, and *social presence*. Presence is the human orientation to the current environment and experience. It is defined, in this application of online learning design, as a required state of alert awareness, receptivity, and connectedness to the social, cognitive, emotional, and physical workings of all individuals in reference to the collective group in the context of their learning environments (adapted from a definition by Rogers & Raider-Roth, 2006, p. 1).

These presences emerge through learner-centered teaching and learning. Both presence and learner-centered approaches produce a more active learning climate, as suggested by foundational thinkers in education (Dewey, 1933; Vygotsky, 1997). Using the collected, shared individual experiences as a significant point of reference in the construction knowledge structures is critical to both learning processes and

learning outcomes. It can be considered a deliberative weaving of co-constructed understanding into individualized tapestries of knowledge. Beyond content or subject-matter expertise, engaged and active learning is seen as a key opportunity for developing competence in higher-order thinking skills (Garrison, 2016), which leads beyond content knowledge into high levels of intellectual development.

In short, the CoI requires that the learning process is explicit through meaningful engagement opportunities, where students explore multiple types of learning materials, rather than teacher-centered direct delivery of content. Drawing from the early direction of Schwab (1966), this teaching practice moves learners deliberately through active inquiry processes. According to Schwab, the active inquiry process starts by using questions and problems to stimulate thinking about the subject. When ready, teachers can invite learners to synthesize by identifying overlaps and relationships between concepts or variables. As learners advance through foundational knowledge in a particular subject, questions and/or problems are presented; learners are encouraged to discover the path to answers themselves. As knowledge and learning skill develops, learners identify the questions, problems, methods, and answers in the same subject themselves; the teacher provides guidance to shape, correct, and verify knowledge claims and facilitates learning.

**Creating a community of inquiry.** This multilayer pedagogical process is supported first by creating community through the original three presences of the CoI framework (social presence, cognitive presence, and teaching presence). These three presences are defined below. Figure 1 outlines the three presences and their respective subcategories, the binary overlaps, and the convergence on the educational experience.

**Teaching presence**, rather than “teacher presence,” is so named to allow for teaching functions for both teachers and learners in a community of inquiry. While the teacher, or instructor of record, plays a leadership role, teaching presence is carefully defined to encourage and allow for peer teaching. To become an effective online teacher, one must deconstruct traditional teaching presence or traditional assumptions about effective teaching and learning, and rebuild it in reference to online teaching and learning (Richardson & Alsup, 2015).

The central organizing activity of the CoI is teaching presence created by the integration of design and organization of a course and its community, facilitation of learning, and direct instruction of content. In these activities, the teacher who is instructor of record or the temporary peer-teachers who emerge in the course at varying times for various purposes provide support for the facilitation and direction of cognitive and social processes. The generation of satisfying learning experiences among students is noted in empirical studies (Zhu, Herring, & Bonk, 2019). This satisfaction is also linked to other presences in a significant way. For example, Shea and Bidjerano (2009) report that the learner experience of teaching presence affects the emergence of social presence.

**Social presence**, in its most current definition, is defined as “the ability of participants to identify with the community (e.g., course of study), communicate purposefully in a trusting environment, and develop interpersonal relationships by way of projecting their individual personalities” (Garrison, 2009, p. 352). Notions of

affective engagement that were part of the original definition of social presence (Garrison et al., 2001) are absent in this newer definition of social presence. This could be attributed to the increased attention being given to emotional presence, not yet identified as a fourth presence but in discussion as a critical element of CoI development and experience (Cleveland-Innes & Campbell, 2012; Dell, 2021; Lehman, 2006; Loderer, Pekrun, & Lester, 2018).

This definition of social presence mediates design thinking about student social activity, distinct from academic activity and in combination with it. The subcategories identify the design elements required, created through pedagogical processes, that will allow each respective presence to emerge. For social presence, these categories are personal expression, group cohesion, and open communication. Personal expression is expected to go beyond dialogue and interaction about course activities and content, an important part of the overlap between cognitive and social presence and between social presence and teaching presence. Personal expression means encouraging students to go beyond dialogue strictly about course activities and content into personal reflections and the presentation of self.

Group cohesion is fostered through the explicit identification and mutual agreement regarding shared purposes and the communal learning space. It emerges when represented by a sense of belonging and acceptance where individuals connect and have an affinity for other individuals in the group. This can be seen where meaningful, if short-term relationships develop, and expressions of a sense of trust and safety are noted. Open communication, the third subelement of social presence, supports both personal expression and group cohesion by allowing time and opportunity to express oneself freely and connect with others. This opportunity can be created in asynchronous virtual meeting places or in synchronous sessions.

**Cognitive presence** is defined as “the extent to which learners are able to construct and confirm meaning through sustained reflection and discourse in a critical community of inquiry” (Garrison et al., 2001, p. 11). While not named as academic work in the CoI, it is in this space that academic debate, deliberation, and discussion occur (Cleveland-Innes & Emes, 2005). In the overlap with social presence, discourse is supported in the course design with multiple opportunities to critically reflect and share personal meanings and applications derived from the knowledge constructed.

Cognitive presence rests on four distinct but overlapping subcategories of practical inquiry: triggering events, exploration, integration, and resolution. A triggering event begins the process of inquiry through stimulation and presentation of information, ideas, or questions new to the audience. It requires attention and thought but needs less effort than the other three categories. Exploration provides the opportunity to examine new material closely from multiple perspectives. Integration of new material is the process of constructing structures and alignments of new information, on its own and in relation to other material, to the point of deep and meaningful understanding. The fourth subcategory, called resolution, brings the reason for covering the material, answering the question, or solving the problem to a logical conclusion. These pedagogical processes supporting the resolution phase of cognitive presence brings closure, whether temporarily or as a relative, momentary

**Table 1** CoI presences and conceptual subcategories

Presence	Subcategories
Social presence	Open communication Group cohesion Interpersonal expression
Cognitive presence	Triggering event Exploration of concepts and issues Integration with current knowledge and context Resolution to close inquiry
Teaching presence	Design and organization Facilitation of discourse Direct instruction

cessation of the topic at hand. The resolution phase is the temporary but definite closure of inquiry, which often ends with the identification of questions still to be answered and issues yet to be addressed.

These three presences represent the original, base model of the CoI. A fourth presence, *emotional presence*, has been suggested (Cleveland-Innes & Campbell, 2012; Stenbom, Jansson, & Hulkko, 2016). Emotional presence encapsulates the affective side of learning, originally identified as part of social presence. The element of emotion and learning has been further identified as something that permeates the model (Majeski, Stover, & Valais, 2018; Swan, 2019; Williams, 2017) (For a brief overview of the subcategories of individual presences, see Table 1).

## Community-Based Design and Delivery in Three Presences

Over time, the identification and accurate measurement of the framework requirements has provided (1) a more detailed examination of the original three presences; (2) the addition of emotional presence; (3) how the presences relate to one another; and (4) how they may be applied in practice (Arbaugh et al., 2008; Cleveland-Innes, Stenbom, & Garrison, manuscript in preparation). This identification and measurement provide empirical evidence to support design and delivery applications.

Establishing deep and meaningful learning requires activity in all four components. However, Akyol and Garrison (2011) report evidence that cognitive presence requires a balance among cognitive, social, and teaching presence. Direct instruction and facilitation of cognitive activity, beyond just explaining content, is a key role for teachers using this framework. This corroborates Archibald's (2010) evidence that teaching presence and social presence explain 69% of the variance in cognitive presence. While it is beyond the scope of this chapter to consider all relational aspects of the presences, the information below identifies application suggestions specific to individual presences with implicit consideration of the other presences at play.

**Applied teaching presence.** Table 2 provides examples of teaching presence and applications for design and delivery. In preparing a course to be delivered as a

**Table 2** Teaching presence indicators and applications for design

Subcategories	Indicators	Applications
Design and organization	<p>I clearly communicate important due dates/time frames for learning activities</p> <p>I clearly communicate important course goals, including explicit teaching about collaborative constructivist learning, design, and metacognitive goals</p> <p>I clearly communicate important course topics</p> <p>I provide clear instructions on how to participate in course learning activities, including explicit teaching about collaborative constructivist learning design</p>	<p>Ensure all course activities and deadlines are available online and send reminders via text, twitter, and encourage peer support check-ins</p> <p>Provide an explicit syllabus with clear course learning objectives and with links to materials</p> <p>As needed and allowed via institutional regulation, provide regular review and adjustment of course goals and content</p> <p>Make CoI design and delivery requirements explicit to students</p>
Facilitation	<p>My actions reinforce the development of a sense of community among course participants</p> <p>I help to identify areas of agreement and disagreement on course topics in a way that facilitates learning</p> <p>I encourage course participants to explore new concepts in my course</p> <p>I provide opportunities for learners to take on the role of teacher when the opportunity arises</p> <p>I keep course participants engaged and participating in productive dialogue</p> <p>I am helpful in guiding the class toward understanding course topics in a way that helps students clarify his/her thinking</p>	<p>Link course content and students' ideas through text and talk</p> <p>Brainstorm and agree to interaction and activity norms</p> <p>Acknowledge and encourage participation in structured and self-directed learning activities</p> <p>Ask questions</p> <p>Allow/assign presentation</p> <p>Share your own analysis and interpretation of course content</p> <p>Acknowledge and redirect as needed using humor, encouragement, and excitement</p>
Direct instruction	<p>I provide feedback in a timely fashion</p> <p>I provide feedback that helps learners understand strengths and weaknesses relative to the course goals and objectives</p> <p>I help to focus discussion on relevant issues in a way that helps students to learn</p>	<p>Open course segments and content areas with advanced organizers that prepare students for next steps</p> <p>Summarize course segments and content areas with reference to activities and individual student contributions</p> <p>Validate student actions and guide with direction and inquiry</p> <p>Maintain presence through regular and frequent interaction with individuals and group</p>

Adapted from Cleveland-Innes, 2019, p. 93

community of inquiry, the design and organization subcategory of teaching presence is enacted. Key to this phase of the design are openings for students to offer suggested adjustments to the course. The choice of learning materials, pedagogical

processes that include both teaching and learning activities, pacing, and assessment are critical elements of teaching presence. It is in the purview of the instructor of record to choose how much of each design and organization component will be handled individually by the teacher and what, and how much, responsibility for each component may be shared with the students. Feng, Xie, and Liu (2017) suggest that “different levels of presence should be emphasized at different stages of the course” (p. 181). This is also true for differing amounts of student input into the design and organization of the course over time. Teachers that observe learners’ behavior and engagement continuously are able to adjust the learning design according to the emerging learner behavior patterns.

Facilitation in this framework is focused on supporting the learning process; learning, to be thought of as a verb in this case, indicates actions related to the process of learning or transformational engagement. In reference to teaching presence in the CoI theoretical framework, facilitation “ensures social presence is established among community members and, in turn, that cognitive processes are directed to personally meaningful and educationally worthwhile outcomes” (Vaughan, Cleveland-Innes, & Garrison, 2013, p. 37). For example, it is important that the need for social connections is made explicit and important by the teacher. This can be done, for example, by telling students about each other and drawing connections between what students are doing or saying.

Direct instruction concentrates on content as the subject matter of the course. Here, learning outcomes are the focus and the learning definition is a noun: knowledge or skill gained from the process of learning. Providing an explicit syllabus that outlines well-articulated learning outcomes is a key to supporting the acquisition of learning outcomes; it is a shared map for every member of the community. These outcomes are then linked to assignments or any activity that engages students in ways that move them toward achieving those outcomes.

**Applied social presence.** Table 3 demonstrates topics of focus for social presence in reference to the subcategories that support the definition of social presence. The indicators provide the student orientation to learning adherents of the CoI required in each subcategory of social presence. Ways to apply these goals are identified in the table. These application suggestions are derived from instructor feedback at development workshops, research literature about teaching and learning, and the authors’ experiences designing and teaching with the CoI framework.

For all presences, and their subcategories, explicit discussion of the hopes and expectations in each category is essential. Instructors should ideally start each course with a review of required learning outcomes and the requirements of each element in the community of inquiry. They should allow time for student reaction about the CoI and feedback regarding clarification or concerns. It is important that instructors set operational norms for community activity such as informal rules for sessions.

Personal expression is the offering of salience of oneself and, in return, expecting to see salience of the other person with whom one is engaged in the interaction (Kreijns, Van Acker, Vermeulen, & Van Buuren, 2014). This can begin with introductions in an online café space, populated first by the instructor and requested of students. Instructors can start with a pre-course survey asking students to identify

**Table 3** Social presence indicators and applications for design

Subcategories	Indicators	Applications
Personal expression	<p>I create opportunities to allow learners to form distinct impressions of some other course participants</p> <p>I create opportunities for students to get to know other learners to create belonging</p> <p>I try to model online or web-based communication as an excellent medium for interaction</p>	<p>Provide and support online spaces and structured activities that encourage and support social interaction</p> <p>Facilitate relationship development among students through group activities and assignments</p> <p>Respond in a timely and personal way to student posts, emails, and other digital communications</p>
Open communication	<p>I create opportunities for learners to develop comfort about interacting with other course participants</p> <p>I try to ensure learners feel comfortable conversing online or in person in my course</p> <p>I work to ensure learners feel comfortable participating in course discussions</p>	<p>Discuss social presence, its value to learning, and set norms for social and academic interaction</p> <p>Review and discuss course climate as it evolves</p> <p>Encourage, validate, and support all students in the presentation of thoughts, feelings, and interpretations</p>
Group cohesion	<p>I work to ensure learners feel comfortable disagreeing with other course participants while still maintaining a sense of trust</p> <p>I work to ensure learners feel their point of view is acknowledged by other course participants</p> <p>I create to ensure that online or in-person discussions can help learners to develop a sense of collaboration</p>	<p>Provide opportunity for individuals to present their ideas, engage in interaction one to one, and work and interact in small and large groups</p> <p>Discuss, work toward consensus, and continue to verify and adjust group norms during the course</p> <p>Use deliberative dialogue principles that include acceptance and validation of everyone's ideas in group norms</p> <p>Make explicit the value of deliberative dialogue and collaborative learning</p>

Adapted from Cleveland-Innes, 2019, p. 94

their background in the subject matter, if any, and their own individual goals for completing the course – both the activity goals and the completion goals. Instructors should acknowledge and validate text or spoken personal expressions that students offer, noting similarities in geographic or occupational places.

The second subcategory of social presence, open communication, is both required for and fostered by personal expression. Open could be seen here as an euphemism for accepting and inclusive. It is represented by actions and opportunities for “continuing a thread, quoting from others’ messages, referring explicitly to others’ messages, asking questions and getting feedback, complimenting or expressing appreciation, and expressing agreement” (Kreijns et al., p. 9). As suggested in the organizational literature, open communication allows community members to interact with each other and share experiences and information (Cherrington, 1989).

Group cohesion is the extent to which the students in a CoI are connected to one another. Like all sound structures, physical or social, the strength of the system or structures rests on the strength of the connections among the elements. Cohesive groups share a common purpose, and all participate in appropriate and supportive ways. Conflict is dealt with respectfully and openly and is accepted as a normal part of the human experience. Members can express feelings, share the leadership of the group, and operate in a space where the rules of operation are transparent, explicit, and agreed upon.

**Applied cognitive presence.** Table 4 offers application suggestions for design and delivery in each of the four subcategories that define cognitive presence. The indicators represent the teacher's observational perspective of student activity and interaction representing cognitive presence in each of the four subcategories. Design and delivery opportunities can support these elements of cognitive presence. The application suggestions provided here are derived from feedback at development workshops, literature reviewing online learning, and the first author's experience designing and teaching with the CoI framework.

In the first consideration of designing a trigger event, inquiry learning requires provision of a focal point for cognitive activity. Questions or problems are two examples of such triggers that stimulate curious attention to course content. "The instructor can bring readings, and other self-regulated student activity, to life by bringing attention to key points. This can be done with visuals, stories, questions, problems and presentation of information" (Vaughan et al., 2013, p. 40).

Cognitive presence will continue where design and delivery engages students in exploring the content reviewed in the triggering event. Problems and questions may be explored, by the individual and/or in the community, through reflection and discourse. Integration describes the accommodation and assimilation of the new insights into existing understandings and principles of practice. Resolution refers to the closure of the inquiry for that section or content, problem, or question. Often a temporary situation, this process includes providing a summary, feedback, and suggestions about what else needs to be considered.

Although listed and presented in a linear fashion, these four subcategories of cognitive presence can occur in almost any order. For example, resolution can cause a return to any of the three other places of practical inquiry. Also, part of design is determining how much time to spend in, for example, triggering thought about seminal concepts in a course as opposed to requiring exploration of the topic or integration with other topics and, finally, resolving the issue or solving the problem.

**Applied emotional presence.** According to Lehman (2006), "Distance education researchers are beginning to incorporate into their research the idea of the role of emotion in creating presence and are influencing the direction of the field" (p. 13). Now seen as a recent rendition of distance education, online learning research identifies the value of emotion in learning in the design and delivery of blended and online learning (Cleveland-Innes & Campbell, 2012; Dell, 2021; Majeski et al., 2018).

Teaching with emotional presence involves encouraging learners to engage with understanding, acceptance, and transparency about their learning-related emotion and that of others. In this way, negative emotion can be minimized as a deterrent to

**Table 4** Cognitive presence indicators and applications for design

Subcategories	Indicators	Applications
Triggering event	<p>I encourage exploration and motivation to explore content-related questions</p> <p>I integrate course activities that pique students' curiosity</p> <p>I pose problems and question prompts that increase student interest in course content</p>	<p>Share your passion and points of interest in reference to the subject matter and everyday life</p> <p>Use varied and unique materials and approaches to engaging students with learning material</p> <p>Use problem-based learning processes that support engagement and higher levels of intellectual development</p>
Exploration	<p>I facilitate online discussions in a way that helps students appreciate different perspectives</p> <p>I create opportunities for brainstorming and finding relevant information that helps learners seek resolution to content-related questions</p> <p>I provide a variety of information sources to help learners explore problems posed in my course</p>	<p>Provide opportunities for application of knowledge outside the class environment</p> <p>Offer opportunity for peer facilitation of forums exploring new topics</p> <p>Provide opportunities to search for content outside course materials</p> <p>Offer library orientation and search skills training for valuable subject-related resources</p>
Integration	<p>I provide opportunities for reflection on course content and discussion that help learners to understand fundamental concepts</p> <p>I create opportunities for learners to combine information to explore questions raised in course activities</p> <p>I select learning activities that help learners to construct explanations/ solutions</p>	<p>Student-driven material choices allow for high engagement with content-related integration and synthesis</p> <p>Self-directed, actively created learning assignments provide students the opportunity to master and apply content in creative ways</p> <p>Discussion and application of knowledge is facilitated as a regular part of course activities</p>
Resolution	<p>I create course components to build conditions for learners to describe ways to test and apply the knowledge learned</p> <p>I create opportunities for reflection that helps learners apply the knowledge created in my course to his/her work or other non-class-related activities</p> <p>I provide opportunities for learners to develop solutions to relevant problems that can be applied in practice</p>	<p>Respond in a timely fashion to provide synergy between posts and individuals as course segments and topics are summarized and closed</p> <p>Course activities and assignments require reflection, application, and critique of course material</p>

learning and used where possible as a motivation for learning. Table 5 provides introductory possibilities for leveraging emotion in support of learning. In the teachers' CoI self-assessment, emotions identified empirically as part of each sub-category within the presences are outlined.

**Table 5** Emotional indicators and applications for design

Subcategories	Indicators	Applications
Related to teaching presence	In my role as instructor, I demonstrate (role model) emotion in my presentations and/or when facilitating discussions, online or in person I acknowledge the emotion expressed by the learners in my course	Model expressions of emotional response in written and oral communications Acknowledge and support student expressions of emotional response in written and oral communications
Related to social presence	I create space for learners to feel comfortable expressing emotion through the online medium or in the in-person classroom I create space to ensure emotion is expressed, online or in person, among the learners in my course	Make explicit the acceptable use of emoticons and emotional language as part of the course learning environment Encourage, acknowledge, and support expressions of emotion during course activities
Related to cognitive presence	I find myself responding emotionally about ideas or learning activities in my course I communicate that expressing emotion in relation to sharing ideas is acceptable in my course	Emotion is identified as a regular part of human existence including learning and thinking Emotional experience and expression are shared, acknowledged, and accepted among all members of the learning community

Adapted from Cleveland-Innes, 2019, p. 95

The original CoI measurement instrument was designed to measure the student experience. The self-assessment tool presented below uses transposed indicators of each presence to assess the teacher's point of view. This self-assessment is offered for individual self-evaluation of current teaching practices. It can also be used as reference for CoI instructional design and delivery.

---

## CoI and Learning Assessment

In the CoI, the emergence of the social, cognitive, and teaching presences fit well with the constructivist, collaborative perspective where the learners are actively participating in their learning. This environment is needed to create a context for sustained discourse, creating a platform for higher-order, deep, and meaningful learning to emerge (Akyol & Garrison, 2011) as is needed in higher education.

Assessment of learning within the community of inquiry framework is not conducted only on specific learning outcomes, but also on the process by which learning occurs (Akyol & Garrison, 2011; Conrad & Openo, 2018). In the CoI framework, the presences are critical for community, inquiry, and deep learning to develop (Vaughan et al., 2013). This is not rote learning or surface learning, and as such is contextual, problem based, and in need of multiple inputs and perspectives. Such learning involves a process to access higher-order learning, and takes advantage of metacognition and reflection to do so.

With this type of deep, contextualized learning that involves critical thinking, the learner needs to be at the center, involving learner teaching presence, whether in design elements, direct instruction, or facilitation (Vaughan et al., 2013). Peer assessment, self-assessment, use of rubrics, and instructor formative feedback can be used to encourage learner engagement in the construction of knowledge. Particularly focusing on the meaningful contributions to discourse (Akyol & Garrison, 2011), specific reflection or feedback activities may include those such as peer assessment on another learner's discussion forum facilitation or presentation of a given topic, self-reflections on what has been learned through the process of a given learning activity, or instructor feedback on the learner's contributions.

One important piece in the community of inquiry, and in the constructivist approach, is that learning is contextualized, and to create such a context, and to ensure that the inquiry process is at play, authentic and personally meaningful problems for the learner should be included in the inquiry process (Ertmer & Newby, 2013). Therefore, the learner's ability to choose the topic or even the assignment can help support the learner's full identification with the project. This can situate the learner in a position of a growing expert, in need of other perspectives and inputs to fully resolve the inquiry.

Higher-order learning is a challenge to assess as part of the formal assignment structures (Akyol & Garrison, 2011). Naturally, the products created can be assessed against how well they meet the specific learning outcomes. However, assessment of discourse contributions and reflections on the learning process can also be a way to assess higher-order learning. Instructors specifically need to acknowledge and validate contributions that exhibit critical reflection and critical analysis, key artifacts of higher-order thinking.

---

## Conclusion

Why move higher education course design to community-based learning? Learning communities support learner engagement and satisfaction, as well as deep learning outcomes. While this is true for all modes of teaching and learning design and delivery, the strategies for creating a sense of community online are quite different (Mullinix, 2018). Community is also a powerful tool in support of inquiry-based learning. Creating communities of inquiry in blended and online learning is one of the most researched pedagogical approaches in universities and colleges. The original Garrison et al. (2001) article explaining this framework has been cited in the scholarly literature over 4000 times. Much of the early research focused on understanding social presence (Richardson & Swan, 2003) as a new way to approach teaching beyond strict transmission models of delivery. A significant amount of research has also been done to measure the components of this framework and how they operate in reference to one another (Arbaugh et al., 2008; Garrison, Cleveland-Innes, & Fung, 2010).

A recent analysis of the literature identified that in measuring and applying the community of inquiry, "the most frequently used and the one adopted the most

commonly in the literature is the CoI survey instrument developed by Arbaugh et al. (2008)” (Olpak, Yagci, & Basarmak, 2016, p. 1090). This chapter offers rationale, and application suggestions, for serious consideration of the CoI as a contemporary framework for online design and delivery, in support of deep and meaningful learning.

### Abstract

Computer-Supported Collaborative Learning (CSCL) research has become pervasive in STEM (science, technology, engineering, and mathematics) education over the last several decades. Guided by sociocultural and social constructivist theories of learning, CSCL focuses on shared meaning making and is influenced by the three pillars of CSCL: enabling technologies, pedagogical designs, and modes of collaboration. This chapter identifies different approaches to CSCL that involve different combinations of these pillars. Based on an extensive literature review, we identify four distinct clusters that represent these different combinations. Focusing on two of these clusters, this chapter (1) identifies robust themes in this field and (2) discusses the positive outcomes associated with these aspects of CSCL. Outcomes include learning gains, process improvements, and affective outcomes. Across clusters, results demonstrate that scaffolding and feedback in different combinations are important for positive outcomes. However, feedback

that is poorly timed or excessive sometimes impedes learning and affective outcomes. Moreover, different combinations are used with learners at different ages and learning goals. Designing CSCL for different learning environments requires considering the complex system of learning environments that emerge from the interaction among the learning contexts, learner characteristics, and learning activities.

## Introduction

Many contemporary theorists characterize learning as that which is fundamentally social rather than individual (Danish & Gresalfi, 2018). Advances in computer technologies have enabled diverse modes of collaboration and set the stage for Computer-Supported Collaborative Learning (CSCL). CSCL refers to collaborative learning that is mediated in some way by computer technology (Stahl, Koschmann, & Suthers, 2014). It rests on three major pillars: the technologies that support and enable CSCL, the pedagogical designs that apply CSCL to learning, and the modes in which learners collaborate. In describing the goal of research in CSCL, Miyake (2007) argued that to understand how CSCL research was fulfilling its goals, it is essential that research on learning “takes collaboration seriously, and implements and evaluates technological support to materialize effective learning designs” (p. 248). This addresses these three key foundations of CSCL. Similarly, Roschelle, Bakia, Toyama, and Patton (2011) have argued that we need to understand the compound resources at play in complex learning environments. By looking at different combinations of CSCL design elements, we move closer to being able to understand how to design for CSCL in different contexts. In this chapter, we will consider how different combinations of these pillars affect the outcomes of CSCL research with a focus on science, technology, engineering, and mathematics (STEM) education, where much CSCL research has been conducted (Jeong & Hmelo-Silver, 2012).

---

## CSCL: An Overview

CSCL is consistent with a connected and ubiquitous vision of learning that takes advantage of unique affordances of technology (Miyake, 2007). Technology can lead to fundamental changes in teaching and learning practices, particularly in providing opportunities for students as engaged participants, working collaboratively in meaningful tasks (Roschelle, 2013). In particular, technology can enable new possibilities for interaction and feedback, communication, scaffolding, as well as providing meaningful tasks (e.g., simulations) and audiences.

The pillars of CSCL, what Kirschner and Erkens (2013) called the tryptic, are the technology, the pedagogy, and what they call the social aspects of learning, which includes the mode of collaboration. CSCL environments may be synchronous, that is, with learners collaborating at the same time, or asynchronous, with learners collaborating at different times. Synchronous collaboration can be at a distance, as in web conferences, or it can be face-to-face. An example of synchronous face-to-face CSCL is secondary school students discussing simulations in their classroom together (e.g., Echeverría et al., 2012; Sinha, Rogat, Adams-Wiggins, & Hmelo-Silver, 2015), whereas an asynchronous CSCL design can involve learners distributed across time and space (e.g., Yukawa, 2006). This review takes a broad view of technology, with the perspective that the computer-supported component of CSCL is used as an inextricable part of collaborative learning in a variety of contexts. Thus, we include technologies that serve a range of functions in CSCL (Jeong & Hmelo-Silver, 2016) and go beyond serving as communication channels.

Within CSCL, the focus is on learning through technology-mediated collaboration as a coordinated effort to build shared knowledge (Roschelle, 2013; Suthers, 2006). Although the CSCL community has largely focused on social constructivist and sociocultural approaches to CSCL (Stahl et al., 2014), a broad range of theoretical perspectives can apply (Hmelo-Silver & Jeong, 2021; Jeong, Hmelo-Silver, & Yu, 2014). An inclusive view of CSCL also needs to consider other theoretical frameworks such as information processing (Jeong et al., 2014). Still, in an earlier review of CSCL, a general constructivist orientation or sociocultural framework accounted for the majority of the CSCL articles (Jeong et al., 2014). Thus, we ground our discussion of the theoretical basis for CSCL in these constructivist and sociocultural frameworks, as they have been the dominant paradigm. In particular, we focus on what affordances are needed for technology to support CSCL.

Within this paradigm, *constructivism* refers to a broad range of theoretical approaches that emphasize active learner processing and knowledge construction either in individual or collaborative settings (Chi & Wylie, 2014). Social constructivism tends to emphasize how knowledge is socially constructed and leads to individual learning. *Sociocultural theory* refers to a family of theories such as Vygotskian approaches, distributed and/or situated cognition, or activity theory that emphasizes the fundamental role of tools, activities, social norms, and systems (Danish & Gresalfi, 2018). These theories consider the role of tools as mediators of learning as well as a means of providing support for task completion. An important but subtle distinction between social constructivism and sociocultural theory is that the former views the social context as an influence on individual learning, whereas the latter considers participation in the sociocultural context part of learning.

These theoretical perspectives help in considering how to design for CSCL, in particular, thinking about the functions that might be addressed in different CSCL designs. Jeong and Hmelo-Silver (2016) proposed seven affordances of CSCL for learning. Affordances refer to the ways that technology can provide opportunities for particular kinds of functions that mediate learning. CSCL technologies provide learners opportunities to (1) engage in a joint task, (2) communicate, (3) share resources, (4) engage in productive collaborative learning processes, (5) engage in

co-construction, (6) monitor and regulate collaborative learning, and (7) find and build groups and communities. Different combinations of these functions can be used in CSCL designs to support a range of instructional designs and pedagogical approaches.

---

## Effects of CSCL on Learning

Recent meta-analyses suggest that CSCL has significant effects on student learning (Chen, Wang, Kirschner, & Tsai, 2018; Jeong, Hmelo-Silver, & Jo, 2019; Vogel, Wecker, Kollar, & Fischer, 2017). Chen et al. (2018) examined the role of collaboration, computer use, and overall CSCL environments on learning. They found overall moderate effects of CSCL on learning outcomes and social interaction with large effects on group tasks. Vogel et al. (2017) restricted their meta-analysis to scaffolding with CSCL scripts. Their results demonstrated small effects on knowledge gains and a moderate effect on collaboration skills. However, they found that scripts were particularly effective for learning domain knowledge when they prompted learners to engage in activities that built on the contribution of other group members or when they provided additional content-specific support. Jeong et al. (2019) restricted their meta-analysis of CSCL to research in STEM education domains but found a similar overall moderate effect size, similar to Chen et al. (2018). They did find, however, that effect sizes were moderated by types of technology and pedagogy, education levels of learners, and modes of collaboration. There were also interactions among these moderator variables. For example, representational tools (e.g., simulations, modeling tools) were more effective in face-to-face than in asynchronous settings as was inquiry learning. The use of scripts and discussion boards were more effective in asynchronous settings.

The results across these meta-analyses suggest that CSCL is effective overall. However, these studies also noted different factors that moderated the effectiveness of these approaches. Jeong, Hmelo-Silver, & Jo (2019) drew from a larger corpus of CSCL research that included research with a larger variety of research methods that were coded for types of technologies, pedagogies, and collaboration mode (McKeown et al., 2017). This meta-synthesis found that there was not just one CSCL but rather four unique interpretable clusters of CSCL designs (presented in order of largest clusters):

- **Face-to-Face Inquiry with Dynamic Feedback** – face-to-face collaboration, inquiry and exploration pedagogies, and dynamic or other tools.
- **Asynchronous Teacher-Structured Discussion** – asynchronous collaboration, discussion or teacher-structured pedagogies, and asynchronous communication technologies.
- **Online Generative Inquiry** – asynchronous or face-to-face collaboration, inquiry and exploration or teacher-structured pedagogies, and sharing and co-construction technology.

- **Synchronous Collaboration** – synchronous collaboration and communication technologies.

Space precludes discussing all these in detail, and thus we focus on the two inquiry-oriented clusters, the first and the third largest, to show how CSCL has been used in different learning designs. We summarize these and provide examples next.

**Face-to-Face Collaborative Inquiry with Dynamic Feedback (F2FCI).** This cluster emphasizes face-to-face collaboration with inquiry and exploration pedagogies using dynamic technological tools such as simulations, games, and immersive technology. In addition, a substantial number of the papers in this cluster also used sharing and co-construction tools. Within the cluster, the majority of papers were in K-12. The inquiry pedagogy was generally supported by rich task contexts such as simulations and games as authentic contexts for inquiry.

**Outcomes.** Learning under this type of CSCL led to significant learning gains, promoted student engagement, and supported positive process outcomes such as critical thinking and reasoning skills. These outcomes cut across quantitative and qualitative studies, disciplinary content, and education levels. K-12 math students improved their problem-solving skills (Gallardo-Virgen & DeVillar, 2011; Roschelle, Rafanan, Estrella, Nussbaum, & Claro, 2010; Sao Pedro, Baker, & Rodrigo, 2014), conceptual understanding in mathematics and physics (Lai & White, 2012; Turcotte, 2012), and group collaboration and communication skills (Chen, Looi, Lin, Shao, & Chan, 2012). In physics, positive effects on learning gains were found in primary and secondary education (Turcotte, 2012; Echeverría et al., 2012, respectively). Primary students experienced positive learning gains and improved critical thinking skills from designing digital science games in an integrated biology and computer science curriculum (Yang & Chang, 2013). Primary students who were guided either with awareness tools or scripts learned more about photosynthesis through a drawing task than students in a control condition (Gijlers, Weinberger, van Dijk, Bollen, & van Joolingen, 2013). Students in both experimental conditions engaged in higher quality discourse than control participants.

F2FCI research also highlighted positive effects on student engagement and affective measures at multiple education levels. Primary students using handheld devices in an authentic outdoor learning task were enthusiastic and developed great interest in the assignment (Avraamidou, 2013). Secondary biology students who participated in a CSCL review game were more engaged than students in the control group who participated in traditional paper and pencil review sessions with CSCL support (Annetta, Minogue, Holmes, & Cheng, 2009). Additionally, computer science secondary and tertiary students felt empowered in their own learning (Tsai, Tsai, & Hwang, 2012).

Furthermore, lessons using dynamic technologies with inquiry and exploration pedagogies promoted meaningful interactions between elementary students, which in turn led to greater learning outcomes (Lai & White, 2012). For example, students engaged in high-quality interaction patterns, which entailed discussing the problem, task delegation, and helping each other in turn complete more assignments correctly than students with poor communication and collaboration (Chen et al., 2012).

Similarly, in the domain of ecology, primary science students engaged in an augmented reality mobile inquiry learning activity produced greater knowledge construction interactions than those in the control group (Chiang, Yang, & Hwang, 2014).

**Factors that support effectiveness.** Overarching themes that emerged from this cluster are that (1) pedagogies that support guided collaborative inquiry and (2) rich problem contexts that establish a joint task promote positive outcomes (Avraamidou, 2013; Chiang et al., 2014; Jaakkola & Nurmi, 2008; Kong, Yeung, & Wu, 2009; Kuo, Hwang, & Lee, 2012; Lai & White, 2012; Loke et al., 2012; Santos-Martin, Alonso-Martínez, Carrasco, & Arnaltes, 2012; Tsai et al., 2012; Yang & Chang, 2013). Authentic problem contexts could be set in games and simulations (e.g., Echeverría et al., 2012; Nelson & Ketelhut, 2008). One way that facilitators provided guided instruction was by giving assistance and feedback throughout collaborative inquiry and by providing authentic problems for problem-based learning (Avraamidou, 2013; Santos-Martin et al., 2012). A similar approach was taken with case-based instruction by developing workshops for pharmacy students to simulate real-life scenarios (Loke et al., 2012).

Instructors provided guided instruction ranging from very open-ended to more highly structured. For example, undergraduate and graduate students were given very open-ended guidelines as they engaged in mobile learning outside of the classroom (Tsai et al., 2012), whereas secondary-level students were provided more facilitation in a student-driven augmented reality game to help them learn electrostatics (Echeverría et al., 2012). Even greater structure was provided for primary grade students who were given systematic processes to follow as they engaged with highly organized inquiry learning to help them with knowledge sharing (Chiang et al., 2014). In a grade 5/6 study of Knowledge Forum, teacher and researcher questions were helpful in advancing student thinking (Turcotte, 2012).

In comparing task awareness tools with process-support scripts, Gijlers et al. (2013) found that support in the form of a script led to more interactive talk and differences in the ways that elementary school learners engaged with the task of drawing the photosynthesis process. The awareness tools, which prompted students about objects that were missing from their drawings, led students to go back to the concepts in their resource text, whereas students in the scripted condition were more likely to integrate elements from their individual drawings into a shared drawing. Guided instruction also took the form of companion worksheets with primary students (Jaakkola & Nurmi, 2008; Lai & White, 2012).

Closely tied to the theme of guided inquiry is feedback (Hmelo-Silver et al., 2007). In studies with F2FCI with dynamic feedback, participants at a variety of educational levels received immediate feedback on a task or problem from facilitators (Avraamidou, 2013; Kong et al., 2009; Santos-Martin et al., 2012), peers (Chen et al., 2012; Chiang et al., 2014; Gallardo-Virgen & DeVillar, 2011; Kuo et al., 2012; Lai & White, 2012), and/or software (Chen et al., 2012; Echeverría et al., 2012; Holmes, 2007; Loke et al., 2012; Roschelle et al., 2010). Software feedback could include direct hints or prompts or be more indirect in providing changes in the state

of a simulation or game in response to learner actions. Teachers noted elementary student achievement and success with technology use required active teacher feedback (Chiang et al., 2014; Kong et al., 2009).

**Factors that inhibit effectiveness.** Collaborative tasks are particularly complex as Gijlers et al. (2013) also demonstrated in their control condition, and they require support. The factors that may inhibit student learning and engagement are related to feedback. An example of the importance of informative feedback emerged from two studies with primary students and teachers. When teachers lack content expertise, the technology itself needs to have that content feedback embedded or risk leaving student questions unanswered, as in an example of using software for learning about electrical circuits (Kong et al., 2009). This is also a problem when a teacher is working with several groups and cannot provide consistent active feedback for each group (Chiang et al., 2014; Kong et al., 2009), or for students who have specific questions about technology or content, and the teacher is unable to answer (Kong et al., 2009).

Although this concern with the lack of consistent, active feedback only emerged between these two studies with primary students, they are pedagogical and technological concerns applicable at all educational levels. Technologies can be used to provide content feedback in such situations, but as Turcotte (2012) noted, just because technology provides affordances for particular kinds of activity such as elaborated explanations, learners do not always take advantage of those affordances.

**Summary and implications.** Among these papers, there was a trend for students to be collaboratively engaged with authentic problems and their learning nurtured by guided instruction, feedback, and discussion. Together, these combinations were associated with significant learning gains, positive student engagement, meaningful interactions between students, and improved group collaboration and communication skills.

Simulation tools and augmented reality games allow students opportunities for practice, feedback, and revision as they collaboratively engage with disciplinary content and practices without the time or expense of physical tools. Learning with authentic problems was supported by opportunities for guided inquiry and immediate feedback from the tools and discussion (i.e., Echeverría et al., 2012; Holmes, 2007). Technology played a role in helping students to work in settings that are more authentic and have opportunities to directly test their ideas and solutions, with the tools providing dynamic feedback. The main difference between the higher education and K-12 school environments was the control retained by the instructor. When this design was used in higher education, students had greater autonomy than primary and secondary education students. Question remained, however, about how much information needs to be embedded in the technology and how to help teachers support their students.

**Online Generative Inquiry (OGI).** This cluster of articles was primarily concerned with integrated learning environments (e.g., learning management systems) or online sharing and co-construction technologies (e.g., wikis, participatory technologies). Asynchronous collaboration with inquiry and exploration pedagogies was a main focus, but collaboration and pedagogy were more varied than in some of

the other clusters. By their nature, integrated environments offered instructors and students a variety of tools that could be used to collaborate asynchronously or in face-to-face environments. Most OGI papers examined learners in higher education, again suggesting some connection between learner education level and collaboration types, consistent with the Jeong et al. (2019) meta-analysis. Communication and discussion occurred through sharing/co-construction tools and integrated environments that allowed direct communication through built-in chat tools or discussion forums.

**Outcomes.** Research in this cluster primarily reported process gains as well as some learning gains. The positive process gains highlighted in this cluster included metacognitive skills supported by a knowledge-building environment (Pifarre & Cobos, 2010) and improved reasoning and collaboration via e-learning environments or wikis (Huang & Nakazawa, 2010). In an undergraduate statistics course, student report writing was completed individually or collectively via a wiki (Neumann & Hood, 2009). There were no differences in terms of final report quality, but students who collaborated within wikis were more engaged and had higher attendance than those who worked alone. However, this technology is not without its challenges, as some students reported dissatisfaction with using the technology, and task completion was negatively affected by low group member participation in some instances (Neumann & Hood, 2009).

Learning gains in this cluster were not uniform. On one hand, collaborative use of a multimedia-enriched concept map produced greater short- and long-term retention scores than a control group that received regular instruction and worked on assignments individually (Marée, van Bruggen, & Jochems, 2013). However, another study found no differences between the final grades of a group that collaborated through wikis and a group that worked independently with a word processor, despite positive engagement (Neumann & Hood, 2009). Mixed learning gains were reported in Krause, Stark, and Mandl (2009) that examined learning gains with students working individually versus pairs, and with some students receiving automatic adaptive feedback in an asynchronous statistics class. In this example, students who received feedback performed better than those who did not. Feedback tended to reduce the gap in outcomes between students with low and high prior knowledge.

**Factors that support effectiveness.** A wiki co-construction environment demonstrated that students reported more interaction with peers than with their instructor and that the instructor moved to more of a moderator role, allowing students to initiate interactions (Huang & Nakazawa, 2010). Students also noted the importance of receiving public feedback about revisions within the wiki where these could be discussed by group members, instead of privately or over other media, allowing the feedback to function as collaborative scaffolding and an anchor for their discussions. In using representational tools, Marée et al. (2013) found that undergraduate science students could learn more with less teacher guidance using multimedia-enriched concept maps with embedded instructions for collaboration.

This OGI research also offered some promising implications about specific technologies and pedagogical practices. For example, in asynchronous discussion threads (i.e., a specific technology), particularly when students act as facilitators

(i.e., a pedagogical practice), they need to understand different types of thread patterns and how questioning, summarizing, pointing, and resolving may affect discussion thread development and closure (Chan, Hew, & Cheung, 2009). Pedagogically, in ICT courses, it is important to integrate the technology being discussed so participants better understand its purpose and also how to use it themselves (Goktas & Demirel, 2012). Krause et al. (2009) supported the notion that feedback, whether from instructors or peers, may promote more reflection, especially when it offers explanations that encourage deeper understanding. Therefore, regardless of the source, feedback should be thoughtful and thorough and encourage students to think beyond remembering information. Pifarre and Cobos (2010) demonstrated the importance of scaffolds in improving peer questioning and co-regulation.

Many of these papers investigated how students used and perceived specific technology. These suggest that the use of collaborative group activities, instructors' timely feedback, and support materials embedded within an integrated system all related to student satisfaction with a variety of STEM-related vocational e-learning courses (Inayat, ul Amin, Inayat, & Salim, 2013). Similar to the F2FCI cluster, when guided instruction and immediate feedback are integrated within these pedagogies and technologies, it can lead to improved student learning (Krause et al., 2009; Marée et al., 2013) and task completion (Hämäläinen & Arvaja, 2009).

Although scripts might be effective for task completion, they do not necessarily avoid variability in collaboration processes among groups. In a study of university students engaging in case-based learning, Hämäläinen and Arvaja (2009) still found differences in frequencies and meaningfulness of collaborative activity with five out of the seven groups showing unequal participation or one group member being dominant. Thus, the structure applied by a script may not be sufficient to promote uniformly productive collaboration.

**Factors that inhibit effectiveness.** Again, feedback was mentioned in relation to factors that inhibit effectiveness. Consistent with findings in other clusters, a lack of feedback can negatively affect students' learning outcomes (Krause et al., 2009). Meanwhile, too much feedback, or using facilitation techniques that resolve conflicts or summarize key points, can lead to discussions closing prematurely (Chan et al., 2009). Without enough guidance regarding the importance of positive collaboration, students may have high task activity, but not necessarily high-quality collaboration (Hämäläinen & Arvaja, 2009).

**Summary and Implications.** Timely guidance from teachers and peers plays an important role in increasing student outcomes as well as favorable perceptions of the environment. The results for this cluster also highlighted the importance of keeping the guidance at an optimal level; there is a delicate balance between too much and not enough feedback or guidance.

In contrast to F2FCI, which also supported inquiry and exploration, communication modalities in this cluster make students' thinking visible in ways that a face-to-face classroom may not allow. Teachers can thus follow persistent threads of synchronous and asynchronous discussion along with the artifacts being created. This gives teachers opportunities for ongoing formative assessment. More speculatively, it may also provide grist for student reflection on these ongoing interactions in

ways that face-to-face discussions that are more ephemeral may not. This may be particularly important in higher education contexts with their larger class sizes that might otherwise offer fewer opportunities for discussion and feedback.

---

## Open Questions and Directions for Future Research

It is clear that the three pillars of CSCL – collaboration, technology, and pedagogy – are used in different combinations to design effective learning environments. However, we need to better understand how to design for the balance between developing appropriate structures and supporting student agency in ambitious learning practices promoted by CSCL (Glazewski & Hmelo-Silver, 2019). This is particularly important in being able to support diverse learners (Uttamchandani, Bhimdiwala, & Hmelo-Silver, 2020). We review this in the context of the major issues this chapter has identified.

First, feedback and support are themes that run through all the clusters, whether the feedback is from the teacher or peers or from tools. Much research has focused on teachers and software but less has addressed ways to support high-quality peer feedback (De Wever, Van Keer, Schellens, & Valcke, 2010). Certainly, research on scripts and roles may be one way to provide such support for good quality peer feedback, but these kinds of interventions tend to focus on process support rather than on feedback. CSCL environments should provide feedback for students and information that allows teachers to support multiple groups (Chiang et al., 2014; Kong et al., 2009). Questions about feedback consider both the timing and quality. Poorly timed feedback that does not address appropriate content, skills, or practices may impede learning. As the reference to synergy in the title suggests, it is important to think about feedback and support as part of the CSCL system of technologies, pedagogies, and collaboration modes. It is important to consider which aspects of feedback and support should be fixed and which should be adaptive.

Second, certain technologies lend themselves better to particular communication channels and/or pedagogical goals. Dynamic representational tools are generally used in face-to-face environments as the F2FCI cluster demonstrates (e.g., Lai & White, 2012; Nelson & Ketelhut, 2008). We conjecture that the rapid cycles of activity and engagement with such tools lend themselves to the immediacy of being in the same place at the same time. Additionally, the tools allow for deictic referencing as learners can easily point to phenomena on-screen and observe the gestures of others.

Our meta-analysis (Jeong et al., 2019) showed that effect sizes were larger when dynamic representational tools were used in face-to-face settings. Similarly, the use of sharing and co-construction tools dominated the OGI cluster. These tools may be more critical for online environments because learners' interaction channels are limited and thus need to be mediated by communication tools. When communicating and collaborating with these tools, learners need to be more explicit about their actions and contributions, which can provide a chance for reflections. Knowledge

co-construction can be fostered when learners can articulate their ideas more clearly and make their contribution explicit.

Third, different learning environments are used for different learners. We found that CSCL involving younger learners tends to involve face-to-face collaboration rather than online collaborations. Online collaboration requires dealing with a broader range of communication modalities and as such may be used for more mature learners (Jeong & Hmelo-Silver, 2012). We do not know if it is because of better self-regulated learning skills for older learners or more convenience or available technology. In general, the trend seems to be for more structure and face-to-face collaboration for younger learners. Moreover, face-to-face CSCL is more commonly used for younger learners, perhaps due to the need for social presence in this population as they tend to be in the same physical space. In addition, technology tools can add to the cognitive demands on learners and pose increasing challenges for regulation that may be difficult for younger learners. However, these challenges are not unique to younger learners. There is a large body of literature that suggests that creating social presence and self-regulated learning is challenging even for more mature learners in online environments (e.g., Garrison, 2007; Järvelä & Hadwin, 2013).

Fourth, CSCL tasks are important, whether providing rich contexts or opportunities for joint construction of artifacts, particularly in those clusters that focus on inquiry and explanation. For example, in F2FCI, the establishment of rich task contexts was supported by the use of technology (e.g., simulations, games, and devices) and collaborative inquiry pedagogy (e.g., Chiang et al., 2014; Lai & White, 2012; Santos-Martin et al., 2012).

These authentic joint tasks promoted positive outcomes. The technology used here allowed learners to engage with tasks that were fundamentally different from what they could do without the CSCL technology. For example, the dynamic feedback from a game or simulation is immediate and is a consequence of particular learner actions. Paper cases that might be used in problem-based learning, for example, only provide predefined resources. In contrast, the OGI cluster uses the affordances of tools that allow construction of shared artifacts such as wikis (Huang & Nakazawa, 2010; Neumann & Hood, 2009), creating a website (Barchard & Pace, 2010), or collaborative concept mapping (Marée et al., 2013).

The last question that research on synthesis of CSCL needs to ask is what does it mean for CSCL to be effective? From different theoretical perspectives and research designs, this can mean many things, making the synthesis process challenging. It may mean CSCL is a black box that can produce content gains measured as pre- to posttest achievement (e.g., Echeverría et al., 2012; Kong et al., 2009; Pifarre & Cobos, 2010). However, it can also mean collective effectiveness such as in the research on knowledge building that focuses on collaborative improvement of community knowledge (e.g., van Aalst, 2009; van Aalst & Chan, 2007). Other authors examine the quality of discourse and patterns of collaboration processes broadly defined (e.g., Sinha et al., 2015; Van Amelsvoort, Andriessen, & Kanselaar, 2007). Still others focus on affective outcomes and learner satisfaction (e.g., Loke et al., 2012; So & Brush, 2008). Much of the research uses multiple measures (e.g.,

Gijlers et al., 2013; Shaw, 2013). In this chapter, we have treated what it means for CSCL to be effective broadly, but we also need to make sure that we make sense of the broad range of outcomes studied in CSCL in a coherent manner.

Together, these themes suggest overarching questions about needing to connect design features and contextual factors. Examining relationships among processes, outcomes, learner characteristics, instructional goals, and design features is critical for understanding more about “what works for whom and under what circumstances” and enabling designers to tailor CSCL designs to the intended settings.

---

## Implications for ODDE

**CSCL as a complex system.** At the start, we noted the importance of considering the compound resources used in CSCL (Roschelle et al., 2011). There is no one-size-fits-all solution, and how CSCL is used in different ODDE environments needs to be tailored to the particular level of the learners and the learning goals. Designers will need to consider how the collaboration modes, technology, and pedagogical choices fit together in ways that are more than the sum of their parts. CSCL is an essential part of the complex system that emerges in enacting learning environments.

**Considerations for practice.** Helping stakeholders become aware of the usefulness of CSCL is a first step in implementing evidence-based practices. This includes reporting on CSCL in practitioner venues and publications. In addition, professional development is important for instructors in order to effectively implement CSCL. Facilitating CSCL requires mastering the technology, tailoring it to tasks, and providing adequate scaffolds that can be differentiated for student skills and prior knowledge.

---

## Conclusions

It is clear that there are different technology-pedagogy-collaboration modes for different learners. We need models that help guide researchers and practitioners in how these CSCL pillars may be synergistically combined, providing the compound resources in appropriate combinations. One way to accomplish this might be to think about the function needed for a set of learning goals and considering how they might be distributed among these pillars. Jeong and Hmelo-Silver (2016), for example, have proposed that technologies serve seven distinct functions in CSCL such as establishing a joint task, providing communication channels, sharing resources, engaging in productive collaborative processes, supporting co-construction, monitoring and regulation, and forming groups and communities. These functions or affordances highlight different ways technology supports are contingent upon collaboration and pedagogy. Further work is needed to better understand how these functions might be used as part of a theory of design for CSCL and the implications for ODDE. The current chapter begins to address these important questions about CSCL and the complexity of these learning environments.

## Abstract

Governments, business leaders, educators, students, and parents realize the need to inculcate a culture of lifelong learning – learning that spans geography, time, and lifespan. This learning has both formal and informal components. In this chapter, we examine the conceptual basis upon which informal learning is defined and some of the tools and techniques used to support informal learning. We overview the rapid development in information and communications technologies that not only creates opportunities for learners, teachers, and researchers but also challenges us to create equitable and culturally appropriate tools and contexts in which high-quality, continuous learning is available to all.

**Introduction**

Before we examine the ways that informal learning is transformed by digital contexts, we must understand what “informal learning” means. Unfortunately, the term has been used by many authors over many years to stand in for a variety of different and sometimes contradictory ideas, approaches, and activities, a fact bemoaned by many (e.g., Eraut, 2004; Livingstone, 2001; Rogoff, Callanan, Gutiérrez, & Erickson, 2016; Schugurensky, 2000).

As Colley, Hodkinson, and Malcom (2002) wryly observed, many authors simply define informal learning as “not formal.” Others attempt contestable definitions, for instance, described informal learning as unstructured, experiential, and non-institutional, begging the question as to what structured, non-experiential, and institutional learning might be, and ignoring the fact that informal learning also occurs in institutions. Schugurensky (2000) identified three forms of informal learning: (1) self-directed learning in which a learner acts with intention and awareness of their learning objectives to acquire specific and usually self-defined knowledge competencies; (2) incidental learning in which learning occurs outside of the intent of the learner, but they are conscious of the newly acquired knowledge; and (3) socialization, in which one acquires knowledge without intent or even awareness that they are learning. However, these can occur in nonsocial learning, too, and all such ways of learning also occur in formal settings, so it still fails to identify what is distinctive. Eraut (2004) sees dimensions of implicit, reactive, and deliberative learning that broadly equate to Shugurensky’s socialization, incidental, and self-directed categories, but, as he noted, there is a fuzzy continuum between formal and informal that admits many exceptions and where counterexamples can easily be found. Though recognizing the problem, Eraut sidesteps resolving it.

We believe that the fuzziness of the term’s application is due in part to a common failure to adequately explain what is meant by *formal learning*. Formal learning is easily recognized in its most archetypal forms as what takes place in educational institutions. However, much learning in formal settings occurs that is hard to describe as formal, enabled through encounters in corridors, inadvertent modelling of roles in the classroom, or discussions in canteens. The lines dividing formal and informal can be hard to discern even at a structural level. Is in-service training formal? Or taking part in a MOOC? Or taking piano lessons? Does it make a difference if those lessons result in grades certified by a government, an academy or by a private educational company? Some authors have used the term *non-formal* to characterize kinds of learning that appear to straddle the borders of formal and informal, but this negative definition simply evades the issue. Further confusion often arises through confounding informal learning with related but orthogonal terms

such as *self-directed learning*, *self-regulated learning*, *lifelong learning*, *incidental learning*, *implicit learning*, and *tacit learning*, all of which may occur in a formal as well as informal contexts.

In the absence of clear defining characteristics, formal learning may better be characterized using Wittgensteinian family resemblances: common traits that may, individually, be shared by informal learning but that, in sufficient numbers, allow us to characterize the learning as more or less formal. Formal learning tends to be externally regulated: frequently in process, nearly always in goals. It usually involves rites of passage such as enrollment, progression, and certification. Formal learning usually follows timelines, rules, customs, and norms. There is often some social or external sanction involved, most notably in the form of certification, not just of learners but of their teachers, textbooks, and institutions. Formal learning often involves rituals – specified or normal ways of doing things. Formal learning normally has a purpose, often expressed as goals, objectives, or outcomes, and is nearly always intentional. The presence or absence of any of these characteristics does not define learning as formal but, when enough of them occur together, it usually is.

Informal learning may also be recognized by clusters of family resemblances. Informal learning is typically self-directed and self-regulated. It may, however, also emerge through shared practices, interests, or goals within a group or network of people (such as those in a workplace or club) or simply through acting in the world. Much is incidental, the result of performing an activity or practice in which learning is not the primary goal but a side effect of doing something else. There may be occasions when informal learners actively seek knowledge, tuition, or guidance, or where they may intentionally perform an activity in order to learn, but it is often just-in-time and short-lived. There are seldom extrinsic measures or rules for it to follow. It is rarely timetabled. It is often open-ended, without a clear beginning or end. Informal learning may occur at any time and any place, including during a formal learning event. Any of these characteristics may occur in a formal learning setting, too, but a large-enough cluster of resemblances leads us to describe it as informal.

Informal and formal learning are not mutually exclusive categories: they lie on a continuum, with much fuzziness at the boundaries. Within a learning trajectory that might, as a whole, be characterized as formal, we may engage in much learning that is not, observing things around us, engaging with others and making connections between ideas at times and places far removed from a formal setting. Similarly, formal elements may play a role in informal learning, as a catalyst, sometimes as a component of it and, sometimes, as we shall see, as a means of certifying it.

To help distinguish more clearly between them, we characterize the learning spectrum from informal to formal as having two distinct but related dimensions: incidental (intentional) and self-directed (dependent) (see Fig. 1). We note that the halfway point between self-directed and dependent is mostly occupied by social ways of learning, in which we are co-participants, both directing and being directed by others.

Table 1 provides some illustrative examples of values for each of the dimensions for a range of learning activities, noting that these are highly contingent, depending on many contextual, personal, and pedagogical variables that may lead to different

**Fig. 1** Related dimensions of formal and informal learning

**Table 1** Examples of applying the informal learning dimensions

Learning activity	Informal/ formal	Intentional/ incidental	Self-directed/ dependent
PhD study	Largely formal	Intentional	Largely self-directed
Improving skills on an instrument while learning to play a tune	Informal	Fairly incidental	Self-directed
Practicing scales	Fairly informal	Intentional	Self-directed
Attending a lecture	Very formal	Very intentional	Very dependent
Following a YouTube tutorial	Informal	Intentional	Fairly dependent
Learning while chatting in a cafe	Very informal	Very incidental	Partly self-directed
Performing a problem-based exercise set by a tutor	Formal	Intentional	Fairly self-directed
Learning how people in a discipline think by attending a lecture and observing the lecturer's attitude (the hidden curriculum)	Formal	Incidental	Largely self-directed

categorizations under different conditions. A learner's trajectory over the course of a sustained learning activity may take them through any or all of the dimensions of informality, intentionality, and self-directedness at different times as well as, occasionally, simultaneously.

## Digital Contexts Are Different

It has been claimed that, when Einstein was asked for his telephone number, he looked it up in a phone book, observing “Why should I memorize something when I know where to find it?” Our “phone book” today is many billions of times bigger than Einstein’s paper catalogue. There are few facts that cannot be found within seconds, as well as countless fictions, half-truths, and abject falsehoods. Equally, we can connect with countless millions of other people. In pre-digital times, we inhabited one environment at a time and learned through our interactions with it. Now, we inhabit many environments between which we can switch at will, and much of the time, our actions are recorded, our interactions are reified, and the things we share may persist indefinitely. We are thus not just dwellers in these environments but active creators of them. Digital learning is different, and so are our learning needs as we have less need-to-know information but instead know where to find it and what to do with it.

The abundance of connections and seemingly limitless availability of information enabled by the Internet has both created new opportunities for learning as well as a greater need for it. We are not enjoying the ease and luxury of idle time as expected by early technology proponents. As the Red Queen in *Through the Looking Glass* put it, “it takes all the running you can do, to keep in the same place. If you want to get somewhere else, you must run at least twice as fast as that!” (Carroll, 1871). This is a necessary feature of technological change. Technologies build upon and from other technologies (Arthur, 2009), and each new technology creates new adjacent possible empty niches (Kauffman, 2019) for newer technologies to fill. Thus, technological growth follows an exponential curve and has done so over many millennia.

In order to “run faster” today, we must be able to access and use more knowledge, become better or differently skilled, and be more motivated to learn. Formal learning that occurs episodically, usually early in life, and that is often removed from its context of application, is not enough. Worse, students are often rewarded for learning as instructors intend and punished for failing to do so, especially through grades and credentials, which can reliably sap away any intrinsic motivation that learners may feel to learn more (Kohn, 1999; Ryan & Deci, 2017). Informal learning that is chosen, or incidental to other things we choose to do that can occur at any time or place, is inherently motivating, meeting needs for competence, autonomy, and, in most cases, relatedness, which are the three cornerstones on which intrinsic motivation depends (Ryan & Deci, 2017). Combined with the cornucopia of knowledge and connections with others that the Internet provides, informal learning is well positioned as the primary means to achieve lifelong learning. However, there is a Faustian bargain to all technologies (Postman, 1998). With each problem a technology solves, new problems are created.

## The Darker Sides of Digital Technologies

The abundance of learning opportunities in cyberspace can be overwhelming and threatening rather than inviting participation in informal learning. Social overload

(McCarthy & Saegert, 1978) was first measured in real-life contexts in which demands of social interaction strain and stress individuals. Although much online informal learning takes place in nonsocial contexts (such as an information search on Wikipedia), systems like Reddit, social networks, and MOOCs use both human and technological inducements to motivate learning. Such systems may create psychological stress in which the perceived demand for reciprocity, desire for social attention, or other social responsibilities become stressful and can lead to abandonment of the learning projects. Cognitive overload occurs when the learners' cognitive, memory, or temporal restrictions preclude effective processing, storage, and utilization of that information (Roetzel, 2019). Systems overload occurs when the complexity of the systems – especially related to overabundance of features and options – impairs learners' cognitive abilities and more importantly their learning efficacy (Fu, Li, Liu, Pirkkalainen, & Salo, 2020). The abundance of information, with no guarantee of consistency, veracity, or efficiency in support of learning, may also lead learners to confusion or inaction. Thus, provision of opportunity itself and pressure from both live peers and motivational algorithms can hinder as well as motivate informal learners.

Though individual motivation is critical, it is not the only factor limiting learning and receiving benefits from that learning. Social factors including fairness, self-efficacy, opportunity, financial resources, time, and support also impact an individual's capacity and agency for successful learning. Issues of access to hardware and network connectivity for informal learning become increasingly important both for individuals and families and for government policy (Boyadjieva & Ilieva-Trichkova, 2018). Equally, the skills to effectively use ever-changing tools become a new learning hurdle (Iordache, Mariën, & Baelden, 2017).

Without guidance by experts and without all the resources available in institutions, informal learners using the Internet may sometimes face insurmountable barriers and difficulties. Without the continued filtering, critical thinking, expert help, process support, and resources of formal learning, informal learners may pursue false or unfruitful paths, may fail to see important aspects of what they are learning, may stumble when faced with resource or cognitive barriers, and may wander without a rudder in a sea of conflicting opinions, truths, half-truths, and lies.

In the rest of this chapter, we provide some thoughts and recommendations for introducing many of the benefits of informal learning into a formal setting and approaches to informal learning that reduce some of the risks.

---

## **Informal Learning in a Digital Context**

### **Social Informal Learning**

Much learning is social in nature. We acquire new knowledge and skill by asking questions, observing and copying behaviors we see demonstrated by others, having to explain ourselves or instruct others, and observing how others react to our

behaviors. This type of learning, sometimes referred to as “social informal learning,” has been the subject of considerable research in learning organizations (e.g., Crans, Bude, Beusaert, & Segers, 2021) and is well-supported online.

### **An Example: Reddit**

One of the most popular tools for online social informal learning is the Reddit system that combines peer support, question and answer, game motivation, access to more knowledgeable others, and recommendation tools – all with free (ad-supported) access. Although there are many thousands of subreddits (delineating topics of interest that can be subscribed and contributed to), among the most popular are the following:

- [r/LifeProTips](#) through which redditors share good ways of doing things, tips, or maxims
- [r/explainlikeim5](#), where experts give advice to beginners in simple words
- [r/ExplainLikeImPhD](#), where more detailed explanations are given
- [r/noStupidQuestions](#), where people can seek advice on any subject
- [r/changemyview](#) where people post contentious opinions and others argue against them

This is just a tiny fraction of the many learning-oriented uses of the site, many of which relate to highly specific skills and interests as well as those that are more general.

In a study of subreddits that they refer to as “learning in the wild,” Del Valle, Gruzd, Kumar, and Gilbert (2020) showed “that informal learning processes . . . are determined by the reciprocal and transitive nature of communicative ties among their members (p. 51).” They also found “that moderators play a key role in fostering interactions (p. 51).” Importantly, rules and norms emerge from members themselves as “new users are able to see and imitate observed practices (p. 53)” and “learning becomes an unregulated, incidental, and experiential process (p. 54).” The authors conclude that factors critical to success in these environments are “visibility, easy entry, lack of testing/examination, anonymity, access to gurus and notoriety—all available with minimal reference to gender, race, formal education, or social economic status.”

Other popular learning support tools of this nature include Quora, Slashdot, Discourse, and the StackExchange family of sites. Countless other independent forums support specialist interests, from owners of a particular brand of camera to stamp collectors. Some are huge. For example, the Amazon-owned Goodreads boasts millions of members, sharing and discussing books. Other more general purpose social media such as Facebook or Twitter serve many additional purposes that have also been shown to support “learning in the wild” (Kumar & Gruzd, 2019).

These sites are heavily used by students on formal courses as a means to complete work set by their instructors and, often, as a means to discuss other aspects of the course. Some may disrupt formal learning: there are subreddits dedicated to support for homework ([r/HomeworkHelp](#)) as well as ways of cheating on online proctored exams ([r/cheatonlineproctor](#)), for example.

Haythornthwaite et al. (2018) developed a coding schema that “contributes a content analysis schema for learning through social media, and an understanding of how knowledge, ideas, and resources are shared in open, online learning forums” (p. 219). This eight-point coding scheme extends and expands the popular COI model (Garrison, Anderson, & Archer, 2000) and coding scheme to this “informal” context. They add a potentially affective component (negative, positive, or neutral explanation, and positive or negative socializing) to the COI codes that documents the increased role of affect and commitment in informal learning – learners are not induced to remain, contribute, and learn by reason of paying a large tuition fee, fear of failure, desire for high grades, or other affective challenges associated with learning in formal education.

### **The Power of the Collective**

Many of these systems benefit from recommender systems, filters, and other tools that aggregate, analyze, and produce views of digital information, from simple “thumbs-up” ratings to full-blown deep learning systems that delve into the content of messages and seek patterns to supply recommendations. What results is a cyborg entity that employs the aggregated behaviors of individuals in a crowd to shape their environment and to provide structure and influence in that environment that we have previously described as a collective (Dron & Anderson, 2009). Karma points (indicators of reputation, gained by having made what the crowd considers to be useful posts in a given area) and up-down ratings on Reddit, StackExchange, Quora, or SlashDot, for example, are used to provide ranking and emphasis for posts and their answers, resulting (in principle) in higher quality, more relevant posts being displayed more prominently.

Though seldom perfect, the algorithms and interfaces often succeed in providing useful recommendations despite vulnerability to gaming by those seeking attention and to the Matthew Effect (the rich get richer while the poor get poorer) that can result in inequitable power distribution among users. Collectives can thus play roles similar to that of a traditional teacher, guiding learners toward help that best suits their needs and interests. However, they are not always *good* teachers. In general-purpose social systems such as Facebook or Twitter, the intent of individuals may only rarely be to learn, and the algorithms may be more concerned with driving engagement or serving the needs of advertisers than with the support of learning. This can result in, among other things, active promotion of false, misleading, or biased content that may be counterproductive to learning. As Dron (2002) found, collectives only make good teachers when the communities on which they are based intend to learn and when the algorithms are not at odds with that intent.

### **Self-Teaching Resources**

Teach-yourself books, manuals, and articles have long been a popular genre among intentional informal learners and remain so. However, to a large extent, they have

been replaced by online resources, many of which are free or ad-supported. Online informal learners may dip into hundreds of relevant articles, courses, videos, and even books, picking and choosing those that most closely match their needs, interests, skills, and tastes, providing support at unprecedented scale. Many of these mirror forms of teaching conventionally found in formal learning, including in many MOOCs that may bear almost all the trappings of traditional institutional teaching. However, without the coercion, formal enrollment, and accreditation frameworks of institutions, the ways in which they are used for learning may be anything but formal. Similarly, many governments, institutions, development agencies, and charitable foundations now support authors and multimedia companies to produce open educational resources (OERs) for formal learning that equally support informal learners.

### **An Example: Online Videos for Informal Learning**

Few readers of this chapter will not have watched a video from YouTube, Vimeo, or another video repository to help them learn something. These videos offer tremendous opportunity at affordable cost to learn long sequences (e.g., a 20-part video series on learning to play the dulcimer) as well as short knowledge insights (e.g., how to clean a clogged drain) and ongoing routine activities (e.g., exercise classes). The 2021 Pew study of adult Americans found that 81% are YouTube users (Auxier & Anderson, 2021) of whom 86% found YouTube videos useful for informal learning (Smith, Toor, & Van Kessel, 2018).

In many ways, these videos substitute student-content interaction (watching the videos) for student-teacher interaction of the classroom. This substitution exponentially reduces cost through capacity to be used and re-used while increasing access through Internet distribution. In a 2017 study of 29,386 comments posted by viewers of 150 education-related videos, Lee, Osop, Goh, and Kelni (2017) concluded that YouTube can support a variety of learning and social affordances.

As Song and Bonk (2016) observe, informal learning must have a “fun” factor as the absence of external motivation may weaken desire to engage in hard work associated with learning challenging information or behaviors. Analyzing the behavior of thousands of participants in a MOOC, Breslow et al. (2013) found a high preference for video rather than text and images among learners. Though sometimes a more time-consuming way to learn simple tasks, videos are often more engaging than static text and images.

Rosenthal (2018) measured both students and community residents use and frequency of watching YouTube videos related to science topics – a type of “free choice science learning.” They concluded that the value of videos that enhance science knowledge of learners is conditioned by their general interest in science, the perceived value of science learning, as well as the entertainment value of the video. However, perhaps the most compelling evidence of YouTube efficacy for informal learning comes from reports from development agencies of rural villagers using the videos to repair water pumps and other equipment provided by donor agencies that, in the past, often sat idle for lack of expertise in repair and maintenance (Change for Children, 2021).

## Supporting the Informal Learning Process

Self-directed learning has long been studied as a component of success in formal education. The converse is also true. We have decades of research on the efficacy of collaborative and cooperative learning in formal education (e.g., Johnson & Johnson, 2008; Slavin, 1996), for the use of experiential learning designs (Lewis & Williams, 1994), the value of a supervisor or mentor (Allen, Witt, & Wheelless, 2006), and other approaches that originated in classrooms. We also note the value of informal learning that arises within effective communities of practice (Viskovic, 2005). All such options are available online, through purpose-built collaboration/cooperation tools like Slack, Github, or email, as well as systems created to support ad-hoc transient learning networks of informal as well as formal learners (Sloep et al., 2007).

### Supportive Physical Contexts

Contextual factors can greatly influence informal learning. For example, in a study of antecedents of informal learning among classroom teachers, Kyndt, Gijbels, Grosemans, and Donche (2016) found that just creating a space and supporting teachers gathering in a common staff room was perceived as critical for peer support, modelling, and problem solving. Similar support can occur online, through tools such as Microsoft Teams, Zoom, or Slack, or more personal instant messaging apps like Signal, Telegram, or iMessage.

Having time to learn is essential. Those whose time is curtailed by external factors including employment, family, and external social demands may have problems in maximizing their informal learning. Place-based learning usually takes time, not just spent learning, but on traveling to libraries, colleges, or other locations where it can occur. Online informal learners can learn wherever and whenever they need to learn, including through mobile phones or streaming audio while traveling.

### Sharing and Reflecting

Effective learning involves more than just reading, watching, engaging, and doing. Yeo (2008) argues that informal workplace learning “is an inductive process of reflection and action, often linked to the learning of others and integrated into daily routines” (p. 318). Mature self-directed learners will often perform many of these roles themselves or seek others who can help, often through online collectives and communities to which they belong. Through engagement in social media and, for some kinds of learning, feedback inherent in the process itself can fulfill some of those roles. Finally, online informal learners benefit from managerial support and scaffolding, especially for reflection and sharing Ellinger (2005).

Moore and Klein (2020) reported that instructional designers tasked with supporting learning of all types within their organization found that sharing of information and resources was perceived as the most effective support for informal learning. One of the most effective ways to achieve such engagement is thus to share one’s learning in a public or semi-public online space, thereby not only reflecting on, demonstrating, and reinforcing the learning but also inviting feedback and support. This is one of the cornerstones of complexivist pedagogical approaches (► [Chap. 10](#),

“Pedagogical Paradigms in Open and Distance Education,” by Dron and Anderson, this volume). The Internet makes such sharing easy and benefits from scale. Rather than simply sharing what we learn with those close to us, we can share with anyone and everyone, and they can respond.

The archetypal tool for open sharing is the blog. Though often considered an elderly technology in an age dominated by huge social media platforms and proprietary organizational tool suites, blogs and similar tools still account for a majority of websites, albeit that most are in the long tail. Larger social platforms with public sharing defaults such as Twitter, Tumblr, YouTube, or TikTok and less open social networks like Pinterest and Facebook are also used to share the outputs and process of learning, often including links to blogs. While only a fraction of these are intentionally part of a learning process, the scale of the Internet means that millions of posts are made every day that, directly or indirectly, contributing to the informal learning of millions (Dron & Anderson, 2014).

Blogs and similar tools are also common in formal learning, especially when using complexivist-inspired pedagogies (Dron & Anderson, 2014). By mixing the formal and informal, students may make the formal more personal and more integrated with their broader learning journeys. The persistence of content on the web allows ideas and even formal courses to grow and evolve, year on year, through contributions from both enrolled students and interested informal learners, all teaching one another while they learn (Lockridge, Levine, & Funes, 2014).

### Tracking Progress

Informal learning, whether intentional or not, is likely to be ineffective unless the learner monitors, analyzes, and reflects on the learning process. This includes not only measuring the productivity of learning tasks but also the monitoring of affective indicators such as boredom, impatience, tiredness, etc. Digital tools can support this. In a professional informal learning context, Littlejohn (2017) believed learning analytics could be used to find expertise, see current interest and level of activity and progress, and provide “a reflective mirror on their own learning activity relative and independent of self-set goals.” The key to all of these visualizations, comparisons, and monitoring efforts is that the result be fed back in useful formats and in a timely fashion to the learner.

Most learning analytics research and development has, so far, focused on its role as an instrument of student management in formal learning. As Klamka (2013) observed, there are many biases and pedagogical assumptions embedded in its use, notably including an objectivist focus on formal learning outcomes. There may, though, be value in capturing aspects of informal learning in the workplace through analysis of interactions on mobile and social systems, and even through analysis of video recordings, using social network analysis and AI tools that seek pedagogical patterns in interactions (ibid, De Laat & Schreurs, 2013). Beyond academia and some workplace settings, the surveillance that many learning analytics systems require may be deemed unacceptable, especially for incidental informal learning. However, tools that support the discovery of learning interactions within social networks and forums, identifying community goals, tasks, and connections, have

been used to good effect (e.g., Petrushyna, Klamma, & Kravcik, 2015), and work continues to automatically identify learning activities and interactions in open, online environments (e.g., Rizk & Rodriguez, 2021).

There are also plentiful tools to support the informal learner in more deliberately structuring and recording their learning. For example, bookmarking systems such as Pocket, Instapaper, or simpler tools built into web browsers can help learners collect, organize, and share resources of interest. Note-taking tools like Evernote, OneNote, Google Keep, or Joplin can serve not only as a repository of ideas, a learning journal, or a record keeping system but can also be used to collect and share and organize links, media, and digital artefacts. Such tools provide significant parts of what has become known as a personal learning environment (PLE). For some, the PLE is no more than a dashboard on a hosted service that brings together different tools and data within a formal system, often incorporating social media artefacts and interactions. For others, it may constitute the entire physical and virtual space that a learner inhabits.

Some researchers, such as Dabbagh and Kitsantas (2012), have explored the possibilities for PLEs to bring formal and informal learning together. They describe the value the PLE brings to the learner, as a means of integrating and accommodating what they learn in all settings. They also bring value to the teacher by making such learning visible and allowing teachers to accommodate and capitalize on knowledge of their students. Yen, Tu, Sujo-Montes, Harati, and Rodas (2019) provided compelling evidence that level of initiative, sense of control, and level of self-reflection are all highly supported by PLEs in both formal and (especially) informal learning. Analytics tools have also been used to help identify learning progress in PLEs (Klamma, 2013).

More recent initiatives, most notably in the conceptualization of the NGDLE (next-generation learning environment) have focused on a diversity of tools and systems that straddle the boundaries of formal and informal learning (Brown, Dehoney, & Millichap, 2015) and that celebrate a diversity of ways and means for learners to learn. While institutions may develop systems and tools for teaching, learners may provide and integrate their own and record lifelong learning journeys in learning record stores (LRSs) provided by institutions or, perhaps, through blockchain technologies that they own and control. This combination of PLE and institutional teaching systems results in shared ownership of the formal learning space.

## **Credentialing Informal Learning**

Credentials for informal learning may be valuable for a few reasons. First, learners are often interested in demonstrating and being recognized for their informal learning accomplishments. Second, many formal education institutions are interested in assisting their learners and increasing market share by attracting learners with ways that their informal learning can be used to shorten and thus reduce the length and cost of their formal education. Finally, both employers and governments are interested in encouraging lifelong learning and finding ways to assess the relevance and veracity of this learning.

Though highly valued, “qualification outcomes [must] be relevant, understood, and trusted—and not just by learners, but by governments, institutions and employers” (Noonan, 2019, p. 8). Maintaining relevance is particularly challenging in contexts of rapid technological, political, and social change. Each of these stakeholders also have come to realize that traditional institutionally published credentials are soon dated, often arbitrary in terms of what and how credentials are awarded and are not scalable, transportable, accessible, or persistent.

A number of digital technologies have been developed to support both delivery and the credentialing of informal learning. These are dealt with at length in this volume including in ► [Chaps. 47, “Accreditation and Recognition of Prior Learning in Higher Education,”](#) by Conrad, ► [69, “Digital Credential Evolution,”](#) by West and Cheng.

### **Challenge Assessments**

Assessment can be more completely decoupled from the learning process. The long history of challenge assessment stretches back to the University of London in the nineteenth Century, which offered examinations to students who had already acquired sufficient knowledge, whether through formal study, informal learning, or both, providing credentials for successful completion of the exam (Namie, 1989). Athabasca University and others continue this tradition to this day, offering a variety of ways in addition to summative exams to meet the challenge.

### **Storing and Sharing Credentials**

When credentials for learning come from multiple sources, institutional and otherwise, it may be hard to keep a track of them, especially when they are micro-credentials, badges, and similar small-scale awards. A centralized system is one effective way to do this because it provides assurance of authenticity. However, over a learner’s lifetime, centralized systems are vulnerable to possible disappearance for many reasons, including attack, insolvency, and obsolescence. In addition, as noted by Bozkurt and Ucar (2020), providers of central systems often have vested interest in gatekeeping and maintaining control of transactions and value – controls that might favor or handicap learners, groups of learners, or certain institutions. Thus, the development of a variety of blockchain applications for both formal and informal learner accreditation are distributed across the network, so they are less vulnerable to attack or decay, their authenticity is less open to questioning, and they are owned by the learners themselves.

The use of blockchain expands the usefulness and functionality, visibility, immutability, and reliability for both microcredentials and e-portfolios and formal learning accreditation. However, despite the hype and support for blockchain use in education by some educational technologists, Bozkurt and Ucar (2020) noted a variety of concerns, many dealing with the inherent technological complexity but an equal number related to throughput, manageability, scale, adoption, and the variety of chains available. These are nascent technologies that may be even more short-lived than the centralized systems they replace.

## Conclusion

Opportunities for and participation in informal learning have expanded exponentially with increase of access to and activity on digital networks – and they will continue to expand. We also can expect that formal learning systems will increase the use of informal learning resources and tools within their formal curriculum. This will create opportunities (and pressures) to develop new systems that take advantage of the accessibility, motivational benefits, and low costs associated with informal learning while retaining the structure and credentialing of formal learning.

Virtually, all learning has an informal element, insofar as what is learned is never static, is constantly reinterpreted and reintegrated after the intentional or unintentional acts that brought it about, and is always integrated by an individual with what they already know. Similarly, much informal learning relies upon at least some formal teaching, whether it be through the use of tutorials, MOOCs, teach-yourself books or websites, or simply watching a YouTube video intended to impart knowledge.

Formal teaching has weaknesses that informal learning can redress. Much formal teaching is low in value because learners have already (whether formally or informally) learned what is being taught. While reframing, rehearsing, and reflecting on existing knowledge can be valuable, it may bore students. Much formal teaching is also actively demotivating, due mainly to the locus of control not being the learner and consequent effects on the learning. Though learners may deliberately delegate control to others from time to time (such as when watching a video tutorial), informal learning is primarily controlled by the learner.

Good teachers already know about their students' informal as well as formal learning, giving freedom to explore areas of interest, utilizing rather than ignoring what students bring to the classroom. They learn what their students know and contextualize how and what they teach to meet their diverse needs, interests, and skills. There is therefore much to be said for helping students to develop skills of sharing their informal learning, through blogs and similar tools, in spaces that the students themselves own but that can be accessed by teachers and fellow learners, and/or through sharing via an institutional LRS. By integrating informal learning, rather than being a sage on the stage or a guide on the side, the teacher becomes a co-traveler, supporting rather than directing the learner's learning journey. This complexivist approach (► [Chap. 10, "Pedagogical Paradigms in Open and Distance Education,"](#) by Dron and Anderson, this volume) recognizes students as active teachers of one another, as individual agents with unique needs, and as people with lives outside the classroom.

Today's digital, networked infrastructure greatly expands the opportunities for informal learning. The means to value, assess, promote, and incorporate this learning into dominant social, commercial, and institutional structures provides both challenge and opportunity for learners, educators, and researchers.

## Abstract

This chapter analyzes the instructional quality and learning design of different categories of online courses and their history, with a special focus on massive open online courses (MOOCs). Online courses have a long tradition that has gained public attention, broad interest, and huge numbers of participants thanks to the introduction of free MOOCs accessible online for all interested learners worldwide. In this chapter, we first define MOOCs, their characteristics, and history. Afterward, theoretical frameworks and practical instruments and tools based on scientific research are presented. From the beginning, the quality of MOOCs (and of online courses in general) has been debated. That led to

discussions about the learning design and outcomes of MOOCs, which we introduce in the next section. Key research findings and practical validated instruments for designing and evaluating MOOCs (and online courses in general) are presented. Then following, the key benefits of MOOCs and the main arguments and scenarios for their usage are summarized. Based on our analysis of the research results, practices, and standards, a framework for categories and types of (massive open) online courses is proposed, called the typologies of online courses (TOC) framework. As part of the global community for open educational resources (OER) and in combination with the UNESCO recommendation on OER, MOOCs can play a significant role in achieving the SDG4 of the United Nations: inclusive and equitable quality education for all. This is true in particular during times of public lockdowns, such as during the ongoing COVID-19 pandemic.

Digital learning and open education · Typologies of online courses framework · Educational impact and evaluation · Open educational resources (OER) · United Nations SDG4 (inclusive and equity quality education for all) · COVID-19 pandemic and new normal · Emergency remote education

---

**Introduction**

The world, educational systems, and all individual learners have globally experienced a dramatic interruption and changes due to the COVID-19 outbreak (Stracke et al., 2022a; WHO, 2020). The pandemic represented a threat to daily life and all communities and societies, which was caused in particular by lockdowns (UNESCO, 2020, 2021). The consequences for educational opportunities were severe, including for higher-education institutions without any digital expertise and infrastructure (OECD, 2021a, 2021b; UNESCO et al., 2020, 2021; United Nations, 2020; UNICEF & The World Bank, 2020, 2021). Currently, research has started to analyze this impact and offered solutions for different regions and countries (Stracke et al., 2021, 2022). From one day to another, digital learning became the “new normal” during the lockdowns, and educators, learners, parents, and policymakers have necessarily made unexpected adjustments and experienced new ways of teaching/learning, often for the first time.

Online courses can provide an answer in these difficult situations to continue the right of education for all. However, their learning design has to be carefully developed to be different from face-to-face education in order to achieve high instructional quality (Bozkurt & Stracke, 2022). This chapter analyzes the specific pedagogical and design requirements for massive open online courses (MOOCs) as a particular type of online course. In addition, we discuss these principles/requirements, online platforms, and the relevant standards in a broad way to be applicable

for online courses in general, as there are no specific platforms or standards for MOOCs.

After these discussions, we synthesize our findings into the typologies of online courses (TOC) framework and discuss identified benefits of MOOCs and the reasons for believing that MOOCs (and online courses in general) can strongly contribute to achieving the sustainable development goals (SDG) of the United Nations (2015) and in particular SDG4: “[e]nsure inclusive and equitable quality education and promote lifelong learning opportunities for all.”

---

## History and Characteristics of MOOCs

The term MOOCs originated in Canada and was first coined in 2008 by Dave Cormier and Bryan Alexander, describing an open online course “Connectivism and Connective Knowledge” at the University of Manitoba. This course was designed by Stephen Downes and George Siemens and was provided to 25 fee-paying students on campus and to 2300 other students from the general public free of charges (Daniel, 2012; deWaard, 2011; Siemens, 2013). The course content was provided through RSS feeds. The concept “all-at-onceness” was used to describe the complexity of MOOCs, implying the use of platforms and social networks, such as Moodle, Skype, Twitter, blogs, and chatrooms, for the distribution of knowledge and learning (Koutropoulos & Hogue, 2012; Levy, 2011).

MOOCs did not receive much attention between 2008 and 2011 (Stracke & Bozkurt, 2019), but this changed when the Stanford University course “Introduction to Artificial Intelligence” was provided. This course, taught by Sebastian Thrun and Peter Norvig, was considered the first successful MOOC, with more than 160,000 people around the world signing up to learn together through a learning management system. Students at the university and online thus had the same content and assessment materials, regardless of prior knowledge, collegiate experience, or socioeconomic status (Cheal, 2013).

After their success, Thrun and Norvig founded the company Udacity, which provides a platform that any university can use to offer MOOCs, stating the motivation behind this as “having done this, I can’t teach at Stanford again. I feel like there’s a red pill and a blue pill, and you can take the blue pill and go back to your classroom and lecture to your 20 students. But I’ve taken the red pill, and I’ve seen Wonderland.” Later, on May 2, 2012, MIT and Harvard University announced a joint project called EdX that aims to provide free courses online.

The definition of MOOCs has also evolved over time since it was first added as an entry in Wikipedia in 2011, where it was defined as:

A Massive Open Online Course (MOOC) is a course where the participants are distributed and course materials also are dispersed across the web. This is possible only if the course is open, and works significantly better if the course is large. The course is not a gathering, but rather a way of connecting distributed instructors and learners across a common topic or field of discourse.

Now, after the rapid development of MOOCs and after 1400 edits on Wikipedia, the definition reads as:

An online course aimed at unlimited participation and open access via the web. In addition to traditional course materials such as filmed lectures, readings, and problem sets, many MOOCs provide interactive user forums to support community interactions between students, professors, and teaching assistants (TAs). MOOCs are a recent development in distance education, which was first introduced in 2008 and emerged as a popular mode of learning in 2012.

Despite the fact that MOOCs are open in nature, there is a continuous debate over whether they are open educational resources (OERs) – a debate that persists in the literature. For instance, Stracke, Downes, Conole, Burgos, and Nascimbeni (2019) stated that OERs are published under an open license, which is not the case for most MOOCs. However, MOOCs could be composed of several OERs. In the same vein, Tlili et al. (2020) supported this idea, claiming that even sustainability models for OERs are different than those found in MOOCs.

---

## Frameworks, Instruments, and Tools for MOOCs

Several theoretical frameworks and practical instruments and tools based on scientific research are developed and presented in this third section. Here, we will broaden our view for online courses in general, as most platforms providing MOOCs are not distinguishing between MOOCs and online courses. Furthermore, the standardization bodies for technology-enhanced learning have not (yet) developed any specific standards for MOOCs, so we discuss key standards relevant for online courses in general.

### Online Courses: Their Platforms and Current Practices

Online courses and learning have become mainstream and significantly popular since the 2000s (Garrett et al., 2020). This has been particularly true for higher education, where online courses have become more popular and mainstream. However, according to Baldwin, Ching, and Friesen (2018), the designers of online courses typically follow the traditional face-to-face ADDIE model, which is considered a limitation to the effectiveness of online courses. The ADDIE model represents five stages of the design process: analyze, design, develop, implement, and evaluate. Online course designers are distinct from those who design face-to-face courses mainly due to their different priorities. Online course designers prioritize and promote more interactions among learners than in physical courses. However, online course designers focus on facilitating learners' interactions and fail to address special needs or offer self-assessment (Bolliger & Martin, 2021). While the popularity of online courses and learning has significantly increased over the years (Shah, 2020),

there is still a significant gap in broad and longitudinal studies that address online courses and learning. This chapter will therefore summarize the current practices of multiple platforms that offer online courses and claim to be leaders in the context of the number of learners, courses, and quality.

Class Central is an online course platform that claims to be “the #1 Search Engine for MOOCs.” The platform contains more than 50,000 courses from several universities (Class Central, 2021). However, the courses in the platform can only be filtered by basic categories, such as collections (self-curated), providers, rankings, and subjects (Class Central, 2021).

Unlike Class Central, Udemy, another giant MOOC platform, offers more courses and better filters. Udemy provides more than 183,000 video-based online courses that users can search through and select by topic. However, within the single topic category, there are other categories, including price, language, levels, features, ratings, subtitles, and video duration (Udemy, 2021). The features category also offers other categories, including coding exercises, subtitles, practice tests, and quizzes.

Another online platform is edX, which follows a similar structure as Udemy but only offers 3000 online courses (edX, 2021). Like Udemy, one can only select one of the subjects listed on the landing page or select courses directly from the navigation bar. However, with edX, one can also select from several categories from search results, including the program, provider, subject, language, learning type, and availability.

Coursera offers about 5000 online courses and has a landing page where users can directly search for a course or select direct links to degrees, goals, providers, skills, certificates, subjects, and free courses (Coursera, 2021). Coursera allows users to choose from several categories in the search results, including the level, language, skills, duration, partners, subject, and learning products (Coursera, 2021).

Other online course platforms including the Khan Academy (2021) provide fewer categories and filter options for users. For instance, in its MOOC List, one can only search between subjects and formal conditions (MOOC List, 2021). FutureLearn also differentiates its courses by their sizes such that they only have categories for short courses, micro-credentials and programs, expert tracks, and online degrees (FutureLearn, 2021). Fordham University offers online learning and is distinguished as Google’s highest-ranking, but its courses are only categorized into three types: synchronous online courses, asynchronous online courses, and hybrid/blended online courses (Fordham University, 2021). A comparison of the definitions and categorizations for online courses used by the mentioned online platforms is shown in Table 1 below: The first column “Categories” presents the clusters, while the other columns list the assigned selection criteria and terms used by the analyzed platforms.

One can identify that the online platforms use varying terminologies as well as the types and number of categories. Most of the platforms distinguish the courses by their content and target audience, meaning they categorize their courses depending on the topics or subjects being taught, the duration or size of the content, and which levels or languages are addressed for the given audience. It is surprising to discover that most of the online platforms do not categorize their courses according to the

**Table 1** A comparison of categories for searching and differentiating online courses in popular online/MOOC platforms

Categories	class central	Udemy	edX	Coursera	Khan Academy	MOOC List	FutureLearn	Fordham University
Objectives				Goals				
Target group		Levels Languages (foreign) subtitles	Program Level Language	Skills Language Level	Levels Languages (foreign) subtitles	Formal conditions		
Pedagogics			Learning type					
Content	Subjects Collections (self-curated)	Topics Duration Price	Subject Availability	Certificates Degrees Subjects Duration Learning products	Topics Duration	Subjects	Sizes	Modes
Assessment		Quizzes Coding exercises Practice tests			Quizzes Coding exercises Practice tests			
Context	Providers	Price	Providers/partners	Free courses Providers/partners	Price			
Evaluation	Rankings	Ratings			Ratings			

design or technologies used. Additionally, categorization based on objectives and pedagogies is rarely used, with the two appearing only once and twice, respectively, in the evaluated platforms. While scientific research and articles suggest that didactics and educational dimensions are critical for online platforms, the data from the online platforms indicates this is not a focus for MOOC providers.

The subsequent section introduces and analyzes current norms and standards relevant for online courses and learning to broaden the comparison with the collected data.

## **Standards and Norms for Online Learning, Courses, and MOOCs**

There is a wide range of terminologies related to norms, guidelines, and standards. This chapter distinguishes between norms created by the two de-jure standardization bodies – the International Organization for Standardization (ISO) and International Electrotechnical Commission (IEC) – legitimated by the national governments and supranational institutions (such as the EU), with guidelines created by institutions or individuals and standards created by authorities. Multiple national and regional standards have been published and made available, such as the International Association for K–12 Online Learning (2011). This name is highly misleading since one may assume that they are developed by an international group or association when, in fact, they are merely a replica of the national United States Standards developed by American authors only (International Association for K–12 Online Learning, 2011).

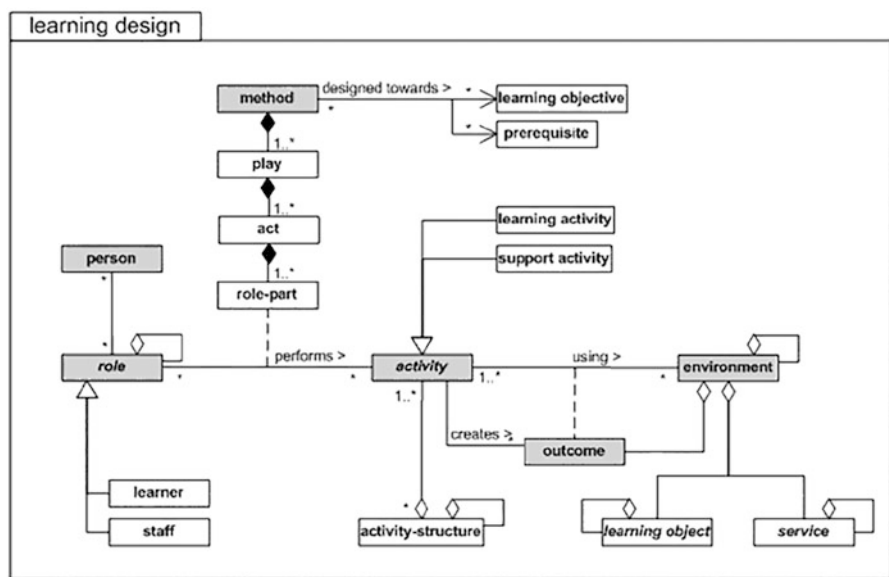

The Institute of Electrical and Electronics Engineers (IEEE) was the first international body to develop international standards that were relevant for online courses. IEEE developed the IEEE Std 1484.1 standard, which specified all the elements of a learning technology system architecture (LTSA) (IEEE, 2003). The architecture also highlighted the relationships between the components in an entirely technology-independent description. Such a technology-independent description is the biggest advantage of this standard (and many others): It allows the standard to be valid for a longer period of time. Through this technology independence, IEEE 1484.1 is still surprisingly useful and adequate currently, despite the fact that it was developed 18 years ago and several technological advances have been made since that time. It presents and defines the components of an online course or a digital environment and their relationships as shown in Fig. 1.

Another international standard developed in 2003, the same year as IEEE 1484.1, was the IMS Learning Design (LD), developed by the IMS Global Learning Consortium Inc., founded on the educational modeling language (EML) as shown in Fig. 2: It presents all elements relevant for the learning design of online or digital courses. It follows the narrative of a stage play and related terms. The IMS LD was extended by Publicly Available Specification (PAS) 1032-2, including three more components: experience, context, and metadata (PAS 1032-2, 2004).

However, there is only one legal, de-jure standard for online courses and digital learning that is approved internationally and is implemented broadly as a norm: It

**Fig. 1** IEEE 1484.1: The LTSA system components (IEEE, 2003)

**Fig. 2** IMS Learning Designs (IMS, 2003)

is the peculiar international quality norm ISO/IEC 40180 (2017), which was developed and approved by all national delegations from the International Standardization Organization (ISO) and the International Electrotechnical Commission (IEC). In the following, we briefly introduce it due to its unique importance as a global norm and its adoption as a national norm in more than 60 countries worldwide.

ISO/IEC 40180 was developed as a regular revision of the prior ISO/IEC 19796-1 (2005) that had been published as the first e-learning norm by IEC and ISO. The norm was developed in the international standardization committee SC36 by IEC

and ISO, managed by Convenor Christian M. Stracke, and approved by all national delegations from about 60 nations in consensus.

ISO/IEC 40180 defines a quality reference framework (QRF) for e-learning. It is important to distinguish this QRF developed by SC36 from the specific QRF for MOOCs developed by MOOQ and described in the following section of this book chapter: MOOQ decided to use the same abbreviation (QRF) for its quality reference framework for MOOCs (Stracke et al., 2018a) since it is based on the QRF by SC36 contained in ISO/IEC 40180 (ISO, 2017).

The QRF of ISO/IEC 40180 contains two core models: the QRF descriptive model, and the QRF quality model.

Figure 3 presents the QRF Quality Model with its seven dimensions (called process categories, in dark gray) and related 38 processes (in light gray). The QRF quality model covers and integrates all dimensions and processes that are relevant for online courses and learning. It is most important to understand that the QRF quality model presents them only as potential options and that, for all processes, it must be decided whether they are relevant for the given situation, target group, and institutional and learning objectives.

If a process is selected as relevant, then it has to be defined according the QRF descriptive model that is shown in Fig. 4. The QRF descriptive model is a master template for describing and defining all selected processes that are relevant in a given task and situation, such as designing an online course.

Figure 5 presents an illustrative example for the usage of the QRF descriptive model: It is a definition of the process “Concept of the contents” (CD.2) from the process category “Conception/Design.”

Since ISO/IEC 40180 provides a complete view of all the possible dimensions and processes using its 7 dimensions and 38 processes, it is used as the foundation of categorizing online courses. Overall, the main benefit of ISO/IEC 40180 is the introduction of a common terminology and structure for online courses and technology-enhanced learning. It allows all involved stakeholders to discuss the requirements and achievements for the needs analysis, conception, realization, and evaluation of any online course and technology-enhanced learning opportunity.

As stated above, the QRF by SC36 should not be confused with the QRF by MOOQ, which is based on the QRF by SC36 and is described in the following section.

---

## Quality, Learning Design, and Outcomes of MOOCs

In the previous section, we discussed the wide variety in how MOOC and online course providers have recently sought to categorize their courses. In contrast, researchers have differentiated and analyzed the difference in MOOCs from the very beginning (Stracke & Bozkurt, 2019).

Since the first MOOCs, the quality of learning within MOOCs was discussed by learners, designers, and researchers along with questions about their educational impact and achievements (Liyaganawardena, Adams, & Williams, 2013; Stracke,

ID	Category	Process Name	Description	Relations
CD.2	Conception/Design	Concept of the contents	Concept of learning and teaching contents	<i>NA.4 Demand analysis</i> <i>FA.2 Qualifications</i>
<b>Sub-processes/ Sub-aspects</b>		Content selection Content Design		
<b>Objective</b>		1 Learner Demand: The goal is to provide content adapted to the needs and demand of the learner. 2 Adaptation: Each course shall provide different content presentation formats and entry points based on the user experience.		
<b>Method</b>		A prototype of the content shall be provided to a group of learners' representatives. In a consensus process, the contents shall be prioritized and agreed on. For each course, classify groups of learners according to their learning type. Adapt presentation format and methods according to these learning types.		
<b>Result</b>		1 Documentation of planned and agreed contents 2 Periodically, evaluate learning performance of different learners (test groups).		
<b>Actors</b>		Curriculum designer, didactic experts, institution accreditation authority, teacher, learners' representatives		
<b>Metrics/Criteria</b>		The content are measured based on their relevance, importance, exemplarity, ...		
<b>Standards</b>		Higher Education Standards		
<b>Annotation/Example</b>				

**Fig. 5** ISO/IEC 40180: Example of a defined process CD.2 (ISO, 2017)

2019; Stracke & Trisolini, 2021; Veletsianos & Shepherdson, 2016; Zawacki-Richter, Bozkurt, Alturki, & Aldraiweesh, 2018). A repeated criticism was the high dropout rate of MOOCs, but it could be clarified that these relatively high figures are not always caused by low quality but by an inaccurate comparison to face-to-face (offline) courses: The dropout rate, for example, is not a valid measurement metric for MOOCs due to their different target groups and the various learning objectives for different students, many of whom only want to get an overview and not finish and pass a complete course (Stracke, 2017a).

In the beginning, quality discussions followed the identified types of MOOCs that were distinguished by their designs, specific learning objectives, and pedagogical

approaches (Davidson, 2013; Stracke, 2017b). That led to two main schools of thought for MOOCs: the cMOOCs and xMOOCs.

On the one hand, cMOOCs were designed to promote collaborative learning processes and network building among all MOOC learners. It was labeled cMOOC due to the so-called “connectivism” that was promoted as a new theory from the very first MOOC “Connectivism and Connective Knowledge” (CCK08) (Bozkurt, Kilgore, & Crosslin, 2018). Today, it is evident that this MOOC type has not created a new pedagogical design theory but is following well-established learning designs from constructivism with a focus on social communication, collaborative exchange, and common learning processes (Stracke et al., 2019). On the other hand, xMOOCs transferred traditional classroom teaching to broad audiences online. It was labeled xMOOC, with “x” symbolizing an extension, as that is what Harvard University used to mark the online courses in its lectures catalogue. In addition, several other types of MOOCs were proposed, but the differentiations between these proposed types are always difficult to discern and are outweighed by the overlaps in MOOCs combining different design approaches (Stracke et al., 2019; Zawacki-Richter et al., 2018).

Another attempt to structure the quality discussion related to MOOCs was the focus on the four abbreviations of massive, open, online, and courses. However, all four criteria are often not realized, and each can be questioned as mandatory conditions for current online courses labeled as MOOCs (Stracke et al., 2019). Only the scalability with large amounts of online learners is unique for MOOCs, but this does not present a pedagogical innovation or new learning style but instead a potential condition that has to carefully be addressed in the learning design.

Thus, a categorization of MOOC types has attempted several times, but we argue such attempts can be discarded, as the diverse learning designs in online courses are not different from “normal” offline courses – the latest research on the quality of MOOCs reveals that there are no specific learning designs for MOOCs (Bozkurt et al., 2018; Stracke et al., 2018b; Stracke & Trisolini, 2021; Zawacki-Richter et al., 2018). However, MOOCs do have specific aspects and opportunities (such as scalability, interactions, and reproducibility) that demand more emphasis on the learning designs and outcomes of MOOCs. Therefore, multidimensional perspectives are required for the design and quality of MOOCs to cover all these important aspects.

The international initiative MOOQ (which stands for the quality of MOOCs) has analyzed the current MOOC offerings and provisions from four perspectives: the learners, designers, facilitators, and providers of MOOCs. The first major research result of MOOQs (Stracke et al., 2018b; Stracke & Tan, 2018) is the different appreciation and valuing of interactions between learners ( $n = 146$ ) and designers ( $n = 52$ ). In the comparative online surveys for MOOC learners and designers, MOOC learners recognized all four interaction types: (a) learners to resources, (b) learners to learners, (c) learners to facilitators, and (d) groups to groups – these were all found to be relevant for the learning outcome (all four relations are significant with  $p < 0.05$ , and three of the four are even very highly significant with  $p < 0.001$ ), while the MOOC designers considered all four interaction types as unimportant (all with non-significant relations).

Based on the overall research, including additional interviews, literature analyses, and workshops in collaboration with more than 10,000 MOOC learners, designers, facilitators, and providers, the research initiative MOOQ ([www.mooc-quality.eu](http://www.mooc-quality.eu)) has developed and continuously improved the QRF for MOOCs (Stracke et al., 2018a).

**Fig. 6** The quality reference framework (QRF) (Stracke et al., 2018a, pp. 10–11)

The QRF for MOOCs is following and adapting the quality norm for digital learning and online courses ISO/IEC 40180 (also called QRF) that was described in the previous section on relevant international standards and norms.

The QRF for MOOCs consists of three dimensions (phases, perspectives, and roles) and provides quality criteria and a quality checklist that is adaptable and has always been adjusted to the given situation, defined learning objectives, and selected target groups (Stracke et al., 2018b). Within the phase’s dimension, the QRF distinguishes five processes (presented in Fig. 6): analysis, design, implementation, realization, and

evaluation. The difference to the five consecutive ADDIE stages is that the QRF defines process categories without any sequence but with a strong recommendation for parallel and iterative cycles (Stracke, 2019). They have to be selected and defined in the design, quality, and evaluation of MOOCs as required. Consequently, they are optional and present the full range of alternatives that have to be adapted to the given situation, target group, and learning objectives (Stracke et al., 2018a).

Within the QRF, the QRF quality checklist asks guiding questions to beginners in the design of MOOCs, and the QRF key quality criteria present the complete list of quality criteria for MOOCs that designers and experts in online education can benefit from.

Finally, a recent systematic literature review on the quality of MOOCs (Stracke & Trisolini, 2021) focused on the analyzed quality criteria and identified 103 studies (following the PRISMA protocol). The comparison and discussion of the results from the 103 studies through iterative validation cycles led to the establishment of a quality framework for MOOCs. This quality framework covers four dimensions (pedagogical, organizational, technical, and social) that are relevant for the quality of MOOCs and thus for their design. It can be used to guide design and evaluation of the learning design of MOOCs and future research related to their quality.

Thus, we can conclude that the research on MOOCs has revealed and addressed quality, learning design, and outcomes as key topics and led to initial instruments, such as the QRF for MOOCs that are currently evaluated in use and validation studies.

---

## Benefits, Arguments, and Scenarios for Using MOOCs

Finally, the key benefits of MOOCs and the main arguments and scenarios for their usage are summarized in this section.

The key benefits of MOOCs can be identified as:

1. Time-independent: Learners can use MOOCs at any time they prefer as long as synchronous parts are not emphasized.
2. Location-independent: Learners can use MOOCs at any location they prefer as long as internet connectivity and an appropriate device are available.
3. Scalable: Educators can address large populations of learners with no limits except technical infrastructure and bandwidth.
4. Equitable: One MOOC is always offering the same conditions and quality for all learners independent from individual form on the day.
5. Inclusive: Different pathways and media channels can be combined in one single MOOC to cover all needs and preferences of learners.
6. Observable: The activities of learners and educators can be easily observed in digital environments as long as legal data protection is fulfilled.
7. Repeatable: One MOOC can be provided many times to allow for many cohorts and sequences.
8. Improvable: A MOOC can be easily reviewed and evaluated for continuous improvement cycles.

In addition, prior discussions on the usefulness and quality of MOOCs can be considered obsolete and outdated given that traditional in-person courses can suffer the same problems in the learning design as MOOCs (if not more) (Stracke, Burgos, et al., 2022; Stracke, Sharma, et al., 2022).

---

## Categories and Types of (Massive Open) Online Courses

Previously, we discussed findings from the research literature that identified quality criteria for the design and evaluation of MOOCs. In this section, we compare and integrate the results from the previous sections to contrast ideas of quality and standards and create a new framework to guide MOOC design.

First, Table 2 shows a comparison of the various categorizations and dimensions used in online courses in comparison to the international norm ISO/IEC 40180 coupled with the international standards IMS LD and IEEE LTSA and with the QRF for MOOCs to generate the typologies of online courses (TOC) framework, as shown below in Table 2. The first column “Categories” presents the clusters, while the other columns list the assigned components and terms discussed in the previous sections.

Table 3 presents the main outcome from the discussion of the literature and the comparison of the platforms and standards. It highlights the eight dimensions that are most important for the categorization of online courses and in particular for the design of MOOCs.

This potential TOC framework can serve as a basis for a future framework on the typologies of online courses that can be derived from the comparison of their different categories as shown in Table 3 above. For achieving that, it requires testing and evaluation in future applications, as well as research and validation studies to gain broad acceptance and richness of detail.

---

## Conclusion

MOOCs, as a special type of online course, offer numerous benefits, and, thus, it is not surprising that their numbers and learners are constantly increasing. The main use of MOOCs is in higher and adult education for professional and personal development, often as free courses to promote the providing universities or to sell certificates after successful completion. However, MOOCs could also be used in school and vocational education and in lifelong learning to enrich educational opportunities and systems through alternatives with high and stable quality and with innovative learning designs.

The presented eight dimensions for a typologies of online courses (TOC) framework provide support for achieving these objectives. Derived from our analysis of current MOOC practices, offers and related standards and guidelines worldwide, these dimensions are marking the necessary perspectives the quality of MOOCs. They offer guidance for the MOOC development and evaluation. They can be applied in all processes and phases during the learning design and implementation

Evaluation	Planning Realization Analysis Optimization/ improvement			Evaluation planning Evaluation realization Evaluation review Improvements and optimization

**Table 3** Dimensions for a typologies of online courses (TOC) framework

Context	The given context is crucial for the design of an online course. Specific conditions and given limitations, such as available resources, have to be identified and considered. Therefore, the design should start with a needs analysis that also reflects requirements and demands of all involved stakeholders
Objectives	This dimension covers the organizational objectives related to the expected impact as well as learning objectives related to the planned learning outcomes
Pedagogy	The pedagogy dimension can be considered most important for overall success and requires close attention and many aspects to be addressed. In online courses, there are several unique opportunities that need to be exploited, such as digital competence building, and automatic self-assessment
Content	Content covers the resources and media that are combined and mixed in the online course
Interaction	Interactions in online courses are enriched by a fourth mode – —the interactions among different groups of learners, (next to the three traditional modes: (a) learners to resources, (b) learners to learners, (c) learners to facilitators as explained above). Online learners and online designers highly value this feature but with diverse expectations
Technologies	Technologies play a special role in online courses, as they have to work, and learners (and designers and facilitators) need the related digital competencies
Support	Support in online courses is crucial for introducing beginners to online learning, giving orientation, and providing feedback
Assessment	The assessment consists of measurement of the learning progress and outcomes achieved by the learners as well as the evaluation of the online course for future improvements

of MOOCs in collaboration among all stakeholders and can be used for the measurement and continuous improvement of the instructional quality of MOOCs as well as for their labeling and distinction by MOOC providers (for promotional purposes) and by MOOC learners (to select the best fitting MOOC).

In summary, we believe that the full potential of MOOCs for all educational systems worldwide has not yet been achieved. As part of the global community for open educational resources (OERs), and in combination with the UNESCO recommendation on OERs (UNESCO, 2019), MOOCs can play a significant role in achieving the United Nations' SDG4: inclusive and equitable quality education for all. This is true in particular in times of public lockdowns, such as in the ongoing COVID-19 pandemic. Further research on MOOCs is required, such as studies on licensing, sustainability and exploitation models, student dropout, teacher attrition, etc. Our long-term research objective is to identify all opportunities for their instructional quality and learning designs as well as for their uses for all learning objectives and target groups as well as in all educational fields.
